

CCIE™ Service Provider Version 4

Written and Lab Exam Comprehensive Guide

**By: Nicholas J. Russo
CCIE™ #42518 (RS/SP)**

About the Author

Nicholas (Nick) Russo, CCIE™ #42518, holds active CCIE certifications in both Routing and Switching and Service Provider. Nick was among the first individuals to pass the CCIE Service Provider version 4 lab examination and this book represents his personal journey towards that end. Nick also holds a Bachelor's of Science in Computer Science, and a minor in International Relations, from the Rochester Institute of Technology (RIT). Nick lives in Maryland, USA with his wife, Carla. They are currently expecting their first child.

Dedications

This book is dedicated to my wife Carla, for without her support, I would have not even started this endeavor. Although I have spent years studying for multiple certifications, she continues to support me in every way. This is the mark of a true companion and I love her dearly for it.

Purpose: This book attempts to cover every topic in the CCIE Service Provider version 4 (SPv4) blueprint. The vast majority of technical topics, even topics only present on the written examination, have corresponding practical labs. In this way, the book is an educational resource focused more on developing true technical experts rather than training individuals to pass a test. By testing many advanced technologies in detail, such as Ethernet VPN and Segment Routing, the reader gains valuable insight as to the future of SP technologies.

Target audience: Individuals using this book should already have a strong understanding of core routing, switching, and SP technologies. The book does not detail the basics of routing, MPLS forwarding, or other topics considered “beneath” the scope of a CCIE certification. Very few of the labs in this book are single-technology focused. This is done intentionally to constantly exercise features working in concert (or disharmony) with one another. Readers should understand this and be knowledgeable on prerequisite topics as discussed in each chapter’s introduction.

Scope: This primarily focuses on CCIE SP version 4 topics as specified in the official blueprint published by Cisco. Other topics that do not appear on the blueprint, such as BGP customer multicast signaling and PPP over Ethernet (PPPoE), are documented briefly in this document as they are relevant for SP networking in general. Nonetheless, this focus remains on the core SP topics in the blueprint since this book is designed for CCIE SPv4 candidates and other SP networking professionals. The length and breadth of a section is often a good measure of how “important” it is. This is helpful for prioritizing one’s study time. Note that some blueprint topics may not be covered in an appropriate level of detail in this book; always consult the official blueprint to determine if a specific technology is testable or not.

How to use this book: The table of contents is hyper-linked to each chapter, so an ordinary “point-and-click” operation is an effective navigation tool. The table of contents is arrayed in a way that makes sense to the author, but this is not necessarily the best sequence to review the labs. Topologies are seldom recycled across major domains unless the topology is well-suited to a number of particular labs. Basic IP addressing and routing configurations will be briefly validated before each lab; this is done to conserve time. The core study topic at hand remains the focus of a particular section.

Reference material: An “*Additional Reading*” comment is included in every major technology area which identifies the suffix of the supporting document relating to a lab. This document will contain the original diagram embedded in the book, as well as all configuration files. These are included separately so that they may be viewed, printed, or modified. Below is a mapping of topic weights by Cisco for reference.

Topic	Written Weight (%)	Lab Weight (%)
Service Provider Architecture and Evolution	10	N/A
Core Routing	23	27
Service Provider Based Services	23	26
Access and Aggregation	17	17
High Availability and Fast Convergence	10	13
SP Security, SP Operation and Management	17	17

Contents

1.	SP architecture concepts	13
1.1	IPv6	13
1.1.1	Definitions	13
1.1.2	Neighbor Discovery details	16
1.2	Broadband Aggregation (BBA)	41
1.2.1	PPP over Ethernet (PPPoE) technology	42
1.2.2	Multi-service PPPoE and LAC/LNS architecture	70
1.3	MEF Ethernet Services Definitions (MEF 6.2)	93
1.4	Platform Architecture	94
1.4.1	Route-Switch Processor (RSP) and Route Processor (RP)	94
1.4.2	Line cards (LC)	95
1.4.3	Switching fabric / backplane and forwarding model	95
1.4.4	Multicast forwarding and hierarchical replication	96
1.4.5	Satellite operations (remote linecards)	96
3.1	WAN technologies	96
3.1.1	Packet over SONET/SDH	96
3.1.2	T1/E1 and T3/E3	97
3.1.3	Dense Wavelength Division Multiplexing (DWDM)	98
3.2	IP connectivity to the customer	99
3.2.1	Digital Subscriber Line (DSL)	99
3.2.2	Cable Internet	99
3.2.3	Wireline	99
4.	Virtualization concepts	100
4.1	SVR vs. HVR	100
4.2	Network Functions Virtualization (NFV)	101
4.3	Software Defined Networking (SDN)	101
5.	Mobility concepts	102
5.1	LTE	102
5.2	Backhaul	104
6.	Describe BGP path attributes	105
7.	Describe MPLS forwarding and control plane mechanisms	107

7.1	Label Distribution Protocol (LDP)	107
7.2	Static label bindings	166
7.3	MPLS IP and MTU minor options	170
8.	Describe MPLS advanced features	200
8.1	Segment Routing	200
8.2	Generalized MPLS (GMPLS)	212
8.3	MPLS Transport Profile (MPLS-TP)	213
8.4	Inter-AS MPLS	235
8.4.1	Option A (Back to back VRF exchange)	258
8.4.1.1	L3VPN	258
8.4.1.2	L2VPN	286
8.4.1.3	MVPN – GRE (Profile 0) and mLDP (Profile 1)	292
8.4.1.4	MPLS TE	310
8.4.1.5	Confederation variation	314
8.4.1.6	Carrier Supporting Carrier (CSC) variation	325
8.4.2	Option B (ASBR VPNv4/v6 eBGP)	331
8.4.2.1	L3VPN	333
8.4.2.2	L2VPN	368
8.4.2.3	mVPN – GRE (Profile 0)	379
8.4.2.4	MVPN – mLDP (Profile 17)	404
8.4.2.5	MPLS TE	413
8.4.2.6	Confederation variation	427
8.4.3	Option C (ASBR eBGP + Label, RR VPNv4 eBGP)	452
8.4.3.1	L3VPN	453
8.4.3.2	L2VPN	501
8.4.3.3	MVPN – GRE (Profile 0)	512
8.4.3.4	MVPN – mLDP (Profile 17)	519
8.4.3.5	MPLS TE	536
8.4.3.6	Confederation variation	563
8.4.4	Option AB Inter-AS hybrid (AKA Option D)	581
8.4.4.1	L3VPN	581
8.4.4.2	L2VPN	613

8.4.4.3	MVPN – GRE (Profile 0) and mLDP (Profile 1)	615
8.4.4.4	MPLS TE	623
8.4.5	Confederation variation	627
9.	Describe multicast P2MP TE	627
10.	Describe EVPN (EVPN and PBB-EVPN)	627
10.1	EVPN	630
10.2	PBB-EVPN	630
11.	Describe IEEE 802.1ad (QinQ), IEEE 802.1ah (Mac-in-Mac), and ITU G.8032 (REP)	646
11.1	802.1ad QinQ	646
11.2	802.1ah MAC in MAC (Provider Backbone Bridges)	648
11.3	Ethernet Ring loop-prevention	648
11.3.1	Cisco Resilient Ethernet Protocol (REP)	648
11.3.2	ITU G.8032	675
12.	Describe broadband forum TR-101 VLAN paradigms (N:1 and 1:1)	675
13.	Describe QoS link fragmentation (LFI), cRTP, and RTP	685
14.	Describe Multichassis/Clustering High Availability (HA)	694
14.1	High Availability (HA) Demonstration (NSF/NSR/GR)	696
14.1.1	IS-IS NSF and NSR	702
14.1.2	OSPFv2 NSF and NSR	707
14.1.3	OSPFv3 GR and NSR	710
14.1.4	BGP GR and NSR	712
14.1.5	LDP GR and NSR	720
14.1.6	RSVP-TE GR	726
14.1.7	EIGRP NSF	734
15.	Describe Layer 1 failure detection	737
16.	Describe BGPsec	740
17.	Describe backscatter traceback	740
18.	Describe lawful-intercept	740
19.	Describe BGP Flowspec	740
20.	Describe DDoS mitigation techniques	740
21.	Describe network event and fault management	741
22.	Describe performance management and capacity procedures	741

23.	Describe maintenance and operational procedures	744
24.	Describe the network inventory management process	745
25.	Describe network change, implementation, and rollback	745
25.1	Processes and best practices	745
25.2	NETCONF and YANG	747
26.	Describe the incident management process based on the ITILv3 framework	750
27.	Describe, implement, and troubleshoot advanced BGP features	751
27.1	Additional Paths (add-path) and Prefix Independent Convergence (PIC)	751
27.2	BGP RT-filter unicast / IPv4 RT-filter feature	818
27.3	BGP RR-group and Selective RT Retention	823
27.4	Accumulated IGP attribute	841
27.4.1	Basic AIGP	841
27.4.2	AIGP with cost-communities and BGP confederations	847
27.5	Cost-Community / Point Of Insertion (POI)	850
27.6	DMZ Link Bandwidth	865
27.7	BGP Multicast VPN (MVPN) Theory	881
27.8	BGP Link State AF and Path Computation Element (PCE)	884
28.	Describe, implement, and troubleshoot MVPN	890
28.1	Profile 0: Default MDT – GRE – PIM C–mcast Signaling (Traditional Draft-Rosen)	891
28.1.1	PIM-ASM in the core	893
28.1.2	PIM-SSM in the core	905
28.1.3	PIM-Bidir in the core	915
28.2	Profile 1: Default MDT – MLDP MP2MP – PIM C–mcast Signaling (Basic mLDLP)	924
28.3	Profile 3: Default MDT – GRE – BGP–AD – PIM C–mcast Signaling	951
28.4	Profile 6: VRF MLDP – In–band Signaling	960
28.5	Profile 7: Global MLDP In–band Signaling	969
28.6	Profile 8: Global Static – P2MP–TE	980
28.7	Profile 9: Default MDT – MLDP – MP2MP – BGP–AD – PIM C–mcast Signaling	987
28.8	Profile 10: VRF Static – P2MP TE - BGP–AD	993
28.9	Profile 11: Default MDT – GRE – BGP–AD – BGP C–mcast Signaling	1000
28.10	Profile 12: Default MDT – MLDP – P2MP – BGP–AD – BGP C–mcast Signaling	1011
28.11	Profile 13: Default MDT – MLDP – MP2MP – BGP–AD – BGP C–mcast Signaling	1030

28.12	Profile 14: Partitioned MDT – MLDP P2MP – BGP-AD – BGP C-mcast signaling	1061
28.13	Profile 17: Default MDT – MLDP P2MP – BGP-AD – PIM C-mcast signaling	1080
29.	Describe and optimize multicast scale and performance	1094
29.1	Inter-AS Multicast and Multicast Source Discovery Protocol (MSDP)	1094
29.2	Multicast Only Fast Re-Reroute (MoFRR)	1158
29.3	Protecting mLDP LSPs with Fast Re-Reroute (FRR)	1173
29.4	MVPN Extranet	1178
29.4.1	PIM/GRE	1179
29.4.2	mLDP	1205
30.	Describe, implement, and troubleshoot MPLS QoS models and related features	1233
30.1	Uniform	1234
30.2	Short pipe	1237
30.3	Pipe (AKA long pipe)	1238
30.4	QoS Policy Propagation through BGP (QPPB)	1240
30.5	QoS specifics on IOS XRv	1246
30.6	Network Based Application Recognition (NBAR) summary and configurations	1251
30.6.1	NBAR Custom Protocols	1253
30.6.2	NBAR Attributes	1258
30.6.3	NBAR Attributes with HTTP	1262
30.6.4	NBAR Protocol-ID	1267
30.6.5	NBAR Protocol Discovery	1268
31.	Describe, implement, and troubleshoot MPLS TE / QoS mechanisms	1270
31.1	MPLS RSVP-TE (General)	1270
31.1.1	TE Topology (TED) construction and RSVP-TE signaling	1270
31.1.2	TE attributes	1297
31.1.3	Directing traffic into TE tunnels and tunnel stitching	1338
31.2	TE Fast-ReRoute (FRR) and rapid provisioning	1363
31.2.1	Link (NHOP), Node (NNHOP), and Path protection – Manual	1363
31.2.2	Automatic tunnels (with OSPF)	1401
31.3	CBTS (IOS) and PBTS (XR)	1451
31.4	DiffServ-aware Traffic Engineering (DS-TE)	1469
31.4.1	Pre-standard Model	1470

31.4.2	IETF Russian Dolls Model (RDM)	1490
31.4.3	IETF Maximum Allocation Model (MAM)	1500
31.4.4	Per-VRF TE techniques	1507
32.	Describe, implement, and troubleshoot E-LAN and E-TREE (extended to general L2VPN)	1540
32.1	MPLS encapsulated L2VPN	1540
32.1.1	Static configuration	1540
32.1.1.1	E-LINE (VPWS)	1540
32.1.1.2	Advanced PW features (CW, Status, etc)	1562
32.1.1.3	E-LAN and E-TREE (VPLS)	1574
32.1.1.4	Multisegment PW (MS-PW) switching	1598
32.1.1.5	EVC rewrite operations	1622
32.1.2	BGP auto-discovery for VPWS/VPLS	1632
32.1.2.1	LDP signaling	1633
32.1.2.2	BGP signaling	1648
32.1.3	Hierarchical VPLS (H-VPLS)	1664
32.1.3.1	MPLS in the Access Network	1664
32.1.3.2	QinQ in the Access Network	1681
32.2	IP encapsulated L2VPN	1688
32.2.1	E-LINE with L2TP	1688
32.2.2	E-LAN and E-TREE using OTV	1714
33.	Describe, implement, and troubleshoot Unified MPLS and CSC	1731
33.1	Carrier Supporting Carrier (CSC)	1731
33.1.1	L3VPN	1739
33.1.2	L2VPN	1750
33.1.3	MVPN (Profile 0 with SSM)	1759
33.1.4	TE and TE-FRR	1768
33.2	Unified (seamless) MPLS	1780
33.2.1	IS-IS	1787
33.2.1.1	L3VPN	1797
33.2.1.2	L2VPN	1812
33.2.1.3	MVPN (mLDP profiles 1 and 17)	1816
33.2.1.4	Inter-area TE and TE-FRR	1824

33.2.2	OSPF (summarized)	1840
33.2.2.1	L3VPN	1843
33.2.2.2	L2VPN	1850
33.2.2.3	MVPN (mLDP profiles 1 and 17)	1856
33.2.2.4	MPLS TE and TE-FRR	1859
34.	Describe, implement, and troubleshoot LISP	1870
35.	Describe, implement, and troubleshoot GRE and mGRE-based VPN	1902
35.1	P2P GRE tunneling and GRE features	1902
35.2	Dynamic Multipoint VPN (DMVPN) basics	1916
35.2.1	Phase 1	1918
35.2.2	Phase 2	1938
35.2.3	Phase 3	1948
35.3	mGRE-based L3VPN	1964
36.	Describe, implement, and troubleshoot IPv6 transition mechanisms	1976
36.1	NAT44 and NAT444	1976
36.2	NAT64 and NAT464	1995
36.3	Dual stack lite (DS-lite)	2035
36.4	IPv6 tunneling over IPv4 networks	2037
36.4.1	GRE / Manual IPv6 tunnels	2038
36.4.2	6to4 automatic tunnels	2041
36.4.3	6 Rapid Deployment (6RD)	2045
36.4.4	Intra-Site Automatic tunnel Addressing Protocol (ISATAP)	2052
36.5	IPv4/IPv6 Internet Access over MPLS using NAT44	2055
37.	Describe, implement, and troubleshoot end-to-end fast convergence	2092
37.1	Loop Free Alternate (LFA) for IPv4	2092
37.1.1	OSPFv2	2092
37.1.1.1	Direct LFA	2092
37.1.1.2	Remote LFA	2106
37.1.2	IS-IS	2121
37.1.2.1	Direct LFA	2121
37.1.2.2	Remote LFA	2127
37.1.3	EIGRP	2131

37.2	Loop Free Alternate (LFA) for IPv6 (XR Only)	2136
37.2.1	OSPFv3	2136
37.2.1.1	Direct LFA	2136
37.2.1.2	Remote LFA	2140
37.2.2	IS-IS	2140
37.2.2.1	Direct LFA	2140
37.2.2.2	Remote LFA	2144
37.3	Convergence optimizations for BGP	2148
37.4	Convergence optimizations for IGPs	2174
37.4.1	IS-IS	2175
37.4.2	OSPFv2 and OSPFv3	2181
38.	Describe, implement, and troubleshoot multi-VRF CE and advanced VRF techniques	2194
38.1	Multi-VRF CE (VRF-Lite)	2195
38.1.1	Basic VRF-Lite	2195
38.1.2	OSPF and sham-links	2198
38.1.3	EIGRP and Site-of-Origin (SoO)	2233
38.1.4	IS-IS	2262
38.1.5	BGP and Site-of-Origin (SoO)	2266
38.1.6	Static routing	2289
38.1.7	RIP	2293
38.2	VRF label modes	2300
38.3	VRF selection for traffic leaking	2314
38.4	VRF route leaking	2318
38.5	L3VPN import/export maps	2338
38.6	Half-Duplex VRF (HDVRF)	2350
38.7	BGP Local Convergence (VRF Local Protection)	2363
39.	Describe, implement, and troubleshoot Layer 2 failure detection	2377
39.1	Link Aggregation Control Protocol (LACP)	2377
39.2	Uni-Directional Link Detection (UDLD)	2388
40.	Describe, implement, and troubleshoot Layer 3 failure detection	2396
40.1	Individual Protocol Hello packets	2396
40.2	Bidirectional Forwarding Detection (BFD)	2415

41.	Describe, implement, and troubleshoot control plane protection techniques	2444
41.1	Control Plane Policing (CPP) in XE and Local Packet Transport Services (LPTS) in XR	2444
42.	Describe, implement, and troubleshoot logging and SNMP security	2461
42.1	Logging	2461
42.2	SNMP security	2461
43.	Describe, implement, and troubleshoot timing	2461
43.1	Network Time Protocol (NTP)	2462
43.2	1588v2 (Precision Time Protocol(PTP))	2480
43.3	Synchronous Ethernet (SyncE)	2482
44.	Describe, implement, and troubleshoot SNMP traps, RMON, EEM, and EPC	2483
44.1	SNMP traps	2484
44.2	Remote Monitor (RMON) in XE and logging correlation in XR	2490
44.3	Embedded Event Manager (EEM)	2503
44.4	Embedded Packet Capture (EPC)	2512
45.	Describe, implement, and troubleshoot port mirroring protocols	2522
45.1	Switch port analyzer (SPAN)	2522
45.2	Remote SPAN (RSPAN)	2527
45.3	Encapsulated RSPAN (ERSPAN)	2530
46.	Describe, implement, and troubleshoot Netflow and IPFIX	2534
46.1	Flexible Netflow (FNF)	2536
46.2	IPFIX	2547
47.	Describe, implement, and troubleshoot IP SLA	2549
47.1	Basic IP SLA probes, responders, features, and configurations	2549
47.2	UDP-jitter and VOIP codec probes	2560
47.3	Advanced ICMP probes	2566
47.4	MPLS probes	2573
47.5	Ethernet probes including ITU-T Y.1731 Basics and Performing Monitoring (PM)	2577
47.6	Miscellaneous probes	2603
47.7	Aggregated statistics, history, group scheduling, and miscellaneous features	2610
47.8	Enhanced Object Tracking (EOT)	2622
47.9	IPv6 SLA	2637
47.10	IOS-XR IP SLA and EOT	2643

48.	Describe, implement, and troubleshoot MPLS OAM and Ethernet OAM	2667
48.1	MPLS ping, MPLS traceroute, and VCCV	2667
48.2	MPLS LSP Monitor (MPLSLM) / LSP Health Monitor	2690
48.3	Ethernet Management Tools (CFM, OAM, and E-LMI)	2703
48.3.1	Connectivity Fault Management (CFM) (802.3ag)	2703
48.3.2	Ethernet OAM (IEEE 802.3ah)	2733
48.3.3	Ethernet Local Management Interface (E-LMI) (MEF.16)	2748
48.3.4	Ethernet CFM, OAM, E-LMI, and Y.1731 on CSR1000v (Comprehensive)	2766
49.	Service Provider security best practices (Comprehensive)	2794
49.1	Control plane security best practices	2795
49.2	Management plane security best practices	2831
49.3	Data plane security best practices	2862
49.4	Advanced security techniques and features	2889

1. SP architecture concepts

1.1 IPv6

1.1.1 Definitions

Link-local address: Addressing within FE80::/10 (FE80:: through FEBF:FFFF...) to be used for communication on a link. The addressing is not routable and all routers must have LL addresses on all interfaces.

Site-local address: Addressing within FEC0::/10 (FEC0:: through FEFF:FFFF...) to be used within an organization. This is similar to RFC 1918 private addressing and is routable., but is discouraged. The unique-local addressing was meant to replace it.

Unique-local address (ULA): Addressing within FC00::/7 (FC00:: through FDFF:FFFF...) to be used within an organization. This replaced site-local addressing and serves the same function.

Multicast addresses: Addressing within FF00::/8 (anything starting with FF) to be used for multicast transport. Within the second byte, the first hex digit represents special flags while the second represents the scope. The flags, in binary, are "ORPT". The most significant bit is always 0 and means nothing.

1. 'R' indicates whether the IPv6 carries a PIM RP address. This is used for embedded RP and the RP address is signaled inside of the IPv6 multicast group.

2. 'P' indicates whether a multicast address is assigned based on the network prefix. This is used for embedded RP and the network prefix is embedded inside of the IPv6 address. If R is 1, P must also be 1, since the embedded RP construct implies that the network prefix is also carried in the IPv6 address. The

opposite is not true as 'P' could be 1 while 'R' is 0; a case may exist where network prefix information is carried in the multicast address but the function is unrelated to embedded RP.

3. 'T' indicates whether a multicast group is transient (dynamically/non-permanently assigned) or not. When T is 0, it assumes a well-known multicast address is used according to IANA. If P is 1, T must also be 1. The opposite is not true as 'T' could be 1 while 'P' is 0. This would represent a normal transient multicast group that does not carry any network prefix information.

The scopes are self-explanatory and are used to contain multicast into administrative regions.

1 - Interface local: Only useful for loopback transmission of multicast

2 - Link-local: Communication on a segment, typically used for IGP, PIM, neighbor discovery (ND), etc

4 - Admin-local: Smallest scope that can be administratively configured; that is, unlike node and link-local, this traffic is routable and the administrator decides what constitutes an "admin-local" boundary. This would be useful for limiting traffic to a set of devices within a site, such as access/distribution/core layers of a LAN-side routing architecture.

5 - Site-local: For use within a site. This would be useful for confining multicast traffic within local branch office. Although PIM dense-mode is not supported in IPv6 on Cisco platforms, a site-local sparse-mode domain may be a good alternative for local multicast confinement.

8 - Organization-local: Spans multiple sites within an organization, such as between branch offices. The information would typically not be allowed to be exchanged over the Internet.

E - Global scope: Sometimes called "VPN scope" by Cisco, this has no scoping limit.

Anycast addresses: Though the concept exists in IPv4, it does not exist on a LAN segment, and IPv6 enables this capability. Configuring an anycast address is essentially the same as a unicast address with duplicate address detection disabled (DAD is discussed later). When a host tries to resolve layer 2 addresses, any node may respond, hence the name anycast.

Solicited-node address: A link-local scope multicast address computed as a function of a node's unicast and anycast addresses. These addresses are formed by taking the low-order 24 bits of an IPv6 address and appending those bits to the prefix FF02::1:FF00::/104 (FF02::1:FF00:: to FF02::1:FFFF:FFFF). The network prefix length of 104 plus the low-order 24 bits of the unicast/anycast address on the interface creates the full 128-bit IPv6 solicited-node address. A node that has multiple prefixes but similar host addresses can therefore join less (hopefully only one) solicited-node multicast address. Every node must join a solicited-node multicast address for every unicast and any cast address on all interfaces, regardless of how they were configured (manual, DHCPv6, SLAAC, etc). This also reduces interrupts on nodes other than the target because the destination is not like an IPv4 ARP broadcast, or even an IPv6 all-nodes multicast. When a node sends traffic to a solicited-node address, it is like a semi-directed broadcast message that targets a very small set of nodes (again, hopefully only one).

Neighbor Solicitation (NS): ICMP type 135. The destination is the solicited-node multicast address of a specific host on the LAN, while the source is the link-local IPv6 address of the source interface. This is

used for LAN discovery and is directly comparable in function to an ARP request. The NS can also have a unicast destination when not being used for discovery. This is used to verify the reachability of a neighbor once discovered as a reachability probe and is known as Neighbor Unreachability Detection (NUD). NUD guarantees two-way communication in this way as well.

Neighbor Advertisement (NA): ICMP type 136. The destination is the link-local IPv6 address of the node that sent the NS (regular unicast packet) and the source is the LL address of the node sending the NA. The layer 2 address is contained within the packet's payload, and on Ethernet media this is the MAC address of the node sending the NA. If a node's layer 2 address changes, an unsolicited NA is sent to the all-nodes multicast address (FF02::1) to update their IPv6 neighbor tables. There is a solicit-flag that is 1 (true) only when the NA is sent in response to an NS, whereas the flag is 0 otherwise.

Router Solicitation (RS): ICMP type 133. These are sent by hosts to discover available routers on the segment. The source is the IPv6 link-local address of the sending interface (or :: if no address has been assigned yet) with a destination of the all-routers (FF02::2) multicast address. In this way, other IPv6 hosts will discard RS packets they receive since they are destined only for IPv6 routers, and because the source address can be unspecified (::), this facilitates SLAAC operation.

Router Advertisement (RA): ICMP type 134. These are periodically sent by routers with a source address of the interface LL address and destination of FF02::1. If sent in reply to an RS, it can also have a destination of the router's LL address that sent the RS. RA messages typically include: one or more prefixes for SLAAC (prefix-length must be 64 bits), prefix lifetime (validity), hop limit (TTL), MTU, and auto-configuration details. RA generation is enabled on Ethernet and FDDI interfaces by default and can be manually suppressed. On all other interfaces, it is disabled by default and can be manually enabled; one such use case of enabling it on a non-LAN interface would be to support ISATAP tunneling towards clients (discussed later). Two flags of are particular interest. The 'M' flag is the managed address configuration flag, which indicates that prefixes are available via DHCPv6. The 'O' flag indicates that other information, such as DNS, is available via DHCPv6 but addresses are not. If the 'M' flag is set, the 'O' flag is redundant/ignored, since all information is returned from DHCPv6 in that case. With both flags clear, this indicates that no information is available via DHCPv6. Regarding the router lifetime, a value of 0 indicates the router should not appear as a candidate default gateway; the lifetime only applies to the router's usefulness as a default gateway and no other RA components (prefixes have their own lifetimes).

Neighbor Redirect (NR): ICMP type 137. Used to notify a host of a better path to reach the destination. Same purpose as an IPv4 ICMP redirect, however the IPv6 NR must know the link-local address of the redirect target (i.e., the other router on the segment that is the better exit point). This LL address is contained in the payload of the NR message. An optional field that should be included, if known, is the target's layer 2 address as well. This saves the host receiving the redirect from having to use an NS to determine the next-hop, if it doesn't already have the information.

There are several validations that occur on these ND packets as well. For example, IPv6 nodes will

discard RA or RS messages that don't have a hop limit (TTL) of 255, which implies their origination was off-link and therefore is probably invalid.

Duplicate Address Detection (DAD): When a new address is configured on a link, DAD is typically run first before assigning the address to the link. The NS message is used with an unspecified source address (::) and the all-nodes multicast address (FF02::1). The tentative LL address that a node is checking for uniqueness is contained within the body of this NS. Two conditions will render the address "duplicate" and therefore unusable: reception of an NA from another node saying the address is already in use on the segment, or reception of an NS from another node that is concurrently trying to determine uniqueness. All IPv6 addresses (global and link-local) are subject to DAD, however DAD for LL addressing must happen first before progressing to additional IPv6 addresses. Cisco does not perform DAD on global or any cast addresses generated from 64-bit interface identifiers, such as EUI-64. It is assumed that these are unique and bypassing DAD is a minor optimization.

Default Router Preference (DRP): Signaled in unused bits within the RA message to provide low, medium, and high preference options for selecting a default gateway when multicast RAs offer it. Failure to evaluate/understand these bits results in a value of "medium".

The IPv6 header differs from the IPv4 header in several ways. As expected, it is much larger at 40 bytes versus 20 bytes; each IPv6 address is 16 bytes by itself. The IPv4 TTL and IP protocol have been renamed to "hop limit" and "next header", but they are still both 1 byte fields with the same function. In IPv4, the TTL comes before the IP protocol, but in IPv6, the fields are reversed with "next header" coming before "hop limit". IPv6 also adds the concept of a flow label which assigns packets to a particular flow. It is 20 bits long, like an MPLS label, but has nothing to do with MPLS. The idea is that routers can do per-flow load sharing based on this information without having to look at higher layer protocols like TCP or UDP ports. Many protocols may have multiple flows but lack the concept of "ports" that TCP and UDP have. There is no way to verify the authenticity of the flow-label and it could be changed in transit, but since it is generally used for load-sharing, this may not be significant. A value of 0 indicates that the packet has not been assigned to a particular flow. Layer 2 (LAG) or layer 3 (CEF) mechanisms may use this for load-sharing.

The "next header" name is more appropriate for IPv6 since it can refer to one of two things. In a normal IPv6 packet, it would refer to the upper-layer protocol, such as 6 for TCP or 17 for UDP. It can also refer to IPv6 extension headers (EH) which immediately follow the normal IPv6 header. These are like IPv4 options that allow IPv6 to carry extra information. Some of these headers include the routing header (43), mobility header (135), fragment header (44), and destination options (60). IPv6 doesn't support fragmentation on the routers, but end hosts do, assuming they support these IPv6 EH options.

1.1.2 Neighbor Discovery details

This lab uses CSRs only since XRv does not appear to support sending RAs under any circumstance. Because XRv is modeled after an RSP, not a line-card, it cannot issue RA messages. I have included configurations for XRv1 and XRv2 that can be hot-swapped with CSR1 and CSR2 should the code be fixed

later. Basic IS-IS single-topology IPv6 routing is used for reachability across the network. CSR4, CSR5, and CSR7 represent end hosts with very little configuration.

First, we will examine the ND process using CSR1 and CSR2. This is simple because there are only two routers on the segment, making the RA/RS process unnecessary. In cases like this, disabling RAs makes sense to conserve resources and increase security. Although not necessary on transit links, I configured a global unicast address range as well. The relevant configuration from CSR1 is shown below; CSR2 has an identical configuration with different host addresses.

```
! CSR1
interface GigabitEthernet2.512
  ipv6 address FE80::11 link-local
  ipv6 address 2020:0:11:12::11/64
  ipv6 nd ra suppress all
```

Debugging ICMPv6 and ND on CSR1 allows us to see many details about what happens during the process described earlier. We bounce CSR1's link to CSR2 to see the full procedure. For clarity, the debug is broken into chunks and explained in line. First, IPv6 ND is notified that the layer 2 components of the link came up, which starts the ND process at layer 3. Before anything else, DAD must be run on the LL address of the link after a short delay. The DAD message is just an NS to the solicited-node

address of CSR1; this is a way to see if anyone else has the same low-order 24 bits of the host address as CSR1. DAD sees no response after 1 second (globally adjustable, as we see later) and declares the address unique. CSR1 then issues an unsolicited NA to the all-nodes multicast group to notify them of its MAC address binding to this IPv6 LL address.

```
R1#debug ipv6 icmp
R1#debug ipv6 nd
22:28:32.249: ICMPv6-ND: (GigabitEthernet2.512) L2 came up
22:28:32.249: IPv6-Addrmgr-ND: DAD request for FE80::11 on
GigabitEthernet2.512
22:28:32.249: ICMPv6-ND: Delay DAD for FE80::11 on GigabitEthernet2.512 by
200 msec
22:28:32.449: ICMPv6-ND: (GigabitEthernet2.512,FE80::11) Sending DAD NS
[6F530]
22:28:32.450: ICMPv6: Sent N-Solicit, Src=::, Dst=FF02::1:FF00:11
22:28:33.449: IPv6-Addrmgr-ND: DAD: FE80::11 is unique.
22:28:33.449: ICMPv6-ND: (GigabitEthernet2.512,FE80::11) Sending NA to
FF02::1
22:28:33.449: ICMPv6-ND: (GigabitEthernet2.512) L3 came up
22:28:33.449: ICMPv6-ND: (GigabitEthernet2.512,FE80::11) Linklocal Up
22:28:33.450: ICMPv6: Sent N-Advert, Src=FE80::11, Dst=FF02::1
```

Next, DAD iterates through the rest of the unicast and anycast addresses on the link. The DAD process for subsequent addresses need not be delayed since there was not another link-up event. The solicited-node address happens to be the same in this case because the host addresses for the LL and global address are the same, but could be different. As expected, there are no duplicate addresses on the LAN between CSR1 and CSR2. CSR1 issues another unsolicited NA, this time sourced from the global address, to notify other nodes on the segment about its global address.

```
! CSR1
22:28:33.449: IPv6-Addrmgr-ND: DAD request for 2020:0:11:12::11 on

to FF02::1
22:28:34.451: ICMPv6: Sent N-Advert, Src=2020:0:11:12::11, Dst=FF02::1
```

A few seconds later, IS-IS converges. Because IS-IS does not rely on IP, CSR1 has no idea about CSR2's existence and has no reason to resolve its layer 2 address. After convergence, IS-IS routes are learned via CSR2 and installed in the routing table, which prompts CSR1 to resolve the IPv6 next-hops, which are LL addresses. The ND state machine for FE80::12 (CSR2 address) transitions from deleted (nonexistent) to incomplete (INCMP). At this time, CSR1 send another NS to CSR2's solicited-node address; it gleans the solicited-node address from the low-order 24 bits of the address it is trying to resolve, which is

FE80::12. About 200 ms later, CSR2 responds with an NA which carries its MAC address. The NA packet is validated for security reasons, and the IPv6 neighbor entry transitions from incomplete to reachable.

```
! CSR1
22:28:40.936: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) ULP neighbour

22:28:41.147: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) INCMP -> REACH
```

We can verify this entry by checking the IPv6 neighbor table, which is like the IPv4 ARP table. We see the IPv6 LL address and MAC address of CSR2 as reachable. Notice there is no entry for CSR2's global unicast address. The only reason CSR1 knew to look for CSR2 was because IS-IS next-hops necessitated it. CSR1 remains ignorant about anyone else on the LAN.

```
R1#show ipv6 neighbors gig 2.512
IPv6 Address                               Age Link-layer Addr State Interface

    via FE80::12, GigabitEthernet2.512
```

We can trick the router into trying to discover a new node in a few ways. The most obvious is to ping a new LL address out of that interface, which will trigger ND. A more subtle way is to configure a static route to a bogus next-hop, which like the IS-IS routes, will trigger ND. Below we configure a bogus default route; IPv6 ND makes three attempts to resolve the layer 2 address (one second apart), then gives up and delete the ND cache entry.

```
! CSR1
ipv6 route ::/0 GigabitEthernet2.512 FE80::BEEF

R1#debug ipv6 icmp
R1#debug ipv6 nd
22:52:28.302: ICMPv6-ND: (GigabitEthernet2.512,FE80::BEEF) DELETE -> INCMP
```

22:52:30.483: ICMPv6: Sent N-Solicit, Src=FE80::11, Dst=FF02::1:FF00:BEEF
22:52:31.573: ICMPv6-ND: (GigabitEthernet2.512,FE80::BEEF) INCMP -> DELETE
22:52:31.573: ICMPv6-ND: Remove ND cache entry

```

We can force ND for CSR2's global unicast address by pinging it. The debug also shows the ICMPv6 echo and echo-reply packets to confirm that everything worked. The first echo request is shown first, with the first echo reply shown last. Notice that CSR1 also receives an NS for its solicited-node address; this is because CSR2 also has to run ND to reach CSR1's global unicast address to send the echo-reply. CSR1 replies with a unicast NA to CSR2 (solicited), and after that, the ICMP flow succeeds.

```

```

We can see the obvious differences in solicited-node addresses between CSR1 and CSR2 on this segment since they have different low-order 24 bit host addresses. We can try to trick DAD by configuring different host addresses on CSR1 and CSR2 but with the low-order 24 bits being equal. We will add these

as additional IPv6 address rather than replace the existing one. We quickly verify the solicited-node addresses on both routers to ensure they are the same for this new IPv6 address.

```
! CSR1
interface GigabitEthernet2.512
  ipv6 address 2020:0:11:12:0:11:0:1212/64

! CSR2
  ipv6 address 2020:0:11:12:0:12:0:1212/64

R1#show ipv6 interface gig2.512 | section group_add
  Joined group address(es):
    FF02::1
    FF02::1:FF00:11
    FF02::1:FF00:1212

R2#show ipv6 interface gig2.512 | section group_add
  Joined group address(es):
    FF02::1
    FF02::2
    FF02::1:FF00:12
    FF02::1:FF00:1212
```

The debug below shows that DAD is smart enough to determine if the address is unique or not. Even if CSR1 and CSR2 have the same solicited-node address, the actual IPv6 address in question is contained within the NS payload. CSR2 is joined to FF02::1:FF00:1212, as is CSR1, so CSR2 actually has to open the packet and process it. Had the host addresses been different, CSR2 would have discarded the packet at layer 3, saving it a little bit of CPU time. The solicited-node is not what DAD uses for its final decision, as it is really used as a CPU interrupt reduction technique. The timestamps are not perfectly synchronized between CSR1 and CSR2, but it is clear that CSR2 receives the DAD NS, does nothing, then receives the authoritative NA from CSR1 declaring the address unique. This is the correct behavior.

```

13:31:32.303: ICMPv6-ND: Validating ND packet options: valid

```

In the event there really is a duplicate address, DAD will detect this. Obviously, the solicited-node multicast addresses will be the same, and opening the packet for processing will alert DAD to the duplicated address on the segment. To save a little bit of memory, we can configure a duplicate address (2020::1212) that uses the same solicited-node address of something each router has already joined, which can reduce the number of solicited-node addresses a router must join. The duplicate address below also joins FF02::1:FF00:1212 since the low-order 24 bits of the host address are 0x001212 in hex. Assuming CSR2 has the address configured and we add it to CSR1 later, the debugs are shown below. CSR1 sends the DAD NS and immediately receives an NA back from CSR2; when the address is unique, the DAD NS should not receive an NA in response. Both routers also display a syslog message in case debugging is not enabled. CSR1 calls this a syslog warning (level 4) since it tried to use an address already in use. CSR2 calls this a syslog informational message (level 6) since someone else is attempting to use an address already valid on CSR2.

```

on GigabitEthernet2.512
13:42:38.058: ICMPv6: Sent N-Advert, Src=2020::1212, Dst=FF02::1

```

We can verify this by checking the interface details on each router. The IPv6 address 2020::1212 is marked as [DUP] to indicate it is a duplicate address on CSR1. CSR2 does not show this because it had the address first; DAD honors “first come, first served” in terms of address claims. The syslog message priorities above seem to support this conclusion as well. We will see how to work around DAD issues later.

```
R1#show ipv6 interface gig2.512 | section Global_uni
Global unicast address(es):
  2020::1212, subnet is 2020::/64 [DUP]
  2020:0:11:12::11, subnet is 2020:0:11:12::/64
  2020:0:11:12:0:11:0:1212, subnet is 2020:0:11:12::/64
```

```
R2#show ipv6 interface gig2.512 | section Global_uni
Global unicast address(es):
  2020::1212, subnet is 2020::/64
  2020:0:11:12::12, subnet is 2020:0:11:12::/64
  2020:0:11:12:0:12:0:1212, subnet is 2020:0:11:12::/64
```

The ND state machine is quick to transition ND entries out of the REACH state. By default, this is 30,000 ms (30 seconds) on all interfaces. It can be tuned globally or at the interface level. Below, CSR1 runs ND to CSR2’s LL address. The entry was in the STALE state, and after the ping, ND transitions the entry to the REACH state. The ND process doesn’t need to occur again since we still had a STALE entry, and the successful ping shows us that the entry is still valid. ND now marks it as REACH, but after 30 seconds, the entry transitions back to the STALE state since no traffic is flowing through this address presently. This STALE state helps the administrator determine how long it has been since traffic was sent to an IPv6 peer.

```
! CSR1
13:52:45.031: ICMPv6: Sent echo request, Src=FE80::11, Dst=FE80::12
13:52:45.034: ICMPv6: Received echo reply, Src=FE80::12, Dst=FE80::11
13:52:45.034: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) ULP indication
13:52:45.034: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) STALE -> REACH
13:53:15.085: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) REACH -> STALE
```

We will adjust this timer on CSR1 facing CSR2 to have a 10 second transition so that ND cache entries are moved to the STALE state more quickly when not used. Running the same ND test again, we can see the transition happens in 10 seconds, as expected.

```
! CSR1
interface GigabitEthernet2.512
  ipv6 nd reachable-time 10000
```

```
R1#show ipv6 interface gig2.512 | include ND_reachable
ND reachable time is 10000 milliseconds (using 10000)
```

```

14:02:25.842: ICMPv6: Sent echo request, Src=FE80::11, Dst=FE80::12
14:02:25.846: ICMPv6: Received echo reply, Src=FE80::12, Dst=FE80::11
14:02:25.846: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) ULP indication
14:02:25.846: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) STALE -> REACH
14:02:35.934: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) REACH -> STALE

```

Entries are removed from the IPv6 ND cache after having been stale for 4 hours by default. This can also be adjusted globally or at the interface level. CSR1 will adjust this globally to delete entries that are stale for 50 seconds. Thus, on the interface to CSR2, an entry moves from REACH to STALE after 10 seconds, then STALE to DELETE after 50 seconds, meaning that there is one minute between traffic sent to a next-hop and the cache entry being totally removed.

```

! CSR1
ipv6 nd cache expire 50

```

There does not appear to be a show command to verify this, but we can check the IPv6 cache statistics to see the number of cache entries in each state. This command was run after the entries aged out (given the 50 second DELETE timer), so there are zero entries in the cache currently.

```

R1#show ipv6 neighbors statistics
IPv6 ND Statistics
  Entries 0, High-water 4, Gleaned 1, Scavenged 3, Static 0
Entry States
  INCMP 0 REACH 0 STALE 0 GLEAN 0 DELAY 0 PROBE 0
Resolutions
  Requested 11, timeouts 10, resolved 7, failed 3
  In-progress 0, High-water 2, Throttled 0, Data discards 0
NUD
  Requested 1, timeouts 0, resolved 1, failed 0
  in-progress 0, high-water 1, throttled 0, current queue 0, queue high-
water 0
  Delayed Queue 0, Delayed Queue High-water 4

```

Repeating the same test again, we confirm this behavior on CSR1 by verifying the timestamps.

```

14:05:53.601: ICMPv6-ND: Remove ND cache entry

```

From the statistics show command, we see there are other states such as GLEAN, DELAY, and PROBE.

The GLEAN state doesn't actually show up in the ND neighbor cache, but it is a valid state. When an unsolicited NA is received on the segment, routers will ignore those entries (like ignoring a gratuitous ARP) to save memory. For example, if we bounce CSR2's interface, it will perform DAD on all of its addresses beginning with its LL address. CSR1 doesn't see the DAD NS because it isn't joined to the same solicited-node address, but it does see the NA that CSR2 sends once DAD declares the address unique. CSR1 does nothing with it; no further processing is done on its IPv6 cache. CSR1 will need it later for IS-IS routing, but that is beyond the scope of this test. Notice that CSR1 has no entry for FE80::12 in its cache.

```
! CSR1
14:13:09.122: ICMPv6: Received N-Advert, Src=FE80::12, Dst=FF02::1
14:13:09.122: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) Received NA from
FE80::12
14:13:09.122: ICMPv6-ND: Validating ND packet options: valid

R1#show ipv6 neighbors gig2.512
[no output]
```

We can configure CSR1 to record these unsolicited NA mappings on a per-interface basis. CSR1 can "glean" that information by snooping the LAN, which may speed convergence and reduce independent ND conversations later. The cost is larger ND caches (more memory) for address that may not be relevant for the traffic patterns on a given LAN. Once configured, we can verify it by checking the IPv6 interface details.

```
! CSR1
interface GigabitEthernet2.512
  ipv6 nd na glean

R1#show ipv6 interface gig2.512 | include glean
ND gleaning on unsolicited neighbor advertisements
```

This time, when CSR2 sends the NA onto the LAN, CSR1 is directed to glean the layer 2 address for this unsolicited NA. The entry is recorded as STALE in the ND cache, which makes sense since CSR1 has no idea if the address is actually reachable as it did not initiate an ND conversation with it, nor direct traffic to/through it. This entry is still subject to the ND expiration timer configured earlier.

```
! CSR1
14:16:45.688: ICMPv6: Received N-Advert, Src=FE80::12, Dst=FF02::1
14:16:45.688: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) Received NA from
FE80::12
14:16:45.688: ICMPv6-ND: Validating ND packet options: valid
14:16:45.688: ICMPv6-ND: Glean unsolicited NA
14:16:45.688: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) Glean
14:16:45.688: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) LLA 0012.1212.1212
14:16:45.688: ICMPv6-ND: (GigabitEthernet2.512,FE80::12) INCMP -> STALE
```

This process happens for all of CSR2's addresses, and CSR1 gleans them all and records them as stale. The IPv6 cache statistics counts them as GLEAN entries, despite their operational capacity being "stale" in a sense.

```

```

IPv6 NUD also accounts the presence of IGP to reduce ND traffic. When routes are learned from an IGP, the next-hop will be a LL address. As seen earlier, installation of those routes in the RIB triggers ND for the next-hops whether traffic is flowing to those destinations or not. The router needing to resolve the remote next-hop sends an NS to the target's solicited-node address. If there is an IGP neighbor with that node, NUD assumes there is reachability to it, and does not wait for the NA to return before identifying the cache entry as REACH. This is enabled by default on all interfaces; the debug below on CSR2 shows that the cache entry was moved to the REACH state before the NA was received from CSR1. CSR2 knows the MAC address for CSR1 only because it received an NS from CSR1 who was performing ND for CSR2 at the same time.

```
! CSR2
15:07:59.194: %CLNS-5-ADJCHANGE: ISIS: Adjacency to R1 (GigabitEthernet2.512)

FE80::11
15:07:59.279: ICMPv6-ND: Validating ND packet options: valid

```

We can disable this behavior on CSR2, which ignores that symmetric NS coming from CSR1 in terms of honoring the source MAC address. Notice that CSR2 still stores the MAC address from CSR1, carried in the NS message. However, this transitions the entry to the DELAY state once CSR2 responds to CSR1's NS with an NA, not the REACH state. While in the DELAY state, the assumption is that we have told our neighbor about our MAC address using a solicited NA, and we are simply waiting for the neighbor to do the same. Until then, the entry is not marked as REACH. NUD is waiting for the solicited NA to come back from CSR1 which authoritatively identifies CSR1's MAC address (and implies reachability without relying on IGP).

```

Next, we will examine the RS and RA messages. Cisco routers will always send RA messages out of their IPv6 LAN interfaces unless suppressed. Suppressing them makes sense on transit links, such as CSR1-

CSR2 and CSR3-CSR6, where there are no hosts. Leaving the “all” keyword off the command only suppresses unsolicited, periodic RA messages. The “all” keyword ensures that router does not respond to RS messages with a solicited RA, either. Only CSR2 is shown, but this is configured on all transit links.

```
! CSR2
interface GigabitEthernet2.512
  ipv6 nd ra suppress all

R2#show ipv6 interface gig2.512 | include ND_RA
ND RAs are suppressed (all)
```

RAs are allowed on the LAN segments upon which CSR4 and CSR5 are hosted. This allows to hosts to discover the routers and automatically obtain IPv6 addresses from the on-link prefix(es).

```
! CSR5
interface GigabitEthernet2.556
  ipv6 address autoconfig default
```

We will examine the basic ND process between a host requiring autoconfiguration and the routers on the segment by debugging on CSR5. As expected, the very first thing all IPv6 nodes do is run DAD for their LL address. Since CSR5 has no explicit LL address, the EUI-64 process is used. This takes the 48-bit MAC address, inserts the hex string 0xFFFE into the middle of it, and sets the U/L bit in the MAC address to 1. With a MAC address of 0055.5555.5555, the EUI-64 address becomes 0255:55FF:FE55:5555. The prefix is FE80::/10 as always; CSR5 ensures its EUI-64 address is unique before doing anything else. After 1 second of not seeing an NA in response, it assumes the address is unique, and sends an unsolicited NA onto the segment to announce it.

```

```

CSR5 also needs a globally routable address, but it has no idea what the on-link prefixes are. It needs to

check for routers on the segment by issuing an RS message to the all-routers multicast group sourced from its LL address.

```
! CSR5
15:33:47.756: ICMPv6-ND: (GigabitEthernet2.556) Sending RS
15:33:47.763: ICMPv6: Sent R-Solicit, Src=FE80::255:55FF:FE55:5555,
Dst=FF02::2
```

CSR5 receives a solicited RA from CSR1 and CSR6 at the same time; we will examine CSR1's RA first. Upon receipt, the RA is validated (hop limit = 255, no bogus flags, etc). Because this was a solicited RA, the host gleans the MAC address based on the source MAC of the Ethernet frame. The entry is marked as STALE, not REACH, since traffic is not yet flowing through these routers. Next, there is a chatty process that is used for default router selection. Since CSR1 is the only router known, it is currently the best, and a default route is installed on CSR5. The RA also carries the on-link prefix 2020:5:6::11/64 which will be used for autoconfiguration soon.

```

```

CSR5 also receives an RA from CSR6. CSR6 is advertising the same on-link prefix, so CSR5 annotates that the prefix is supported by CSR6 as well since it already tracked this existing prefix. CSR6's MAC address is gleaned just like CSR1's. CSR5 continues to use CSR1 as its default-router since there are no preferences configured and CSR1 is the older entry.

```

```

Mixed in with the debugs above is the DAD process for the global address derived from

autoconfiguration. For clarity, I grouped those debug messages below. The computed autoconfiguration address uses EUI-64 as well, which means both the LL and global addresses have the same host address. Thus, only a single solicited-node multicast group must be joined, shown below. After sending the NS, DAD waits for 1 second, as usual, then declares this global unicast address unique. The ND process finishes with an unsolicited NA for other hosts on the segment; recall that routers will ignore this by default and not use them for gleaned adjacencies unless configured.

```

  FF02::2
  FF02::1:FF55:5555
```

Continuing with our verification, CSR5 maintains these two routers as STALE entries until it actually sends traffic through them. Since CSR1 is the default gateway, sending traffic off-link will move CSR1 from STALE to REACH via the NUD process.

```
R5#show ipv6 neighbors gig2.556
```

IPv6 Address	Age	Link-layer Addr	State	Interface
FE80::6	24	0066.6666.6666	STALE	Gi2.556
FE80::11	24	0011.1111.1111	STALE	Gi2.556

Since CSR1 is the default gateway, sending traffic off-link will move CSR1 from STALE to REACH via the ND process. The age also resets to 0, since the “age” column represents the last time an ND conversation occurred with the given cache entry. Because CSR1 does not have the MAC address of CSR5 mapped to CSR5’s global address, it issues an NS message for it, to which CSR5 responds.

```

If CSR5 wants to send traffic to the segment between CSR6 and CSR3, it still sends traffic to CSR1 initially. This is suboptimal and is handled with redirect messages. First, we verify that CSR1 is actually routing to CSR6 via the host LAN to which CSR5 is joined. For clarity, many of the basic NA/NS messages are stripped from the debugs since that process has been examined thoroughly.

```
R1#show ipv6 route 2020:0:3:6::/64

```

```
Last updated 00:32:25 ago
```

When CSR5 sends packets to this destination, they first go to CSR1. CSR1 issues a redirect message to CSR5 inform it of the better gateway. The target address is carried in the payload and identifies CSR6's LL address as the next-hop. CSR5 does not appear to honor the redirect, but I wanted to show the mechanism.

```
! CSR1
```

```
ICMPv6-ND: (GigabitEthernet2.556,2020:0:3:6::6) Sending REDIRECT, target
FE80::6

! CSR5
```

```
ICMPv6: Received Redirect, Src=FE80::11, Dst=2020:5:6:11:255:55FF:FE55:5555
```

Another interesting characteristic of the ND cache is the PROBE state. This is NUD in action, sending targeted (unicast) NS messages to verify reachability. The reason CSR5 performs this towards CSR6 is because the initial packet is asymmetrically routed. CSR5 sent it to CSR1, but the reply came from CSR6. CSR5 cannot guarantee that two-way reachability exists with CSR6 despite knowing it's MAC address from the RA. The cache entry transitions from the PROBE state once the solicited NA is received from the neighbor.

```
! CSR5
ICMPv6: Received echo reply, Src=2020:0:3:6::6,

ICMPv6-ND: (GigabitEthernet2.556,FE80::6) PROBE -> REACH
```

We will briefly examine anycast addressing on the LAN as well. Earlier, we saw how DAD can determine if there are duplicate addresses on a LAN; clearly this does not make sense for anycast gateways where the same IPv6 address may exist on the LAN. In XE, we can append the “anycast” keyword to an IPv6 address that essentially disables DAD for the address. In XE and XR, we can disable DAD for the entire interface, which affects all prefixes. We will use both methods on CSR1 and CSR6 while adding a new anycast IPv6 address to the subnet. We will ensure this new address is within the same on-link prefix so the composition of the RA message need not change. The method used on CSR1 is the only way to configure anycast addresses on XR.

```
! CSR1
interface GigabitEthernet2.556
  ipv6 address 2020:5:6:11::611/64
  ipv6 nd dad attempts 0

! CSR6
interface GigabitEthernet2.556
  ipv6 address 2020:5:6:11::611/64 anycast

R1#show ipv6 interface gig2.556 | section Global_uni|DAD
Global unicast address(es):
  2020:5:6:11::11, subnet is 2020:5:6:11::/64
  2020:5:6:11::611, subnet is 2020:5:6:11::/64
  ND DAD is disabled

R6#show ipv6 interface gig2.556 | section Global_uni|DAD
```

```
Global unicast address(es):
  2020:5:6:11::6, subnet is 2020:5:6:11::/64
  2020:5:6:11::611, subnet is 2020:5:6:11::/64 [ANY]
ND DAD is enabled, number of DAD attempts: 1
```

Debugging ND on CSR1 shows that the DAD software process is invoked for all three addresses, but immediately returns that the addresses are unique without actually doing anything. The timestamps prove this.

```
! CSR1
16:40:22.787: IPv6-Addrmgr-ND: DAD request for FE80::11 on
GigabitEthernet2.556
16:40:22.787: IPv6-Addrmgr-ND: DAD: FE80::11 is unique.
16:40:22.788: IPv6-Addrmgr-ND: DAD request for 2020:5:6:11::11 on
GigabitEthernet2.556
16:40:22.788: IPv6-Addrmgr-ND: DAD: 2020:5:6:11::11 is unique.
16:40:22.788: IPv6-Addrmgr-ND: DAD request for 2020:5:6:11::611 on
GigabitEthernet2.556
16:40:22.788: IPv6-Addrmgr-ND: DAD: 2020:5:6:11::611 is unique.
```

The output is similar on CSR6, but only for the anycast address. The other addresses undergo the normal DAD process.

```

```

There are several other important RA options as well. We can have multiple on-link prefixes but only offer a subset of them to clients for autoconfiguration. For example, CSR2 and CSR3 are both routers serving network access to CSR4. They have a global unicast prefix as well as a unique-local prefix for intra-site routing. The client should typically not use ULA for autoconfiguration if its wants Internet reachability. Both CSR2 and CSR3 can suppress this prefix from their RA messages so that CSR4 is not

aware of its existence. CSR2 and CSR3 have nearly identical configurations, not counting the host addresses, so only CSR2 is shown. We can verify the prefixes advertised by an IPv6-enabled router interface as well; the ULA prefix has the 'N' flag to indicate it is not advertised, while the global unicast address is. CSR4 only sees the global prefix as a result.

```
! CSR2
interface GigabitEthernet2.542
  ipv6 address FE80::12 link-local
  ipv6 address 2020:3:4:12::12/64
  ipv6 address FD00:3:4:12::12/64
  ipv6 nd prefix FD00:3:4:12::/64 no-advertise

R2#show ipv6 interface gig2.542 prefix
IPv6 Prefix Advertisements GigabitEthernet2.542
Codes for 1st column:
  A - Address, P - Prefix-Advertisement, O - Pool
  U - Per-user prefix
Codes for 2nd column and above:
  D - Default
  N - Not advertised, C - Calendar
```

```
PD default [LA] Valid lifetime 2592000, preferred lifetime 604800
AD 2020:3:4:12::/64 [LA] Valid lifetime 2592000, preferred lifetime 604800
PAN FD00:3:4:12::/64 [LA] Valid lifetime 2592000, preferred lifetime 604800
```

CSR4 only sees the global prefix as a result and computes its EUI-64 address accordingly.

```
R4#show ipv6 routers | include ^Router|Prefix
Router FE80::12 on GigabitEthernet2.542, last update 1 min
  Prefix 2020:3:4:12::/64 onlink autoconfig
Router FE80::3 on GigabitEthernet2.542, last update 1 min
  Prefix 2020:3:4:12::/64 onlink autoconfig

R4#show ipv6 interface gig2.542 | section Global_uni
Global unicast address(es):
  2020:3:4:12:244:44FF:FE44:4444, subnet is 2020:3:4:12::/64 [EUI/CAL/PRE]
    valid lifetime 2591882 preferred lifetime 604682
```

We can adjust the unsolicited RA interval and the corresponding lifetime as well. The lifetime is relevant for how long the default routing can be considered valid, not the RA itself. Debugging on CSR4, we can see that every 20 seconds, an RA from CSR2 is received (green). Every 30 seconds, an RA from CSR3 is received (yellow). For debugging brevity, we look at the ICMPv6 packet exchange without examining the ND process. To prevent RA synchronization, the timers are randomized within a range; the values configured above are maximum values. The minimum is 75% of the maximum and the actual timer used is a random number in that range. The minimum can be adjusted as well, but 75% is a good value. Thus, CSR2's RAs are sent at a rate of 15 – 20 seconds while CSR3's RAs are sent at a rate of 22.5 – 30 seconds.

```

! CSR2
interface GigabitEthernet2.542
  ipv6 nd ra lifetime 200
  ipv6 nd ra interval 20

! CSR3
interface GigabitEthernet2.542
  ipv6 nd ra lifetime 300
  ipv6 nd ra interval 30

! CSR4
16:57:59.614: ICMPv6: Received R-Advert, Src=FE80::3, Dst=FF02::1

16:59:04.014: ICMPv6: Received R-Advert, Src=FE80::12, Dst=FF02::1

```

The Default Router Preference (DRP) feature provides basic “low, medium, high” priorities as a tiebreaker for selecting a default router. On the LAN with CSR4, both CSR2 and CSR3 are originating RAs. CSR2 is configured with a priority of “high” while CSR3 uses the default priority of “medium”. We can confirm this on both routers by checking the IPv6 interface details.

```

! CSR2
interface GigabitEthernet2.542
  ipv6 nd router-preference High

R2#show ipv6 interface gig2.542 | include preference
ND advertised default router preference is High

R3#show ipv6 interface gig2.542 | include preference
ND advertised default router preference is Medium

```

Debugging IPv6 ND on CSR4, it receives unsolicited RAs from both CSR2 and CSR3 periodically. CSR4 can see this DRP value and always select CSR2 when it is available. Notice that the RA lifetimes are shown in this output as well, which are different than the prefix lifetimes. The RA lifetime measures how long this router is useful as a default router; prefix lifetimes are examined next.

```

R4#show ipv6 routers detail
IPv6 ND Routers (table: default)
Router FE80::12 on GigabitEthernet2.542, last update 0 min
  Rank 0xC19 (elegant), Default Router
  Hops 64, Lifetime 200 sec, AddrFlag=0, OtherFlag=0, MTU=1500
  HomeAgentFlag=0, Preference=High, trustlevel = 0
  Reachable time 0 (unspecified), Retransmit time 0 (unspecified)

```

```

Prefix 2020:3:4:12::/64 onlink autoconfig
Valid lifetime 2592000, preferred lifetime 604800
Router FE80::3 on GigabitEthernet2.542, last update 0 min
Rank 0xC11 (eligible)
Hops 64, Lifetime 300 sec, AddrFlag=0, OtherFlag=1, MTU=1500
HomeAgentFlag=0, Preference=Medium, trustlevel = 0
Reachable time 0 (unspecified), Retransmit time 0 (unspecified)
Prefix 2020:3:4:12::/64 onlink autoconfig
Valid lifetime 2592000, preferred lifetime 604800

```

The valid and preferred lifetimes are used to denote how long a prefix can be used or preferred. The preferred lifetime cannot exceed the valid lifetime, and these values can be tuned per-prefix. However, all routers on the segment should agree on the values or else the router will display an error message showing the differences.

```

! CSR2
interface GigabitEthernet2.542
  ipv6 nd prefix 2020:3:4:12::/64 200 180

! CSR2
%IPV6_ND-3-CONFLICT: Router FE80::3 on GigabitEthernet2.542 conflicting ND
setting prefix 2020:3:4:12::/64 valid lifetime, difference 2591800 seconds

! CSR3
%IPV6_ND-3-CONFLICT: Router FE80::12 on GigabitEthernet2.542 conflicting ND
setting prefix 2020:3:4:12::/64 valid lifetime, difference 2591800 seconds

```

For consistency, we configure these settings on CSR3 as well (not shown), then verify it on both routers and the client (CSR4).

```

R2#show ipv6 interface gig2.542 prefix | include 2020
PA 2020:3:4:12::/64 [LA] Valid lifetime 200, preferred lifetime 180

R3#show ipv6 interface gig2.542 prefix | include 2020
PA 2020:3:4:12::/64 [LA] Valid lifetime 200, preferred lifetime 180

R4#sh ipv6 router | include ^Router|Prefix|Valid
Router FE80::12 on GigabitEthernet2.542, last update 0 min
  Prefix 2020:3:4:12::/64 onlink autoconfig
  Valid lifetime 200, preferred lifetime 180
Router FE80::3 on GigabitEthernet2.542, last update 0 min
  Prefix 2020:3:4:12::/64 onlink autoconfig
  Valid lifetime 200, preferred lifetime 180

```

There are several other options we can enable per-prefix as well, such as whether the prefix can be used for autoconfiguration, whether it is on-link, etc. We will configure a bogus prefix on CSR2 only which is not on-link and cannot be used for autoconfiguration. Notice that we do not need to configure an IPv6 address on CSR2 for this prefix.

```
! CSR2
interface GigabitEthernet2.542
  ipv6 nd prefix 2020:FFFF:FFFF:FFFF::/64 infinite infinite no-autoconfig no-
onlink
```

```
R2#show ipv6 interface gig2.542 prefix | include FFFF
P 2020:FFFF:FFFF:FFFF::/64 [] Valid lifetime infinite, preferred lifetime
infinite
```

CSR4 learns the prefix but it cannot use it for much, at present. There is no ND route for it (no connected, on-link route) and it cannot be used for auto-configuration.

```
R4#show ipv6 routers default
Router FE80::12 on GigabitEthernet2.542, last update 0 min
  Hops 64, Lifetime 200 sec, AddrFlag=0, OtherFlag=0, MTU=1500
  HomeAgentFlag=0, Preference=High, trustlevel = 0
  Reachable time 0 (unspecified), Retransmit time 0 (unspecified)
  Prefix 2020:3:4:12::/64 onlink autoconfig
    Valid lifetime 200, preferred lifetime 180
  Prefix 2020:FFFF:FFFF:FFFF::/64
    Valid lifetime infinite, preferred lifetime infinite
```

```
R4#show ipv6 route nd | begin ^ND
ND  ::/0 [2/0]
    via FE80::12, GigabitEthernet2.542
NDp 2020:3:4:12::/64 [2/0]
    via GigabitEthernet2.542, directly connected
```

Next, we will examine DHCPv6 for stateless autoconfiguration. DHCPv6's role in this design is to issue non-address related configuration, such as DNS servers, domain names, SNTP servers, etc. This information doesn't need to be bound to a host and can be handed out freely to SLAAC clients upon request. A router signals that it is capable of providing DHCPv6 "other" configurations by setting the 'O' flag in the RA, described earlier. CSR3 will be the DHCPv6 server and will notify CSR4 about some non-address configurations. CSR4 doesn't have to use CSR3 as a default gateway to use this service, either. We verify that CSR4 can see this 'O' flag set in the RA from CSR3 but not CSR2.

```
! CSR3
ipv6 dhcp pool DHCPV6_POOL
  dns-server 2020::BEEF
  domain-name lab.local
  sntp address 2001:0:3:7::3

interface GigabitEthernet2.542
  ipv6 nd other-config-flag
  ipv6 dhcp server DHCPV6_POOL
```

```
R4#show ipv6 routers | include Router|Other
Router FE80::12 on GigabitEthernet2.542, last update 0 min
  Hops 64, Lifetime 200 sec, AddrFlag=0, OtherFlag=0, MTU=1500
Router FE80::3 on GigabitEthernet2.542, last update 0 min
  Hops 64, Lifetime 300 sec, AddrFlag=0, OtherFlag=1, MTU=1500
```

When CSR4 receives a solicited RA from CSR3 after having sent an RS (assume a link-up event on CSR4), it will notice the 'O' flag and invoke the DHCPv6 process to send traffic to the DHCPv6 servers and relay agents multicast group (FF02::1:2). Configuring the DHCPv6 pool on CSR3 causes it to listen to this group as a DHCPv6 server. The other group, FF05::1:3 is for DHCPv6 servers only, not relay agents, but serves the same function except is routable based on the scope bits.

```

REQUEST (STATELESS) on GigabitEthernet2.542
```

CSR3 replies to the DHCP information request with the DNS servers and domain-list. CSR4 did not ask for the SNTP servers, as seen above, so the DHCPv6 server did not respond with it. The response is a unicast reply to the clients LL address; CSR4 then saves the new DNS and domain information.

```

We can also test the stateful DHCPv6 behavior. This allows a DHCPv6 server to hand out IPv6 addresses from a specific prefix (pool) as in DHCPv4. We can extend our DHCPv6 pool to add a prefix, then offer it to CSR7 on a new interface. The 'M' and 'O' flags are set on this interface which allows CSR7 to get all of its information, both addressing and "other", from the DHCPv6 server. We confirm that CSR7 sees both of these flags in the RA from CSR3.

```

! CSR3

Unfortunately, XE does not appear to support stateful DHCPv6 client at this time. “ipv6 address dhcp” is not a supported option, but we will show the rest of CSR7’s configuration for completeness. With IPv6 enabled, a LL address can be obtained automatically. We also tell ND to automatically configure the prefix and default-route based on the address received, which would normally come from DHCPv6 in a functional design.

```
R7(config-subif)#ipv6 address ?
WORD                General prefix name
X:X:X:X::X          IPv6 link-local address
X:X:X:X::X/<0-128>   IPv6 prefix
autoconfig           Obtain address using autoconfiguration

! CSR7
interface GigabitEthernet2.537
  ipv6 enable
  ipv6 nd autoconfig prefix
  ipv6 nd autoconfig default-route
```

Additional Reading – Reference configurations “ipv6-nd”

1.2 Broadband Aggregation (BBA)

BBA is a sizable topics and only the basic concepts are covered here. Below are some example BBA architectures and definitions:

1. Direct connections from DSLAM/ANs to BNGs.
2. DSLAM/AN to an aggregate Ethernet switch, then to BNG, in a hub-spoke criss-form; classic design.
3. DSLAM/AN to an aggregate Ethernet switch, all of which are tied into a ring where the BNGs also reside.

BNG - Broadband Network Gateway. Sits between the DSLAM, or aggregator of DSL connections, and the IP network of the network service provider (NSP). It may encompass the BRAS, but the two are not the same. Some architectures may introduce dual BNGs, for example dedicating one to video services and another to all other. In dual-BNG scenarios, BOTH BNGs do not have to meet all requirements, as long as the union of the BNG capabilities does.

BRAS - Broadband remote access server. This is the aggregation point between the NSP and the access network, typically using IP. It is also an injection point for policies, such as IP QoS.

BBA - Broadband aggregation. This commonly relies on L2TP. The main component of L2TP is a reliable control channel that is responsible for session setup, negotiation, and teardown, and a forwarding plane that adds negotiated session IDs and forwards traffic. Layer 2 circuits terminate in a device called an

L2TP access concentrator (LAC), and the PPP sessions terminate in an L2TP network server (LNS). The LNS authenticates the user and is the endpoint for PPP negotiation. The LAC is closer to the customer than the LNS, and is the “downstream tail end” of the L2TP tunnel, whereas the LNS is the “upstream head end”. Thus, the PPPoE frames are tunneled inside L2TP to the LNS. The LAC connects to the LNS using a LAN or a WAN connection, and L2TP rides over the top of this. The LAC directs the subscriber session into L2TP tunnels based on the domain of each session.

1.2.1 PPP over Ethernet (PPPoE) technology

PPPoE is commonly used for BBA because it offers all of the benefits of PPP (authentication, directional call control, compression, encryption, etc) but can use Ethernet at layer 2 as transport. Many callers can “dial in” to the BNG on a shared segment and gain network connectivity in this way. Unlike Ethernet, clients cannot talk to one another, and this method works well with the N:1 VLAN paradigm discussed later, which further restricts peer-to-peer connectivity at layer 2. XR supports PPPoE server only, but XRV does not appear to support PPPoE at all. The CSR1000v supports both roles, but some features are unsupported. Currently, I have discovered that Microsoft Point to Point Encryption (MPPE) and compression (stac, predictor) are not supported. The CSR generates a log message when you try to configure these features to indicate that it’s virtual-access interface is incapable of supporting them.

```
%FMANRP_ESS-4-FULLVAI: Session creation failed due to Full Virtual-Access  
Interfaces not being supported. Check that all applied Virtual-Template and  
RADIUS features support Virtual-Access sub-interfaces. swidb= 0x7F1E9054C508,  
ifnum= 19
```

To represent a PPPoE-based BBA architecture that is somewhat realistic, we will use a hierarchical access/aggregation network (similar network used for NAT444, NAT464, etc). CSR8, CSR9, and CSR10 are the PPPoE servers while CSR2 through CSR7 are the PPPoE clients. The clients are like CPE routers in residential areas while the PPPoE servers are the BNGs. XRV1 and XRV2 are Internet gateways, and XRV3 is the Internet. Because XR does not support IPv6 SLAAC, CSR1 has several VRFs to similar a client behind each CPE router. Basic NAT44 is used to translate private CPE addressing to global addressing at the CPE; hierarchical NAT is discussed in a dedicated chapter. NAT is not the focus of this lab so very basic NAT techniques are used, otherwise the PPPoE design would be very unrealistic with IGP running everywhere.

First, we will configure PPPoE between CSR8 and CSR2; as the access concentrator (AC), CSR8 only has one client. The AC uses a virtual-template interface and the client uses a dialer interface. We will negotiate the client IP address using IP control protocol (IPCP) which is a function of PPP. The addresses issued to clients will be handed out from a local pool (not DHCP). We can also apply limits to the number of client sessions the server will accept; in this case, we say there can be only one per-MAC and per-VLAN. This prevents CSR2 from dialing into CSR8 multiple times. We must adjust the MTU on the PPPoE virtual interfaces to be 8 bytes less than the supported layer 3 MTU since PPPoE adds 8 bytes of encapsulation. To support IPv6, we create two pools. The first is meant to service the transit links (the configuration below has a tricky error; will be fixed later) and the second is a way to “delegate” a downstream IPv6 prefix for the client to use. In this way, DHCPv6 can offer CSR2 a LAN-side public prefix so that CSR2 doesn’t have to manually configure it. This prefix is exchanged using IPv6 ND, so we must unsuppress the RA advertisements on the BNG.

```
! CSR8
bba-group pppoe PPPOE_28
 virtual-template 28
  sessions per-mac limit 1
  sessions per-vlan limit 1
  ipv6 address FE80::8 link-local

ip local pool PPPOE_POOL_V4 209.2.8.100 209.2.8.149
```

```

ipv6 local pool PPPOE_POOL_V6 2001:10:2:80::/60 64
ipv6 local pool PD_POOL_V6 2001:192:168:80::/60 64

```

```

interface Virtual-Template28
  mtu 1492
  ip unnumbered Loopback28
  peer default ip address pool PPPOE_POOL_V4
  peer default ipv6 pool PPPOE_POOL_V6
  ipv6 enable
  no ipv6 nd ra suppress
  ipv6 nd ra lifetime 60
  ipv6 nd ra interval 10 5
  ipv6 dhcp server DHCP_POOL_V6

```

The client configuration is similar to the BNG. Dialers are not PPP-encapsulated by default, so we must specify this as well. NAT44 is enabled but it does not affect IPv6 traffic at all. We assign a dial-pool number which is applied at the interface level from which the session initiation occurs. We instruct the client to install a default route to the IPCP negotiated address, and for IPv6 we likewise install a default route to the BNG router discovered through IPv6 ND. The IPv6 prefix-delegation allows CSR2 to learn a prefix from the IPv6 local pool defined on CSR8 to use for its LAN segment.

```

! CSR2
interface Dialer28
  mtu 1492
  ip address negotiated
  ip nat outside
  encapsulation ppp
  dialer pool 28
  dialer idle-timeout 0
  dialer persistent
  ipv6 address autoconfig default
  ipv6 dhcp client pd PPPOE_ISP_PREFIX
  ppp ipcp route default

interface GigabitEthernet2.528
  pppoe-client dial-pool-number 28

```

First, we will enable PPP and PPPoE debugging on the client and server to watch the sequence of events. The PPP debugging is not specific to PPPoE at all and shows many low-level details. The PPPoE discovery packets seen below are described now. For clarity, the packets from the debug are shown in-line with the descriptions below.

```

! CSR2 and CSR8
debug pppoe events
debug pppoe packets
debug ppp negotiation

```

1. PPPoE Active Discovery Initiation (PADI): Sent to the Ethernet broadcast address (ffff.ffff.ffff) with a source MAC of the client. This is used to discover all ACs on the segment. Later, we will examine service-names, and only ACs with a matching service name should respond. This is similar to a DHCPDISCOVER and the PADI is sent from CSR2 to CSR8 as shown below. The destination MACs are shown in pink with source MACs in green. Notice that the PPPoE discovery ethertype is 0x8863, which is non-IP traffic (cyan, only shown once). Upon receipt, CSR8's debug shows a nice summary of the PADI header information to include remote (R) and local (L) MAC addresses, VLAN ID, and interface. The "I" before the word PADI means incoming. The server also annotates that the client's service tag is null, so no special treatment is being requested, and any server may respond. The code for PADI is 0x09 (codes are discussed later).

```
! CSR2

D2 00 00 06 00 00 0F 20
Service tag: NULL Tag
```

2. PAD Offer (PADO): The response from the AC is a unicast Ethernet frame back to the source and is sent from ACs that are capable of servicing the client. This is similar to a DHCP OFFER. CSR8 originates this message and sends it to CSR2 as a unicast frame, again with a null service tag. The PADO is outbound as denoted by the "O". CSR2 receives this PADO; we can tell because the "I" before PADO means incoming and the local MAC address is CSR2's Ethernet interface (destination of the frame). The PADO code is 0x07.

```

F4 D5
```

3. PAD Request (PADR): The client selects one of the ACs and sends a unicast Ethernet frame to it requesting to connect. This is like a DHCPREQUEST. For some reason, the output on CSR2 is inconsistent with the format seen with the PADI and PADO thus far. It simply says the PADR was sent but doesn't parse any details for us. We can easily pick out the MAC addresses and see that this is destined as a unicast frame to CSR8. When CSR8 receives it, it prepares an encapsulation string for the session. This includes the full layer 2 encapsulation of the PPPoE data frames; notice the ethertype is 0x8864 now, also non-IP, and is used for PPPoE bearer traffic. first two bytes of the PPPoE header represent this new ethertype (green). The first 4 bits in the next byte represents version and the second 4 bits represents type (cyan, both must be 1). This is the third byte of the PPPoE header. The next byte represents a code used for discovery and session stages, and is zero here (pink). The next 2 bytes (0x0013) represents the session ID, which is decimal 19 in this case (grey). The last 2 bytes represent the length of the packet at layer 3, which varies per packet and is shown as zero in the debug (red). The PADR code is 0x19.

4. PAD Session (PADS): The server acknowledges and accepts the offer which completes the PPPoE session. This packet also contains the session ID. This is like a DHCPACK. Now that the session ID has been established, the debug messages pertinent to this session will include the number (in decimal) within the debug logs. CSR8 sends the PADS back to CSR2 with this number embedded in the PPPoE header; previously it was zero for the initial PAD exchanges. The PPPoE header is shown in yellow; we can see the layer 3 packet length is 0x2A (42 in decimal). CSR2 receives this PADS packet and decodes the encapsulation string, which is identical to what CSR8 generated upon receipt of the PADR. The PADS code is 0x65.

Although not part of a successful PPPoE discovery process, a PAD Termination (PADT) is sent when the session should be torn down. From CSR2's perspective, we can see the PADT is exchanged mutually between client and server depending on who terminates the session. Session ID is 31 for this session only because I added this paragraph at the end of the testing. Most of the packet is padding since the termination message is carried as a message code (0xA7) inside of the PPPoE header, which of course includes the session ID (0x1F = 31).

```

Once the PPPoE discovery process is complete, the traditional PPP negotiation must occur. In our case, three protocols must be negotiated. As done earlier, the output is shown in sections.

1. Link Control Protocol (LCP): LCP negotiates basic PPP parameters such as packet size, method of transmission, authentication, etc. The detailed codes will not be examined here, but we can watch the LCP process. One of the first things the PPP/LCP process figures out is that, because it is within a PPPoE session, it establishes that the AC is being called (call-in) and the client is calling (call-out). This is shown in the debug logs during the magic number negotiation. This negotiation is just an agreement between both routers that the number selected can be used; MRU is also negotiated as part of determining the packet sizes. The “I” and “O”, as with PPPoE discovery, represent inbound and outbound packets. Each router sends both inbound and outbound configuration requests (CONFREQ) and acknowledgements (CONFACK). Rejected configurations generate configuration reject (CONFREJ) messages, which is often due to authentication failures. Four colors are used to show the same messages displayed on CSR2 and CSR8 for mapping purposes. Once LCP is “open”, other higher-layer protocols can begin negotiating over PPP.

```

```

2. IP control protocol (IPCP): Since both routers want to use IPv4 on the link, those parameters must be negotiated as well. In this case, CSR2 has no IP address, and indicates this in its initial outbound CONFREQ. Interestingly, CSR8 offers the address of 209.2.8.107 using a CONFNACK (negative ACK) message, which triggers a CONFREQ from CSR2 to request that same address. CSR8 confirms it with a CONFACK. This process is shown and yellow, and the simpler exchange of CSR2 learning CSR8's static address is shown in green. After IPCP is open, each one installs a connected host route to the remote peer via the PPP interface. This allows hosts in different subnets to communicate over PPP.

```

3. IPV6CP: Like IPCP, IPv6 information is negotiated over the link also. In this case, 64-bit interface-IDs are exchanged over the link which make up the host portion of an IPv6 LL address. The address don't make it into the IPv6 RIB but are tracked internally by PPP for forwarding. CSR2 informs CSR8 that it wants to use the address ending in DB00 (Green) and CSR8 informs CSR2 that it wants to use the address ending in 4D00 (yellow).

```

At this point, we will verify everything with show commands. The client and server both show the summary information for each PPPoE session in similar formats. Note: The session bounced once during the course of documenting the feature so the session ID incremented from 19 to 20. This output shows us the remote and local MAC addresses, port, VLAN, virtual interface, session ID, and state. It is the most valuable PPPoE show command. The string “PTA” means locally terminated and is present only the AC; it stands for PPP Termination and Aggregation.

```

R2#show pppoe session
    1 client session

```

Uniq ID	PPPoE SID	RemMAC LocMAC	Port	VT	VA VA-st	State Type
N/A	20	0050.56a9.fb1c 0050.56a9.be8a	Gi2.528	Di28	Vi1 UP	UP

```

R8#show pppoe session
    1 session in LOCALLY_TERMINATED (PTA) State

```

```

1 session total

Uniq ID  PPPoE  RemMAC      Port      VT  VA      State
      SID  LocMAC      Port      VA-st    Type
      20    20    0050.56a9.be8a  Gi2.528  28  Vi2.1    PTA
                0050.56a9.fb1c  VLAN:3528  UP

```

Some outputs/commands reference the session ID, so it is important to understand that concept. It may be useful to look at packet counters as well, shown below. ACs also maintain a summary view of all PPPoE sessions, included those forwarded past the AC or in a transient state.

```

R8#show pppoe session packets
Total PPPoE sessions 1

```

```

SID  Pkts-In      Pkts-Out  Bytes-In  Bytes-Out
20    882          1448      13651     50867

```

```

R8#show pppoe summary

```

```

PTA : Locally terminated sessions

```

```

FWDED: Forwarded sessions

```

```

TRANS: All other sessions (in transient state)

```

	TOTAL	PTA	FWDED	TRANS
TOTAL	1	1	0	0
GigabitEthernet2	1	1	0	0

The PPP show commands also give additional information which is specific to PPP. This includes PPP subprotocol negotiation details. We can see a summary of all PPP sessions on both routers and their negotiated protocols. Notice the peer name is blank since there is no authentication happening presently. Both CSR2 and CSR8 show that LCP, IPCP, and IPV6CP were successfully negotiated.

```

R2#show ppp all

```

Interface/ID	OPEN+	Nego*	Fail-	Stage	Peer Address	Peer Name
Vi1	LCP+	IPCP+	IPV6CP+	LocalT	209.2.8.8	

```

R8#show ppp all

```

Interface/ID	OPEN+	Nego*	Fail-	Stage	Peer Address	Peer Name
Vi2.1	LCP+	IPCP+	IPV6CP+	LocalT	209.2.8.108	

Looking at the details on CSR8, we can see there is a ton of PPP information for each sub-protocol. The items of greatest significance are highlighted. Note that the IPv6 address exchanges are not visible with any other show command to my knowledge. CSR2's output is very similar and is omitted for brevity.

```

R8#show ppp interface virtual-access2.1

```

```

Vi2.1 No PPP serial context

```

```

PPP Session Info

```

```

One particularly important piece of the IPV6CP debugging not shown above indicates an issue with assigning a prefix to the PPPoE client. This is poorly documented and not well known, so I highlight it. CSR8 says that it cannot allocate a prefix from the local pool since CSR2 has no remote name. The PPP show commands earlier prove this. We can rectify this by configuring a PAP username on CSR2 and tell CSR8 to use PAP authentication. PAP details are examined later.

```

! CSR8
Vi2.1 IPV6CP: Cannot use a pool without remote name

! CSR2
interface Dialer28
 ppp pap sent-username R2 password 0 PAP

! CSR8

```

```
username R2 password 0 PAP
interface Virtual-Template28
 ppp authentication pap callin
```

Although the IPV6CP debugs don't show the local IPv6 prefix being allocated to CSR2, it did actually work. CSR8 shows that one of its local prefixes was allocated for this purpose and CSR2 shows it as a global unicast address on its dialer interface.

```
R8#show ipv6 local pool
```

Pool	Prefix	Free	In use
PPPOE_POOL_V6	2001:10:2:80::/60	15	1
PD_POOL_V6	2001:192:168:80::/60	15	1

```
R2#show ipv6 interface dialer 28 | section Global
Global unicast address(es):
  2001:10:2:80:21E:14FF:FE15:DB00, subnet is 2001:10:2:80::/64
[EUI/CAL/PRE]
  valid lifetime 2591997 preferred lifetime 604797
```

Interestingly, IPV6CP relies on ordinary IPv6 ND to issue this prefix. CSR8 includes this prefix in an RA on the PPPoE virtual interface, which was pulled from the IPV6CP local pool. Upon receipt of the RA from CSR8, CSR2 uses this as the "on-link" prefix for the dialer interface.

```
CSR8#debug ipv6 nd
ICMPv6-ND: (Virtual-Access2.1,FE80::21E:E6FF:FE4D:4D00) Sending RA (60) to
FF02::1
ICMPv6-ND: MTU = 1492
ICMPv6-ND: prefix 2001:10:2:80::/64 [LA] 2592000/604800
CSR2#debug ipv6 nd
ICMPv6-ND: (Dialer28,FE80::21E:E6FF:FE4D:4D00) Received RA
ICMPv6-ND: Validating ND packet options: valid
ICMPv6-ND: Prefix : 2001:10:2:80::, Length: 64, Vld Lifetime: 2592000, Prf
Lifetime: 604800, PI Flags: C0
ICMPv6-ND: Update on-link prefix 2001:10:2:80::/64 on
Dialer28/FE80::21E:E6FF:FE4D:4D00, lifetime 2592000
```

This is not the same as prefix delegation, which is shown next. This process relies on DHCPv6 and not IPv6 ND to distribute those delegated prefixes.

```
! CSR2 and CSR8

dist 1 iaid 000C0001 vrf default

```

When CSR8 selects a prefix from its local pool, it also installs a static route on the AC to reach that prefix. This is very useful because it can be redistributed into IGP as needed to provide Internet connectivity. This is redistributed into IS-IS (configuration not shown), as verified below. Short of running IGP, this is an excellent, dynamic approach to issuing IPv6 prefixes to PPPoE clients.

```

R8#show ipv6 route 2001:192:168:80::/64
Routing entry for 2001:192:168:80::/64
    Known via "static", distance 1, metric 0
    Redistributing via isis 1112
    Route count is 1/1, share count 0
    Routing paths:
        FE80::21E:14FF:FE15:DB00, Virtual-Access2.1
    Last updated 00:09:40 ago

```

```

R8#show isis database 12 R8.00-00 detail | begin IPv6_Add
IPv6 Address: 2001:10:8:12::8
Metric: 0          IPv6 (MT-IPv6) 2001:192:168:80::/64

```

Below, we see that CSR2 receives this PD prefix from CSR8 and binds it to the string "PPPOE_ISP_PREFIX" which can be used elsewhere.

```

! CSR2

IPv6 DHCP: Processing options
IPv6 DHCP: Adding prefix 2001:192:168:80::/64 to PPPOE_ISP_PREFIX

```

CSR2 can use this as another IPv6 prefix on its LAN interface. The configuration is similar to the IPV6 general prefix construct and this prefix will be included in the RA messages by default. I also add a static IPv6 prefix to this link also to support non-SLAAC capable clients, such as XRv4, but remove it from the RA so that SLAAC-capable clients don't select addresses from that prefix. The "N" flag in the show command indicates that it is not included in the RA. Also note the NAT44 inside interface, which is unrelated to IPv6 but important for IPv4 connectivity to the Internet.

```

! CSR2
interface GigabitEthernet2.524
 ip nat inside
 ipv6 address FE80::2 link-local
 ipv6 address 2001:192:168:2::2/64
 ipv6 address PPPOE_ISP_PREFIX ::2/64
 ipv6 nd prefix 2001:192:168:2::/64 no-advertise
 ipv6 nd ra lifetime 30
 ipv6 nd ra interval 10 5

```

```
R2#show ipv6 interface gigabitEthernet 2.524 prefix
```

```
IPv6 Prefix Advertisements GigabitEthernet2.524
```

Codes for 1st column:

A - Address, P - Prefix-Advertisement, O - Pool

U - Per-user prefix

Codes for 2nd column and above:

D - Default

N - Not advertised, C - Calendar

```

PD default [LA] Valid lifetime 2592000, preferred lifetime 604800
PAN 2001:192:168:2::/64 [LA] Valid lifetime 2592000, preferred lifetime
604800
AD 2001:192:168:80::/64 [LA] Valid lifetime 2592000, preferred lifetime
604800

```

CSR2 has a classic CPE configuration with NAT44 (seen already) is configured with a DHCP pool to service its hosts. Since NAT44 occurs, CSR8 only needs to reach the post-NAT public address on CSR2's dialer interface.

```

! CSR2
ip dhcp excluded-address 192.168.2.0 192.168.2.20
ip dhcp pool DHCP_POOL_V4
 network 192.168.2.0 255.255.255.0
 default-router 192.168.2.2

```

CSR1 is configured as a DHCPv4 client and an IPv6 SLAAC client. AS such, it receives an address/prefix for both protocols along with a default route. CSR1 now has full Internet connectivity for IPv4 and IPv6, and this represents a typical DSL deployment.

```
R1#show ip interface brief gigabitEthernet 2.524
Interface                IP-Address      OK? Method Status      Protocol
GigabitEthernet2.524    192.168.2.21    YES DHCP    up          up
```

```
R1#show ipv6 interface brief gigabitEthernet 2.524
GigabitEthernet2.524    [up/up]
FE80::250:56FF:FEA9:1AAA
2001:192:168:80:250:56FF:FEA9:1AAA
```

```
R1#show ip route vrf 2 0.0.0.0
Routing Table: 2

Success rate is 100 percent (5/5), round-trip min/avg/max = 4/6/15 ms
```

```
R1#ping vrf 2 2bad:beef:13:aaaa::a
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 2BAD:BEEF:13:AAAA::A, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 5/7/13 ms
```

We will briefly examine service tags. We know this information is carried back and forth in the PPPoE discovery packets when negotiating a session between client and AC. If a client specifies a service tag that no ACs can service, they can respond with a PADO for that client since a “Null” service at the AC

essentially means “any service”. The client requests “BLUE” and the server responds with “BLUE”, despite “BLUE” not being configured anywhere on CSR8.

```
! CSR2
interface GigabitEthernet2.528
  pppoe-client dial-pool-number 28 service-name "BLUE"

! CSR8
PPPoE 0: I PADI R:0050.56a9.be8a L:ffff.ffff.ffff 3528 Gi2.528
contiguous pak, size 44
  FF FF FF FF FF FF 00 50 56 A9 BE 8A 81 00 0D C8
  88 63 11 09 00 00 00 14 01 01 00 04 42 4C 55 45
  01 03 00 08 87 00 00 0B 00 00 23 1D
Service tag: BLUE
PPPoE 0: O PADO, R:0050.56a9.fb1c L:0050.56a9.be8a 3528 Gi2.528
Service tag: BLUE
contiguous pak, size 70
  00 50 56 A9 BE 8A 00 50 56 A9 FB 1C 81 00 0D C8
  88 63 11 07 00 00 00 2E 01 01 00 04 42 4C 55 45
  01 03 00 08 87 00 00 0B 00 00 23 1D 01 02 00 02
  52 38 01 04 00 10 97 58 88 C2 01 8F 8A 96 23 D2
  F7 0E E3 54 F4 D5
```

Configuring CSR8 with service “RED” under the BBA means that it will only service clients with a service containing the string “RED”. The “contains” keyword indicates we can use a partial match. CSR2 will keep sending PADI messages to CSR8, which never responds with a PADO.

```
! CSR8
bba-group pppoe PPPOE_28
  virtual-template 28
  service name contains RED
PPPoE 0: I PADI R:0050.56a9.be8a L:ffff.ffff.ffff 3528 Gi2.528
contiguous pak, size 44
  FF FF FF FF FF FF 00 50 56 A9 BE 8A 81 00 0D C8
  88 63 11 09 00 00 00 14 01 01 00 04 42 4C 55 45
  01 03 00 08 87 00 00 0B 00 00 23 1D
PPPoE 0: Requested service-name BLUE has no partial match with RED,
discarding PADI R:0050.56a9.be8a L:ffff.ffff.ffff 3528 Gi2.528
```

Updating CSR8 to include the string “BLU” means that it can service CSR2, since “BLU” is contained within “BLUE”. CSR8 shows the match and sends a PADO back to CSR2.

```
! CSR8
bba-group pppoe PPPOE_28
  virtual-template 28
  service name contains BLU
PPPoE 0: I PADI R:0050.56a9.be8a L:ffff.ffff.ffff 3528 Gi2.528
```

contiguous pak, size 44

```
FF FF FF FF FF FF 00 50 56 A9 BE 8A 81 00 0D C8
88 63 11 09 00 00 00 14 01 01 00 04 42 4C 55 45
01 03 00 08 87 00 00 0B 00 00 23 1D
```

PPPoE 0: Requested service-name BLUE partial match with BLU

Service tag: BLUE

PPPoE 0: O PADO, R:0050.56a9.fb1c L:0050.56a9.be8a 3528 Gi2.528

Service tag: BLUE

However, if the client has a null service but the BBA point specifies a string, the session cannot form. CSR8 is still expecting a partial match with the “BLU” string. The BBA has restrictive logic whereby only clients requesting that specific service can be serviced by the BBA in question. This can be used for simple load-sharing, where different strings can be used by different ACs on a LAN segment. This can be overridden with the “accept-null-service” option under the BBA configuration if needed.

! CSR2

```

PPPoE 0: Discarding PADI with empty service-name R:0050.56a9.be8a

L:ffff.ffff.ffff 3528 Gi2.528

Before continuing, we fix the client to be back in “BLUE” service again. There are other ways to setup PPP networks, although CSR2/CSR8 is the most common. CSR9 is an AC that has clients CSR3, CSR4, and CSR5. CSR9 uses DHCP to hand out addresses to PPP, which is similar to the local-pool but uses a centralized DHCP process. The pool is still local to CSR9, but other hosts can also use addresses from this pool, not just PPP. IPCP is still used to issue IP addresses to clients, but DHCP or static addressing could technically be used. Rather than use IPv6 DHCP prefix delegation (PD), we can run IGP over the link to exchange IPV6 prefixes. This is not common but certainly works. We also enable PAP and CHAP authentication with a custom AAA method list. If RADIUS/TACACS were in play, the PPP sessions could be authenticated against a remote AAA server. In this case, the method-list just uses the local database. CSR9 prefers to use CHAP but can fallback to PAP. Notice that CSR9 enables ISIS on this link for IPv4; this is only to advertise the /24 connected prefix into ISIS for routing reachability. Passive-interface cannot be used on the virtual-template since it is always down. Each client has a separate VLAN for connectivity to the BNG, which conforms to the TR-101 1:1 VLAN paradigm.

! CSR9

bba-group pppoe PPPOE_P2MP

virtual-template 345

```

interface GigabitEthernet2.549
  pppoe enable group PPPOE_P2MP

interface GigabitEthernet2.559
  pppoe enable group PPPOE_P2MP

```

Aside from interface enumerations, CSR3 and CSR4 have identical configurations. They both use the same CHAP hostname as well, and refuse to use the insecure PAP method. They install default routes for IPv4 and IPv6 negotiated addresses.

```

! CSR3 and CSR4
interface Dialer3
  description CPE OUTSIDE
  mtu 1492
  ip address negotiated
  ip nat outside
  encapsulation ppp
  dialer pool 3
  dialer idle-timeout 0
  dialer persistent
  ipv6 address autoconfig default
  ipv6 enable
  ospfv3 9 ipv6 area 0

```

```

ospfv3 9 ipv6 network point-to-point
ppp chap hostname CHAP
ppp chap password 0 CHAP
ppp pap refuse
ppp ipcp route default

interface GigabitEthernet2.539
  pppoe-client dial-pool-number 3

```

CSR5 is very similar except it refuses CHAP and uses PAP. CHAP refusal is necessary since it is the preferred authentication method on the AC; failing to explicitly refuse CHAP means that authentication will fail and PAP will not be used for fallback.

```

! CSR5
interface Dialer5
  mtu 1492
  ip address negotiated
  ip nat outside
  encapsulation ppp
  dialer pool 5
  ipv6 address autoconfig default
  ospfv3 9 ipv6 area 0
  ospfv3 9 ipv6 network point-to-point
  ppp chap refuse
  ppp pap sent-username PAP_R5 password 0 PAP_R5
  ppp ipcp route default

interface GigabitEthernet2.559
  pppoe-client dial-pool-number 5

```

The only new thing to research with this design is the authentication, since IPv6 prefix-delegation is not in play, and OSPFv3 over a P2P link is not new. CSR3 and CSR9 negotiate CHAP authentication and it is successful. CSR3 receives the inbound challenge from R9, sends a response using username CHAP (which has a valid local-database entry on CSR9). CSR9 then responds that authentication was successful.

```

! CSR3
Vi2 CHAP: Redirect packet to Vi2
Vi2 CHAP: I CHALLENGE id 1 len 23 from "R9"
Vi2 LCP: State is Open
Vi2 CHAP: Using hostname from interface CHAP

```

```

ppp45 CHAP: O CHALLENGE id 1 len 23 from "R9"
ppp45 LCP: State is Open
ppp45 CHAP: I RESPONSE id 1 len 25 from "CHAP"
ppp45 PPP: Phase is FORWARDING, Attempting Forward
ppp45 PPP: Phase is AUTHENTICATING, Unauthenticated User
ppp45 PPP: Phase is FORWARDING, Attempting Forward
Vi2.4 PPP: Phase is AUTHENTICATING, Authenticated User
Vi2.4 CHAP: O SUCCESS id 1 len 4

```

CSR5 and CSR9 fail to negotiate CHAP since CSR5 refuses it, and instead authenticate with PAP. The CHAP failure is not shown in the debug since the messages sent by CSR5 (low level PPP information) carried it. PAP has less chatter than CHAP but still has an explicit authentication request from the client and response to the server. PPP authenticate in general can be done in either direction or bidirectionally, but normally the AC will authenticate the client only. For additional security, the client can authenticate the server since PPP is a peer-to-peer protocol, generally speaking. PPPoE is not used in this fashion but authentication is transport-independent.

```

! CSR5
Vi3 PPP: Phase is AUTHENTICATING, by the peer
Vi3 PAP: Using hostname from interface PAP
Vi3 PAP: Using password from interface PAP

Vi2.1 PAP: O AUTH-ACK id 1 len 5

```

Verifying the PPPoE sessions on CSR9 shows 3 subscribers, each on a different VLAN, but all in the PTA state. This shows that PPPoE is working properly. Since each PPPoE client has a statically-configured IPv6 LAN prefix, we use OSPFv3 to learn them at the BNG. CSR9 has OSPFv3 neighbors with all subscribers through the PPPoE session as well.

```

! CSR9
R9#show pppoe session
    3 sessions in LOCALLY_TERMINATED (PTA) State
    3 sessions total

```

```

Last, we examine the DHCPv4 proxy service in conjunction with PPP. The equivalent for IPv6 would be using some AAA server to issue IPv6 prefixes for prefix-delegation, but that is not tested here. In this example, PPPoE clients CSR6 and CSR7 dial-in to CSR10 and request addresses via IPCP. Because CSR10 has neither local pools nor DHCP pools configured, it sends the requests to a remote DHCP server (CSR9) much like a DHCP relay. That DHCP server will issue addresses on a per hostname basis, which implies that one of two things must happen: authentication must be used so the server sees hostnames, or the server must be configured to assign different hostnames behind the scenes to each client. Failure to do this will result in the same client-ID presented to the DHCP server, which results in the same IPCP address allocated to multiple clients. This ultimately breaks routing. CSR10 uses local DHCPv6 for PD but rather than call a local pool, it assigns specific prefixes to CSR6 and CSR7. The hexadecimal values are the DHCPv6 unique ID (DUID) of each client, which we verify later. I also add several other minor PPP IPCP and IPV6CP options to enforce uniqueness among addressing for clients, but the “username” uniqueness is what allows this design to actually work. The BBA configuration includes 2 sessions per VLAN since all PPPoE speakers are on the same segment in this broadband design, but each client can only have one session. The throttling ensures that a PPPoE client cannot try to initiate more than 5 sessions in 5 minutes, and if it does, it is blocked for 0 minutes (not blocked at all). We can set the 802.1p bits in the 802.1q VLAN tag to be CoS 7 so that the PPPoE control traffic is less likely to be dropped during times of congestion. The reason two DHCP servers are defined is because the addressing is somewhat asymmetric; CSR10 can reach CSR9’s loopback, but when CSR9 responds, it does so from a suppressed transit link as the source. CSR10 needs to account for this source or else the DHCP OFFER is automatically rejected, which explains the two DHCP server commands.

```

! CSR10
ipv6 dhcp pool DHCP_PD_R6_R7_SPECIFIC
 prefix-delegation 2001:192:168:7::/64 00030001001E49CAA400 lifetime infinite
infinite
 prefix-delegation 2001:192:168:6::/64 00030001001EBD696200 lifetime infinite
infinite

ip dhcp-server 10.9.9.9
ip dhcp-server 10.9.11.9
ip address-pool dhcp-proxy-client

```

```

bba-group pppoe PPPOE_VLAN
  virtual-template 67
  sessions per-mac limit 1
  sessions per-vlan limit 2
  sessions per-vlan throttle 5 5 0
  control-packets vlan cos 7

interface Virtual-Template67
  mtu 1492
  ip unnumbered Loopback67
  peer ip address forced

  no ipv6 nd ra suppress
  ipv6 nd ra lifetime 60
  ipv6 nd ra interval 10 5
  ipv6 dhcp server DHCP_PD_R6_R7_SPECIFIC
  ppp ipcp mask reject
  ppp ipcp username unique
  ppp ipcp address required
  ppp ipcp address unique
  ppp ipv6cp address unique

interface GigabitEthernet2.556
  pppoe enable group PPPOE_VLAN

```

The client configuration is nothing special, and is nearly identical on CSR6 and CSR7; only CSR6 is shown. Both clients receive IPCP addresses and perform NAT44 to give access for their LAN hosts. They also learn IPv6 prefixes via DHCPv6 PD for their LANs to access the IPv6 Internet.

```

! CSR6
interface Dialer6
  description CPE OUTSIDE
  mtu 1492
  ip address negotiated
  ip nat outside
  encapsulation ppp
  dialer pool 6
  dialer idle-timeout 0
  dialer persistent
  ipv6 address autoconfig default
  ipv6 dhcp client pd PREFIX_FROM_ISP
  ppp ipcp route default

interface GigabitEthernet2.556
  pppoe-client dial-pool-number 6

```

To support this design, we also need to add a new DHCP pool to service CSR10's PPPoE clients. The pool is configured on CSR9.

```
! CSR9
ip dhcp excluded-address 209.56.70.0 209.56.70.20
ip dhcp pool DHCP_PROXY_V4
 network 209.56.70.0 255.255.255.0
 default-router 209.56.70.10
```

As a general comment, the debug below shows what happens if the DHCP server from which the DHCP OFFER is received is not explicitly configured on the proxy router. The DHCP OFFER arriving on CSR10 is automatically rejected if 10.9.11.9 is not configured as an explicit DHCP server.

```
CSR10#debug dhcp
DHCP: offer received from 10.9.11.9
DHCP: offer: server 10.9.11.9 not in approved list
```

On CSR10, we examine the debugs to see how a client dials in. The initial PPP LCP process is unchanged as the DHCPv4 process is invoked by IPCP, and upper layer PPP sub-protocol. IPCP is "stalled" waiting for an address.

```
! CSR10
Vi2.1 IPCP: Stalled on pool request
Vi2.1 IPCP: CP stalled on event[IPCP Allocate Address]
Vi2.1 IPCP: Stalled on option [Address]
```

At this point, the DHCP process sends a DHCPDISCOVER to the DHCP server. The discover is sent twice, once to each server, but we know 10.9.11.9 is unroutable. The reply comes from 10.9.11.9 (CSR9 transit link) and contains the address 209.56.70.22.

```
! CSR10
DHCP: proxy allocate request
DHCP: new entry. add to queue
DHCP: SDiscover attempt # 1 for entry:
DHCP: SDiscover: sending 276 byte length DHCP packet
DHCP: SDiscover 276 bytes
DHCP: SDiscover 276 bytes

DHCP: Received a BOOTREP pkt
DHCP: offer received from 10.9.11.9
DHCP: SRequest attempt # 1 for entry:
DHCP: SRequest- Server ID option: 10.9.11.9
DHCP: SRequest- Requested IP addr option: 209.56.70.22
DHCP: SRequest placed lease len option: 75144
DHCP: SRequest: 294 bytes
DHCP: SRequest: 294 bytes
```

```

DHCP: SRequest: 294 bytes
DHCP: XID MATCH in dhcp_for_us()
DHCP: Received a BOOTREP pkt
DHCP Proxy Client Pooling: ***Allocated IP address: 209.56.70.22

```

This address is returned to the IPCP process for allocation to the client. IPCP is now “unstalled”. An inbound CONFREQ arrives with all zeroes, essentially requesting an address. The AC uses the CONFNAK message, sent outbound to the client, as a method of offering an address. The client then formally request the address and the AC confirms it. This is the same mechanism seen earlier for local-pool IPCP address allocation.

```

! CSR10

Vi2.1 IPCP: O CONFACK [ACKrcvd] id 2 len 10
Vi2.1 IPCP: Address 209.56.70.22 (0x0306D1384616)

```

The DHCP server now shows two addresses allocated to clients CSR6 and CSR7. The PPP details on CSR10 can show which address went to which host. Notice the single digit difference in the client-ID, which was done by CSR10 by making the usernames unique on call-in. Without this, the DHCP server thinks that the same client keeps asking for an address, so it responds with the same address over and over, which is not valid as it breaks routing on CSR10.

```

R9#show ip dhcp binding 209.56.70.22

Interface/ID	OPEN+	Nego*	Fail-	Stage	Peer Address	Peer Name
Vi2.2	LCP+	IPCP+	IPV6CP+	LocalT	209.56.70.23	
Vi2.1	LCP+	IPCP+	IPV6CP+	LocalT	209.56.70.22	

We can also verify the DUIDs on the clients, which do not appear configurable. To issue specific IPv6 prefixes to clients, we can map these DUIDs to manual prefixes inside the DHCPv6 pool on CSR10. This is less dynamic but more granular than using a local pool. AAA attributes allow for this functionality as well, but that is not tested here. One would have to do this first on a router if trying to assign specific PD prefixes to a CPE device via DHCPv6.

```
R6#show ipv6 dhcp
```

```
This device's DHCPv6 unique identifier(DUID): 00030001001EBD696200
```

```
R7#show ipv6 dhcp
```

```
This device's DHCPv6 unique identifier(DUID): 00030001001E49CAA400
```

To verify the CoS markings applied to CSR10, we can enable PPPoE packet debugging on CSR10 and CSR9 to compare the differences. Within CSR9's dot1q PADO header, the 4 bits preceding the VLAN ID are 0000; the first 3 bits represent the CoS which is 000, or 0 in decimal. The packet PADO from CSR10, however, has bits 1110 (0xE) which is 111, or 7. This CoS marking applies to PADO and PADS packets for PPPoE discovery, as well as PPP's LCP, NCP sub-protocols (IPCP, IPV6CP, etc), keepalives, and authentication. CSR10's PADO, PADS and PADT are shown to prove this; notice that the PADT does not have this marking set.

For client connectivity, we use the same method on CSR6 and CSR7 as we did on CSR2. This involves a local DHCPv4 pool and NAT44 for IPv4 connectivity, with IPv6 PD for the IPv6 hosts. The configuration on all devices, include the CSR1 client VRFs, is not shown. We can verify connectivity for IPv4 and IPv6 using both CSR6 and CSR7 below. Unfortunately, despite being in different VRFs, XE does not let us configure multiple IPv6 ND defaults on multiple interfaces. We manually configure static routes for VRF 6 and 7 as a result (not shown).

R1#ping vrf 6 13.144.2.1

Type escape sequence to abort.

Sending 5, 100-byte ICMP Echos to 13.144.2.1, timeout is 2 seconds:

!!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 4/6/13 ms

R1#ping vrf 6 2bad:beef:13:aaaa::a

Type escape sequence to abort.

Sending 5, 100-byte ICMP Echos to 2BAD:BEEF:13:AAAA::A, timeout is 2 seconds:

!!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 6/8/16 ms

R1#ping vrf 7 13.144.2.1

Type escape sequence to abort.

Sending 5, 100-byte ICMP Echos to 13.144.2.1, timeout is 2 seconds:

!!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 4/6/15 ms

R1#ping vrf 7 2bad:beef:13:aaaa::a

Type escape sequence to abort.

Sending 5, 100-byte ICMP Echos to 2BAD:BEEF:13:AAAA::A, timeout is 2 seconds:

!!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 6/7/12 ms

1.2.2 Multi-service PPPoE and LAC/LNS architecture

This section tests using “smart” PPPoE server selection as well as a basic LAC/LNS architecture using PPPoE as the access technology. The technical PPPoE and L2TP details are summarized since the architecture is the focus in this section; those technologies have their own sections. The network is shown below which is very similar to the PPPoE technology architecture. This time, CSR2 and CSR3 are PPPoE clients with CSR8 and CSR9 as ACs on the same LAN. CSR10 is an LNS with CSR4 and CSR5 as LACs. CSR6 and CSR7 are PPPoE clients like CSR2 and CSR3. This allows us to test PPPoE in conjunction with L2TP VPDN technologies. The upper-level architecture is still BGP-oriented since XRv does not support PPPoE or any L2VPN features, and CSR1 is generally used for most tests because it supports IPv6 SLAAC (XR in general does not).

CSR2 wants to join the "RED" service and states this in its PADI as seen in the PPPoE technology section. Both CSR8 and CSR9 offer "RED" service, but CSR9's PADO is delayed by about 1 second. Cisco will round these backoff timers to the closest multiple of 256 ms, which is why I chose 1024 ms. The PADI is a layer 2 broadcast, and both ACs will respond, but CSR2 will use CSR8's PADO since it was received first. The PADO delay timer, combined with service-name selection, is how one can achieve granularity/load-sharing with BNG nodes. Basic features like DHCPv6 PD and local pools are not shown again on the ACs since they are the same as the earlier examples. No new complexity is being introduced with those

technologies. The interface to which the VTs are unnumbered is advertised into IS-IS passively, and the netmask is big enough to encompass the entire local pool. In this way, routing to the PPPoE clients is cleanly achieved without manual configuration. IPv6 static routes generated by DHCPv6 for PD are also redistributed into IS-IS.

```
! CSR8

  ip unnumbered Loopback209
  peer default ip address pool PPPOE_BLUE_IPV4
  ipv6 enable
  no ipv6 nd ra suppress
  ipv6 nd ra interval 30
  ipv6 dhcp server DHCPV6_PD

interface GigabitEthernet2.589
  pppoe enable group PPPOE_RED

interface GigabitEthernet3.589
  pppoe enable group PPPOE_BLUE

```

The client configurations are shown below. Basic features like NAT44 and DHCPv4 are not shown again since they are the same as the earlier examples. No new complexity is being introduced with those technologies. CSR3's dialer is identical to CSR2's with the exception of numbering, so it is not shown again. The only difference is the service-name.

```

! CSR2
interface Dialer2
  mtu 1492
  ip address negotiated
  ip nat outside
  encapsulation ppp
  dialer pool 2
  dialer idle-timeout 0
  dialer persistent
  ipv6 address autoconfig default
  ipv6 dhcp client pd PPPOE_ISP_PREFIX
  ppp ipcp route default

interface GigabitEthernet2.589
  pppoe-client dial-pool-number 2 service-name "RED"

! CSR3
interface GigabitEthernet2.589
  pppoe-client dial-pool-number 3 service-name "BIG_BLUE_HOUSE"

```

We can watch the session establish when CSR2 initiates the discovery process. The debug on CSR2 (with timestamps) clearly shows the outgoing PADI, followed by two incoming PADOs.

```

R2#debug pppoe event
R2#debug pppoe packet
00:04:51.747: pppoe_send_padi
00:04:51.750: PPPoE 0: I PADO R:0050.56a9.fb1c L:0050.56a9.be8a 3589 Gi2.589

```

```

00:04:53.011: PPPoE 0: I PADO R:0050.56a9.d672 L:0050.56a9.be8a 3589 Gi2.589
00:04:53.796: PPPOE: we've got our pado and the pado timer went off
00:04:53.796: OUT PADR from PPPoE Session

00:04:53.802: IN PADS from PPPoE Session

```

CSR8 receives the PADI and matches it to the RED service. The PADO is immediately sent in reply, to which CSR2 then issues a PADR. The PPPoE discovery process continues normally and the session is formed between CSR2 and CSR8 (debug is trimmed).

```

! CSR8
00:04:51.155: PPPoE 0: I PADI R:0050.56a9.be8a L:ffff.ffff.ffff 3589 Gi2.589
00:04:51.155: PPPoE 0: Requested service-name RED partial match with RED
00:04:51.155: Service tag: RED
00:04:51.155: PPPoE 0: O PADO, R:0050.56a9.fb1c L:0050.56a9.be8a 3589 Gi2.589

```

CSR9 also receives the PADI and matches it to the RED service. It sees the PADI twice, once for RED and one for BLUE matching, and fails the BLUE match as expected. The PADO is sent about 1 second later, and CSR2 never replies with a PADR back to CSR9. CSR9 creates no PPPOE state and acts as if nothing happened.

```

! CSR9

CSR2 successfully received an IP address via IPCP (CSR8 local pool) and an IPv6 address via autoconfiguration, which was exchanged with IPV6CP. We also validate that IPv6 prefix delegation worked using DHCPv6; CSR2 receives a prefix from the pool of prefixes and CSR8 creates a static route to be redistributed into IGP.

Looking at CSR3 as a client, CSR8 does not offer the BLUE service but CSR9 does. Since CSR3 wants to join the BLUE service, only one PADO will be received from CSR9 since CSR8 cannot support it. CSR9 also supports clients with the "null" service to catch clients by default. For brevity we will debug only PPPoE events, not packets.

```
R3#debug pppoe packet
```

As a final verification to ensure NAT44 is working on CSR2 and CSR3, as well as IPv6 global unicast routing, we will send traffic from CSR1 to the Internet via both clients for both protocols. This feature is sometimes called the “smart” PPPoE server selection mechanism.

```

R1#ping vrf 2 13.144.2.1

```

Next, we progress to the LAC/LNS configuration. CSR4 and CSR5 are LACs that create L2TP tunnels to the LNS. The PPPoE sessions terminate on the LACs, but all of the intelligent PPP negotiation happens with the LNS. The LAC simply forward the PPP connections onto the LNS inside of an L2TP tunnel. This allows the CPE routers to appear directly connected to the LNS. For brevity, only CSR4 and CSR6 will be analyzed in terms of LAC and CPE; CSR5 and CSR7 are configured almost identically. IPCP and IPV6CP work exactly as one would expect; the only caveat is that all of this logic is centralized on the LNS, not the LACs. First, we will examine the CPE configurations, which are literally identical to the configurations on CSR2 and CSR3. The differences are shown below; the PAP hostname includes the domain-name so that the Virtual Private Dial-up Network (VPDN) process can match this user to a vpdn-group. All other CPE settings, such as NAT, IPCP, DHCPv6 PD, MTU, etc are the same as CSR2 and CSR3.

```
! CSR6  
interface Dialer6

  pppoe-client dial-pool-number 7
```

The LAC configuration is a little more involved. This is where the PPPoE logic terminates as there is a BBA configured on the interfaces towards the CPEs. The LAC will initiate L2TP tunnels to CSR10's LAN interface IP address (any reachable address is fine) provided the dialing user is within the lab.local domain. This is why the PAP username is valuable (CHAP can be used also). Before configuring any VPDN features, we must enable the process globally, and in this case, we want to perform domain-based matching. Notice that the LAC must be configured to authenticate CPE's via PAP despite not actually doing it. When creating L2TP tunnels, both CSR4 and CSR5 will use the name "LAC45" to identify themselves.

```
! CSR4
```

```

vpdn enable
vpdn search-order domain

vpdn-group LAC
 request-dialin
 protocol l2tp
 domain lab.local
 initiate-to ip 10.45.10.10
 local name LAC45
 l2tp tunnel password 0 L2TP_AUTH

bba-group pppoe LAC
 virtual-template 10
 sessions per-mac limit 2

interface Virtual-Template10
 mtu 1492
 no ip address
 ppp authentication pap callin

interface GigabitEthernet2.546
 pppoe enable group LAC

```

Last, we configure the LNS. AAA must be enabled or else authentication will fail, but we can simply use the local database. Usernames are manually configured for R6 and R7, which must include the domain-name as well since that is part of the PAP hostname string. The LACs requested dial-in, and the LNS accepts dial-in. It will terminate any L2TP tunnel from devices with hostname “LAC45”, which is both CSR4 and CSR5. Like the BBA object, the VPDN-group on the LNS will reference a virtual-template. This is configured just like CSR8 and CSR9 in terms of PPP options and protocols. Here, we can configure IPCP and IPV6CP to enable IPv4/v6 reachability to the CPEs. PAP authentication is also enabled on this interface. The local pools and other unrelated objects are not shown.

```

! CSR10
aaa new-model
aaa authentication login default none
aaa authentication ppp default local

username R6@lab.local password 0 R6
username R7@lab.local password 0 R7

vpdn enable
vpdn-group LNS
 accept-dialin

  peer default ip address pool LNS_POOL
  ipv6 enable
  no ipv6 nd ra suppress
  ipv6 nd ra interval 30
  ipv6 dhcp server DHCPV6_PD
  ppp authentication pap callin

```

With CSR7 disabled for now, we will debug the PPPoE, PPP, L2TP, and VPDN activities as necessary on CSR6, CSR4, and CSR10. First, the PPPoE exchange happens between the CPE and the LAC, and is limited to only those nodes. The LNS is unaware of what flavor of PPP is used on the access link. The PPPoE basic exchange is shown below.

```

R6#debug pppoe event
R6#debug ppp negotiation
02:22:07.093: Sending PADI: Interface = GigabitEthernet2.546

Next, CSR6 tries to authenticate via PAP. At this point, LCP is open and CSR6 is waiting for a response back from the LNS, so the LAC cannot respond to this. CSR4 claims there is no method list to authenticate this user after the AUTH-REQ is received from CSR6.

! CSR6

```

```

At this point, CSR4 knows that LCP was successful and that it must generate an L2TP tunnel to the LNS to complete the authentication process. The VPDN process matches the LAC group and initiates the tunnel to 10.45.10.10 as user LAC45. The L2TP tunnels comes up shortly thereafter. Most of the L2TP and VPDN debug isn't very helpful, but the key parts are shown below. CSR4 "forwards" the PPP session into the tunnel after negotiating LCP (to some extent) and forwarding the other PPP protocols (PAP, etc) onto the LNS.

```

CSR10 is now actively participating in the PPP connections with CSR6, the CPE. “FORCED” messages are exchanged within LCP to identify the handoff, and then the PAP process continues. The LNS then authenticates the user via PAP and sends the AUTH-ACK back towards the CPE. AT this point, the LAC does nothing except pass traffic back and forth.

```

```

The CPE receives this AUTH-ACK several milliseconds later since the VPDN/L2TP process took time. The remaining IPCP and IPV6CP debugs are not interesting since this is normal PPP negotiation at this point; the CPE is not aware of anything special and sees only a basic PPPoE session. Likewise, there is nothing else interesting to see on CSR10 since it is negotiating these protocols with CSR6.

```

! CSR6
02:22:09.210: Vi2 PAP: I AUTH-ACK id 1 len 5
02:22:09.210: Vi2 PPP: Phase is FORWARDING, Attempting Forward

02:22:09.211: Vi2 PPP: Phase is ESTABLISHING, Finish LCP
02:22:09.212: Vi2 PPP: Phase is UP
[snip]

```

We can verify the connectivity in stages. First, we verify that PPPoE is functional. The CPE sees the session as UP, but the LAC sees it as forwarded and not PTA as seen earlier. This makes sense because although the LAC “terminates” the PPPoE session, it is only terminating the transport; all of the PPP intelligent negotiation happens with the LNS. The MAC addresses shown below are the MACs of CSR6 (DE0D) and CSR4 (2C57), since the LNS is not aware that PPPoE is used.

```

R6#show pppoe session
      1 client session

```

Uniq ID	PPPoE	RemMAC	Port	VT	VA	State
	SID	LocMAC			VA-st	Type
N/A	24	0050.56a9.2c57	Gi2.546	Di6	Vi2	UP
		0050.56a9.de0d			UP	

```

R4#show pppoe session
      1 session in FORWARDED (FWDED) State
      1 session total

```

Uniq ID	PPPoE	RemMAC	Port	VT	VA	State
	SID	LocMAC			VA-st	Type
30	24	0050.56a9.de0d	Gi2.546	10	N/A	FWDED
		0050.56a9.2c57	VLAN:3546			

Next, we verify PPP connectivity. CSR6 and CSR10 show normal output; this makes sense because they negotiated all of the PPP upper-layer protocols required for communication. In passing, we can also see that an IPv4 address was issued to CSR6 from the local pool on the LNS via IPCP. The details on CSR10 reveal that LCP is “jammed”, meaning that it is being forced open not because it was negotiated with the peer, but because of another process. In this case, VPDN/L2TP is holding it open. There is otherwise nothing special about these PPP parameters.

```

CSR4 shows new information; it was initially involved in negotiating LCP and LCP was shown as “open” in the debugs, so it is shown as such. PAP never really completed since it was forwarded to the LN, so it is listed as “negotiating”. We can look at the details of this PPP session by hex ID since there isn’t an interface associated with it.

62430      62075      10.45.10.10  est,UP     R6@lab.local, Gi2.546:3546
```

The information is similar on the LNS. The difference is that the remote name is LAC45, which was configured under the VPDN-group on the LAC and matched by the LNS. CSR10 sees the session to CSR6 via CSR4’s transport address. These 10.45.10.0/24 addresses are the tunnel endpoints.

```

2641	62430	39858	R6@lab.local, Vi3.1	est	00:44:34	88

With CSR6 connected, we will bring up CSR7 next. This time, we will enable more detailed L2TP debugs CSR10 (LNS) without enabling any PPPoE, PPP, or VPDN debugs. Since CSR6 and CSR7 are logically equivalent, we use this debugging approach for variety. This will allow us to see the details of the L2TP tunnel and session construction. The debugs are verbose so only the most critical parts are shown. First, the LAC determines that a tunnel is needed to 10.45.10.10, which is the LNS IP address identified in the VPDN group. Soon, the LAC determines its source IP address of 10.45.10.5 and uses L2TP over UDP, along with its local hostname LAC45, to initiate the tunnel. Because there are no existing sessions between these routers, a new L2TP control channel must be created. This requires the LAC (initiator) to send an SCCRP to the LNS.

```
R5#debug l2tp events

```

CSR10 receives the SCCRQ and continues signaling the control channel back to 10.45.10.5. The SCCRQ is processed so that LAC45 can be matched to a VPDN group. After that, the LNS sends the SCCRP back to the LAC.

```

```

CSR5 receives the SCCRP, authenticates the LNS, and replies with a SCCCN to indicate the control channel tunnel is built. CSR10 receives the SCCCN, authenticates the LAC, and moves the control channel to the established state, just as CSR5 did when it sent the SCCCN.

```
! CSR5

```

Now, CSR5 must initiate a call to CSR10 for this particular PPP session. It sends an ICRQ to CSR10 who matches this to the VPDN application. It checks the access circuits (which I assume are the connected interfaces) then replies with an ICRP.

```
! CSR5
19:25:22.055: L2TP 0000D:08037:00000C6B: FSM-Sn do Tx-ICRQ

! CSR10

```

We can verify this similarly as we did for CSR4 and CSR6. Checking the LAC (CSR5), we can see the PPPoE session is forwarded and that PPP LCP has negotiated completely. The remote PPPoE MAC (EA77) is CSR7 and the local MAC (DC63) is CSR5.

```
R5#show pppoe session
      1 session  in FORWARDED (FWDED) State
      1 session  total
```

Uniq ID	PPPoE SID	RemMAC LocMAC	Port	VT	VA VA-st	State Type
13	3	0050.56a9.ea77 0050.56a9.dc63	Gi2.557 VLAN:3557	10	N/A	FWDED

```
R5#show ppp all
Interface/ID OPEN+ Nego* Fail- Stage Peer Address Peer Name
-----
0xAB00000D LCP+ PAP* Fwded 0.0.0.0 R7@lab.local
```

The L2TP tunnel (control channel) is formed to CSR10. The session uses this control channel as it references the tunnel ID of 44384 and is also terminated on CSR10, the LNS. The session shows the username of R7 so it is clear that this session is associated with a given user.

```
R5#show l2tp tunnel summary
L2TP Tunnel Information Total tunnels 1 sessions 1
LocTunID RemTunID Remote Name State Remote Address Sessn L2TP Class/
Count VPDN Group
44384 31646 R10 est 10.45.10.10 1 LAC
```

```
R5#show l2tp session brief
L2TP Session Information Total tunnels 1 sessions 1
LocID TunID Peer-address State Username, Intf/
sess/cir Vcid, Circuit
3179 44384 10.45.10.10 est,UP R7@lab.local, Gi2.557:3557
```

The LNS shows two L2TP tunnels and two sessions. There will always be one tunnel per LAC and one session per user; the number of tunnels will always be less than or equal to the number of users as a result. Since the tunnels used the same remote name for the control channel, the only way to tell the difference is by examining the remote IP address.

```
R10#show l2tp tunnel
L2TP Tunnel Information Total tunnels 2 sessions 2
LocTunID RemTunID Remote Name State Remote Address Sessn L2TP Class/
Count VPDN Group
31646 44384 LAC45 est 10.45.10.5 1 LNS
39858 62075 LAC45 est 10.45.10.4 1 LNS
```

```
R10#show l2tp session brief
```

```
L2TP Session Information Total tunnels 2 sessions 2
LocID      TunID      Peer-address      State      Username, Intf/
sess/cir   Vcid, Circuit
39823      31646      10.45.10.5        est,UP     R7@lab.local, Vi3.2
2641      39858      10.45.10.4        est,UP     R6@lab.local, Vi3.1
```

To create additional calls through a LAC, we can add a new dialer to CSR7. We won't use this for routing or anything intelligent; we don't even have to configure IPv4 or IPv6. Just building the PPPoE session to the LAC is enough to cause a new L2TP session to establish. L2TP achieves scalability by mapping new sessions to existing tunnels between a common set of endpoints.

```
! CSR7
interface Dialer77
  mtu 1492
  encapsulation ppp
  dialer pool 77
  dialer idle-timeout 0
  dialer persistent
  ppp pap sent-username R77@lab.local password 0 R77

interface GigabitEthernet2.557
  pppoe-client dial-pool-number 77

! CSR10
username R77@lab.local password 0 R77
```

Now, the LAC sees two PPPoE sessions between the same pair of MAC addresses. The only difference is the session ID which is included in the encapsulation string as a demultiplexer.

```
R5#show pppoe session
  2 sessions in FORWARDED (FWDED) State
  2 sessions total
```

Uniq ID	PPPoE SID	RemMAC LocMAC	Port	VT	VA VA-st	State Type
13	3	0050.56a9.ea77	Gi2.557	10	N/A	FWDED
		0050.56a9.dc63	VLAN:3557			
14	4	0050.56a9.ea77	Gi2.557	10	N/A	FWDED
		0050.56a9.dc63	VLAN:3557			

There is still only a single L2TP control channel, but there are two sessions that rely on it now. The sessions have different local IDs and usernames, but otherwise go to the same LNS.

```
R5#show l2tp tunnel
L2TP Tunnel Information Total tunnels 1 sessions 2
LocTunID  RemTunID  Remote Name  State  Remote Address  Sessn L2TP Class/
Count VPDN Group
```

```
44384      31646      R10          est      10.45.10.10      2      LAC
```

```
R5#show l2tp session brief
```

```
L2TP Session Information Total tunnels 1 sessions 2
```

LocID	TunID	Peer-address	State	Username, Intf/ sess/cir	Vcid, Circuit
21902	44384	10.45.10.10	est,UP	R77@lab.local,	Gi2.557:3557
3179	44384	10.45.10.10	est,UP	R7@lab.local,	Gi2.557:3557

As expected, the LNS sees two control channels (one per LAC) but three sessions (one per user). The sessions for R7 and R77 use tunnel ID 31646 which maps to CSR5, the LAC with two calls behind it. For variety, we use the “show vpdn” command, which displays the same L2TP information arrayed differently. Each control channel is displayed separately with all supported sessions beneath it. The control-channel to 10.45.10.5 has 2 sessions which are shown next. Then, the control-channel to CSR4 is shown with its session as well. The usernames are shown with the sessions for clarity.

```
R10#show vpdn
```

```
L2TP Tunnel and Session Information Total tunnels 2 sessions 3
```

LocTunID	RemTunID	Remote Name	State	Remote Address	Sessn Count	L2TP VPDN	Class/Group

LocTunID	RemTunID	Remote Name	State	Remote Address	Sessn Count	L2TP VPDN	Class/Group
39858	62075	LAC45	est	10.45.10.4	1	LNS	

LocID	RemID	TunID	Username, Intf/ Vcid, Circuit	State	Last Chg	Uniq ID
2641	62430	39858	R6@lab.local, Vi3.1	est	17:48:38	88

At this point, we can validate the IPv4 and IPv6 unicast routing. We saw earlier that IPv4 addresses were properly exchanged using IPCP by checking the PPP details. We will verify the routing table by checking connected host routes on CSR6 and CSR7. These address were issued from the LNS’ local pool.

```
R6#show ip route connected | include Dialer
```

```
C      209.10.10.10 is directly connected, Dialer6
C      209.10.10.61 is directly connected, Dialer6
```

```
R7#show ip route connected | include Dialer
```

```
C      209.10.10.10 is directly connected, Dialer7
C      209.10.10.59 is directly connected, Dialer7
```

Additionally, we verify that both CSR6 and CSR7 were able to receive IPv6 prefixes from DHCPv6. They are applied to the CPE LAN interfaces to support SLAAC.

```
R6#show ipv6 general-prefix
IPv6 Prefix PPPOE_ISP_PREFIX, acquired via DHCP PD
2001:192:168:A1::/64 Valid lifetime 2527643, preferred lifetime 540443
GigabitEthernet2.564 (Address command)
```

```
R7#show ipv6 general-prefix
IPv6 Prefix PPPOE_ISP_PREFIX, acquired via DHCP PD
2001:192:168:A0::/64 Valid lifetime 2589055, preferred lifetime 601855
GigabitEthernet2.574 (Address command)
```

Both CSR6 and CSR7 should have IPv4 and IPv6 default routes to the LNS as well. The IPv4 default route was automatically added by IPCP, and the IPv6 default route was added by IPv6 ND (SLAAC).

```
R6#show ip route 0.0.0.0
Routing entry for 0.0.0.0/0, supernet
  Known via "static", distance 1, metric 0, candidate default path
  Routing Descriptor Blocks:
  * 209.10.10.10
    Route metric is 0, traffic share count is 1
```

```
R6#show ipv6 route ::/0
Routing entry for ::/0
  Known via "ND", distance 2, metric 0
  Route count is 1/1, share count 0
  Routing paths:
  FE80::21E:14FF:FE6F:8300, Dialer6
    Last updated 00:07:58 ago
```

```
R7#show ip route 0.0.0.0
Routing entry for 0.0.0.0/0, supernet
  Known via "static", distance 1, metric 0, candidate default path
  Routing Descriptor Blocks:
  * 209.10.10.10
    Route metric is 0, traffic share count is 1
```

```
R7#show ipv6 route ::/0
Routing entry for ::/0
  Known via "ND", distance 2, metric 0
  Route count is 1/1, share count 0
  Routing paths:
  FE80::21E:14FF:FE6F:8300, Dialer7
    Last updated 00:08:46 ago
```

A quick confirmation of routing on the LNS is helpful as well. The routing table is not clear as to which IPv4 address was assigned to which client, so we can check the PPP IPCP details. Thanks to PAP, we can

see the username in the PPP summary, and conclude that Vi3.1 is for R6 and Vi3.2 is for R7. The third session to “R77” uses Vi3.3 but failed to negotiate IPCP, has no IPv4 address, and thus is not used for IPv4 routing.

```
R10#show ip route connected | include Virtual-Access
C      209.10.10.59/32 is directly connected, Virtual-Access3.2
C      209.10.10.61/32 is directly connected, Virtual-Access3.1
```

```
R10#show ppp all
```

Interface/ID	OPEN+	Nego*	Fail-	Stage	Peer Address	Peer Name
Vi3.1	LCP+	PAP+	IPCP+	IPV6>	LocalT	209.10.10.61 R6@lab.local
Vi3.3	LCP+	PAP+	IPCP-	IPV6>	LocalT	0.0.0.0 R77@lab.local
Vi3.2	LCP+	PAP+	IPCP+	IPV6>	LocalT	209.10.10.59 R7@lab.local

We also confirm that the LNS installed static routes for the two IPv6 prefixes issued to the CPEs via DHCPv6 PD. 2001:192:168:A0::/64 was issued to CSR7 and 2001:192:168:A1::/64 was issued to CSR6, according to the outgoing interfaces in the routing table. This is consistent with the CPE verifications we did earlier. These static routes are redistributed into ISIS, and we can verify this in the ISIS LSPDB.

```
R10#show ipv6 route static | begin ^S
S      2001:192:168:A0::/64 [1/0]
      via FE80::21E:49FF:FECA:A400, Virtual-Access3.2
S      2001:192:168:A1::/64 [1/0]
      via FE80::21E:BDFF:FE69:6200, Virtual-Access3.1
```

```
R10#show isis database detail level-2 R10-00.00 | include MT-IPv6
Metric: 10          IS (MT-IPv6) XRv1.00
Metric: 0           IPv6 (MT-IPv6) 2001:192:168:A0::/64
Metric: 0           IPv6 (MT-IPv6) 2001:192:168:A1::/64
```

Note that the LACs play no role in routing whatsoever. Looking briefly at CSR4, it generally only has routes to the LNS; in this case, a connected LAN. For IPv6, it has no routes at all, and it is not even enabled for IPv6. There is no reason for it to be unless the L2TP endpoint was an IPv6 address, which may not be supported in all versions of IOS.

```
R4#show ip route | begin Gateway
Gateway of last resort is not set

      10.0.0.0/8 is variably subnetted, 2 subnets, 2 masks
C      10.45.10.0/24 is directly connected, GigabitEthernet2.545
L      10.45.10.4/32 is directly connected, GigabitEthernet2.545

R4#show ipv6 route | begin Applic
a - Application
L      FF00::/8 [0/0]
```

via Null0, receive

Finally, we confirm connectivity from the client simulator (CSR1) for both CPE routers using both IPv4 and IPv6.

```
R1#ping vrf 6 13.144.2.1

1.3 MEF Ethernet Services Definitions (MEF 6.2)

Ethernet services as defined by MEF are shown below. For each type of service, there are port-based (private) and VLAN-based (virtual private) variations.

E-LINE: “Point-to-point” Ethernet virtual circuit. It functions just like an Ethernet cable in terms of its layer 2 capabilities. Only the low-level, layer-1 signaling is not shared between customer devices across an E-LINE.

- a. **EPL:** Ethernet Private Line. Simple P2P service with low delay and low loss. No service multiplexing or CoS applications is allowed (except for basic CIR/PIR policing). This is literally a P2P connection between two sites and multiple C-VLAN tags are not allowed for service mapping. Bundling is also disallowed and the maximum number of EVC is fixed at 1, but there is no limit on source MAC addresses that can be used. Technically, each node at the end of the link is identified as a “root” node and a maximum of two UNIs can exist in the EPL. The CE-VLAN IDs, including their CoS markings, must be preserved across the EVC.
- b. **EVPL:** Ethernet Virtual Private Line. P2P Ethernet service where service multiplexing (more than one EVC) is allowed. The individual EVCs can be given special CoS parameters. An individual EVC would be created by allowing multiple C-VLAN IDs and mapping each to a different EVC. It’s like a collection of P2P links, but the EVCs are separate P2P links, so not like a LAN. This is loosely analogous to OSPF P2MP network type in a hub-and-spoke design. Many of the same capabilities/limitations apply for EVPL as they did for EPL, except bundling is possible. The CE-VLAN IDs, including their CoS markings, do not have to be preserved across the EVC, which implies C-VLAN rewrite operations are permitted.

E-LAN: MP2MP EVC. It's like an emulated LAN design. Because this is a true LAN, every node is set to have "root" status so it can talk to every other node directly. The maximum number of UNIs is three or greater, otherwise it would just be an E-LINE. The EVC type is classified as "Multipoint-to-multipoint".

- a. **EP-LAN:** LAN services with similar behavior as EPL. Bundling and service multiplexing are disabled as the LAN service is port-based, and an EVC maximum of 1 is imposed. CE-VLAN ID and CoS values must be preserved across the private LAN service.
- b. **EVP-LAN:** LAN services with similar behavior as EVPL. Bundling is possible and service multiplexing is enabled as the LAN service is VLAN-based with no EVC maximum. However, C-VLAN ID and CoS values don't have to be preserved across the private LAN service.

E-TREE: P2MP E-LAN service where the leaves/spokes can communicate with the root/hub but not with one another. It's like an emulated private VLAN design. The most common use is in franchise operations where small offices/sites need not communicate directly. Technically, it could also be a MP2MP partial mesh if there are multiple root nodes. The root nodes must be set to "root" mode so they can talk to all nodes. The remaining nodes are placed in "leaf" mode so they only have connectivity to roots. An E-TREE must have at least two leaves; the only exception is starting with two "roots" and adding leaves later. The EVC is classified as "rooted-multipoint".

- a. **EP-TREE:** This has the same characteristics of an EP-LAN with the additional reachability restrictions determined by the placement of root/leaf nodes.
- b. **EVP-TREE:** This has the same characteristics of an EVP-LAN with the additional reachability restrictions determined by the placement of root/leaf nodes.

1.4 Platform Architecture

This section focuses primarily on the ASR9000 architecture and its forwarding processes.

1.4.1 Route-Switch Processor (RSP) and Route Processor (RP)

The ASR9000 series router will have a set of RSPs or RPs, depending on its size. The purpose of the RSP/RP is to be the centralized control-plane of the router. Packets punted by line-cards or information directed to the router itself (such as BGP updates) is processed here. They are not designed for forwarding traffic, but are capable of doing it slowly. These cards also contain coaxial ports for precision time sources/methods (SyncE, IEEE 1588, GPS, etc). They also contain the traditional management interfaces such as USB, console, auxiliary, and network management Ethernet ports. RSP cards can be clustered together (there are dedicated ports on the RSP for it) which allow multiple routers to be tied together to create one large logical entity. The difference between an RSP and RP is the presence or absence of the switching fabric. To connect remote linecards, an internal switching fabric is used as a high-speed transport between ingress and egress linecards. On platforms that use RSPs, such as ASR9001, ASR9006, and ASR9010, this switching fabric is part of the RSP. This doesn't mean the traffic is processed-switched nor punted to the routing engine, just that the high-speed backplane is physically on the card. On the ASR9922, the largest router, RPs are used, not RSPs. The RPs only serve the routing control-plane function since 7 additional fabric cards can be added for additional resiliency. This large router decouples the switching fabric from the routing engine from a hardware perspective.

1.4.2 Line cards (LC)

Linecards are modules that can be added to a router to add specific capabilities. Typically, linecards will be densely populated with low speed ports, sparsely populated with high speeds ports, or somewhere in between. They also can support additional media types such as frame-relay, ATM, SONET/SDH, T1/T3, E1/E3, etc. Linecards have their own set of computing resources which are optimized for forwarding frames in and out. Most linecards have some limited control-plane intelligence so that basic functions like ARP, BFD, ACL, QoS, and Netflow can be offloaded from the RSP/RP. The linecards have network processors (NP) which are mapped to a number of individual ports. Often times the port to NP ratio is between 3:1 and 6:1, which means that there are still a lot of NPs on a linecard to process transit network traffic. The NPs are connected to fabric interface ASIC (FIA) which are self-explanatory; they connect linecards to the switching fabric. This is how inter-LC traffic transits across a router. Typically there will be fewer FIAs than NPs, just as there are fewer NPs than physical ports, so there is some hierarchy to the forwarding model within the LC. The NP is not the same as the LC-CPU, which is only consulted occasionally as discussed later.

1.4.3 Switching fabric / backplane and forwarding model

The switching fabric is used to connect all components of a router. It is physically present on RSPs in the ASR9010 and smaller, yet is a dedicated card on the ASR9922. Unlike some other routers, there are no “shortcut” paths where linecards can exchange information directly. All packets must traverse the switch fabric as it is an integral part of the 3 stage forwarding process. Shortcuts are unnecessary since the bandwidth of the switch fabric is so high, which simplifies the design. Forwarding happens in 3 stages: ingress linecard, switch fabric, and egress linecard. When packets arriving at the ingress LC, the traffic is classified one of two ways: transit, host, or exception.

1. Transit traffic is simple as the LC will consult its FIB on the NP (LCs have a copy of the FIB so the RSP is not interrupted), perform a rewrite (MAC address, MPLS label, etc), and forward to the switch fabric via the FIA. This is true even if the egress LC is the same as the ingress LC. This “hairpin” isn’t a big deal; there are no shortcuts within a linecard in the ASR9000 platforms. Once on the switch fabric, which is the second stage, the packet is forwarded to the appropriate egress LC. Even if traffic is going between two adjacent ports that share a linecard’s NP, the traffic still transits the switching fabric. Once on the fabric, the second stage of forwarding occurs as the traffic is delivered to the proper egress LC. The third stage involve the egress LC delivering the packet to the proper NP, and ultimately the proper physical port. Sometimes this is described as “2 phase” forwarding where only the ingress and egress LC decisions are made, and the switching fabric forwarding doesn’t count as a stage. An additional feature of this feature is that egress NPs can signal “backpressure” to the upstream FIA during periods of congestion. The ingress FIA facing the fabric can buffer traffic as necessary.
2. Host-traffic destined “for us” will either be punted to the LC-CPU or RSP, depending on the update. An ARP update would go to the LC-CPU while a BGP update would go to the RSP. This traffic is also subject to LPTS, which is described later. Link-local traffic, such as IPv6 ND or IGPs, also falls into this category. Any kind of management traffic, such as telnet/SSH, is also forwarded to the RSP/RP for processing since the intent is to manage the router itself.

3. Exception traffic is traffic that should have been transit traffic but wasn't due to some condition, such as TTL expiration. This is forwarded to the LC-CPU. The only exception to this rule is IGMP snooping, which is punted to the RSP CPU.

1.4.4 Multicast forwarding and hierarchical replication

The ASR9000 replicates multicast traffic as close to the egress point as possible, even inside the router itself. When a multicast packet is received, the ingress LC tags the packet (in software, no change to the packet) with a fabric group ID and multicast group ID. When the packet ultimately arrives at the fabric, because all transit packets must cross the switching fabric, the FGID is used to determine which egress LCs need the packet. The fabric then replicates the packet as necessary to each egress LC, keeping in mind the ingress LC might be in the set of egress LCs as well. The LC switch fabric uses the MGID to replicate the packet to downstream FIAs, and the FIAs use the MGID as well to replicate the packet down to egress NPs. The egress NPs consult their MFIBs to replicate the packets to multiple ports, if necessary. In this way, there are 4 stages of replication: switching fabric, LC fabric, FIA, and egress NP.

1.4.5 Satellite operations (remote linecards)

The ASR9000 platforms also support the concept of a remote linecard, known as the ASR9000v. This is somewhat similar to a Nexus 2000 fabric extender (FEX) which connects to a Nexus 5000 switch. The ASR9000v can be connected to the ASR9000 using up to (4) 10 GbE links (can be bundled). The remaining (44) ports can support 1 GbE connections. There is no local switching done on the satellite, much like the N2K FEX. All operations, to include QoS, is done on the host device (ASR9000 router). The ASR9000v discovery mechanism works like CDP since "NV" has its own discovery mechanism. The satellite heartbeat is once per second to ensure it remains reachable. The satellite is configured from the ASR9000 and certain satellite ports can be assigned to specific 10 GbE uplinks or ether-channel ports that connect the host to the satellite.

3.1 WAN technologies

3.1.1 Packet over SONET/SDH

Synchronous Optical Networking (SONET) and Synchronous Digital Hierarchy (SDH) send multiple digital signals over fiber concurrently. SONET is prevalent in the USA and Canada and is defined by ANSI. SDH is prevalent everywhere else and is an ITU standard. One major difference in these technologies is that the header information (such as IP or Ethernet headers) are not necessarily transmitted first, but are interleaved with the payload at layer 1. Some bytes from the header are sent, then bytes from the payload, and this process is repeated multiple times until the packet is totally sent. Graphically, the packet would look like a rectangle if each of the transmission were placed atop one another, and this is how SONET reassembles the packet (at a high level).

SONET and SDH both support many low-level alarms which obviate overlay failure detection techniques like BFD. Many of these alarms are self explanatory, but I add a brief comment in parenthesis after some of them.

```
RTR12410-1(config-if)#pos report ?  
all      all Alarms/Signals
```

b1-tca B1 BER threshold crossing alarm
 b2-tca B2 BER threshold crossing alarm
 b3-tca B3 BER threshold crossing alarm
 lais Line Alarm Indication Signal (if SLOF or SLOS, set at remote end)
 lrdi Line Remote Defect Indication
 pais Path Alarm Indication Signal (defect noticed on peer signal; minor)
 plop Path Loss of Pointer
 prdi Path Remote Defect Indication (issue with a node two sites away)
 rdool Receive Data Out Of Lock
 sd-ber LBIP BER in excess of SD threshold
 sf-ber LBIP BER in excess of SF threshold
 slof Section Loss of Frame (errors in the framing pattern/alignment)
 slos Section Loss of Signal (0->1 or 1->0 bit transitions not seen)

SONET keepalives are also independent between peers. One side can have it enabled, and the other can have it disabled. The timers can also be mismatched. The CRC for a POS interface defaults to 16 bits but can be increased to 32 for extra resiliency. The automatic protection switching (APS) feature allows for a pair of SONET links to serve as active/standby. The Working (W) link is backed up by the Protect (P) link and the failover time is about 50 ms. The two links must be in the same APS group. The routers communicate APS information using the Protect Group Protocol (PGP). These concepts of working/protect links are also extended to MPLS Transport Profile (MPLS-TP) as discussed later.

For OAM functionality, a Data Communication Channel (DCC) exists over SONET/SDH as well. It can also be used for remote provisioning over a SONET link. This is somewhat similar to Ethernet LMI (E-LMI) and other OAM protocols add to Ethernet to support service provider operations.

The chart below summarizes the speeds for common circuit names. Remember that SONET OC-1 is 51.84 Mbps and SDH STM-1 is 155.52 Mbps, and achieve the rest of the number is simple multiplication. For example, an OC-3 is 3 OC-1s, and $51.84 * 3 = 155.52$. An OC-24 is 8 OC-3s and an STM-64 is 16 OC-4s, for example. The OC designation refers to a signal in its optimal form and the frame format represents the size of data carried. An OC-3, technically speaking, consists of 3 STS-1s, not 3 OC-1s. Of note, a SONET OC-192 is often time compared against 10 GbE because their speeds are almost identical (cyan).

SONET OC Level	SONET frame format	SDH level and frame format	Line rate
OC-1	STS-1 (810 bytes)	STM-0	51.84 Mbps
OC-3	STS-3	STM-1	155.52 Mbps
OC-12	STS-12	STM-4	622.08 Mbps
OC-24	STS-24	N/A	1.244 Gbps
OC-48	STS-48	STM-16	2.488 Gbps
OC-192	STS-192	STM-64	9.953.28 Gbps
OC-768	STS-768	STM-256	39.813 Gbps

3.1.2 T1/E1 and T3/E3

T-carrier and E-carrier technologies have been around for many years and are typical WAN circuit designations. They are time division multiplexing (TDM) based and are similar in many ways. Each of

them are a collection of 64 kbps channels, called DS0s, which are aggregated into a larger bundle to form these specifications. Each DS0 carries 8 bits every 125 us, which is 64 kbps. T-carriers are common in North America, Japan, and South Korea. E-carriers are common in Europe. A T1 consists of 24 DS0s while an E1 consists of 32, yielding 1.536 Mbps and 2.048 Mbps, respectively. However, once all 24 of the DS0s carry their data, an extra framing bit as adding for OAM functionality, yielding a 193 bit T-1 frame. For this reason, a T1 is said to have 1.544 Mbps line rate speed. The logic is extended to T3 circuits where even more framing bits are used, and the logic is similar for E3. The math behind it is beyond the scope of this summary.

Certain network devices may allow the network administrator to break out DS0s individual for various purposes. For example, the 8 kbps channels could each carry a voice phone call, and some DS0s within a T1/E1 could be dedicated for that. Remaining channels could be bonded for data transmission. The initial function of these circuits was to carry phone calls.

The chart below summarizes the speeds for the 4 main circuit types above.

Circuit / Carrier	Composition	Data rate
T1 / DS1	24 DS0 + 1 frame bit	1.544 Mbps
T3 / DS3	28 DS1 + 69 frame bit	44.736 Mbps
E1	30 DS0 (or E0)	2.048 Mbps
E3	16 E1 + frame bits	34.368

3.1.3 Dense Wavelength Division Multiplexing (DWDM)

Wavelength division multiplexing (WDM) is a method of transmitting many different wavelengths of light onto a single fiber media. This is the same thing as frequency division multiplexing (FDM), which is a term used in radio frequency networking, but the concept is the same. WDM is typically used when referring to optical carriers. Dense WDM is an enhancement to the original WDM (coarse WDM) to stuff more wavelengths onto a single medium, which increases the bandwidth. The two ends of a link will have a multiplexer and demultiplexer to combine and restore the signal, respectively. An optical supervisor channel (OSC) can also be transmitted over the same optical medium to serve OAM purposes; it is analogous to SONET's DCC. Many types of modulation are supported over this medium, to include AM, FM, PSK, QAM, and others. The major benefit of DWDM is that it can expand optical capacity without having to lay more fiber. The channel spacing between wavelengths becomes smaller as technology matures and more wavelengths can be "stuffed" onto a fiber pair. DWDM is most commonly used for commercial long-haul systems and often uses C-band frequencies. Most DWDM deployments run on single-mode fiber, which is built for long-haul transmissions at higher data rates and has a diameter of 9 um. SMF only allows a single ray (mode) of light, which requires more precise lasers. This also increases the range significantly as light does not bounce around within the fiber core as reflected by the cladding. Multi-mode fiber is more common at the premises with a core diameter of ~62.5 um. MMF requires less precise LEDs as light sources since rays can bounce around within the core, but distance is severely limited when compared to SMF. The light bounding inside the MMF causes distortion which limits range, but is much more affordable than SMF.

3.2 IP connectivity to the customer

Because broadband implementation can be a sizable topic, the entire BBA and PPPoE sections demonstrate some of the network connectivity techniques and architectures. This section gives a brief overview of the access technologies only.

3.2.1 Digital Subscriber Line (DSL)

DSL is a widely deployed “last-mile” access technology, typically for residential and small/medium enterprise (SME) customers. It relies on existing telephone lines which are already widespread across the world. DSL passes digital data over telephone lines by using a different set of frequencies than are used to carry phone conversations. Intelligent filtering prevents the voice and data frequencies from interfering with one another. A DSL connection is generally comprised of a DSL modem at the customer end and a DSL access multiplexer (DSLAM) at the provider end. The DSLAM aggregates many DSL connections and, using some kind of transport media like ATM or Ethernet, connects to the BRAS described earlier. There are many types of DSL, most of which are just newer versions and better speeds, but there are two main variants.

SDSL: Symmetric DSL means that the download (from provider to customer) and upload (to provider from customer) speeds are the same. If two sites are considered “peer”, that is, being used as a WAN mechanism to link offices, this would be an appropriate choice. It also may be appropriate for a SME HQ site that is sending a fair amount of data to the Internet.

ADSL: Asymmetric DSL means that the download speed is much faster than the upload speed. Technically the opposite also qualifies as ADSL but doesn’t really exist. This is the most common form of DSL deployed for residential access as most consumers want to download much more information than they upload.

3.2.2 Cable Internet

Like DSL, cable Internet access uses an existing infrastructure that is very common in many homes, which is cable television. This uses coaxial cables as compared to phone lines, but still requires a modem to transmit digital data over the cable lines, much like DSL. At the cable TV provider facility, there are a series of “splitter” devices that ensure data traffic can flow bidirectionally. That is to say, users can upload and download information. This is similar to telephony where calls can be placed or answered. Cable TV however, is receive-only, so TV traffic is still only allowed downstream.

3.2.3 Wireline

Any delivery mechanism that relies on wires, which includes DSL and cable Internet, is considered wireline. Those aforementioned technologies are subsets of this topic, so rather than discuss them again, I will discuss other wireline technologies. Although considered prohibitively expensive and unnecessary years ago, “fiber to the premises” is becoming more popular. This is a dedicated fiber connection to each residence or business, which generally provides superior service. It also commands a premium price (at the time of this writing) in some areas, and is not available everywhere. Rather than re-use existing telephone or cable TV lines, this builds a dedicated network connection. The benefit is

that, with service providers offering IP-based TV and telephony solutions, the existing phone and cable lines may become obsolete. The single fiber connection could conceivably be the only network connection necessary in the future to provide TV, telephone, and Internet service to customers.

4. Virtualization concepts

4.1 SVR vs. HVR

Software-Isolated Virtual Router (SVR): Achieves isolation between different routing instances in software exclusively. This means that the VRs contend for the same set of physical resources. There are three models for achieving this, but the underlying point is that hardware resources are always shared in the data plane. The most obvious and practical example of an SVR in the Cisco world is a VRF. Other vendors may reference to these SVR constructs as routing-instances.

- a. **Overlay:** Guest OSes overlay atop a host operating system. Scales poorly as it introduces resource contention issues. The host OS would be a Type 1 hypervisor, by loose definition.
- b. **Kernel:** Integrates virtualization into the kernel itself (like a Type 2 hypervisor). This essentially turns the kernel into an OS that provides an interface by which VMs communicate with hardware. Introduces extra complexity and instability into the kernel.
- c. **Application:** Doesn't use multiple OSes but virtualizes individual applications. Lower overhead but complicates design, testing, and management of the SVRs. Applications would also need to understand some virtualization aspects, requiring application rework.

Hardware-Isolated Virtual Router (HVR): Dedicated hardware components (cards in a chassis) to both the control and data planes of a router. The only thing shared in an HVR system is "sheet metal" and potentially blowers, electrical lines, and other basic service components. No virtualization is needed in either plane and eliminates contention between VRs. They are more resilient (an attack targeting one does not affect another), easier to manage (clear separation of management boundaries), and scale better (adding more HVRs mean more HW, but also more performance).

For data centers, SVR makes more sense. Rack space/power tend to be premium resources, while router scale is of little consequence. In a DC, routers are typically gateways to provide DC services and are not bearing the load of east-west traffic in a DC. Routing tables are relatively small and transit bandwidth is also. The routers in a DC also tend to need the same or similar feature sets, and since SVRs are hosted on a single platform, this is achieved automatically. DCs are also managed by common entities with multiple administrative domains, so using SVRs is a good choice.

For SP POPs, the situation is almost the opposite. Rack space/cooling are typically easier to come by since the provider probably owns the premises, where DC's tend to rent it. The routers need to be very powerful in both the control and data planes (not including non-transit devices like BGP route-reflectors or out-of-band management devices). In terms of features, a PE and P router have very different roles, so enabling/optimizing for certain feature performance matters based on placement. Management-wise, the scope of administration is more stove-piped so having HVRs is a better option in an SP environment.

Cisco routers running IOS-XR (ASR9K, CRS, etc) can have their cards allocated to secure domain routers (SDRs). Each router is effectively an HVR, sharing only the chassis and the low-level control mechanisms inside of it. They are otherwise totally isolated with their own RPs, forwarding line cards, and other components allocated by the administrator. Connections across SDRs would be external (use cables, no backplane magic). The HVR approach scales linearly with the number of SDRs; with SVRs, the capability of the system is divided every time a new SVR is introduced. The main downside to HVRs is that more routers requires more money, where SVRs are typically free.

4.2 Network Functions Virtualization (NFV)

NFV decouples network functions from hardware appliances and puts them into software, typically as virtual machines. The idea is that provisioning new network components/services, such as firewall, router, load balancer, etc, becomes much faster and easier. This is basically a fancy way of using vFirewalls and vRouters in a network to virtualize some/all of the network functions. The term is quite self-explanatory. Product-wise, the Cisco CSR1000v, XRv, ASAv, vWLC, and several others all contribute to the concept of NFV in some capacity. Almost all of the studying in this lab was done using NFV by that definition. The specific benefits of NFV come from being able to rapidly provision network functions, string them together in a customer-desired topology, and offer this as a network service for a fee. Simply virtualizing network devices isn't very exciting by itself, but the ability to rapidly provision network services for customers is impossible with physical appliances.

4.3 Software Defined Networking (SDN)

Not to be confused with NFV, SDN's goal is to remove the control-plane (brains) from network devices and centralize it in software. The forwarding devices in the data plane (muscles) would be control-plane-less (or with a limited, distributed control-plane for failover). There are many different opinions/designs being proposed for SDN. One extreme is to have all of the brains centralized in a controller while the forwarding devices are commodity items with no intelligence whatsoever (complete centralization). Another extreme is the current deployment of a "legacy" network, which is a totally distributed control-plane. Hybrid approaches tend to Cisco's focus area whereby a centralized controller can optimize particular application flows but devices are still intelligent enough to operate autonomously if required. This forms the basis of their Application-Centric Infrastructure (ACI) model commonly used in Cisco-based data centers. Many SDN standards are still emerging and most new products today claim support for some of these SDN interfaces that allow them to control or be controlled.

Cisco's Performance Routing (PfR) is, in my opinion, the first actually-deployed quasi-SDN solution on the market. It has matured significantly over the past several years and is used extensively in intelligent WAN (IWAN) deployments to reduce costs/optimize bandwidth for enterprise networks. PfR is beyond the scope of CCIE SP and is not evaluated in detail here.

While the "white box" model of total centralization is considered the target architecture by many, it brings other challenges. Packets with IP router alert options or MPLS router alert labels must be punted to the SDN controller, which is over the network. The controller is then responsible for making a

forwarding decision, which puts it in the transit path for some flows. This could be considered a security risk and certainly comes with a performance impact. It may complicate basic MPLS OAM functionality as it relies on IP and MPLS router alert mechanisms. The concern is valid for low-level protocols like IPv4 ARP, IPv6 ND, VFD, QoS, ACL, etc; The ASR9000 offloads these to line-cards to protect the RSP/RP. Other challenges include maintaining a very robust and high-speed management network required to sustain the chatter between SDN controllers and client devices.

5. Mobility concepts

5.1 LTE

Long Term Evolution (LTE) architecture consists of many various components and interfaces shown in the diagram below. The individual parts and their interactions are described here.

UE: User Equipment. This would be an end-user device like a cell phone. Each UE contains a Universal Integrated Circuit Card (UICC). Within the context of LTE, this is also called the SIM (Subscriber Identity Module). In a cell phone, the SIM identifies a phone's number, billing plan, and all other network-related information.

eNodeB: Also called eNB. These are base stations that control the mobile nodes in one or more calls. A base station that is supporting a specific mobile node is reference as the mobile node's "serving eNB". LTE mobile nodes can only communicate with one base station at a time. The eNB has two primary functions: send/receive radio transmissions and to control low-level signaling such as handover commands. eNBs are connected to one another to support mobility events (for packet forwarding and handover) using the X2 interface, and connect to upstream data networks via the S1 interface. The eNodeBs do not need to be fully meshed. The UEs talk to eNodeBs via the LTE-Uu interface.

RAN: Radio Access Network. This is a way of providing backhaul from access networks to the provider's core network. Backhaul is discussed later.

UMTS: Universal Mobile Telecommunication System. This was the third generation (3G) network upon which 4G LTE was built. This was a combination of circuit and packet switched architectures which was more hierarchical (sometimes called "lumpy" by those who prefer "flat" networks) than the current 4G LTE architecture.

E-UTRAN: Evolved UMTS Terrestrial RAN. This encompasses the entire LTE access network, which general consists of eNodeB radios. The E-UTRAN is responsible for mobility control, radio admission control, eNB configuration and provisioning, and dynamic resource allocation (scheduling). LTE is designed to be all-IP (only packet switched) with a flatter architecture. Peak download rates are ~299.6 Mbps with peak upload rates of 75.4 Mbps (highly dependent on equipment, environment, etc). There are many standardized "cell widths" as well: 1.4 MHz, 3 MHz, 5 MHz, 10 MHz, 15 MHz and 20 MHz.

EPC: Evolved Packet Core. This is a network that contains several sub-components described below. It is responsible for forwarding traffic, handover events, filtering, billing, and accounting.

HSS: Home Subscriber Server is a central database that contains information about all of the subscribers within a given network.

PDN Packet Data Network. Any external network beyond the LTE architecture, such as the Internet.

P-GW: PDN Gateway. This communicates with external PDNs using the SGi interface. Each PDN is identified by a different access point name so that multiple PDNs can exist. The P-GW allocates IP address to the UEs and performs packet filtering for security purposes. The IP addresses allocated to UE's is likely dependent on the PDN to which the P-GW is connected.

S-GW: Serving Gateway. This acts as a router and forwards data between the eNodeB and the PDN Gateway. Only the S-GW and P-GW actually forward bearer traffic; the majority of LTE components are for signaling/control only. The interface between S-GW and P-GW will be either S5 or S8. S5 is used when the S-GW and P-GW are in the same network, and S8 is used when they are in different networks. The S-GW communicates to the E-UTRAN via the S1-U interface. The S-GW is also the mobility anchor point, which is used for encapsulating (tunneling) traffic between S-GWs when mobility events occur.

MME: Mobility Management Entity. Facilitates mobility-related signaling between the HSS and the E-UTRAN devices. It is the main control entity for the entire E-UTRAN and is also responsible for authentication services. The MME communicates to the HSS using the S6a interface and to the E-UTRAN using the S1-MME interface. MMEs can communicate to one another using the S10 interface.

PCRF: Policy Control and Charging Rules function. Mainly responsible for QoS policy, flow-based charging functionality, and policy control enforcement function (PCEF). It connects to the P-GWs via the Gx interface so the edge of the EPC can appropriately bill subscribers in the E-UTRAN, treat their traffic according to SLAs, etc.

5.2 Backhaul

Generally speaking, a backhaul link is any link that connects the small subnetworks at the edges (access or aggregation networks) to the core network. Within the context of LTE, this would provide the transport for the eNodeB to the S-GW, or the S1-U interface described in the LTE section. It could also carry inter-eNodeB traffic/signaling for mobility events (X2 interface) or eNodeB to MME signaling (S1-MME interface). Traditionally, backhaul links have been TDM-based, such as T1/E3. Multiple TDM links could be bundled together to support higher bandwidth backhaul links, but over time this became less profitable. Ethernet has been used very successfully given its lower cost and higher bandwidth compared to traditional TDM technologies. SONET/SDH can also be used but is less common. Wireless backhaul can be popular for a number of reasons, but comes with drawbacks as well. The benefits of wireless backhaul using microwave links is that they are easy/fast to deploy and allow moving POPs as necessary. They tend to be slower than wired connections (less bandwidth) and are viewed as a temporary measure. Assuming high towers are available, microwave links are more desirable, cheaper, and more scalable than copper links, but not as desirable as fiber. Cell towers, for example, are migrating from wireless to fiber optic connections. For smaller nodes where POPs require mobility, wireless backhaul is the best option for the RAN. Wireless links can be licensed or unlicensed; the FCC regulates power output restraints both, but the difference is that spectrum for unlicensed bands is not managed by anyone.

6. Describe BGP path attributes

This section will not belabor the extensively documented BGP best-path selection algorithm. Instead, I will comment heavily on the lesser known caveats. Before best-path runs, there are some pre-checks:

1. **Next-hop reachability:** Mandatory, well-known, and transitive. There must be a route to the BGP next-hop. It can be BGP for recursive lookups also, but ultimately a connected route is at the bottom of every recursive route lookup anyway provided there isn't a fault. Failure to meet this reachability condition results in (inaccessible) appearing next to the next-hop value.
2. **iBGP synchronization:** Often off by default, this rule states that for an iBGP route to be considered for best-path, there must be a matching IGP route in the routing table. Matching means exact prefix length match, so less specific aggregates cannot satisfy the iBGP synchronization condition. Static routes can also satisfy this rule, but IGP routes are typically used. It's original purpose was to ensure one did not create multihop iBGP peerings where routers in the transit path were not running BGP at all. **Note: if the underlying IGP is OSPF and synchronization is enabled, the OSPF and BGP RIDs must match for the iBGP route to be synchronized.**
3. **Pre-bestpath cost-community:** Optional, non-transitive. This feature is tested heavily in this document. If the pre-bestpath point of insertion (POI) is passed in a prefix via extended communities, it is considered before any other best-path attribute. The rules for its operation are defined in the appropriate section of this document, but in summary, it is the ultimate "trump card" for influencing the best-path selection short of route filtering.

The selection process begins with the following steps, summarized from the attached Cisco reference:

1. **Weight:** Optional, local only. Higher is better, and locally originated prefixes are assigned a value of 32,768 by default. This default weight optimization makes the "local origination" step moot since local prefixes are almost always preferred.
2. **Local preference:** Mandatory, non-transitive. Higher is better with a default value of 100. Typically assigned inbound to an eBGP peer to affect traffic flows outbound. A number greater than 100 forces traffic in an AS to exit towards a particular eBGP peer, and a number less than 100 makes an egress point less desirable. This attribute is maintained across confed-external boundaries.
3. **Accumulated IGP (AIGP):** Documented heavily in its own chapter, this feature is allows BGP to add the IGP metric to the BGP next-hop with the remote ASes metric value. It's like MED except higher in the best-path selection but also accounts for the local IGP costs, too. Effectively, it is an end-to-end cost carried inside of BGP.
4. **Locally originated better than BGP learned:** Given the weight assigned by Cisco routers for locally originated prefixes, local origination beats even local preference by default. Otherwise, routes locally originated by a router ("sourced") are preferred over any learned BGP routes.
5. **AS-path length:** Mandatory, transitive, and well-known. The local AS is appended to an UPDATE message when routes are advertised out of an AS. Within a confederation, the values are placed into a parenthesized list and treated as a single AS. When existing a confederation, this list is

collapsed into the AS number for the entire AS. AS path pre-pending is commonly set outbound to influence traffic flows inbound (opposite utility as local preference).

6. **Origin:** Mandatory, transitive, and well-known. IGP implies the route was derived from IGP (network statement), EGP is a legacy option soon to be deprecated, and incomplete implies unknown origin (redistribution). It isn't commonly used for path selection but can be used either inbound or outbound to influence flows out or in, respectively.
7. **Multi-exit discriminator (MED):** Optional, non-transitive. Used to carry the IGP metric to remote ASes to "hint" at the best path within the source AS network. Can be set outbound to influence flows inbound, similar to AS-path pre-pending. AIGP extends the idea of MED by taking the same (or similar) value and evaluating it sooner in concert with the BGP next-hop metric. In a multi-homed environment, if there are multiple peer ASes, this feature cannot be used since MED is non-transitive, so AS-path prepending would work instead.
8. **Neighbor type:** eBGP preferred over iBGP. Confed-external is treated the same as confed-internal, so this would be a tie in that case. The idea is to have "hot potato" routing by default where getting traffic out of the AS is preferable.
9. **IGP metric to the BGP next hop:** Computed locally based on the recursive route lookups. Lower numbers are preferred since that implies a shortly IGP path to the next BGP router in the topology. Summed with AIGP, if configured, to determine lowest path-cost metric end to end.

The following steps are considered "tie breakers" because after this point, from a performance and optimal routing perspective, BGP cannot tell if there is one path obviously better than the others.

10. **IGP cost-community:** Optional, non-transitive. This feature is tested heavily in this document. If the IGP point of POI (which is the default) is passed in a prefix via extended communities, it is considered as the first "tie breaker". You can use this in your routes to further "hint" the best path without changing real BGP attributes. The rules for its operation are defined in the appropriate section of this document.
11. **Multipath:** Not really a selection criterion, but this is normally where multipath determinations would go. Multipath rules can be relaxed for iBGP unequal cost (where the IGP metric can be unequal), as well as the AS-path numbers.
12. **For eBGP only, select the oldest route:** This appears at the bottom of the route details when using the "show bgp afi safi x.x.x.x" command. The idea is to reduce churn in the eBGP topology by selecting the most stable route.
13. For iBGP or eBGP with the "**always compare RID**" configured, select the route coming from the lowest BGP RID. It's generally not used, because selecting the oldest eBGP route helps reduce churn in the BGP process for eBGP peers. For iBGP routes coming from a route-reflector (or had an RR anywhere in the path), a field known as the "originator" is compared instead. The value of this option is for more deterministic eBGP routing when evaluating tie-breakers.
14. **For iBGP, select the route with the lowest cluster-list length:** The idea is to pick the route that was reflected the fewest number of times.

15. **Lowest peer address:** This is the final tie-breaker and is a totally arbitrary selection criterion. This is not the lowest peer BGP RID; it is the lowest peer address where the TCP session is established.

7. Describe MPLS forwarding and control plane mechanisms

There are many control-plane components to MPLS. The details of LDP and static bindings are described here since other methods like BGP, RSVP-TE, and SR are detailed in their own sections. These protocols are discussed very briefly here for completeness.

LDP is a very common method for allocating labels for IP prefixes within an MPLS core. It typically runs one-to-one with the underlying IGP so that all IP-enabled links are also MPLS-enabled, provided the destination is an IP prefix.

BGP can also be used to distribute transport labels. This is commonly called the “labeled-unicast” address family and is relevant for IPv4 and IPv6. It is commonly used to support 6PE, Unified MPLS, and Carrier supporting Carrier (CSC) architectures. Each of these topics is examined in great detail, so this is just meant to be a summary. The additional IPv4/v6 label capability is advertised during the BGP peer negotiation to determine whether peers can exchange labels or not. Failure to negotiate this AFI means that the IPv4/v6 session can still form and distribute IPv4/v6 prefixes, but not MPLS labels.

RSVP with traffic engineering (TE) extensions can be used to build LSPs in a network enabled for TE. This is explained in great detail later in this book. The reason it is mentioned here is because, like BGP, it could theoretically be used to completely replace LDP.

Segment Routing (SR) is designed to actually replace LDP by carrying the prefix-to-label bindings inside of IGP messages, such as IS-IS LSPs and OSPF LSAs. This removes the need for advanced LDP features like IGP synchronization which is described later.

7.1 Label Distribution Protocol (LDP)

As mentioned earlier, LDP is commonly used within a core to provide transport service between MPLS service endpoints. First, we begin with some definitions.

Label distribution modes:

Downstream on Demand (DoD): Each LSR requests a label binding for a FEC following that IP routing path. There is only one binding per FEC received and only from its downstream LSR. The LIB only shows one remote binding. This is only used on Label Controlled (LC) ATM interfaces.

Unsolicited downstream (UD): Each LSR distributes a label binding for all IGP routes to all neighboring LSRs without being asked to do so. The LIB will likely show a binding from each neighbor. This is used on all interfaces except LC-ATM.

Label retention modes:

Liberal Label Retention (LLR): All labels are stored in the LIB for a given FEC. Only the label from the downstream LSR, according to the FIB, is installed in the LFIB. The others are for backup only and this facilitates FRR. Better for HA and used on all interfaces except LC-ATM.

Conservative Label Retention (CLR): Only the label from the downstream LSR is stored in the LIB. Better for memory conservation and only used on LC-ATM interfaces.

LSP control modes:

Independent: Each LSR creates a local binding for a FEC as soon as it recognizes the FEC (that is, the IP prefix is in the FIB via IGP). No other LSR is involved. Disadvantage is that some LSRs forward packets before the LSP is set up. Used in most Cisco platforms.

Ordered: LSR only creates a binding for a FEC if it realizes that it is the egress LSR, or if it received a label binding from the next-hop for this FEC. Only allocates labels for connected routes or IGP routes for which it has received a binding from the next-hop LSR. Used on Cisco ATM switches.

The focus of this test is LDP and basic MPLS forwarding, so advanced MPLS services (L3VPN, L2VPN, TE, etc) are not examined in any detail. The network is a large IS-IS and OSPF domain with multiple levels and areas. Although not relevant for LDP (and probably a bad design), I illustrate this to show that LDP is IGP-agnostic and LSPs can be built across IGP boundaries provided there is IP reachability. Note that CSR7 has connections to XRv1 in both areas 0 and 1.

The basic interface and IGP configurations are not shown, but the highlights are shown below. Of note, CSR3 is an L1/L2 router that leaks /32 level-2 routes into level-1 to complete the LSPs. Failure to do this will break LSPs as we will see later as LDP bindings are prefix-specific. With the exception of the L2-into-

L1 leaking, the full IS-IS configuration is shown since it is near-identical on all IS-IS routers. CSR4 and XRv1 are OSPF ABRs but have no special filtering configured since area 1 is a non-stub area.

```
! CSR3
ip prefix-list PL_HOST_ROUTES seq 5 permit 0.0.0.0/0 ge 32

route-map RM_L2_INT0_L1 permit 10
  match ip address prefix-list PL_HOST_ROUTES

router isis LDP
  net 00.0000.0000.0003.00
  advertise passive-only
  metric-style wide
  log-adjacency-changes all
  redistribute isis ip level-2 into level-1 route-map RM_L2_INT0_L1
  passive-interface Loopback0
  address-family ipv6
    multi-topology
  advertise passive-only
```

CSR6 and XRv2 mutually redistribute between IS-IS and OSPF, and use administrative distance (AD) to ensure IS-IS routes are never learned via OSPF, which could cause loops. I use a parameterized RPL structure on XRv2 for modularity, and re-use route-maps on CSR6. There are better and more strict ways to accomplish the redistribution, but since it isn't the focus of this lab, I use a fast method.

```
! XRv2
prefix-set PS_HOST_ROUTES
  92.0.0.0/24 ge 32
end-set

route-policy RPL_MATCH_IF_DEST($PS)
  if destination in $PS then
    pass
  endif

router isis LDP
  address-family ipv4 unicast
  redistribute ospf 92 level-1 route-policy RPL_MATCH_IF_DEST(PS_HOST_ROUTES)

router ospf 92
  distance ospf external 255
  redistribute isis LDP route-policy RPL_MATCH_IF_DEST(PS_HOST_ROUTES)

! CSR6
ip prefix-list PL_HOST_ROUTES seq 5 permit 92.0.0.0/24 ge 32

route-map RM_REDIST_FILTER permit 10
  match ip address prefix-list PL_HOST_ROUTES
```

```

router ospf 92
 redistribute isis LDP level-1 subnets route-map RM_REDIST_FILTER

router isis LDP
 redistribute ospf 92 route-map RM_REDIST_FILTER level-1

```

Once all of the basic interfaces, routing, and redistribution are configured, every router should be able to see the loopbacks of every other router. I will test this at CSR1 and XRv3, since those are at the edges of the network. Fortunately, the routing table is sorted so we can quickly scan to see 14 loopbacks on each. Reachability could be broken, but since we will be configuring MPLS, we don't care right now.

```

R1#show ip route 92.0.0.0 255.255.255.0 longer-prefixes | begin Gateway
Gateway of last resort is not set

```

```

```

There are two main ways to enable LDP: at the interface level, or automatically on a 1:1 basis with IGP. I use a combination of methods throughout the topology to make things interesting, but the effect is the same regardless of which method is used. I personally prefer auto-config because its less typing and automatically enables LDP wherever IGP is enabled; in many cases this can be tuned on a per-level or per-area basis. It also accounts for any new IGP-enabled interfaces in the future, which helps maintain IGP/LDP synchronization. First, we will look at the simpler manual method. This is configured on CSR10, and while the command makes no explicit reference to LDP, it enables MPLS for IP prefixes. The default protocol used for IP label bindings is LDP, which is different than Cisco's Tag Distribution Protocol (TDP) which is older and inferior. We also need LDP enabled for static label bindings as seen later. After configuring this, we can quickly verify that LDP is enabled for this interfaces as shown below.

```
! CSR6
interface GigabitEthernet2.530
  mpls ip
```

```
interface GigabitEthernet2.504
  mpls ip
```

```
R10#show mpls interfaces
```

Interface	IP	Tunnel	BGP	Static	Operational
GigabitEthernet2.530	Yes (ldp)	No	No	No	Yes
GigabitEthernet2.504	Yes (ldp)	No	No	No	Yes

The alternative method is to use auto-config, shown on CSR3. We can optionally specify either level-1 or level-2 if we want to be granular, but since CSR3 is the L1/L2 router, we enable it for both levels. Then, we verify it is enabled on all IS-IS interfaces.

```
! CSR3
router isis LDP
  mpls ldp autoconfig
```

```
R3#show mpls interfaces
```

Interface	IP	Tunnel	BGP	Static	Operational
GigabitEthernet2.523	Yes (ldp)	No	No	No	Yes
GigabitEthernet2.530	Yes (ldp)	No	No	No	Yes
GigabitEthernet2.534	Yes (ldp)	No	No	No	Yes

If we look at the detailed interface command on both CSR3 and CSR10, it will tell us whether LDP has been enabled via the interface command (mpls ip) or auto-config via IGP. We will look at the link that CSR3 and CSR10 share to show the difference.

```
R10#show mpls interfaces gigabitEthernet 2.530 detail
```

```
Interface GigabitEthernet2.530:
  Type Unknown
  IP labeling enabled (ldp) :
```

```

    Interface config
    LSP Tunnel labeling not enabled
    IP FRR labeling not enabled
    BGP labeling not enabled
    MPLS operational
    MTU = 1500

R3#show mpls interfaces gigabitEthernet 2.530 detail
Interface GigabitEthernet2.530:
    Type Unknown
    IP labeling enabled (ldp) :
    IGP config
    LSP Tunnel labeling not enabled
    IP FRR labeling not enabled
    BGP labeling not enabled
    MPLS operational
    MTU = 1500

```

Auto-config may not be appropriate for all interfaces. For example, a router may have 100 interfaces but only 90 should be MPLS enabled. Rather than configure “mpls ip” 90 times, you can select individual interfaces to disable auto-config. As an example, CSR7 and XRv1 have two parallel links between themselves. VLAN 517 is MPLS-enabled by VLAN 571 should not be, and both routers use auto-config. In XE, we can disable this on a per-link basis at the interface level. On XR, we perform the same logic under the LDP process.

```

! CSR7
interface GigabitEthernet2.571
    no mpls ldp igp autoconfig

! XRv1
mpls ldp
interface GigabitEthernet0/0/0/0.571
    address-family ipv4
    auto-config disable

```

To verify it, we can check to see if MPLS is enabled on those specific interfaces. XE shows no output, which is implicit confirmation that MPLS is not enabled on this link. XR gives explicit confirmation to arrive at the same conclusion.

```

R7#show mpls interfaces gigabitEthernet 2.571
Interface          IP          Tunnel    BGP Static Operational
[no output]

RP/0/0/CPU0:XRv1#show mpls interfaces gigabitEthernet 0/0/0/0.571
Interface is not MPLS-enabled: 'GigabitEthernet0/0/0/0.571'

```

Before continuing with any advanced topics, we will examine the LDP discovery and neighbor formation process. First, LDP sends hello packets to the all-routers multicast group of 224.0.0.2 using UDP port 646. Unlike many other protocols, LDP does not introduce a new IP protocol for its operation, using UDP and TCP only. During the initial session discovery, we can reveal these details with a debug command. Below, CSR3 sends an LDP hello on the link towards CSR10, and CSR10 does the same. Upon receiving the LDP hello, CSR3 creates a new session for neighbor 92.0.0.10:0, where the last 0 represents the label space. System-wide label space is represented with a value of 0, while interface-specific label spaces use other numbers but only have relevance for ATM. These are not examined here.

```
! CSR3
debug mpls ldp transport events interface g2.530

ldp: Send ldp hello; GigabitEthernet2.530, src/dst 92.3.10.3/224.0.0.2,
inst_id 0
ldp: Rcvd ldp hello; GigabitEthernet2.530, from 92.3.10.10 (92.0.0.10:0),
intf_id 0, opt 0xC
ldp: ldp Hello from 92.3.10.10 (92.0.0.10:0) to 224.0.0.2, opt 0xC
ldp: New adj 0x7F97D1A384C0 for 92.0.0.10:0, GigabitEthernet2.530
ldp:      adj_addr/xport_addr 92.3.10.10/92.0.0.10
```

The next batch of debug indicates that TCP port 646 has been opened for packets from 92.0.0.10. The link address 92.3.10.10 was the source of the hello packets, but the TCP session is sourced from the LDP router-ID by default, which is set to loopback0.

```
! CSR3
ldp: Request adj send hello back on GigabitEthernet2.530 to (xport addr
92.0.0.10) in 1 msec
ldp: local interface = GigabitEthernet2.530, holdtime = 15000, peer
92.3.10.10 holdtime = 15000
ldp: Link intvl min cnt 2, intvl 5000, interface GigabitEthernet2.530
ldp: Opening listen port 646 for 92.0.0.10 (for hellos from 92.3.10.10)
```

Most of the debugs are noisy and not terribly useful, but here we can see the TCP session forming. CSR10 uses source port 19889 with destination port 646, which was opened on CSR3. The TCP TCB process finds an adjacency which means the session can be locally processed. Once data is transported across the TCP session, the session is assumed to be up.

```
! CSR3
ldp: Incoming {ldp conn 92.0.0.3:646=>92.0.0.10:19889} with normal priority
ldp: Process work item for incoming call
ldp: Found adj 0x7F97D1A384C0 for 92.0.0.10 (Hello xport addr opt)
[snip]
ldp: Data received for adj 0x7F97D1A384C0 from 92.3.10.10!
created dhcb: tableid 0, local 92.0.0.3, target 92.0.0.10
ldp: Setup directed hello for 92.0.0.10, holding_timer = 0
%LDP-5-NBRCHG: LDP Neighbor 92.0.0.10:0 (1) is UP
```

We can check to see the neighbor being up on CSR3. This output is verbose but very important. First we see the peer identity, which is its router-ID, along with our local router-ID. Then, we see the TCP connection endpoints and their TCP ports; by default, this is between the router-IDs. The discovery sources show all methods by which CSR10 was discovered, and in this case, it was from LDP hello packets on Gig2.530 from 92.3.10.10. Last, the addresses local to CSR10 are considered “bound” to this LDP peer, which is critical for MPLS forwarding. If CSR3 has an IGP route with a next-hop of any CSR10 interface, it must use the LDP label from CSR10.

```
R3#show mpls ldp neighbor 92.0.0.10
Peer LDP Ident: 92.0.0.10:0; Local LDP Ident 92.0.0.3:0
TCP connection: 92.0.0.10.19889 - 92.0.0.3.646
State: Oper; Msgs sent/rcvd: 57/32; Downstream
Up time: 00:11:53
LDP discovery sources:
  GigabitEthernet2.530, Src IP addr: 92.3.10.10
Addresses bound to peer LDP Ident:
  92.3.10.10      92.0.0.10      92.10.14.10
```

The LDP neighbor table will show fully-negotiated neighbors with operational TCP sessions. Sometimes, when troubleshooting, the neighbor isn’t fully operational, or there are problems with its formation. In those cases, we can also see the LDP discovery methods. For each interface. The “xmit” and “recv” options show where LDP hellos are being sent and received, respectively. Based on CSR3’s location in the network, it should ideally have 4 LDP neighbors since it has bidirectionally discovered 4 other LDP speakers across its 3 connected interfaces.

```
R3#show mpls ldp discovery
Local LDP Identifier:
  92.0.0.3:0
Discovery Sources:
Interfaces:
  GigabitEthernet2.523 (ldp): xmit/recv
    LDP Id: 92.0.0.9:0
    LDP Id: 92.0.0.2:0
  GigabitEthernet2.530 (ldp): xmit/recv
    LDP Id: 92.0.0.10:0
  GigabitEthernet2.534 (ldp): xmit/recv
    LDP Id: 92.0.0.14:0
```

We can drill into more details with this command as well. This shows interface-level details such as the hello/hold interval, transport address (discussed later), and authentication options.

```
R3#show mpls ldp discovery detail | begin 530
  GigabitEthernet2.530 (ldp): xmit/recv
    Enabled: IGP config;
```

```

Hello interval: 5000 ms; Transport IP addr: 92.0.0.3
LDP Id: 92.0.0.10:0
  Src IP addr: 92.3.10.10; Transport IP addr: 92.0.0.10
  Hold time: 15 sec; Proposed local/peer: 15/15 sec
  Reachable via 92.0.0.10/32
  Password: not required, fallback, in use
Clients: IPv4, mLDP

```

[snip]

After the sessions are formed, LDP will be exchanging labels with the peer. To see this, we will flap the neighbor with CSR10 and enable another debug. The first thing LDP does after the neighbor comes up is advertises its local interfaces without any label bindings. This is what populates the “peer identity bindings” seen in the LDP neighbor table. Again, this is critical for MPLS forwarding since LDP must be aware of all local interfaces enabled for MPLS when selecting labels for forwarding.

```

! CSR3
R3#debug mpls ldp advertisements

```

```

%LDP-5-NBRCHG: LDP Neighbor 92.0.0.10:0 (1) is UP
lcon: Send initial advertisements to peer 92.0.0.10:0
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.0.0.3
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.3.10.3
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.2.3.3
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.3.14.3

```

Next, LDP actually begins to distribute labels. Every prefix for which label allocation and advertisement is allowed (controlled by filters which are seen later) is advertised. This is coupled with the local labels from CSR3. Notice that all of CSR3’s transit links are assigned labels as well, since those count as IGP routes. All connected interfaces are advertised with some kind of null label, typically implicit-null (label 3). I have omitted some of the output because it is highly repetitive since CSR3 allocates a label for all loopbacks, of which there are 14. When the label exchange is complete, CSR3 “deassigns” CSR10 from its workflow for label advertising. Notice that remote prefixes, such as CSR10 and XRv4 loopbacks, are assigned labels from CSR3’s global pool of labels, which is 3000 – 3999.

```

! CSR3
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.0.0.3/32, label 3
      (imp-null) (#2)
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.0.0.10/32, label
      3000 (#4)
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.0.0.14/32, label
      3002 (#58)
[snip]
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.2.3.0/24, label 3
      (imp-null) (#79)
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.3.10.0/24, label 3
      (imp-null) (#81)

```

```
lcon: peer 92.0.0.10:0 (pp 0x7F97D1D0C2A0): advertise 92.3.14.0/24, label 3
(imp-null) (#83)
[snip]
lcon: (default) Deassign peer id; 92.0.0.10:0: id 0
```

We can verify that CSR10 received these label bindings by checking the label information base (LIB). The label values in the LIB match what CSR3 advertised via LDP.

```
R10#show mpls ldp bindings 92.0.0.3 32 neighbor 92.0.0.3
lib entry: 92.0.0.3/32, rev 94
remote binding: lsr: 92.0.0.3:0, label: imp-null
R10#show mpls ldp bindings 92.0.0.10 32 neighbor 92.0.0.3
lib entry: 92.0.0.10/32, rev 101
remote binding: lsr: 92.0.0.3:0, label: 3000
R10#show mpls ldp bindings 92.0.0.14 32 neighbor 92.0.0.3
lib entry: 92.0.0.14/32, rev 144
remote binding: lsr: 92.0.0.3:0, label: 3002
```

This is where the LDP/CEF interaction becomes important. Now that CSR10 learned labels from CSR3, it needs to be able select the proper label when sending traffic to a destination. For example, let's assume CSR10 wants to send traffic to CSR8. The first thing it does is consult its routing table (ignore the FIB for now). The route is an IGP route from CSR3 with a next-hop of 92.3.10.3. This means we MUST use an LDP label (cannot be BGP, RSVP-TE, etc) that was learned via whichever LDP peer is bound to address 92.3.10.3.

```
R10#show ip route 92.0.0.8
Routing entry for 92.0.0.8/32
Known via "isis", distance 115, metric 30, type level-2
Redistributing via isis LDP
Last update from 92.3.10.3 on GigabitEthernet2.530, 00:29:20 ago
Routing Descriptor Blocks:
* 92.3.10.3, from 92.0.0.3, 00:29:20 ago, via GigabitEthernet2.530
Route metric is 30, traffic share count is 1
```

Assuming we didn't know which router was bound to 92.3.10.3, we can check the LDP neighbor table. CSR10 has two neighbors: XRv4 and CSR3. We clearly see that 92.3.10.3 is bound to CSR3.

```
R10#show mpls ldp neighbor
Peer LDP Ident: 92.0.0.14:0; Local LDP Ident 92.0.0.10:0

  92.0.0.3          92.3.10.3          92.2.3.3          92.3.14.3

```

CSR10 must consult its LIB to find out what label it should use to reach 92.0.0.8/32 via 92.3.10.3. This label would have been allocated by CSR3, and we find value 3011. The LIB must be consulted after the route lookup occurs, because if we jumped right to this step, it is not clear whether label 3011 or 94008 should be used. Liberal label retention, discussed earlier, means that routers will hold onto all labels they learn even if they aren't programmed into the LFIB. This is to support fast reconvergence without having to readvertise labels constantly. Coupled with IP fast-reroute, this removes the need for LDP to have an FRR capability with respect to IP prefix label binding advertisement.

```

R10#show mpls ldp bindings 92.0.0.8 32
lib entry: 92.0.0.8/32, rev 143
  local binding: label: 10011
  remote binding: lsr: 92.0.0.14:0, label: 94008
  remote binding: lsr: 92.0.0.3:0, label: 3011

```

The combination of the IP next-hop and associated label are programmed into the FIB. The FIB is consulted when an IP packet arrives (or is locally generated) at a router, and the act of adding labels atop an IP packet is called “imposing” or “pushing” the label. The word “imposition” is used to describe the process as well. Part of the reason MPLS is very efficient is that the label operations happen in CEF, so the RIB/LIB lookups are bypassed for normal transit traffic along an LSP.

```

R10#show ip cef 92.0.0.8
92.0.0.8/32
  nexthop 92.3.10.3 GigabitEthernet2.530 label 3011

```

We can go into great detail with the FIB adjacency information. The internal FIB details show an “output chain”, or process of encapsulation events, which shows the label push occurring just before the layer 2 encapsulation. Since it is an Ethernet interface, the outer-most encapsulation is still a standard Ethernet header. It is using VLAN 3530 so a dot1q VLAN tag is added as well. At the end of the encapsulation string is 0x8847, which indicates an MPLS unicast packet being transported. The label value is not shown here (this is a generic output not specific to any LSP) but we know it would be 3011 in our case.

```

R10#show ip cef 92.0.0.8 internal | begin output_chain
output chain:
  label 3011
  TAG adj out of GigabitEthernet2.530, addr 92.3.10.3 7FBC3F46FAC0

```

```

R10#show adjacency gigabitEthernet 2.530 link mpls 92.3.10.3 encapsulation
Protocol Interface Address
TAG GigabitEthernet2.530 92.3.10.3(14)
Encap length 18
005056A98CCF005056A9F96181000DCA
8847
L2 destination address byte offset 0
L2 destination address byte length 6
Link-type after encap: dot1Q
Provider: ARPA

```

Assuming CSR10 encapsulates the packet correctly, CSR3 will consult its LFIB upon receiving the packet. This is because an MPLS packet, not an IP packet, was received. When label 3011 arrives, CSR3 is performing ECMP to reach CSR8. This is because the routing table has two ECMP paths, so the RIB (and therefore the FIB/LFIB) installs both. Load-sharing is done like it is for IPv4, where the source/destination IPv4 addresses are inputs to the LFIB sharing mechanism. The same is true for IPv6 packets. For non-IP traffic (Ethernet frames inside L2VPN, etc), the bottom label is used.

```

R3#show mpls forwarding-table labels 3011 detail
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id Switched      interface
3011       2002       92.0.0.8/32 0             Gi2.523    92.2.3.2
MAC/Encaps=18/22, MRU=1500, Label Stack{2002}

9003       92.0.0.8/32 0             Gi2.523    92.2.3.9
MAC/Encaps=18/22, MRU=1500, Label Stack{9003}
005056A9D672005056A98CCF81000DC38847 0232B000
No output feature configured
Per-destination load-sharing, slots: 1 3 5 7 9 11 13 15

```

Specifically, since the source is CSR10's loopback and the destination is CSR8's loopback, we can find the exact path using a show command. The packet will be sent to CSR9 in this specific case.

```

CSR3#show mpls forwarding-table exact-route label 3011 ipv4 source 92.0.0.10
destination 92.0.0.8
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id Switched      interface
3011       9003       92.0.0.8/32 0             Gi2.523    92.2.3.9

```

CSR9 performs PHP since it is the next-to-last hop towards CSR8. CSR8 instructs CSR9 to pop the topmost label by advertising an implicit-null label for this prefix. We can confirm this by checking the LIB as well.

```

R9#show mpls forwarding-table labels 9003
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop

```

Label	Label	or Tunnel Id	Switched	interface	
9003	Pop Label	92.0.0.8/32	3114	Gi2.589	92.8.9.8

```
R9#show mpls ldp bindings 92.0.0.8 32 neighbor 92.0.0.8
lib entry: 92.0.0.8/32, rev 10
remote binding: lsr: 92.0.0.8:0, label: imp-null
```

A quick traceroute on CSR10 shows the LSP as we traced it. It uses label 3011 to send traffic to CSR3 for prefix 92.0.0.8/32, then CSR3 swaps it to label 9003 based on the ECMP hash algorithm.

```
R10#traceroute 92.0.0.8 source 92.0.0.10
Type escape sequence to abort.
Tracing the route to 92.0.0.8
VRF info: (vrf in name/id, vrf out name/id)
 1 92.3.10.3 [MPLS: Label 3011 Exp 0] 4 msec 4 msec 5 msec
 2 92.2.3.9 [MPLS: Label 9003 Exp 0] 20 msec 20 msec 20 msec
 3 92.8.9.8 20 msec 11 msec 11 msec
```

We quickly look at CSR7 and XRv1 where there is a link that is not MPLS enabled. The route to 92.0.0.11/32 is labeled (implicit-null, still counts as labeled) yet the route to 92.0.0.13/32 is not. This is because of the way IGP converged; CSR7's route to XRv3 is via an OSPF area 1 route which traverses a non-MPLS link. CSR7's route to XRv1's loopback is via an OSPF area 0 route which traverses an MPLS enabled link.

Local	Outgoing	Prefix	Bytes	Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched		interface	
7009	Pop Label	92.0.0.11/32	4578		Gi2.517	92.11.7.11

Local	Outgoing	Prefix	Bytes	Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched		interface	
7011	No Label	92.0.0.13/32	0		Gi2.571	92.7.11.11

Even though CSR7 has labeled paths to XRv3, it cannot use these labels since IGP directs the route over a non-MPLS enabled interface. It would be great if CSR7 could use label 91005 to direct traffic through XRv1, since traffic is being sent to XRv1 anyway.

```
R7#show mpls ldp bindings 92.0.0.13 32
lib entry: 92.0.0.13/32, rev 46
local binding: label: 7011
remote binding: lsr: 92.0.0.11:0, label: 91005
remote binding: lsr: 92.0.0.6:0, label: 6012
```

```
R7#show ip route 92.0.0.13
Routing entry for 92.0.0.13/32
Known via "ospf 92", distance 110, metric 4, type intra area
```

```
Last update from 92.7.11.11 on GigabitEthernet2.571, 03:50:01 ago
Routing Descriptor Blocks:
* 92.7.11.11, from 92.0.0.13, 03:50:01 ago, via GigabitEthernet2.571
  Route metric is 4, traffic share count is 1
```

As a quick fix, we can apply a static route to CSR7 to direct traffic to this loopback towards XRv1 using the MPLS-enabled link. This wouldn't be possible with OSPF dynamically due to the intra-area vs. inter-area route preference. Static routes count as IGP routes from the perspective of LDP, which means LDP-bound labels can be used when a static route for a given prefix is installed in the RIB. Both the FIB and LFIB are updated to reflect this change.

```
! CSR7
ip route 92.0.0.13 255.255.255.255 GigabitEthernet2.517 92.11.7.11
```

```
R7#show ip route 92.0.0.13
Routing entry for 92.0.0.13/32
  Known via "static", distance 1, metric 0
  Routing Descriptor Blocks:
  * 92.11.7.11, via GigabitEthernet2.517
    Route metric is 0, traffic share count is 1
```

```
R7#show ip cef 92.0.0.13
92.0.0.13/32
  nexthop 92.11.7.11 GigabitEthernet2.517 label 91005
```

```
R7#show mpls forwarding-table 92.0.0.13 32
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id  Switched     interface
7011      91005      92.0.0.13/32    0            Gi2.517    92.11.7.11
```

We quickly confirm the LSP from CSR7 to XRv3 via XRv1 (VLAN 517) which overrides the OSPF topology. When XRv1 receives packets with label 91005, it swaps this label for 5005 which was CSR5's local label for 92.0.0.13/32. CSR5 pops the topmost label since it is the penultimate hop, which exposes the IP packet to XRv3. We use traceroute to confirm the full path and label operations along the way.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91005
Local  Outgoing  Prefix      Outgoing  Next Hop      Bytes
Label  Label      or ID       Interface  Hop           Switched
-----
91005  5005      92.0.0.13/32  Gi0/0/0/0.541  92.4.11.5    792
```

```
R5#show mpls forwarding-table labels 5005
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id  Switched     interface
5005      Pop Label  92.0.0.13/32    7194         Gi2.553    92.5.13.13
```

```
R7#traceroute 92.0.0.13 source 92.0.0.7
```

```
Type escape sequence to abort.

```

An important concept in LDP is the RID. This has to be a routable address as we have seen earlier. Unlike most other protocols, this is used for session establishment and is more than just a unique ID formatted like an IPv4 address. This is how the TCP session is formed (can be adjusted as discussed later), but for clarity we can force the RID to be tied to a specific interface. On all XE routers, the following command is applied. If you specify the “force” keyword, it will reset the current session to use the new address. Excluding that option means that it will only change when it has the opportunity. (router reload, etc).

```
! All XE routers
mpls ldp router-id Loopback0 force
```

XR doesn’t give you the choice of interfaces, but allows you to specify the RID by IPv4 address. We also do this on every node, except the last octet changes on each router. Only XRv1 is shown for brevity.

```
! XRv1
mpls ldp
  router-id 92.0.0.11
```

We can tune a few options with the LDP with respect to timers. LDP maintains two separate sets of timers: discovery and maintenance. The discovery timers include the hello and hold down timers which is similar to OSPF, EIGRP, or IS-IS. These can be adjusted globally. Focusing on CSR8, we can see the timers are 5 seconds for hello and 15 seconds for hold down. We also see that there is some kind of negotiation for holddown timers since both the local and peer timers are shown.

```
R8#show mpls ldp discovery detail
Local LDP Identifier:
  92.0.0.8:0
Discovery Sources:
Interfaces:
  GigabitEthernet2.528 (ldp): xmit/recv
    Enabled: IGP config;
    Hello interval: 5000 ms; Transport IP addr: 92.0.0.8
    LDP Id: 92.0.0.2:0
    Src IP addr: 92.2.8.2; Transport IP addr: 92.0.0.2
    Hold time: 15 sec; Proposed local/peer: 15/15 sec
    [snip]
  GigabitEthernet2.589 (ldp): xmit/recv
    Enabled: IGP config;
    Hello interval: 5000 ms; Transport IP addr: 92.0.0.8
    LDP Id: 92.0.0.9:0
```

```
Src IP addr: 92.8.9.9; Transport IP addr: 92.0.0.9
Hold time: 15 sec; Proposed local/peer: 15/15 sec
[snip]
```

We can adjust these timers globally. On CSR8, we will reduce the hello timer to 3 and the hold time to 12. Looking at the discovery details again, we can see that the lower hold time is preferred, and routers can still use independent hello timers. This is somewhat similar to BGP or BFD timer negotiation since timers can be mismatched, but are ultimately converged on a common set of values for at least some of the timers.

```
! CSR8
mpls ldp discovery hello interval 3
mpls ldp discovery hello holdtime 12

R8#show mpls ldp discovery detail
Local LDP Identifier:
  92.0.0.8:0
Discovery Sources:
Interfaces:
  GigabitEthernet2.528 (ldp): xmit/recv
    Enabled: IGP config;
    Hello interval: 3000 ms; Transport IP addr: 92.0.0.8
    LDP Id: 92.0.0.2:0
    Src IP addr: 92.2.8.2; Transport IP addr: 92.0.0.2
    Hold time: 12 sec; Proposed local/peer: 12/15 sec
    [snip]
  GigabitEthernet2.589 (ldp): xmit/recv
    Enabled: IGP config;
    Hello interval: 3000 ms; Transport IP addr: 92.0.0.8
    LDP Id: 92.0.0.9:0
    Src IP addr: 92.8.9.9; Transport IP addr: 92.0.0.9
    Hold time: 12 sec; Proposed local/peer: 12/15 sec
    [snip]
```

Looking at CSR2 to confirm this, we can see the local hold time is 15 seconds and the remote is 12 seconds, yet 12 was selected. The routers will always agree on the discovery hold time. Also notice that CSR2's hello timer was automatically adjusted (but not in the configuration). The LDP discovery hello timer must be at least three times as frequent as the hold time. Because CSR2 had to reduce its hold time from 15 to 12 seconds, a hello timer of 5 seconds was too slow.

```
R2#show mpls ldp discovery detail
[snip]
GigabitEthernet2.528 (ldp): xmit/recv
  Enabled: IGP config;
  Hello interval: 4000 ms; Transport IP addr: 92.0.0.2
  LDP Id: 92.0.0.8:0
  Src IP addr: 92.2.8.8; Transport IP addr: 92.0.0.8
```

```
Hold time: 12 sec; Proposed local/peer: 15/12 sec
[snip]
```

We can also see this by looking at the neighbor details. This command also reveals the maintenance hold down timers as well, also known as the keep-alive or KA timer of 180 seconds (3 minutes) by default. The KA interval is also shown, which is 60 seconds by default.

```
R8#show mpls ldp neighbor 92.0.0.2 detail | include time
Up time: 00:41:42; UID: 7; Peer Id 2
    holdtime: 12000 ms, hello interval: 3000 ms
Peer holdtime: 180000 ms; KA interval: 60000 ms; Peer state: estab
```

We can change this in global configuration mode as well. This only affects new sessions, not existing ones, and the parser tells you this. We will clear the session between CSR8 and CSR2 to see the difference. Like the discovery hold down timer, the lower value is negotiated between the peers, and the KA interval is always one third of the KA hold time (not configurable). Both CSR2 and CSR8 are using the value of 120 seconds (2 minutes) for KA hold time and 40 seconds for KA interval.

```
R8(config)#mpls ldp holdtime 120
% Previously established sessions may not use the new holdtime.
```

```
R8#show mpls ldp neighbor 92.0.0.2 detail | include time
Up time: 00:00:23; UID: 8; Peer Id 0
    holdtime: 12000 ms, hello interval: 3000 ms
Peer holdtime: 120000 ms; KA interval: 40000 ms; Peer state: estab
```

```
R2#show mpls ldp neighbor 92.0.0.8 detail | include time
Up time: 00:00:45; UID: 12; Peer Id 3
    holdtime: 12000 ms, hello interval: 4000 ms
    holdtime: infinite, hello interval: 10000 ms
Peer holdtime: 120000 ms; KA interval: 40000 ms; Peer state: estab
```

The feature works similarly on XR. We configure some new values on XRv3; of note, the new discovery hold time is greater than the default on CSR5, so we expect 15 seconds to be used. The session holdtime is also too slow, so the default of 180 should be negotiated. XRv3 can still use its custom discovery hello interval of 4 seconds since this more than 3 times as frequent as the lowest holdtime.

```
! XRv3
mpls ldp
  session holdtime 240
  discovery
    hello holdtime 20
    hello interval 4
```

```
RP/0/0/CPU0:XRv3#show mpls ldp neighbor 92.0.0.5 detail | include KA
```

```

```

```
(expiring in 11.4 sec)
```

There is also a protection mechanism built into LDP to prevent two LSRs from constantly trying to establish LDP peerings when they are incompatible. For example, perhaps there are significant version differences or other negotiated parameters/capabilities preventing the peer from forming. Constantly trying to establish sessions can tax an LSR's resources, so tuning the backoff timers is an option. The initial backoff timer (the first failure) is 15 seconds and the longest backoff time is 120 seconds, by default. We will adjust these to more aggressive values on CSR5 and XRv3 as a demonstration, although we can't reliably test it. The configuration and show commands are simple, and XR appears to display a table of backed-off sessions, as applicable.

```
! CSR5
```

```
mpls ldp backoff 5 60
```

```
! XRv3
```

```
mpls ldp
```

```
session backoff 5 60
```

```
R5#show mpls ldp backoff all
```

```
LDP initial/maximum backoff: 5/60 sec
```

```
RP/0/0/CPU0:XRv3#show mpls ldp backoff
```

```
Backoff Time:
```

```
Initial:5 sec, Maximum:60 sec
```

```
Backoff Table:
```

```
No Entry
```

Next, we will configure additional LDP features. The first and most commonly used is authentication. This gives MD5 protection to the TCP sessions between LDP peers. I will configure it everywhere in the topology using the simplest method to start. This says that a single "fallback" password is used for all

peers (as opposed to peer-specific passwords). XE also requires the operator to identify this security option as “required” or else it is considered optional.

```
! All XE routers
mpls ldp password fallback LDP_AUTH
mpls ldp password required

! All XR routers
mpls ldp
 neighbor
  password clear LDP_AUTH
```

Looking at CSR10, we can see that the MD5 password is required and in use. The fallback password is used since there are no specific passwords defined.

```
R10#show mpls ldp neighbor password
Peer LDP Ident: 92.0.0.14:0; Local LDP Ident 92.0.0.10:0
TCP connection: 92.0.0.14.19636 - 92.0.0.10.646
Password: required, fallback, in use
State: Oper; Msgs sent/rcvd: 73/74
Peer LDP Ident: 92.0.0.3:0; Local LDP Ident 92.0.0.10:0
TCP connection: 92.0.0.3.646 - 92.0.0.10.24379
Password: required, fallback, in use
State: Oper; Msgs sent/rcvd: 44/58
```

We can also quickly check the status of MD5 authentication by checking the neighbor details and filtering on the TCP sessions. This will show each neighbor in one line, along with its MD5 status. This also works on XR and is my favorite way to quickly check LDP neighbors for being up and authenticated.

```
R10#show mpls ldp neighbor detail | include TCP
TCP connection: 92.0.0.14.19636 - 92.0.0.10.646; MD5 on
TCP connection: 92.0.0.3.646 - 92.0.0.10.24379; MD5 on
```

```
RP/0/0/CPU0:XRv4#show mpls ldp neighbor detail | include TCP
TCP connection: 92.0.0.1:646 - 92.0.0.14:21418; MD5 on
TCP connection: 92.0.0.3:646 - 92.0.0.14:23273; MD5 on
TCP connection: 92.0.0.10:646 - 92.0.0.14:58993; MD5 on
```

Alternatively, we can go directly to the TCB and look for the MD5 option for a given TCP session. The TCP table brief reveals the TCBs, and we select the one representing the connection to CSR3. We can clearly see that the MD5 option was negotiated. Note that the “lossless password switchover” feature is enabled, which means that we can apply a key-chain with time constraints for automatic rollover if we wish.

```
R10#show tcp brief
TCB          Local Address          Foreign Address          (state)
```

```

7FBC417C11F8  92.0.0.10.646          92.0.0.14.19636      ESTAB
7FBC4148F918  92.0.0.10.24379          92.0.0.3.646         ESTAB

```

```

R10#show tcp tcb 7FBC4148F918 | section Option
Option Flags: non-blocking reads, non-blocking writes,
MD5 lossless password switchover, Retrans timeout

```

We can also specify per neighbor passwords. On CSR10, we will configure a customer password for the peer XRv4. Since we haven't configured it on XRv4 yet, the LDP neighbor will eventually fail. Both routers will immediately begin generating log messages since the MD5 authentication no longer matches. The key to this log message is port 646; this is how we can tell it is an LDP session versus any other TCP session (BGP, MSDP, etc). Once the password matches, the error messages cease.

```

! CSR10
mpls ldp neighbor 92.0.0.14 password LDP_AUTH_CUSTOM

! CSR6
%TCP-6-BADAUTH: Invalid MD5 digest from 92.0.0.14(58815) to 92.0.0.10(646)
tableid - 0

! XRv4
tcp[389]: %IP-TCP-3-BADAUTH : Invalid MD5 digest from 92.0.0.10:646 to
92.0.0.14:58815

```

The configuration on XR is very straightforward; we just need to define a more specific per-neighbor password for CSR10. XR also requires the label space (0 for system-wide) to be included for this command. If we check the neighbor password details on CSR10, we now see that XRv4 has a "neighbor" password as opposed to "fallback". CSR3 still uses the fallback password since no specific password was defined for that peer.

```

! XRv4
mpls ldp
neighbor
92.0.0.10:0 password clear LDP_AUTH_CUSTOM

R10#show mpls ldp neighbor password
Peer LDP Ident: 92.0.0.3:0; Local LDP Ident 92.0.0.10:0
TCP connection: 92.0.0.3.646 - 92.0.0.10.24379
Password: required, fallback, in use
State: Oper; Msgs sent/rcvd: 56/69
Peer LDP Ident: 92.0.0.14:0; Local LDP Ident 92.0.0.10:0
TCP connection: 92.0.0.14.58993 - 92.0.0.10.646
Password: required, neighbor, in use
State: Oper; Msgs sent/rcvd: 17/18

```

XR does not appear to support key-chains for LDP passwords, so we will implement password rollover between CSR6 and CSR7. These routers are running OSPF and have an LDP session between them. Both of them currently use the fallback password with all peers.

```
R6#show mpls ldp neighbor password
  Peer LDP Ident: 92.0.0.2:0; Local LDP Ident 92.0.0.6:0
    TCP connection: 92.0.0.2.646 - 92.0.0.6.13774
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 1102/1093
  Peer LDP Ident: 92.0.0.7:0; Local LDP Ident 92.0.0.6:0
    TCP connection: 92.0.0.7.11800 - 92.0.0.6.646
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 1066/1042
  Peer LDP Ident: 92.0.0.4:0; Local LDP Ident 92.0.0.6:0
    TCP connection: 92.0.0.4.646 - 92.0.0.6.22345
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 1067/1070
[snip, lots of neighbors]
```

```
R7#show mpls ldp neighbor password
  Peer LDP Ident: 92.0.0.6:0; Local LDP Ident 92.0.0.7:0
    TCP connection: 92.0.0.6.646 - 92.0.0.7.11800
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 1043/1068
  Peer LDP Ident: 92.0.0.11:0; Local LDP Ident 92.0.0.7:0
    TCP connection: 92.0.0.11.39991 - 92.0.0.7.646
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 1028/1042
```

CSR6 and CSR7 will both implement a simple key-chain that uses two passwords. One is good for five minutes, while the second is good forever. This allows us to simply roll their clocks back to the time when the first key is valid, then not have to worry about it every again once the second key is valid. We use a simple symmetric key design (we could use different send/accept lifetimes to authenticate TCP segments in either direction). There is a one minute carry-over time, and we can notify LDP about this using the rollover commands. This means that once the next-key is active, the “rollover” process will take up to 1 minute to complete, which is fine in this case.

```
! CSR6 and CSR7
mpls ldp password rollover duration 1

key chain KC_LDP_AUTH
  key 1
    key-string LDP_AUTH_1
    accept-lifetime 00:00:00 May 23 2005 00:05:00 May 23 2005
    send-lifetime 00:00:00 May 23 2005 00:05:00 May 23 2005
    cryptographic-algorithm md5
  key 2
```

```
key-string LDP_AUTH_2
accept-lifetime 00:04:00 May 23 2005 infinite
send-lifetime 00:04:00 May 23 2005 infinite
cryptographic-algorithm md5
```

The mechanism to apply this keychain is a little odd. You define LDP password “options” which invoke the key-chains. These options are tied to ACLs that match LDP router-IDs that indicate to which neighbors this should apply. Neighbors for whom there is no specified option will continue to use the fallback password. Only CSR6’s configuration is shown since CSR7’s configuration is identical except that it creates ACL_R6 and references CSR6’s LDP router-ID.

```
! CSR6
ip access-list standard ACL_R7
 permit 92.0.0.7

mpls ldp password option 1 for ACL_R7 key-chain KC_LDP_AUTH
```

Checking CSR6 and CSR7, we can see this new password option in use. Other neighbors, such as CSR2 and XRv1, are not using this new option and continue to use the fallback password.

```
R6#show mpls ldp neighbor password
[snip]
  Peer LDP Ident: 92.0.0.2:0; Local LDP Ident 92.0.0.6:0
    TCP connection: 92.0.0.2.646 - 92.0.0.6.28586
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 29/28
  Peer LDP Ident: 92.0.0.7:0; Local LDP Ident 92.0.0.6:0
    TCP connection: 92.0.0.7.48539 - 92.0.0.6.646
    Password: required, option 1 (KC_LDP_AUTH), in use
    State: Oper; Msgs sent/rcvd: 24/11

R7#show mpls ldp neighbor password
  Peer LDP Ident: 92.0.0.11:0; Local LDP Ident 92.0.0.7:0
    TCP connection: 92.0.0.11.39991 - 92.0.0.7.646
    Password: required, fallback, in use
    State: Oper; Msgs sent/rcvd: 1061/1074
  Peer LDP Ident: 92.0.0.6:0; Local LDP Ident 92.0.0.7:0
    TCP connection: 92.0.0.6.646 - 92.0.0.7.48539
    Password: required, option 1 (KC_LDP_AUTH), in use
    State: Oper; Msgs sent/rcvd: 14/28
```

All of the relevant LDP password logging is enabled by default, but I will apply the commands to CSR6 and CSR7 just in case. These commands cause the system to generate syslog messages when passwords are rolled over.

```
! CSR6 and CSR7
```

```
mpls ldp logging password rollover
mpls ldp logging password configuration
```

Next, we will adjust the clocks to be midnight on 23 May 2005. We immediately check the key chain to see that key 1 is now valid on one of the routers.

```
! CSR6 and CSR7
R7#clock set 00:00:00 23 may 2005

R7#show key chain KC_LDP_AUTH
Key-chain KC_LDP_AUTH:
  key 1 -- text "LDP_AUTH_1"
    accept lifetime (00:00:00 UTC May 23 2005) - (00:05:00 UTC May 23
2005) [valid now]
    send lifetime (00:00:00 UTC May 23 2005) - (00:05:00 UTC May 23 2005)
[valid now]
  key 2 -- text "LDP_AUTH_2"
    accept lifetime (00:04:00 UTC May 23 2005) - (infinite)
    send lifetime (00:04:00 UTC May 23 2005) - (infinite)
```

In about 1 minute (slightly less), the password changes from LDP_AUTH_2 to LDP_AUTH_1 since we manually changed the clock. The log message shows that the change occurred, and we expect to see another change in about 4 minutes. We aren't focusing on this change since it's an artificial one; we care more about crossing the time boundary naturally.

```
! CSR6
May 23 00:00:49.888: %LDP-5-PWDCFG: Password configuration changed for
92.0.0.7:0
```

```
! CSR7
May 23 00:00:57.923: %LDP-5-PWDCFG: Password configuration changed for
92.0.0.6:0
```

While we wait for the time to hit the 5 minute mark, notice that while the clock is in between 4:00 and 5:00 minutes, both keys are valid. This isn't really necessary since LDP will be rolling over password as soon as 5 minutes is up, but I wanted to demonstrate it.

```
R6#show clock
00:04:35.905 UTC Mon May 23 2005

R6#show key chain KC_LDP_AUTH
Key-chain KC_LDP_AUTH:
  key 1 -- text "LDP_AUTH_1"
    accept lifetime (00:00:00 UTC May 23 2005) - (00:05:00 UTC May 23
2005) [valid now]
    send lifetime (00:00:00 UTC May 23 2005) - (00:05:00 UTC May 23 2005)
[valid now]
```

```
key 2 -- text "LDP_AUTH_2"
    accept lifetime (00:04:00 UTC May 23 2005) - (infinite) [valid now]
    send lifetime (00:04:00 UTC May 23 2005) - (infinite) [valid now]
```

At the 5 minute mark (approximately), we see additional log messages to show the password changing again. This is LDP using key 2 in addition to key 1 for the purpose of rollover.

```
! CSR6
May 23 00:04:49.889: %LDP-5-PWDCFG: Password configuration changed for
92.0.0.7:0
```

```
! CSR7
May 23 00:04:57.922: %LDP-5-PWDCFG: Password configuration changed for
92.0.0.6:0
```

We can check the “pending” passwords on both routers to see the rollover in progress. Both of them show LDP password option 1 and the associated key chain marked as “stale”, which implied rollover is occurring.

```
R6#show mpls ldp neighbor password pending
Peer LDP Ident: 92.0.0.7:0; Local LDP Ident 92.0.0.6:0
TCP connection: 92.0.0.7.48539 - 92.0.0.6.646
Password: required, option 1 (KC_LDP_AUTH), stale (rollover)
State: Oper; Msgs sent/rcvd: 37/23
```

```
R7#show mpls ldp neighbor password pending
Peer LDP Ident: 92.0.0.6:0; Local LDP Ident 92.0.0.7:0
TCP connection: 92.0.0.6.646 - 92.0.0.7.48539
Password: required, option 1 (KC_LDP_AUTH), stale (rollover)
State: Oper; Msgs sent/rcvd: 23/37
```

After exactly 1 more minute, which is the LDP rollover duration timer, we can see the passwords change again. This signals the completion of the rollover process since key 1 is no longer valid for LDP usage. There are no more pending password changes on CSR6 and CSR7 since the rollover has completed. We can see the “current” passwords on CSR7 to see that option 1 is no longer stale, but is actively in use.

```
! CSR6
May 23 00:05:49.888: %LDP-5-PWDCFG: Password configuration changed for
92.0.0.7:0
```

```
! CSR7
May 23 00:05:57.923: %LDP-5-PWDCFG: Password configuration changed for
92.0.0.6:0
```

```
R6#show mpls ldp neighbor password pending
[no output]
```

```
R7#show mpls ldp neighbor password pending
```

```
[no output]
```

```
R7#show mpls ldp neighbor password current
```

```
Peer LDP Ident: 92.0.0.11:0; Local LDP Ident 92.0.0.7:0
TCP connection: 92.0.0.11.39991 - 92.0.0.7.646
Password: required, fallback, in use
State: Oper; Msgs sent/rcvd: 1081/1094
Peer LDP Ident: 92.0.0.6:0; Local LDP Ident 92.0.0.7:0
TCP connection: 92.0.0.6.646 - 92.0.0.7.48539
Password: required, option 1 (KC_LDP_AUTH), in use
State: Oper; Msgs sent/rcvd: 34/47
```

Shortly after the last configuration change, each router generates a syslog message once the rollover is confirmed. As you can see, the process is fairly involved but the logging is excellent.

```
! CSR6
```

```
May 23 00:06:10.453: %LDP-5-PWDRO: Password rolled over for 92.0.0.7:0
```

```
! CSR7
```

```
May 23 00:05:55.464: %LDP-5-PWDRO: Password rolled over for 92.0.0.6:0
```

Earlier I mentioned the concept of a transport address. This is simply the TCP source address for the session; by default, the router-ID is used. In some corner cases, this may need manual adjustment. For example, let's assume the link between XRv2 and CSR4 has a transparent firewall that only allows link-local traffic on port 646 for UDP and TCP. The TCP session between the loopbacks would be blocked by this firewall, so to work around it, we can source the TCP session from the connected interfaces for that link only. This means that all other sessions can continue to use the router-ID for their TCP connection. The word "discovery" is relevant because this applies to dynamically-discovered LDP peers only.

```
! CSR4
```

```
interface GigabitEthernet2.542
 mpls ldp discovery transport-address interface
```

```
! XRv2
```

```
mpls ldp
interface GigabitEthernet0/0/0/0.542
 address-family ipv4
 discovery transport-address interface
```

Using my favorite LDP show command, we quickly confirm that the transport addresses have been changed for the session between CSR4 and XRv2 only. The other sessions remain unaffected since the modification is relevant only to neighbors discovered on a given interface. This change has no effect on MPLS forwarding, label bindings, or anything of the sort.

```
R4#show mpls ldp neighbor detail | include TCP
```

```
TCP connection: 92.4.12.12.20508 - 92.4.12.4.646; MD5 on
TCP connection: 92.0.0.11.12011 - 92.0.0.4.646; MD5 on
TCP connection: 92.0.0.5.43590 - 92.0.0.4.646; MD5 on
TCP connection: 92.0.0.6.12154 - 92.0.0.4.646; MD5 on
```

```
RP/0/0/CPU0:XRv2#show mpls ldp neighbor detail | include TCP
TCP connection: 92.4.12.4:646 - 92.4.12.12:20508; MD5 on
TCP connection: 92.0.0.9:646 - 92.0.0.12:33163; MD5 on
TCP connection: 92.0.0.6:646 - 92.0.0.12:19816; MD5 on
```

If we check the discovery details, we can see that the entry for XRv2 differs slightly from the others. The specific IP address is listed since this is used as the remote transport address on this interface. The other discovery entries need not display this since it is assumed the LDP router-ID is used for TCP transport. XR is more explicit and clearly shows the transport address for all neighbors, even though where the transport address and LDP router-ID are equal. We can clearly see CSR4's custom transport address in XRv2's output.

```
R4#show mpls ldp discovery
Local LDP Identifier:
  92.0.0.4:0
Discovery Sources:
Interfaces:
  GigabitEthernet2.546 (ldp): xmit/recv
    LDP Id: 92.0.0.6:0
  GigabitEthernet2.541 (ldp): xmit/recv
    LDP Id: 92.0.0.11:0
    LDP Id: 92.0.0.5:0
  GigabitEthernet2.542 (ldp): xmit/recv
    LDP Id: 92.0.0.12:0; IP addr: 92.4.12.12
```

```
RP/0/0/CPU0:XRv2#show mpls ldp discovery
Local LDP Identifier: 92.0.0.12:0
Discovery Sources:
Interfaces:
  GigabitEthernet0/0/0/0.542 : xmit/recv
    VRF: 'default' (0x60000000)
    LDP Id: 92.0.0.4:0, Transport address: 92.4.12.4
    Hold time: 15 sec (local:15 sec, peer:15 sec)

  GigabitEthernet0/0/0/0.562 : xmit/recv
    VRF: 'default' (0x60000000)
    LDP Id: 92.0.0.6:0, Transport address: 92.0.0.6
    Hold time: 15 sec (local:15 sec, peer:15 sec)

  GigabitEthernet0/0/0/0.592 : xmit/recv
    VRF: 'default' (0x60000000)
    LDP Id: 92.0.0.9:0, Transport address: 92.0.0.9
    Hold time: 15 sec (local:15 sec, peer:15 sec)
```

Next, we will examine LDP session protection (SP). We know that the LDP session is actually a TCP session between peers since the LDP multicast hellos are just used for discovery. All of the label exchanges happen within the TCP exchanges. If a link between two routers fails, the LDP hello messages are not seen, and the router deletes the LDP session. The consequence of this action is that all of the labels learned from that peer are purged from the LIB. Before configuring SP, we will demonstrate this on CSR10 and CSR3. Shutting down the link to CSR10 on CSR3 causes the LDP neighbor to fail, as seen below. I show the label bindings for the 14 loopbacks being withdrawn. The TIB is synonymous with LIB and is legacy terminology.

```
R10#debug mpls ldp bindings
LDP Label Information Base (LIB) changes debugging is on
lcon: tibent(92.0.0.1/32): label 3003 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.2/32): label 3007 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.3/32): label imp-null from 92.0.0.3:0 removed
lcon: tibent(92.0.0.4/32): label 3004 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.5/32): label 3010 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.6/32): label 3014 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.7/32): label 3009 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.8/32): label 3011 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.9/32): label 3012 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.10/32): label 3000 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.11/32): label 3008 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.12/32): label 3001 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.13/32): label 3005 from 92.0.0.3:0 removed
lcon: tibent(92.0.0.14/32): label 3002 from 92.0.0.3:0 removed
```

Since CSR3 is no longer an LDP neighbor, there are no bindings learned from that peer. We could have stored those labels temporarily to allow the link to come back up, and due to liberal label retention, could potentially re-route alternative MPLS paths via XRv4, since those labels would still be in the LIB.

```
R10#show mpls ldp bindings neighbor 92.0.0.3
[no output]
```

In large topologies, this might be a lot of information and originally took some time to exchange in the first place. At the cost of leaving those labels in memory, we can configure the routers to sustain their TCP session provided there is IP reachability between their transport addresses. This is why using the LDP router-ID as the transport address is generally desirable. Like authentication, we will enable the feature everywhere as a starting point.

```
! All XE routers
mpls ldp session protection
```

```
! All XR routers
mpls ldp
```

session protection

Entering this command doesn't generate any log messages since it isn't used for discovery. In addition to the link hellos, it establishes a targeted LDP (tLDP) session with each neighbor as well. Once a neighbor is dynamically-discovered, SP automatically created a tLDP hello towards it. This is a unicast hello that is analogous to an OSPF or EIGRP unicast hello on an NBMA interface, except it has a larger TTL. Looking at CSR10's LDP discovery cache, we can see a new stanza at the bottom to show targeted sessions. It introduces the terms "active" and "passive". Active implies that the local router is configured to originate this session while xmit means the router is actually sending hellos. Passive is the opposite, where the router is not explicitly configured to receive the connection but accepts it passively, and rcv complements this state by saying hellos are received. Long story short, we can see bidirectional tLDP hello exchanges with XRv4 and CSR3.

```
R10#show mpls ldp discovery
Local LDP Identifier:
 92.0.0.10:0
Discovery Sources:
Interfaces:
  GigabitEthernet2.530 (ldp): xmit/rcv
    LDP Id: 92.0.0.3:0
  GigabitEthernet2.504 (ldp): xmit/rcv
    LDP Id: 92.0.0.14:0
Targeted Hellos:
 92.0.0.10 -> 92.0.0.3 (ldp): active/passive, xmit/rcv
    LDP Id: 92.0.0.3:0
 92.0.0.10 -> 92.0.0.14 (ldp): active/passive, xmit/rcv
    LDP Id: 92.0.0.14:0
```

If we look at the discovery details for these targeted sessions, we can see their origin. Later, we will see tLDP used for L2VPN, TE, and many other applications. In this case, the sessions were generated by the LDP session protection (LDP SP) feature. We can clearly see the transport addresses as shown below, and as an added benefit, these targeted sessions are authenticated. This is NOT an additional TCP connection, since there is only one TCP connection per set of neighbors regardless of how many adjacencies they have.

```
R10#show mpls ldp discovery detail | begin Target
Targeted Hellos:
 92.0.0.10 -> 92.0.0.3 (ldp): active/passive, xmit/rcv
  Enabled by: LDP SP,
    Hello interval: 10000 ms; Transport IP addr: 92.0.0.10
    LDP Id: 92.0.0.3:0
    Src IP addr: 92.0.0.3; Transport IP addr: 92.0.0.3
    Hold time: 90 sec; Proposed local/peer: 90/90 sec
    Reachable via 92.0.0.3/32
    Password: required, fallback, in use
 92.0.0.10 -> 92.0.0.14 (ldp): active/passive, xmit/rcv
```

```

Enabled by: LDP SP,
  Hello interval: 10000 ms; Transport IP addr: 92.0.0.10
  LDP Id: 92.0.0.14:0
    Src IP addr: 92.0.0.14; Transport IP addr: 92.0.0.14
  Hold time: 90 sec; Proposed local/peer: 90/90 sec
  Reachable via 92.0.0.14/32
  Password: required, neighbor, in use

```

Next, we shut down CSR3's interface to CSR10 again. CSR10 will re-route traffic to XRv4 in its LFIB, but still retains labels from CSR3. Technically, the LDP neighbor is still up, and the debug does not reveal any label purging. The neighbor discovery sources no longer include VLAN 530 as that link was shutdown, but the targeted hello continues to keep the session alive.

```

R10#show mpls ldp neighbor 92.0.0.3
  Peer LDP Ident: 92.0.0.3:0; Local LDP Ident 92.0.0.10:0
    TCP connection: 92.0.0.3.646 - 92.0.0.10.31875
    State: Oper; Msgs sent/rcvd: 7/24; Downstream
    Up time: 00:02:46
    LDP discovery sources:
      Targeted Hello 92.0.0.10 -> 92.0.0.3, active, passive
    Addresses bound to peer LDP Ident:
      92.0.0.3          92.2.3.3          92.3.14.3

```

A quick look at the LIB to query labels from CSR3 shows no changes. All of the labels are still present, but none will be used for forwarding as the LFIB shows.

```

R10#show mpls ldp bindings neighbor 92.0.0.3
  lib entry: 92.0.0.1/32, rev 145
    remote binding: lsr: 92.0.0.3:0, label: 3003
  lib entry: 92.0.0.2/32, rev 135
    remote binding: lsr: 92.0.0.3:0, label: 3007
  lib entry: 92.0.0.3/32, rev 94
    remote binding: lsr: 92.0.0.3:0, label: imp-null
  lib entry: 92.0.0.4/32, rev 140
    remote binding: lsr: 92.0.0.3:0, label: 3004
[snip]

```

```

R10#show mpls forwarding-table

```

Local	Outgoing	Prefix	Bytes Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched	interface	
10000	94005	92.0.0.3/32	0	Gi2.504	92.10.14.14
10001	94004	92.0.0.6/32	0	Gi2.504	92.10.14.14
10002	9413	92.0.0.13/32	0	Gi2.504	92.10.14.14
10003	94012	92.0.0.5/32	0	Gi2.504	92.10.14.14

```

[snip]

```

Assuming we had some debugs running when the link was shut down, we can actually see what SP was doing behind the scenes. A hold-up timer of 86400 seconds (24 hours) begins once the link fails, which means that after this amount of time, SP will stop holding the session active. SP moves from the ready state to the protecting state and starts the hold-up timer. At some point it makes sense to flush stale labels from the LIB, and 24 hours is the default so that routine link maintenance that makes more than a few minutes (cleaning fiber ports, rearranging cable runs, etc) doesn't introduce LIB churn. We can see these defaults by checking the neighbor details, which also shows the time remaining for the SP hold-up.

```
R10#debug mpls ldp session protection
LDP session protection events debugging is on

! CSR10
LDP SP: 92.0.0.3:0: last primary adj lost; starting session protection holdup
timer
LDP SP: 92.0.0.3:0: LDP session protection holdup timer started, 86400
seconds
LDP SP: 92.0.0.3:0: state change (Ready -> Protecting)
%LDP-5-SP: 92.0.0.3:0: session hold up initiated

R10#show mpls ldp neighbor 92.0.0.3 detail | begin Session Protect
LDP Session Protection enabled, state: Protecting
    duration: 86400 seconds
    holdup time remaining: 86155 seconds
```

When the link comes back up, CSR10 stops the SP hold-up timer and changes the protection state back to ready. The hold-up timer stops counting and is removed from the LDP neighbor output.

```
! CSR10
LDP SP: 92.0.0.3:0: primary adj restored; stopping session protection holdup
timer
LDP SP: 92.0.0.3:0: state change (Protecting -> Ready)
%LDP-5-SP: 92.0.0.3:0: session recovery succeeded

R10#show mpls ldp neighbor 92.0.0.3 detail | begin Session Protect
LDP Session Protection enabled, state: Ready
    duration: 86400 seconds
```

Let's pretend that CSR10 is low on memory and should not retain these labels for a long time. We can reduce the hold-up timer to a shorter time, say 60 seconds, so that a link outage longer than that will flush labels from the LIB. This timer is only locally significant and does not have to match throughout the network. It does, however, mean that CSR3 will continue to store all of CSR10's labels for 24 hours, which doesn't make sense from a design perspective when the peer uses a different timer. The minimum time is 30 seconds and the maximum time is infinite (never flush labels from the LIB, generally a bad idea). We quickly check to ensure the configuration worked and that SP is ready.

```
! CSR10
mpls ldp session protection duration 60
```

```
R10#show mpls ldp neighbor 92.0.0.3 detail | begin Session Protect
      LDP Session Protection enabled, state: Ready
      duration: 60 seconds
```

When CSR3 shuts down its interface to CSR10, SP activates. This is no different than earlier except we see the timer is now 60 seconds. CSR10 still has all of CSR3's labels in the LIB as well.

```
! CSR10
LDP SP: 92.0.0.3:0: last primary adj lost; starting session protection holdup
timer
LDP SP: 92.0.0.3:0: LDP session protection holdup timer started, 60 seconds
LDP SP: 92.0.0.3:0: state change (Ready -> Protecting)
%LDP-5-SP: 92.0.0.3:0: session hold up initiated
```

```
R10#show mpls ldp neighbor 92.0.0.3 detail | begin Session Protect
      LDP Session Protection enabled, state: Protecting
      duration: 60 seconds
      holdup time remaining: 41 seconds
```

```
R10#show mpls ldp bindings neighbor 92.0.0.3
lib entry: 92.0.0.1/32, rev 145
    remote binding: lsr: 92.0.0.3:0, label: 3003
lib entry: 92.0.0.2/32, rev 135
    remote binding: lsr: 92.0.0.3:0, label: 3007
lib entry: 92.0.0.3/32, rev 94
    remote binding: lsr: 92.0.0.3:0, label: imp-null
lib entry: 92.0.0.4/32, rev 140
[snip]
```

After the timer expires and the link doesn't come up, SP moves the session into state "none" which effectively tears down the session. This flushes all labels from the LIB, as designed, since the neighbor no longer exists.

```
! CSR10
LDP SP: 92.0.0.3:0: LDP session protection holdup timer expired
LDP SP: 92.0.0.3:0: disabling session protection: holdup timer expired
LDP SP: 92.0.0.3:0: state change (Protecting -> None)
%LDP-5-SP: 92.0.0.3:0: session recovery failed
```

```
R10#show mpls ldp bindings neighbor 92.0.0.3
[no output]
```

```
R10#show mpls ldp neighbor 92.0.0.3
[no output]
```

Since this feature works identically in XR, we won't test it in detail. However, the detailed LDP neighbor command shows similar output to XE; this shows the SP state, hold-up (duration) timer, and any ACLs applied. ACLs are discussed next.

```
RP/0/0/CPU0:XRv1#show mpls ldp neighbor 92.0.0.4 detail | begin Session Prot
Clients: Session Protection
Session Protection:
  Enabled, state: Ready
  Duration: 86400 sec
```

SP can also be configured to only protect certain peers by supplying an ACL. This makes sense on nodes where there is only one path, and the overhead from the targeted sessions adds no value. As such, we will remove session protection from CSR1 and XRv3 entirely (not shown). However, CSR5 and XRv4 will still try to offer SP to those routers by default since we did not filter it. Notice that both CSR5 and XRv4 are trying to run SP with XRv3 and CSR1 respectively. The sessions are active and the routers are sending tLDP hellos, but there is nothing coming back. This is a waste of resources on CSR5 and XRv4.

```
R5#show mpls ldp discovery | begin Target
Targeted Hellos:
  92.0.0.5 -> 92.0.0.4 (ldp): active/passive, xmit/recv
    LDP Id: 92.0.0.4:0
  92.0.0.5 -> 92.0.0.11 (ldp): active/passive, xmit/recv
    LDP Id: 92.0.0.11:0
  92.0.0.5 -> 92.0.0.13 (ldp): active, xmit
```

```
RP/0/0/CPU0:XRv4#show mpls ldp discovery | begin Target
Targeted Hellos:
  92.0.0.14 -> 92.0.0.1 (active), xmit

  92.0.0.14 -> 92.0.0.3 (active), xmit/recv
    LDP Id: 92.0.0.3:0
    Hold time: 90 sec (local:90 sec, peer:90 sec)

  92.0.0.14 -> 92.0.0.10 (active), xmit/recv
    LDP Id: 92.0.0.10:0
    Hold time: 90 sec (local:90 sec, peer:90 sec)
```

To correct this inefficiency, we configure XRv4 and CSR5 not to offer the feature to those stub routers. If the link hello adjacency fails, there is no other way to reach those routers, so SP is not valuable. I use different ACL logic for variety, where CSR5 shows a stricter control to ensure only loopback addresses can be SP targets.

```
! CSR5
ip access-list standard ACL_LDP_SESS_PROTECT
deny 92.0.0.13
permit 92.0.0.0 0.0.0.255
```

```
mpls ldp session protection for ACL_LDP_SESS_PROTECT
```

```
! XRv4
```

```
ipv4 access-list ACL_LDP_SESS_PROTECT
```

```
10 deny ipv4 host 92.0.0.1 any
```

```
20 permit ipv4 any any
```

```
mpls ldp
```

```
session protection for ACL_LDP_SESS_PROTECT
```

Before checking the LDP discovery updates, we can ensure the configurations were successful. Since the command is configured globally, we can select any neighbor to see the ACL applied.

```
R5#show mpls ldp neighbor 92.0.0.11 detail | begin Session Prot
```

```
LDP Session Protection enabled, state: Ready
```

```
acl: ACL_LDP_SESS_PROTECT, duration: 86400 seconds
```

```
RP/0/0/CPU0:XRv4#show mpls ldp neighbor 92.0.0.10 detail | begin Session Prot
```

```
Clients: Session Protection
```

```
Session Protection:
```

```
Enabled, state: Ready
```

```
ACL: 'ACL_LDP_SESS_PROTECT', Duration: 86400 sec
```

We can check CSR5 to ensure it is not “actively” sending targeted hellos to 92.0.0.13. Notice that only CSR4 and XRv1 are listed as targets for tLDP hellos. The same is true for XRv4 which only targets CSR3 and CSR10 now.

```
R5#show mpls ldp discovery | begin Target
```

```
Targeted Hellos:
```

```
92.0.0.5 -> 92.0.0.4 (ldp): active/passive, xmit/recv
```

```
LDP Id: 92.0.0.4:0
```

```
92.0.0.5 -> 92.0.0.11 (ldp): active/passive, xmit/recv
```

```
LDP Id: 92.0.0.11:0
```

```
RP/0/0/CPU0:XRv4#show mpls ldp discovery | begin Target
```

```
Targeted Hellos:
```

```
92.0.0.14 -> 92.0.0.3 (active), xmit/recv
```

```
LDP Id: 92.0.0.3:0
```

```
Hold time: 90 sec (local:90 sec, peer:90 sec)
```

```
92.0.0.14 -> 92.0.0.10 (active), xmit/recv
```

```
LDP Id: 92.0.0.10:0
```

```
Hold time: 90 sec (local:90 sec, peer:90 sec)
```

Although it may not seem obvious, you can emulate SP without enabling the specific feature. SP is a very simple logic: when a peer is dynamically discovered, create a tLDP session to it, and if the primary

adjacencies (links) fail, continue to use a targeted session just to maintain the LIB. SP does not attempt to sustain MPLS forwarding as this is the job of FRR. We could just manually configure a tLDP session between two routers to achieve the same effect. We will demonstrate this on XRv1 and CSR7. This also implies we should disable SP for those peers, which we accomplish with an ACL again. Even though these routers only share one MPLS link, the non-MPLS link can still backup a session.

```
! CSR7
ip access-list standard ACL_LDP_SESS_PROTECT
  deny 92.0.0.11
  permit 92.0.0.0 0.0.0.255

mpls ldp session protection for ACL_LDP_SESS_PROTECT

! XRv1
ipv4 access-list ACL_LDP_SESS_PROTECT
  10 deny ipv4 host 92.0.0.7 any
  20 permit ipv4 92.0.0.0 0.0.0.255 any

mpls ldp
  session protection for ACL_LDP_SESS_PROTECT
```

Next, we will manually configure the tLDP sessions. The configuration is very simple on both XE and XR.

```
! CSR7
mpls ldp neighbor 92.0.0.11 targeted ldp

! XRv1
mpls ldp
  address-family ipv4
  neighbor 92.0.0.7 targeted
```

Looking at the targeted hellos on CSR7, we can clearly see a difference between this manual session and the SP session to CSR6. The session to XRv1 is identified as “LDP config” which means it was manually configured. Other than that, everything else looks the same, which means it should perform the same function as SP.

```
R7#show mpls ldp discovery detail | begin Targeted
Targeted Hellos:
  92.0.0.7 -> 92.0.0.6 (ldp): active/passive, xmit/recvd
    Enabled by: LDP SP,
    Hello interval: 10000 ms; Transport IP addr: 92.0.0.7
    LDP Id: 92.0.0.6:0
    Src IP addr: 92.0.0.6; Transport IP addr: 92.0.0.6
    Hold time: 90 sec; Proposed local/peer: 90/90 sec
    Reachable via 92.0.0.6/32
    Password: required, option 1 (KC_LDP_AUTH), in use
  92.0.0.7 -> 92.0.0.11 (ldp): active/passive, xmit/recvd
```

Enabled by: LDP Config,

```
Hello interval: 10000 ms; Transport IP addr: 92.0.0.7
LDP Id: 92.0.0.11:0
  Src IP addr: 92.0.0.11; Transport IP addr: 92.0.0.11
  Hold time: 90 sec; Proposed local/peer: 90/90 sec
  Reachable via 92.0.0.11/32
  Password: required, fallback, in use
```

If the primary MPLS link between the two routers fail, CSR7 will still have other paths to reach XRv1, and vice versa. As such, the failure of the link should not affect the LDP session since a static tLDP hello exchange will concur to occur, provided there is IP reachability. Below, we can see that VLAN 517 is no longer a discovery source for 92.0.0.11:0, but the tLDP session remains. The same is true for XRv1 who can no longer discover CSR7 dynamically, but maintains the tLDP session.

```
R7#show mpls ldp discovery
Local LDP Identifier:
  92.0.0.7:0
Discovery Sources:
Interfaces:
  GigabitEthernet2.567 (ldp): xmit/recv
    LDP Id: 92.0.0.6:0
Targeted Hellos:
  92.0.0.7 -> 92.0.0.6 (ldp): active/passive, xmit/recv
    LDP Id: 92.0.0.6:0
  92.0.0.7 -> 92.0.0.11 (ldp): active/passive, xmit/recv
    LDP Id: 92.0.0.11:0
```

```
RP/0/0/CPU0:XRv1#show mpls ldp discovery 92.0.0.7:0
Local LDP Identifier: 92.0.0.11:0
Discovery Sources:
  Targeted Hellos:
    92.0.0.11 -> 92.0.0.7 (active), xmit/recv
      LDP Id: 92.0.0.7:0
      Hold time: 90 sec (local:90 sec, peer:90 sec)
```

A quick check of the LIB on both CSR7 and XRv1 shows that the labels have been exchanged. Unlike the SP default hold-up timer, this session will stay up forever, and could be a workaround for environments where not all routers support the dynamic SP feature.

```
R7#show mpls ldp bindings neighbor 92.0.0.11
lib entry: 92.0.0.2/32, rev 36

```

```
Local binding: label: 91008
```

```
Remote bindings: (4 peers)
```

Peer	Label
92.0.0.7:0	7002

Note: The targeted session is not a magic trick you can use to fix broken LSPs. The MPLS forwarding table is still based on IP routing, and there isn't a path to XRv1 anymore. Just because the labels are preserved doesn't mean they will be used; a snapshot of CSR7 confirms this as CSR6 is the preferred path for many of the router loopbacks now. Unless there is an MPLS-enabled interface to the neighbor, the tLDP session is just to preserve labels, not to directly fix forwarding issues.

```
R7#show mpls forwarding-table
```

Local	Outgoing	Prefix	Bytes	Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched		interface	
7001	6000	92.0.0.2/32	0		Gi2.567	92.6.7.6
7002	6007	92.0.0.3/32	0		Gi2.567	92.6.7.6
7003	6009	92.0.0.4/32	82646		Gi2.567	92.6.7.6

[snip]

As discussed earlier, there are discovery and maintenance timers, and these apply to targeted LDP sessions as well. The maintenance timer isn't specific to dynamic or targeted session since there is only one LDP session between routers, so we won't look at adjusting that again. However, XE and XR appear to have different behaviors with regards to targeted LDP session hold timers for discovery. XE claims the hold time is infinite while XR claims it is 90 seconds (or 9 times the hello interval of 10 seconds). I believe this may be a cosmetic error on XE because XR states that both the local and remote hold times are 90 seconds.

```
R7#show mpls ldp neighbor 92.0.0.11 detail | begin LDP disc
```

```
LDP discovery sources:
```

```
Targeted Hello 92.0.0.7 -> 92.0.0.11, active, passive;
```

```
holdtime: infinite, hello interval: 10000 ms
```

```
GigabitEthernet2.517; Src IP addr: 92.11.7.11
```

```
holdtime: 15000 ms, hello interval: 5000 ms
```

```
RP/0/0/CPU0:XRv1#show mpls ldp discovery 92.0.0.7:0 | begin Target
```

```
Targeted Hellos:
```

```
92.0.0.11 -> 92.0.0.7 (active), xmit/recv
```

```
LDP Id: 92.0.0.7:0
Hold time: 90 sec (local:90 sec, peer:90 sec)
```

By checking the LDP parameters, we can further solidify our claim that this is a cosmetic output issue on XE. CSR7 claims that its tLDP hello holdtime is 90 seconds by default. It makes sense that the two platforms would agree on these defaults.

```
R7#show mpls ldp parameters | include time
Session hold time: 180 sec; keep alive interval: 60 sec
Discovery hello: holdtime: 15 sec; interval: 5 sec
Discovery targeted hello: holdtime: 90 sec; interval: 10 sec
```

```
RP/0/0/CPU0:XRv1#show mpls ldp parameters | include time
Hold time: 180 sec
Link Hellos:      Holdtime:15 sec, Interval:5 sec
Targeted Hellos: Holdtime:90 sec, Interval:10 sec
Housekeeping periodic timer: 10 sec
```

If we change CSR7 to a lower value, we would expect XRv1 to negotiate to that lesser value. This is also a global configuration parameter. We can see that changing CSR7 adjusts the local parameters, and XRv1 negotiates this timer for the specific session (discovery only) with CSR7.

```
! CSR7
mpls ldp discovery targeted-hello holdtime 80

R7#show mpls ldp parameters | include time
Session hold time: 180 sec; keep alive interval: 60 sec
Discovery hello: holdtime: 15 sec; interval: 5 sec
Discovery targeted hello: holdtime: 80 sec; interval: 10 sec
```

```
RP/0/0/CPU0:XRv1#show mpls ldp discovery 92.0.0.7:0 | begin Target
Targeted Hellos:
  92.0.0.11 -> 92.0.0.7 (active), xmit/recv
    LDP Id: 92.0.0.7:0
      Hold time: 80 sec (local:90 sec, peer:80 sec)
```

If we configure an even lower timer on XRv1, we expect XRv1's local parameters to change and CSR7 to agree to this lower value. Because of XE's output format, the value always says "infinite" but we can check on XRv1 to see the 70 second and 80 second parameters being exchanged. 70 seconds is what is negotiated between the peers.

```
! XRv1
mpls ldp
  discovery
    targeted-hello holdtime 70
```

```
RP/0/0/CPU0:XRv1#show mpls ldp parameters | include time
  Hold time: 180 sec
  Link Hellos:      Holdtime:15 sec, Interval:5 sec
  Targeted Hellos:  Holdtime:70 sec, Interval:10 sec
  Housekeeping periodic timer: 10 sec

RP/0/0/CPU0:XRv1#show mpls ldp discovery 92.0.0.7:0 | begin Target
  Targeted Hellos:
    92.0.0.11 -> 92.0.0.7 (active), xmit/recv
    LDP Id: 92.0.0.7:0
      Hold time: 70 sec (local:70 sec, peer:80 sec)
```

Next, we will look at another powerful LDP feature known as IGP synchronization or simply “IGP sync”. IGP sync is meant to solve the problem of IGP and LDP having two different views, or being in two different states, of a particular link. Packet loss can occur if IGP and LDP are not synchronized; I will illustrate an example. A new IGP adjacency forms on a link. The IGP converges quickly and runs SPF for all remote prefixes before the LDP session fully forms (distributes labels, etc). Traffic will be routed out of this link as raw IP traffic until the LFIB is programmed with the proper labels, and this will break any LSPs using this interface for a short time. We can demonstrate this on CSR4; the shortest-path to CSR7 is via the directly connected link to CSR6. If LDP fails on this link, but OSPF remains intact, the RIB will still prefer this link despite it not being MPLS-capable.

```
R4#show ip cef 92.0.0.7
92.0.0.7/32
  nexthop 92.4.6.6 GigabitEthernet2.546 label 6008
```

We can kill the LDP session many ways. One way is to apply an ACL that denies UDP/TCP 646 on the interface. Another option is to create a static null route for 92.0.0.6/32, which is the transport address for the LDP session. I will use the latter approach. We can manually clear the neighbor to speed things up.

```
! CSR6
ip route 92.0.0.6 255.255.255.255 null0

R4#clear mpls ldp neighbor 92.0.0.6
%LDP-5-NBRCHG: LDP Neighbor 92.0.0.6:0 (5) is DOWN (User cleared session manually)
```

Despite this, OSPF remains intact, and CSR7 is still reachable via this link. We can see that the traffic is not MPLS encapsulated since the FIB no longer has a label binding for this prefix out of this interface. Although this particular fabricated failure isn’t realistic, it gives us time to verify the fault; IGP sync is meant to protect against short-term black-holes due to convergence issues, but also protects against blatant mis-configurations like this as well. If the entire link went down, OSPF would converge, but as of now the network is in a broken state.

```

R4#show ip cef 92.0.0.7
92.0.0.7/32
  nexthop 92.4.6.6 GigabitEthernet2.546

R4#traceroute 92.0.0.7 source 92.0.0.4
Type escape sequence to abort.
Tracing the route to 92.0.0.7
VRF info: (vrf in name/id, vrf out name/id)
 1 92.4.6.6 3 msec 3 msec 3 msec
 2 92.6.7.7 4 msec 4 msec 3 msec

```

Before continuing, we will remove the static route so the network is repaired. IGP sync can be enabled within the OSPF or IS-IS processes to apply to all IGP-enabled links. Like LDP auto-config, it makes sense to use this approach when there are many interfaces requiring synchronization. In XR, this is only supported for OSPF, as IS-IS requires it explicitly on a per-link basis. We will use the process-level approach on many routers. XRv2 shows IGP sync enabled on a per-interface basis for both IS-IS and OSPF. XE only allows IGP sync to be enabled per-process. Basically, sync is enabled everywhere except towards CSR1 and XRv3. CSR5 explicitly disables IGP sync on this interface, whereas XRv4 never enabled it towards CSR1 in the first place. The same is true for CSR7 and XRv1 on the non-MPLS link they share.

```

! CSR4, CSR5, CSR6, CSR7, XRv1
router ospf 92
  mpls ldp sync

! CSR5 only
interface GigabitEthernet2.553
  no mpls ldp igp sync

! CSR7 only

      mpls ldp sync disable

! CSR2, CSR3, CSR8, CSR9, CSR10
router isis LDP
  mpls ldp sync

! XRv4
router isis LDP
  interface GigabitEthernet0/0/0/0.504
    address-family ipv4 unicast
      mpls ldp sync
  interface GigabitEthernet0/0/0/0.534

```

```

address-family ipv4 unicast
  mpls ldp sync

! XRV2
router ospf 92
  area 0
    interface GigabitEthernet0/0/0/0.542
      mpls ldp sync

    interface GigabitEthernet0/0/0/0.562
      mpls ldp sync

router isis LDP
  interface GigabitEthernet0/0/0/0.592
    address-family ipv4 unicast
      mpls ldp sync

```

We can spot-check a few nodes to ensure IGP sync is working properly. Looking at CSR3, we can see 3 interfaces enabled for IGP sync even though there are 4 LDP neighbors. Since this is a per-interface configuration, the LDP peer router-IDs are listed in each interface stanza. We can see that sync is enabled and that the peers are reachable. This is the expected state for IGP sync when the network is stable.

```

R3#show mpls ldp igp sync
  GigabitEthernet2.523:
    LDP configured; LDP-IGP Synchronization enabled.
    Sync status: sync achieved; peer reachable.
    Sync delay time: 0 seconds (0 seconds left)
    IGP holddown time: infinite.
    Peer LDP Ident: 92.0.0.9:0; 92.0.0.2:0
    IGP enabled: ISIS LDP
  GigabitEthernet2.530:
    LDP configured; LDP-IGP Synchronization enabled.
    Sync status: sync achieved; peer reachable.
    Sync delay time: 0 seconds (0 seconds left)
    IGP holddown time: infinite.
    Peer LDP Ident: 92.0.0.10:0
    IGP enabled: ISIS LDP
  GigabitEthernet2.534:
    LDP configured; LDP-IGP Synchronization enabled.
    Sync status: sync achieved; peer reachable.
    Sync delay time: 0 seconds (0 seconds left)
    IGP holddown time: infinite.
    Peer LDP Ident: 92.0.0.14:0
    IGP enabled: ISIS LDP

```

On XRV4, we see similar results. Sync is working to CSR10 and CSR3 but not CSR1. It was never configured to CSR1 since there are no redundant paths. The parenthesis message is a little misleading,

but the overall status of “not ready” means that sync isn’t enabled to CSR1 as expected. A quick look at CSR5 shows similar output as IGP sync is disabled towards XRv3 as well.

```
RP/0/0/CPU0:XRv4#show mpls ldp igp sync
GigabitEthernet0/0/0/0.504:
  VRF: 'default' (0x60000000)
  Sync delay: Disabled
  Sync status: Ready
  Peers:
    92.0.0.10:0

GigabitEthernet0/0/0/0.514:
  VRF: 'default' (0x60000000)
  Sync delay: Disabled
  Sync status: Not ready (Initial update to peer not done yet)

GigabitEthernet0/0/0/0.534:
  VRF: 'default' (0x60000000)
  Sync delay: Disabled
  Sync status: Ready
  Peers:
    92.0.0.3:0

R5#show mpls ldp igp sync
GigabitEthernet2.541:
  LDP configured; LDP-IGP Synchronization enabled.
  Sync status: sync achieved; peer reachable.
  Sync delay time: 0 seconds (0 seconds left)
  IGP holddown time: infinite.
  Peer LDP Ident: 92.0.0.11:0; 92.0.0.4:0
  IGP enabled: OSPF 92
  GigabitEthernet2.553:
    LDP configured; LDP-IGP Synchronization not enabled.
```

The mechanics of IGP sync are very simple. When an LDP session fails on a link where IGP is still enabled, the sync process will raise the link cost to the maximum so that the link is less preferred than any other alternative. Going back to CSR4, we re-enable the static null route to 92.0.0.6/32 which breaks the LDP session. We can debug IGP sync at the same time to watch what happens in the background. After flapping the neighbor, it never comes back but sync takes action by notifying OSPF about the change.

```
R4#debug mpls ldp igp sync
LDP-IGP Synchronization debugging is on

LDP-SYNC: Gi2.546, OSPF 92: notify status (required, not achieved, delay,
holddown infinite) internal status (not achieved, timer not running)
LDP-SYNC: Gi2.546, 92.0.0.6: Adj being deleted, sync_achieved goes down
```

We can see that CSR4 now prefers a valid labeled path via XRv2. However, when we check the OSPF interface costs, nothing has changed. Without digging deeper, IGP sync seems like magic.

```
R4#show ip cef 92.0.0.7
92.0.0.7/32
  nexthop 92.4.12.12 GigabitEthernet2.542 label 92009
```

```
R4#show ip ospf interface brief
```

Interface	PID	Area	IP Address/Mask	Cost	State	Nbrs	F/C
Lo0	92	0	92.0.0.4/32	1	LOOP	0/0	
Gi2.542	92	0	92.4.12.4/24	1	P2P	1/1	
Gi2.546	92	0	92.4.6.4/24	1	P2P	1/1	
Gi2.541	92	1	92.4.11.4/24	1	BDR	2/2	

The secret lies within the OSPF router LSA (LSA1). This is where IGP sync makes it changes; it doesn't actually change the configuration, but rather manipulates the SPF inputs by adjusting the LSA1. Looking at the details, we can see CSR4 has two transit links in area 0. One of them now has a cost of 65535, which is the link to CSR6. This is the result of IGP sync, and now the path through XRv2 is the shortest path.

```

If we check the IGP sync details, we can see that the peer remains reachable (IGP works) but synchronization with LDP has not been achieved on this link. This is an indication that this particular link is out of sync. However, traceroute reveals that the path to CSR7 is MPLS enabled, which means customer traffic (L3VPN, L2VPN, etc) can still flow properly.

```

R4#show mpls ldp igp sync interface gig2.546
    GigabitEthernet2.546:
        LDP configured; LDP-IGP Synchronization enabled.
        Sync status: sync not achieved; peer reachable.
        Sync delay time: 0 seconds (0 seconds left)
        IGP holddown time: infinite.
        IGP enabled: OSPF 92

R4#traceroute 92.0.0.7 source 92.0.0.4
Type escape sequence to abort.
Tracing the route to 92.0.0.7

  3 92.6.7.7 19 msec 9 msec 11 msec

```

When we restore the LDP session on this link, IGP sync restores the original OSPF metric once the LDP session is complete. That is to say, once the labels have been exchanged and programmed to CSR4's LFIB, normal forwarding can continue and IGP sync will re-synchronize. Initially, when the session starts and no LDP updates have been sent, IGP sync ignores this because it doesn't qualify as being fully up.

```

! CSR4
LDP-SYNC: Gi2.546: No session or session has not send initial update, ignore
adj joining event.
%LDP-5-NBRCHG: LDP Neighbor 92.0.0.6:0 (3) is UP

```

Very shortly thereafter, LDP begins the label exchange which means IGP sync honors the adjacency change and deactivates from this link.

```

! CSR4
LDP-SYNC: Gi2.546: session 92.0.0.6:0 came up, sync achieved up
LDP-SYNC: Gi2.546, OSPF 92: notify status (required, achieved, no delay,
holddown infinite) internal status (achieved, timer not running)

```

A quick check of the LSA1 shows the restoration of the original OSPF cost, and checking the FIB shows that the labeled traffic is forward through CSR6 again.

```

R4#show ip ospf 92 0 database router self-originate | begin Number of
Number of Links: 3

Link connected to: a Stub Network
(Link ID) Network/subnet number: 92.0.0.4
(Link Data) Network Mask: 255.255.255.255

```

```
R4#show ip cef 92.0.0.7
92.0.0.7/32
  nexthop 92.4.6.6 GigabitEthernet2.546 label 6008
```

Next, we will test the feature with IS-IS on XR. We will configure XRv2 with an ACL that blocks UDP/TCP 646 on the interface to CSR9. This will break the session, but both routers will still have an IGP adjacency (and thus an IP route for one another's transport addresses).

```
! XRv2
ipv4 access-list ACL_DENY_LDP
 10 deny udp any any eq ldp
 20 deny tcp any any eq ldp
 30 permit ipv4 any any

interface GigabitEthernet0/0/0/0.592
  ipv4 access-group ACL_DENY_LDP ingress
```

To speed things up, we will clear the LDP session manually only XRv2. We also enable IGP sync debugging so we can see the failures occur. IGP sync moves the adjacency out of the synchronized state and notifies IS-IS of the issue. We can see that this interface is not synchronized.

```
! XRv2
debug mpls ldp igp sync

mpls_ldp[1048]: DBG-ISync[1], Intf GigabitEthernet0_0_0_0.592: Adj 92.9.12.9
being deleted, sync achieved goes down
mpls_ldp[1048]: DBG-ISync[1], ldp_isync_announce_status: Intf
GigabitEthernet0_0_0_0.592 (ifh 0x900); notify 1, (sync 0, nsf 0) -> (sync 0,
nsf 0)

RP/0/0/CPU0:XRv2#show mpls ldp igp sync interface gig0/0/0/0.592
GigabitEthernet0/0/0/0.592:
  VRF: 'default' (0x60000000)
  Sync delay: Disabled
  Sync status: Not ready (No hello adjacency)
```

Notice that IGP sync causes the IS-IS cost on the interface to CSR9 to be increased to the maximum metric within the IS-IS LSP. This is the equivalent behavior in IS-IS as we saw in OSPF. Because there are no alternative paths, XRv2 still installs this route in the RIB, but it doesn't matter since there is no LDP reachability on the link due to the traffic filter. If there were alternative paths, they would have been selected when IS-IS ran SPF. The link isn't invalidated, it just isn't preferred.

```

```

Something similar happens on CSR9. IGP sync sees there is a fault and increases the IS-IS cost to XRv2 to the max-metric. However, CSR9 has an alternate route via CSR2 (CSR6 is the ASBR) which is a more realistic use for IGP sync.

```
R9#show mpls ldp igp sync interface gig2.592
GigabitEthernet2.592:
  LDP configured; LDP-IGP Synchronization enabled.

```

We can adjust the IGP sync hold-down time as well. This is a global setting on XE that tells LDP how long to wait for synchronization, and there does not appear to be an XR equivalent. By default, it will wait forever, but my experience shows me that that is always the case. I've never personally seen this value do anything, but the configuration is applied to CSR9. I also cannot think of a case where you would want this to be anything other than infinity, since failing to synchronize a link quickly doesn't mean IGP should suddenly start using it. I set the timer to 30000ms (30ms) on CSR9, then verify any IGP sync interface to show the change.

```

! CSR9
mpls ldp igp sync holddown 30000

R9#show mpls ldp igp sync int gig2.589
GigabitEthernet2.589:
  LDP configured; LDP-IGP Synchronization enabled.
  Sync status: sync achieved; peer reachable.
  Sync delay time: 0 seconds (0 seconds left)
  IGP holddown time: 30000 milliseconds.
  Peer LDP Ident: 92.0.0.8:0
  IGP enabled: ISIS LDP

```

There is also a sync delay parameter which is supported on XE and XR. This tells LDP how long to wait before declaring a link synchronized after the link comes back (and subsequently restoring the cost to the normal value). By default, this is 0 seconds, which means that as soon as a link comes back online, synchronization is immediately announced. This is generally not desired and could introduce churn into the IGP process. Continuing to use the backup path is better than rushing to a new link that might flap

again 5 seconds later. I set it to 45 seconds on both CSR9 and XRv2, and then verify it quickly on both sides.

```
! CSR9
interface GigabitEthernet2.592
  mpls ldp igp sync delay 45

mpls ldp
  interface GigabitEthernet0/0/0/0.592
    igp sync delay on-session-up 45

R9#show mpls ldp igp sync interface gig2.592
  GigabitEthernet2.592:
    LDP configured; LDP-IGP Synchronization enabled.
    Sync status: sync achieved; peer reachable.
    Sync delay time: 45 seconds (0 seconds left)
    IGP holddown time: 30000 milliseconds.
    Peer LDP Ident: 92.0.0.12:0
    IGP enabled: ISIS LDP

RP/0/0/CPU0:XRv2#show mpls ldp igp sync interface gig0/0/0/0.592
GigabitEthernet0/0/0/0.592:
  VRF: 'default' (0x60000000)
  Sync delay: 45 sec
  Sync status: Ready
  Peers:
    92.0.0.9:0
```

If we reapply the ACL on XRv2 to break the LDP session then remove it after the session fails (basically, flap the LDP session), we will see that the IGP sync process will wait 45 seconds on both sides before declaring the link synchronized after the link comes back up. This is the first set of log messages we see.

```
! CSR9
%LDP-5-NBRCHG: LDP Neighbor 92.0.0.12:0 (4) is UP
LDP-SYNC: Gi2.592: session 92.0.0.12:0 came up, sync_achieved up
LDP-SYNC: Gi2.592: Delay notifying IGP of sync achieved for 45 seconds

! XRv2
%ROUTING-LDP-5-NBR_CHANGE : VRF 'default' (0x60000000), Neighbor 92.0.0.9:0
is UP (IPv4 connection)
mpls_ldp[1048]: DBG-ISync[1], Intf GigabitEthernet0_0_0_0.592:
ldp_isync_up_adj_core delay_sync 1 delay_cfgd 1 gr_enabled 0 gr_recon 0
event 0x1 isync_flag 0
mpls_ldp[1048]: DBG-ISync[1], Intf 'GigabitEthernet0_0_0_0.592': Tmr started:
'IGP-Sync Intf Delay' (45s,0ms)
```

During this 45 minute period, we quickly check the IGP sync status on both routers. Both of them are counting down from 45 to 0, and until then, the IS-IS link is still carrying the max-metric. XE says synchronization is achieved, which is technically true, but the countdown is the hint that max-metric is still advertised. XR has better output and uses the word “deferred” to explicitly suggest that full synchronization waiting for the delay timer to expire.

```
R9#show mpls ldp igp sync interface gig2.592
GigabitEthernet2.592:
  LDP configured; LDP-IGP Synchronization enabled.
  Sync status: sync achieved; peer reachable.
  Sync delay time: 45 seconds (29 seconds left)
  IGP holddown time: 30000 milliseconds.
  Peer LDP Ident: 92.0.0.12:0
  IGP enabled: ISIS LDP

RP/0/0/CPU0:XRv2#show mpls ldp igp sync interface gig0/0/0/0.592
GigabitEthernet0/0/0/0.592:
  VRF: 'default' (0x60000000)
  Sync delay: 45 sec
  Sync status: Deferred (35 sec remaining)
```

The next set of debugs, occurring 45 seconds after the first batch, indicates that full synchronization has been announced to the IGP. Using the sync delay can protect against consistently unstable links.

```
! CSR9
LDP-SYNC: Gi2.592: Delay timer expired, notify IGP of sync achieved
LDP-SYNC: Gi2.592, ISIS LDP: notify status (required, achieved, no delay,
holddown 30000) internal status (achieved, timer not running)

! XRv2

expired)
mpls_ldp[1048]: DBG-ISync[1], ldp_isync_announce_status: Intf
GigabitEthernet0_0_0_0.592 (ifh 0x900); notify 1, (sync 1, nsf 0) -> (sync 1,
nsf 0)
```

Next, we will quickly examine what happens when we have the opposite problem. That is, IS-IS fails to form on a link but LDP forms just fine. We can break IS-IS in many ways, but the simplest would be a network type mismatch. This problem is much more rare and less significant, but it is worth examining.

```
! CSR9
interface GigabitEthernet2.592
  no isis network point-to-point
```

Interestingly, this does not cause any problems nor does it trigger IGP sync at all. Since IGP will obviously converge around it, there is no possibility of blackholing traffic over this link, so IGP sync can remain

blind to this condition. CSR9 has chosen a valid alternative path for all of its IGP prefixes. Eventually, the LDP session will time out and IGP sync will be lost, but at this point in time, the network has already converged so IGP sync doesn't need to act quickly, even though sync isn't achieved.

```
R9#show isis neighbors
```

```
Tag LDP:
```

System Id	Type	Interface	IP Address	State	Holdtime	Circuit Id
R2	L1	Gi2.523	92.2.3.2	UP	24	R3.01
R3	L1	Gi2.523	92.2.3.3	UP	6	R3.01
R8	L1	Gi2.589	92.8.9.8	UP	23	01

```
R9#show mpls ldp igp sync interface gig2.592
```

```
GigabitEthernet2.592:
```

```
LDP configured; LDP-IGP Synchronization enabled.
```

```
Sync status: sync achieved; peer reachable.
```

```
Sync delay time: 0 seconds (0 seconds left)
```

```
IGP holddown time: 30000 milliseconds.
```

```
Peer LDP Ident: 92.0.0.12:0
```

```
IGP enabled: ISIS LDP
```

Before continuing, all broken network types, ACLs, and null routes from previous tests are removed so the network is stable. Next, we will look at label allocation and filtering/advertising. Label allocation is the process of assigning local labels to prefixes. We can control this by applying prefix-lists (XE) or ACLs (XR) to the LDP process to determine for which prefixes we allocate labels. This can greatly reduce LIB size if, for example, labels are only allocated for host-routes. Bear in mind that local labels must be allocated for any remote prefix that can be an LSP endpoint. First, we show output on CSR9 with the command disabled, and LIB entries are created for all transit links. This is generally worthless unless there are hosts on those LAN segments that require their traffic to be MPLS-encapsulated as it transits the network.

```
R9#show mpls ldp bindings 92.8.9.0 24
```

```
lib entry: 92.8.9.0/24, rev 40
```

```
local binding: label: imp-null
```

```
R9#show mpls ldp bindings 92.9.12.0 24
```

```
lib entry: 92.9.12.0/24, rev 42
```

```
local binding: label: imp-null
```

Like setting the RID, this is a technique I almost always configure by default. There is even a keyword for host-routes that makes it very easy. I enable this on all XE and XR routers to start.

```
! All XE routers
```

```
mpls ldp label
```

```
allocate global host-routes
```

```
! All XR routers
```

```
mpls ldp
 address-family ipv4
  label
  local
  allocate for host-routes
```

After enabling this command, a quick check on CSR9 shows a LIB that contains only host-route entries. There are no local bindings for these prefixes anymore.

```
R9#show mpls ldp bindings 92.8.9.0 24
 lib entry: 92.8.9.0/24, rev 45
    no local binding
```

```
R9#show mpls ldp bindings 92.9.12.0 24
 lib entry: 92.9.12.0/24, rev 46
    no local binding
```

We can also apply list-based filters rather than use the “host-routes” keyword. For simplicity, I configure prefix and access-lists that accomplish the same thing except explicitly. Personally, I like the prefix-list more because it lets me match the mask value, whereas the ACL in XR does not. Technically a prefix like 92.0.0.0/30 would get a label on XRv2, but not CSR7. This is just a CLI limitation on XR.

```
! CSR7
ip prefix-list PL_LOOPBACKS seq 5 permit 92.0.0.0/24 ge 32

mpls ldp label
 allocate global prefix-list PL_LOOPBACKS

! XRv2
ipv4 access-list ACL_92_NET
 10 permit ipv4 92.0.0.0 0.0.0.255 any

mpls ldp
 address-family ipv4
  label
  local
  allocate for ACL_92_NET
```

To verify these configurations, we will select a transit link for which CSR7 and XRv2 have IGP routes and expect to see no corresponding labels in the LIB.

```
R7#show mpls ldp bindings 92.4.12.0 24
 lib entry: 92.4.12.0/24, rev 61
    no local binding
```

```
RP/0/0/CPU0:XRv2#show mpls ldp bindings 92.4.12.0/24
[no output]
```

Once labels are allocated, they can be selectively advertised to neighbors, as well as selectively accepted on ingress from other neighbors. This might be used to reduce overall LIB size or force traffic to some destinations to never be MPLS-encapsulated. Intelligent label filtering is usually focused on reducing LIB size. For example, every LDP router will allocate and advertise a label for every IGP route it learns. The labels are advertised to all peers and retained in their LIBs. In our topology, there is never a case where XRv4 would need to learn any label from CSR1 except for CSR1's local prefixes. The same is true for the relationship between CSR5 and XRv3. However, XRv4 and CSR5 still need to advertise all of the IGP routes with their corresponding labels to CSR1 and XRv3, respectively, so the filters are not always obvious to visualize. Outbound filtering is simpler on XR than XE, so we start there first. XRv4 will advertise labels for CSR8 and XRv3 loopbacks to CSR1. This means that CSR1 will only be able to push labels if LSP goes to CSR8 or XRv3.

```
! XRv4
ipv4 access-list ACL_PERMIT_LOOPBACKS
 10 permit ipv4 host 92.0.0.8 any
 20 permit ipv4 host 92.0.0.13 any

mpls ldp
 address-family ipv4
  label
  local
  advertise
    to 92.0.0.1:0 for ACL_PERMIT_LOOPBACKS
```

When we check CSR1's LIB, we only see label bindings for the specified prefixes. Quickly checking the FIB, we can see that CSR8's loopback has the label bound properly, but CSR9's loopback is untagged. This can be used as a memory saving technique to keep the LIB as small as possible.

```
R1#show mpls ldp bindings neighbor 92.0.0.14
 lib entry: 92.0.0.8/32, rev 127
   remote binding: lsr: 92.0.0.14:0, label: 94007
 lib entry: 92.0.0.13/32, rev 132
   remote binding: lsr: 92.0.0.14:0, label: 94008

R1#show ip cef 92.0.0.8
92.0.0.8/32
  nexthop 92.1.14.14 GigabitEthernet2.514 label 94007

R1#show ip cef 92.0.0.9
92.0.0.9/32
  nexthop 92.1.14.14 GigabitEthernet2.514
```

We can also configure inbound label filtering on XRv4. For example, there is never a case where XRv4 would need to learn a label for 92.0.0.1/32 from XRv3 or CSR10. This is because those routers will never

have an alternate path to CSR1, so retaining the labels is worthless. First, we check the LIB and see that XRv4 has labels from all three of its LDP neighbors when it really only needs the implicit-null label from CSR1.

```
RP/0/0/CPU0:XRv4#show mpls ldp bindings 92.0.0.1/32
92.0.0.1/32, rev 16
  Local binding: label: 94003
  Remote bindings: (3 peers)
    Peer                Label
    -----
    92.0.0.1:0          ImpNull
    92.0.0.3:0          3003
    92.0.0.10:0         10012
```

We apply the configuration below so that XRv4 will not learn these labels for 92.0.0.1/32 from CSR3 and CSR10. This makes sense because there is never a case when XRv4 would route traffic to 92.0.0.1/32 via those LSRs. In short, the rule for inbound filtering on XR is configured under the “label remote accept” stanza, while outbound filtering is configured under the “label local advertise” stanza.

```
! XRv4
ipv4 access-list ACL_R1_LOOPBACK
 10 deny ipv4 host 92.0.0.1 any
 20 permit ipv4 any any

mpls ldp
 address-family ipv4
  label
   remote
    accept
     from 92.0.0.3:0 for ACL_R1_LOOPBACK
     from 92.0.0.10:0 for ACL_R1_LOOPBACK
```

After applying this configuration, XRv4 rejects the labels from the specified peers. It only have one label in the LIB for this prefix which was learned from CSR1.

```
RP/0/0/CPU0:XRv4#show mpls ldp bindings 92.0.0.1/32
92.0.0.1/32, rev 16
  Local binding: label: 94003
  Remote bindings: (1 peers)
    Peer                Label
    -----
    92.0.0.1:0          ImpNull
```

The configuration in XE is less straightforward. We will configure CSR5 to only advertise labels for 92.0.0.8/32 and 92.0.0.1/32 towards XRv3. The configuration appears simple at first.

```

! CSR5
ip access-list standard ACL_LOOPBACKS
  permit 92.0.0.1
  permit 92.0.0.8

ip access-list standard ACL_XRV3
  permit 92.0.0.13

mpls ldp advertise-labels for ACL_LOOPBACKS to ACL_XRV3

```

However, XRv3 still has all of the labels for all loopbacks from CSR5 despite configuring advertisement of only specific prefixes towards XRv3 on CSR5.

```

RP/0/0/CPU0:XRv3#show mpls ldp bindings neighbor 92.0.0.5:0
92.0.0.1/32, rev 77
  Local binding: label: 93008
  Remote bindings: (1 peers)
    Peer          Label
    -----
    92.0.0.5:0    5008
92.0.0.2/32, rev 43
  Local binding: label: 93013
  Remote bindings: (1 peers)
    Peer          Label
    -----
    92.0.0.5:0    5010
[snip]

```

The issue is that XE assumes that you want to advertise all labels with all prefixes to all peers until you explicitly tell it to stop. This means that you have to explicitly advertise labels to other peers as well. To disable label advertisement in general, we use the command below. Now, XRv3 only has the two labels to which it is entitled, and no more.

```

! CSR5
no mpls ldp advertise-labels

RP/0/0/CPU0:XRv3#show mpls ldp bindings neighbor 92.0.0.5:0
92.0.0.1/32, rev 77
  Local binding: label: 93008
  Remote bindings: (1 peers)
    Peer          Label
    -----
    92.0.0.5:0    5008
92.0.0.8/32, rev 44
  Local binding: label: 93014
  Remote bindings: (1 peers)
    Peer          Label
    -----

```

92.0.0.5:0 5015

This introduces a new problem. Since CSR5 totally stopped advertising labels (except for the few to XRv3), XRv1 and CSR4 now learn no labels from CSR5. This obviously breaks MPLS transport to most of the nodes in the network.

```
RP/0/0/CPU0:XRv1#show mpls ldp bindings neighbor 92.0.0.5:0
[no output]
```

```
R4#show mpls ldp bindings neighbor 92.0.0.5
[no output]
```

We can correct this by instructing CSR5 to advertise labels for all prefixes to all neighbors that are not XRv3. Personally, I feel like this is overkill and difficult to maintain. That is probably why the XR configuration is much simpler as the CLI syntax is newer (XE behavior is carried over from classic IOS).

```
! CSR5
ip access-list standard ACL_ANY
 permit any
ip access-list standard ACL_NOT_XRV3
 deny 92.0.0.13
 permit any

mpls ldp advertise-labels for ACL_ANY to ACL_NOT_XRV3
```

Now, we confirm XRv3 only has the 2 labels it's supposed to, while XRv1 and CSR4 have them all.

```
RP/0/0/CPU0:XRv3#show mpls ldp bindings neighbor 92.0.0.5:0
92.0.0.1/32, rev 77
  Local binding: label: 93008
  Remote bindings: (1 peers)
    Peer          Label
    -----
    92.0.0.5:0    5008
92.0.0.8/32, rev 44
  Local binding: label: 93014
  Remote bindings: (1 peers)
    Peer          Label
    -----
    92.0.0.5:0    5015
```

```
RP/0/0/CPU0:XRv1#show mpls ldp bindings neighbor 92.0.0.5:0
92.0.0.1/32, rev 77
  Local binding: label: 91011
  Remote bindings: (4 peers)
    Peer          Label
    -----
```

```

          92.0.0.5:0          5008
92.0.0.2/32, rev 23
  Local binding: label: 91007
  Remote bindings: (4 peers)
      Peer          Label
      -----
92.0.0.5:0          5010
[snip]

R4#show mpls ldp bindings neighbor 92.0.0.5
  lib entry: 92.0.0.1/32, rev 83
    remote binding: lsr: 92.0.0.5:0, label: 5008
  lib entry: 92.0.0.2/32, rev 28
    remote binding: lsr: 92.0.0.5:0, label: 5010
  lib entry: 92.0.0.3/32, rev 49
    remote binding: lsr: 92.0.0.5:0, label: 5014
[snip]

```

There is a special command we can use on XE to see which advertisement ACLs apply to which prefixes. I show two examples below. First, the output shows all configured prefix and peer ACLs as reference, and then iterates over matching LIB entries. For 92.0.0.7/32, the prefix ACL is the one that matches all prefixes, and the peer ACL matches everything except XRv3. This “match” means that the label for this prefix can be advertised according to those rules. The LIB entry for 92.0.0.8/32 is also shown. This matches a more specific ACL containing CSR8 and CSR1 loopbacks only, and is specific to XRv3.

```

R5#show mpls ldp bindings 92.0.0.7 32 advertisement-acls
Advertisement spec:
  Prefix acl = ACL_LOOPBACKS; Peer acl = ACL_XRV3
  Prefix acl = ACL_ANY; Peer acl = ACL_NOT_XRV3

  lib entry: 92.0.0.7/32, rev 166
    Advert acl(s): Prefix acl ACL_ANY; Peer acl ACL_NOT_XRV3

R5#show mpls ldp bindings 92.0.0.8 32 advertisement-acls
Advertisement spec:
  Prefix acl = ACL_LOOPBACKS; Peer acl = ACL_XRV3
  Prefix acl = ACL_ANY; Peer acl = ACL_NOT_XRV3

  lib entry: 92.0.0.8/32, rev 126
    Advert acl(s): Prefix acl ACL_LOOPBACKS; Peer acl ACL_XRV3

```

The command also exists on XR but is less valuable. Here is the sample output from XRv4. It just lists prefixes with no valuable information provided regarding advertisement ACLs.

```

RP/0/0/CPU0:XRv4#show mpls ldp bindings advertisement-acls
Advertisement Spec: None

```

Local Label Allocation Spec:
Host routes only

92.0.0.1/32, rev 16
92.0.0.2/32, rev 25
92.0.0.3/32, rev 17
[snip]

XE inbound filtering is more straightforward. CSR5 receives labels for all IGP routes learned by XRv3, which is all of the loopbacks. CSR5 has no reason to learn any label from XRv3 except for XRv3's loopback (some kind of null label). We can filter these other labels from the LIB. Below is a "before" snapshot of CSR5's LIB entries learned from XRv3.

```
R5#show mpls ldp bindings neighbor 92.0.0.13
lib entry: 92.0.0.1/32, rev 160
remote binding: lsr: 92.0.0.13:0, label: 93008
lib entry: 92.0.0.2/32, rev 161
remote binding: lsr: 92.0.0.13:0, label: 93013
lib entry: 92.0.0.3/32, rev 162
remote binding: lsr: 92.0.0.13:0, label: 93015
[snip]
```

The configuration on CSR5 is below. We can be efficient and re-use an ACL from earlier that simply matches 92.0.0.13. Since the neighbor is specified in the command, we only have one ACL as input. Now, CSR5 only learns one label from XRv3, which is for its loopback prefix using implicit-null.

```
! CSR5
mpls ldp neighbor 92.0.0.13 labels accept ACL_XRV3

R5#show mpls ldp bindings neighbor 92.0.0.13
lib entry: 92.0.0.13/32, rev 131
remote binding: lsr: 92.0.0.13:0, label: imp-null
```

The idea behind these label filters is to sustain the LSPs between CSR1, CSR8, and XRv3. As such, these routers should be able to send MPLS-encapsulated traffic to one another with no breaks in the LSP. We will test a few paths to ensure that our label filters did not break these paths. Since no label filtering was done towards CSR8, we won't verify LSPs sourced from CSR8 since it is highly unlikely they are broken. Below, we can see all 4 traceroutes are fully MPLS-encapsulated.

```

```

The last LDP feature we examine is LDP implicit withdraw. In newer IOS releases, when LDP needs to change a label binding for a particular prefix, that update is preceded by a label withdraw message. This is an explicit message which informs the peer that the label you had before is no longer valid, and then the new one is advertised. In older releases, this process was implicit and there was no explicit label withdraw. This command is enabled on a per neighbor basis to enable the old-style behavior. This does not appear to be supported in XR at all. We can enable LDP message reception debugging on XRv3 to see this.

```
RP/0/0/CPU0:XRv3#debug mpls ldp messages received
```

On CSR5, we will further constrain the label advertisement by removing the ability to advertise labels for 92.0.0.1/32. This will trigger an explicit label withdraw message from CSR5 to XRv3. The message contents are unreadable but we clearly see the message being received.

```
R5(config)#ip access-l standard ACL_LOOPBACKS
```

```
R5(config-std-nacl)#no 20 permit 92.0.0.1
```

```
! XRv3
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): Rcvd 'LABEL-  
WITHDRAW' msg (size 24, seq 7); 'Prefix' FEC
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): TLVs: (2)
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): #1:
```

```
idx=18, type=0x100, U/F=0/0
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): #2:
```

```
idx=30, type=0x200, U/F=0/0
```

When we add the ACL entry back for 92.0.0.1/32 (not shown), CSR5 sends a label mapping message, as discussed earlier, which advertises a particular label for the prefix.

```
! XRv3
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): Rcvd 'LABEL-  
MAPPING' msg (size 24, seq 11); 'Prefix' FEC
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): TLVs: (2)
```

```
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      #1:
idx=18, type=0x100, U/F=0/0
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      #2:
idx=30, type=0x200, U/F=0/0
```

Removing entries from an ACL is always going to trigger a withdraw since there is no new label being advertised. Instead, we will configure a static local label on CSR5. This new value is guaranteed to be different than the existing value. Static labels are covered in detail in the next section, but in this case, we just configure the in-label (local label) on CSR5. We also must define a static label range first as well.

```
! CSR5
mpls label range 5000 5999 static 500 599
mpls static binding ipv4 92.0.0.1 255.255.255.255 501
```

The result is that XRv3 receives a label withdraw immediately followed by a label mapping message. This is expected since implicit-withdraw is not enabled by default. This is CSR5 withdrawing the old LDP-allocated label and advertising the statically configured one in an LDP mapping message.

```
! XRv3
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): Rcvd 'LABEL-
WITHDRAW' msg (size 24, seq 11); 'Prefix' FEC
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      TLVs: (2)
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      #1:
idx=18, type=0x100, U/F=0/0
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      #2:
idx=30, type=0x200, U/F=0/0
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): Rcvd 'LABEL-
MAPPING' msg (size 24, seq 12); 'Prefix' FEC
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      TLVs: (2)
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      #1:
idx=18, type=0x100, U/F=0/0
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0):      #2:
idx=30, type=0x200, U/F=0/0
```

Now, we will enable implicit withdraw on CSR5 and change the static label once again. This time, CSR5 only sends a label mapping, which overwrites the existing LIB entry. This new label mapping message serves as an implicit withdraw to save LDP overhead. Because the label was overwritten, the need for an explicit withdrawal is eliminated.

```
! CSR5
mpls ldp neighbor 92.0.0.13 implicit-withdraw
mpls static binding ipv4 92.0.0.1 255.255.255.255 502

! XRv3
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): Rcvd 'LABEL-
MAPPING' msg (size 24, seq 17); 'Prefix' FEC
```

```

mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): TLVs: (2)
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): #1:
idx=18, type=0x100, U/F=0/0
mpls_ldp[1048]: DBG-MsgRcv[1], VRF(default): Peer(92.0.0.5:0): #2:
idx=30, type=0x200, U/F=0/0

```

The next section contains the configurations for this section since it builds on this lab.

7.2 Static label bindings

This section is a continuation from the LDP lab above. Despite all of the advanced LDP options we configured, we can also manually build LSPs. This is similar to MPLS transport profile (MPLS-TP) where the LSPs must be provisioned statically on all LSRs along the LSP. However, the static LSPs in XE and XR are still somewhat reliant on LDP being enabled, which is unlike MPLS-TP. The static label feature allows us to custom-define local labels, as well as label swapping for forwarding. This can interwork with LDP labels so the path can be static for a few hops, then dynamic via LDP for the remaining hops. We will examine building a static LSP from CSR1 to CSR3, transiting XRv4. The idea is to sustain the MPLS connectivity between CSR1, CSR8, and XRv3 which was the theme in the last lab. This is configuration intensive but not difficult. Beginning with CSR1, we need to allocate local labels for both 92.0.0.8 and 92.0.0.13. We also need to identify what are the remote labels for this prefix and towards which next-hop. These out-labels on CSR1 must be statically defined as local labels on XRv4, which mimics the behavior of LDP where this happens automatically. As a final measure to ensure LDP bindings are not advertised, we totally disable label advertisement on CSR1.

```

! CSR1
no mpls ldp advertise-labels
mpls static binding ipv4 92.0.0.8 255.255.255.255 103
mpls static binding ipv4 92.0.0.8 255.255.255.255 output 92.1.14.14 9408
mpls static binding ipv4 92.0.0.13 255.255.255.255 113
mpls static binding ipv4 92.0.0.13 255.255.255.255 output 92.1.14.14 9413

```

After adding this configuration, the first issue we see indicates a label conflict. Because we have learned dynamic labels from XRv4, those are preferred over the statically defined out-labels. We can correct this one of two ways: filter labels inbound on CSR1, or filter them outbound on XRv4.

```

R1(config)# mpls static binding ipv4 92.0.0.8 255.255.255.255 output
92.1.14.14 9408
% Next hop 92.1.14.14 is an LDP peer (92.0.0.14:0)
% Label learned from peer, if any, takes precedence
% Continuing with configuration of the label

```

For simplicity, I will filter all label advertisements on XRv4 temporarily. Additionally, I will add in the appropriate static label bindings for the prefixes we are testing. Notice that the local labels 9413 and 9408 are the same out-labels we configured on CSR1. XRv4 will swap these labels for new labels that are local on CSR3, which we will also configure. To reach XRv4, since it is the penultimate hop, we configure

it to pop the topmost label when traffic arrives with label 9401. This is part of the reverse LSP but we configure it now for completeness.

```
! XRv4
mpls ldp
  address-family ipv4
    label
      local
        advertise
        disable

mpls static
  address-family ipv4 unicast
    local-label 9401 allocate per-prefix 92.0.0.1/32
    forward
      path 1 nexthop GigabitEthernet0/0/0/0.514 92.1.14.1 out-label pop

    local-label 9408 allocate per-prefix 92.0.0.8/32
    forward
      path 1 nexthop GigabitEthernet0/0/0/0.534 92.3.14.3 out-label 308

    local-label 9413 allocate per-prefix 92.0.0.13/32
    forward
      path 1 nexthop GigabitEthernet0/0/0/0.534 92.3.14.3 out-label 313
```

After these changes, we will perform some verification. Now that CSR1 does not learn LDP labels from XRv4, we should see the static labels in the LFIB. On XRv4, we see the static label in its LFIB as well.

R1#show mpls forwarding-table labels 100 - 199

Local	Outgoing	Prefix	Bytes Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched	interface	
103	9408	92.0.0.8/32	0	Gi2.514	92.1.14.14
113	9413	92.0.0.13/32	0	Gi2.514	92.1.14.14

RP/0/0/CPU0:XRv4#show mpls forwarding labels 9400 9499

Local	Outgoing	Prefix	Outgoing	Next Hop	Bytes
Label	Label	or ID	Interface		Switched
9401	Pop	92.0.0.1/32	Gi0/0/0/0.514	92.1.14.1	528
9408	308	92.0.0.8/32	Gi0/0/0/0.534	92.3.14.3	0
9413	313	92.0.0.13/32	Gi0/0/0/0.534	92.3.14.3	0

Next, we need to configure CSR3 with some label bindings. At a minimum, we need to configure local labels for 92.0.0.8/32 and 92.0.0.13/32 using values 308 and 313, since that is what XRv4 is sending outbound towards CSR3. We don't have to define a local label for 92.0.0.1/32, since LDP can do that; other routers can use this dynamic label to send traffic to CSR3 who will swap it for a static label towards XRv4 (specifically value 9401).

```

! CSR3
mpls static binding ipv4 92.0.0.1 255.255.255.255 output 92.3.14.14 9401
mpls static binding ipv4 92.0.0.8 255.255.255.255 308
mpls static binding ipv4 92.0.0.13 255.255.255.255 313

```

CSR3's LFIB is very interesting because we see LDP and static LSP being connected properly in both directions. The first output shows the static local labels, which is traffic destined for CSR8 and XRv3. Traffic arrives with a static label and is swapped to one of two dynamic labels, depending on the ECMP decision. The second output shows a dynamic local label allocated to LDP peers, but it is swapped to a static label for transmission to XRv4. The static range on every router is the dynamic range divided by ten, which makes it easy to spot at a glance.

```

R3#show mpls forwarding-table labels 300 - 399

```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Outgoing interface	Next Hop
308	2002	92.0.0.8/32	384	Gi2.523	92.2.3.2
	9007	92.0.0.8/32	570	Gi2.523	92.2.3.9
313	2012	92.0.0.13/32	2514	Gi2.523	92.2.3.2
	9006	92.0.0.13/32	2670	Gi2.523	92.2.3.9

```

R3#show mpls forwarding-table 92.0.0.1 32

```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Outgoing interface	Next Hop
3003	9401	92.0.0.1/32	0	Gi2.534	92.3.14.14

Next, we will manually trace the paths to ensure the label stacks are built properly. From CSR1, we will trace the LSP to CSR8. Even though the label wasn't learned from LDP, it still shows up in the LIB using the LDP show commands (I presume this is why LDP is required to be enabled for static labels to work). Since the traffic sourced from CSR1 is IP, the FIB is consulted, and label 9408 is pushed.

```

R1#show mpls ldp bindings 92.0.0.8 32
  lib entry: 92.0.0.8/32, rev 151
    local binding:  label: 103
    remote binding: lsr: 92.0.0.14:0, label: 9408

R1#show ip cef 92.0.0.8
92.0.0.8/32
  nexthop 92.1.14.14 GigabitEthernet2.514 label 9408

```

XRv4 is an ordinary P router that performs a swap operation from label 9408 to label 308. Both of these are static labels.

```

RP/0/0/CPU0:XRv4#show mpls forwarding labels 9408

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched

```
-----
9408    308          92.0.0.8/32          Gi0/0/0/0.534 92.3.14.3      0
```

CSR3 is also a P routers performing a label swap, but it also connected the static and LDP LSPs. The exact path selects CSR2 based on the IPv4 source/destination ECMP hash.

```
R3#show mpls forwarding-table labels 308
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
308	2002	92.0.0.8/32	384	Gi2.523	92.2.3.2
	9007	92.0.0.8/32	570	Gi2.523	92.2.3.9

```
R3#show mpls forwarding-table exact-route label 308 ipv4 source 92.0.0.1 destination 92.0.0.8
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
308	2002	92.0.0.8/32	384	Gi2.523	92.2.3.2

CSR2 performs a normal pop operation (PHP) and delivers the IP packet to CSR8. We use traceroute on CSR1 to confirm the path and label swaps along the way. We can clearly see that CSR3 is the point at which the static and LDP LSPs connect.

```
R2#show mpls forwarding-table labels 2002
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
2002	Pop Label	92.0.0.8/32	12248	Gi2.528	92.2.8.8

```
R1#traceroute 92.0.0.8 source 92.0.0.1
```

Type escape sequence to abort.

Tracing the route to 92.0.0.8

VRF info: (vrf in name/id, vrf out name/id)

```
 1 92.1.14.14 [MPLS: Label 9408 Exp 0] 7 msec 5 msec 6 msec
 2 92.3.14.3  [MPLS: Label 308 Exp 0] 28 msec 30 msec 30 msec
 3 92.2.3.2   [MPLS: Label 2002 Exp 0] 21 msec 20 msec 20 msec
 4 92.2.8.8   21 msec 11 msec 11 msec
```

Tracing in the reverse direction from CSR8, we see two labels in the LIB learned from LDP and two ECMP paths to reach 92.0.0.1/32. Based on the ECMP hash, CEF selects CSR9 using label 9011.

```
R8#show mpls ldp bindings 92.0.0.1 32
```

```
lib entry: 92.0.0.1/32, rev 55
```

```
local binding: label: 8013
```

```
remote binding: lsr: 92.0.0.9:0, label: 9011
```

```
remote binding: lsr: 92.0.0.2:0, label: 2013
```

```
R8#show ip cef 92.0.0.1
```

```
92.0.0.1/32
```

```

nexthop 92.2.8.2 GigabitEthernet2.528 label 2013
nexthop 92.8.9.9 GigabitEthernet2.589 label 9011

```

```

R8#show ip cef exact-route 92.0.0.8 92.0.0.1
92.0.0.8 -> 92.0.0.1 => label 9011TAG adj out of GigabitEthernet2.589, addr
92.8.9.9

```

CSR9 swaps 9011 for 3003 and sends the packet to CSR3. Nothing special here.

```

R9#show mpls forwarding-table labels 9011

```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
9011	3003	92.0.0.1/32	570	Gi2.523	92.2.3.3

Next, CSR3 receives the packet with LDP label 3003 and swaps it for the static label 9401. This is connecting an LDP LSP to a static LSP, the reverse of what we saw earlier.

```

R3#show mpls forwarding-table labels 3003

```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
3003	9401	92.0.0.1/32	1944	Gi2.534	92.3.14.14

We manually programmed XRv4 to pop the topmost label when sending traffic to CSR1 for prefix 92.0.0.1/32, so label 9401 is removed to reveal the raw IP packet to CSR1. We confirm with traceroute, keeping in mind that starting it from CSR8 is going to alternative between ECMP paths (process switched). Traffic that was actually CEF-switched would always go through CSR9, though.

```

RP/0/0/CPU0:XRv4#show mpls forwarding labels 9401

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched

Additional Reading – Reference configurations “mpls-ldp”

7.3 MPLS IP and MTU minor options

Rather than pollute the LDP lab by disabling the handy traceroute tool, I built another lab so we can demonstrate TTL handling and IP default route labeling supported in XE and XR. The lab will also focus on the extremely important but often overlooked issue of MPLS fragmentation and MTU adjustment. The network diagram is below and is a single BGP AS providing L3VPN (VPNv4/v6) to three customer sites. The customer sites use BGP as the PE-CE routing protocol and also for the backdoor link between XRv4 and CSR5. CSR1 is multi-homed to two PEs. The network core uses IS-IS with LDP and RSVP-TE, and both CSR7 and XRv3 are RR's with BGP add-path enabled for fast convergence. Most of these features are not relevant for testing the MPLS minor options, but it is good to have a moderately complex network rather than testing in isolation.

We will quickly skim the relevant configurations of the network. IS-IS configuration is L2 everywhere and is not examined. LDP is enabled on all IS-IS links with targeted session accepted everywhere for PE-P and P-P TE tunnel support. We can verify these things quickly; using a single command, I can see all of the IS-IS LSPs and their links. We can see 9 total vertices (7 routers and 2 DIS) with all of their links. This is very easy to read and it a good way to verify the IS-IS topology without relying on the RIB or ping/traceroute.

We can also verify the LDP bindings very quickly. The summary command below shows that there are 7 prefixes with label bindings in the LIB, which equates to each loopback in the core. We can prove this by checking the LIB entries in summary form as well; we only see one prefix per router.

```
R7#show mpls ldp bindings summary
Total number of prefixes: 7
Generic label bindings
```

	assigned	learned
prefixes	in labels	out labels
7	7	35

```
Total tib route info allocated: 9
Previous tib remote label entries allocated Current/Total: 0/0
Previous tib remote label queues allocated Current/Total: 0/0

```

MPLS-TE is enabled on every IGP enabled interface. We can quickly check the TED as well, observing that it is identical to the IS-IS database in terms of links. The first 7 entries are router nodes (actual routers), while the last 2 are network nodes (DIS). There are no TE tunnels in the network at present.

```

Next, we will quickly check the BGP details. Both CSR7 and XRv3 are RR's for VPNv4 and VPNv6. CSR7 is a "shadow RR" which advertises its second-best path to all clients, while XRv3 has no special BGP add-path/PIC configuration. This is mostly to support left-to-right traffic towards CSR1. First, we verify all of the sessions are up from the RR's for both AFIs. Each CE contributes 4 routes to the VPN, and since CSR1 is dual-homed, both XRv2 and CSR9 advertise the same prefixes. In total, 4 routes are learned from each PE.

```

R7#show bgp vpnv4 unicast all summary | begin ^Neighbor
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd

```

The PE-CE links run independent IPv4/v6 BGP sessions for simplicity as XE and XR treat merged sessions differently. CSR1 uses weight from CSR9 to select it as the preferred exit point for outbound traffic. It also sets a high MED outbound to CSR9 to “hint” to AS 211 that XRv2 is the preferred ingress point into AS 65000. As an added bonus, I use an AS-path technique to ensure CSR1 does not become a transit router by only advertising routes with an AS-path length of the empty string (local routes only). We won’t verify every single aspect of this configuration for brevity.

```
! CSR1
ip as-path access-list 1 permit ^$

route-map RM_SET_MED permit 10
  set metric 111
route-map RM_SET_WEIGHT permit 10
  set weight 111

router bgp 65000
  address-family ipv4
    neighbor 10.1.9.9 route-map RM_SET_WEIGHT in
    neighbor 10.1.9.9 route-map RM_SET_MED out
    neighbor 10.1.9.9 filter-list 1 out

  address-family ipv6
    neighbor FD00:10:1:9::9 route-map RM_SET_WEIGHT in
    neighbor FD00:10:1:9::9 route-map RM_SET_MED out
    neighbor FD00:10:1:9::9 filter-list 1 out
```

The shadow RR configuration on CSR7 is shown below since it is worth revisiting (the details are in the BGP additional-paths section). We will see that the best-path to CSR1’s loopbacks is via XRv2, so CSR7 will advertise the alternative path via CSR9. We can see this by checking the outbound advertised-routes on the RR towards XRv1 in both AFIs.

```
! CSR7
address-family vpnv4
  bgp additional-paths select backup
  bgp additional-paths install
  no bgp recursion host
  neighbor IBGP advertise diverse-path backup

address-family vpnv6
  bgp additional-paths select backup
  bgp additional-paths install
  no bgp recursion host
  neighbor IBGP advertise diverse-path backup
```

Because the best path for routes from CSR1 is via XRv2, CSR7 selects the routes from CSR9 as backups and advertises those. Because the IGP cost was not a factor (MED was), we don’t need to tell the RRs to ignore the IGP cost in the best-path calculation as is often required.

```

```

CSR6 and XRv1 both install these backup paths. This allows them to quickly failover if XRv2 fails or the primary route is otherwise lost. Again, none of this is directly relevant to MPLS minor options, but we want to make sure the network is functional before continuing.

```

! CSR6
router bgp 211
  address-family vpnv4
    bgp additional-paths select backup
    bgp additional-paths install
    no bgp recursion host

```

```

address-family vpnv6

```

Since there is a backdoor between CSR5 and XRv4, the primary path should be the MPLS network. Rather than adjust BGP path selection, I use aggregation and longest-match routing to achieve this. CSR5 aggregates its loopbacks as a summary-only BGP aggregate. This also has the no-export community so

that it never gets advertised to the SP. CSR5 unsuppresses the longer matches and advertises those to CSR6, but only the summary goes to XRv4 since there is no unsuppress map on that peer. Also note that CSR5 uses an alternative technique to prevent transit-AS service. CSR1 used AS-path regex while CSR5 uses the no-export community inbound from CSR6.

```
! CSR5
route-map RM_SET_NO_EXPORT permit 10
  set community no-export additive
route-map RM_UNSUPPRESS permit 10

router bgp 65000
  address-family ipv4
    aggregate-address 10.0.5.0 255.255.255.252 summary-only route-map RM_SET_NO_EXPORT
    neighbor 10.5.6.6 unsuppress-map RM_UNSUPPRESS
    neighbor 10.5.6.6 route-map RM_SET_NO_EXPORT in

  address-family ipv6
    aggregate-address ::10:0:5:0/112 summary-only attribute-map RM_SET_NO_EXPORT
    neighbor FD00:10:5:6::6 unsuppress-map RM_UNSUPPRESS
    neighbor FD00:10:5:6::6 route-map RM_SET_NO_EXPORT in
```

Since XR does not appear to support an unsuppress map, we create the summary as an additional route then manually filter the longer-matches from the iBGP backdoor on XRv4. For practice, I use fancy RPLs which recycle prefix-sets that match all loopbacks regardless of mask, then apply a second inline prefix-set to ensure only host routes within that primary range are matched. These are dropped when routes are advertised to CSR5 via iBGP.

```
! XRv4
prefix-set PS_LOOPBACKS
  10.0.14.0/24 le 32
end-set

prefix-set PS_LOOPBACKS_V6
  ::10:0:14:0/112 le 128
end-set

route-policy RPL_DENY_HOST_ROUTES
  if destination in PS_LOOPBACKS and destination in (0.0.0.0/0 ge 32) then
    drop
  else
    pass
  endif
end-policy

route-policy RPL_DENY_HOST_ROUTES_V6
  if destination in PS_LOOPBACKS_V6 and destination in (:::/0 ge 128) then
    drop
  else
```

```

        pass
    endif
end-policy

router bgp 65000
  address-family ipv4 unicast
    aggregate-address 10.0.14.0/30 route-policy RPL_SET_NO_EXPORT

  address-family ipv6 unicast
    aggregate-address ::10:0:14:0/112 route-policy RPL_SET_NO_EXPORT

  neighbor 10.5.14.5
    address-family ipv4 unicast
    route-policy RPL_DENY_HOST_ROUTES out

  neighbor fd00:10:5:14::5
    address-family ipv6 unicast
    route-policy RPL_DENY_HOST_ROUTES_V6 out

```

Since this configuration is very involved, we will quickly check CSR5 advertised routes. Towards the provider, the host routes are allowed, but not the summary. Towards the backdoor peer, the summary is allowed, but not the local host routes. Other routes from CSR1 are still allowed as they were not suppressed by the summary nor explicitly filtered.

We conduct a similar set of checks on XRv4. The results are nearly identical despite the configuration method being different. The host-routes are advertised to the provider and the summary is advertised to the iBGP backdoor peer, but not vice versa.

We conduct 3 traceroutes to verify connectivity. From XRv4, we trace to CSR5 to ensure MPLS is used. Also from XRv4, we trace to CSR1 to ensure XRv2 is the ingress point into AS 65000. Last, we trace from CSR1 to CSR5 to ensure CSR9 is the egress point from AS 65000. This concludes the basic network verification.

The first and most important thing to do is adjust MTU. We will focus on the link between CSR7 and XRv1 so we can see XE and XR commands together. The XE command to reveal the MPLS MTU is intuitive but the XR one is not. We must invoke the interface manager (IM) process, but this also shows us the other relevant MTUs such as IPv4, IPv6, CLNS, etc.

```
R7#show mpls interfaces GigabitEthernet2.571 detail
Interface GigabitEthernet2.571:
  Type Unknown
  IP labeling enabled (ldp) :
    IGP config
  LSP Tunnel labeling enabled
  IP FRR labeling not enabled
  BGP labeling not enabled
  MPLS operational
  MTU = 1500
```

```
RP/0/0/CPU0:XRv1#show im database interface gigabitEthernet 0/0/0/0.571 |
begin Protocol
  Protocol          Caps (state, mtu)
  -----
  None              vlan_jump (up, 1518)

  arp               arp (up, 1500)
  clns              clns (up, 1500)
  ipv4              ipv4 (up, 1500)
  mpls              mpls (up, 1500)
  ipv6              ipv6_preswitch (up, 1500)
  ipv6              ipv6 (up, 1500)
```

Considering the MPLS MTU is equal to the IPv4/v6 MTUs, this is going to cause a problem. If a customer sends 1500 byte packets into the network, we know that at least one 4-byte MPLS shim-header will be added to the packets in the case of L3VPN. In some designs, this could be closer to 5 labels as seen in the carrier supporting carrier (CSC) section, and for L2VPN, may include a 4-byte control-word (CW). While the traffic still flows, it will be fragmented. This is only true for IPv4 traffic; IPv6 traffic or non-IP traffic is simply discarded. First, we will prove the easier claim about IPv6. The PE imposes a two-label stack of {7001 92010} which is 8 bytes of encapsulation. This allows XRv4 to send packets up to 1492 bytes in size, but not 1493 bytes or larger.

```
RP/0/0/CPU0:XRv1#show cef vrf J ::10:0:1:0 | utility egrep 'via|labels'

Sending 5, 1493-byte ICMP Echos to ::10:0:1:0, timeout is 2 seconds:
.....
Success rate is 0 percent (0/5)
```

The situation is similar for IPv4. Going to CSR1, there are still 2 labels {7001 92006} which is 8 bytes of encapsulation. This time we perform 3 pings. First, we send packets of size 1492 which DF-bit set, which we expect to work. Next, we sent packets too large with DF-bit set and watch them fail. Third, we clear the DF-bit, which allows the packets to be fragmented before CEF imposes the labels, and this only works for IPv4. This is not a good practice since fragmentation is generally viewed unfavorably in IP networks due to increased CPU load and process switching on network devices. If fragmentation must occur, it makes more sense to offload it to end-hosts.

```

Since MPLS encapsulation is inserted after the layer 2 header but before the layer 3 header, we can conclude that the layer 2 MTU $\geq$ MPLS MTU $\geq$ layer 3 MTU. In our case, the layer 2 MTU is 1518 to account for 14 bytes of Ethernet and 4 bytes of 802.1q encapsulation. The MPLS and IPv4/v6 MTUs are both 1500, so the formula holds true. Ideally, none of these MTUs would ever be equal, as it introduces the problems shown above. If we adjust the interface MTU, this value is inherited by all protocols enabled on that interface as well. We will set it to 2000 on the physical interfaces of CSR7 and XRv1.

```
! CSR7
interface GigabitEthernet2
    mtu 2000

! XRv1
interface GigabitEthernet0/0/0/0
    mtu 2000
```

Now, the IPv4, IPv6, and MPLS MTUs are all 2000, which is better but still kind of sloppy. If for whatever reason an IP packet of size 2000 entered an ingress LSR, we would have the same issue. For that reason, it makes sense for the MTU formula to be layer 2 MTU $>$ MPLS MTU $>$ layer 3 MTU. The option of equality is removed which means the outer encapsulation MTU should be strictly greater than anything inside. XR displays the information differently, subtracting 14 bytes to account for the Ethernet header and allowing 4 extra bytes for 802.1q. We can still see that IPv4/v6 and MPLS MTUs are equal, though.

```
R7#show mpls interfaces GigabitEthernet2.571 detail | include MTU
MTU = 2000
```

```
R7#show ip interface gigabitEthernet 2.571 | include MTU
MTU is 2000 bytes
```

```
R7#show ipv6 interface gigabitEthernet 2.571 | include MTU
MTU is 2000 bytes
```

```
RP/0/0/CPU0:XRv1#show im database interface gigabitEthernet 0/0/0/0.571 |
begin Protocol
```

Protocol	Caps (state, mtu)
-----	-----
None	vlan_jump (up, 2004)
None	spio (up, 2004)
None	dot1q (up, 2004)
arp	arp (up, 1986)
clns	clns (up, 1986)
ipv4	ipv4 (up, 1986)
mpls	mpls (up, 1986)
ipv6	ipv6_preswitch (up, 1986)
ipv6	ipv6 (up, 1986)

Let's assume that our network supports 1500 byte IPv4 and IPv6 packets and that jumbo frames are not allowed. We are essentially going to allow "baby giants", which are frames just slightly larger than 1500 bytes, but not enormous 9000-byte packets. To do this, we will adjust the IP and IPv6 MTUs on our logical interfaces between CSR7 and XRv1 to 1500. Be mindful of adjusting MTUs as some protocols, such as OSPF, require them to match in most cases (can be ignored, but this is bad practice).

```
! CSR7
interface GigabitEthernet2.571
 ip mtu 1500
 ipv6 mtu 1500

! XRv1
interface GigabitEthernet0/0/0/0.571
 ipv4 mtu 1500
 ipv6 mtu 1500
```

When we verify the MTUs now, we can see the IPv4 and IPv6 MTUs are back to 1500, but the MPLS MTU remains unchanged. The MPLS MTU is still using the same value as was configured on the physical interface, which makes sense. Since MPLS encapsulates IPv4/IPv6, it wouldn't make sense for it to assume any MTU settings from those tunneled protocols.

```
R7#show mpls interfaces GigabitEthernet2.571 detail | include MTU
MTU = 2000
```

```
R7#show ip interface gigabitEthernet 2.571 | include MTU
MTU is 1500 bytes
```

```

  ipv6              ipv6 (up, 1500)
```

Let's consider our network for a moment. At present, all LSPs in this network use 1 or 2 labels in the stack. If we built a TE tunnel from PE-P or P-P, there could potentially be 3 labels. Without TE-FRR or CSC in the network, or any fancy features like flow-aware transport (FAT), entropy labels, control-words, etc, we can assume the maximum label stack depth is 3. Thus, it would make sense for the MPLS MTU to be at least 1512, where the additional 12 bytes accounts for 3 labels. Since the MPLS MTU is currently 2000, we wouldn't have the fragmentation issues anymore, but I adjust the MPLS MTU for completeness.

```
! CSR7
interface GigabitEthernet2.571
  mpls mtu 1512

! XRv1
interface GigabitEthernet0/0/0/0.571
  mpls
    mtu 1512
```

Now, we see the MTUs are properly adjusted. One note about MTU adjustment; the layer 2 network (in this case Ethernet) must also support MTUs larger than 1500 for this to work. Had we been dealing with L2VPNs, our MPLS MTU would have to be larger to account for tunneled Ethernet headers, control-words, and other components. The math follows the same logic and is not worth demonstrating. I set the MTU to 2000 as a demonstration, but the physical switched network in this lab supports MTUs of up to 9000 bytes.

```
R7#show mpls interfaces GigabitEthernet2.571 detail | include MTU
MTU = 1512
```

```
RP/0/0/CPU0:XRv1#show im database interface gigabitEthernet 0/0/0/0.571 |
begin Protocol
  Protocol          Caps (state, mtu)
  -----
None               vlan_jump (up, 2004)
None               spio (up, 2004)
None               dot1q (up, 2004)
arp                arp (up, 1986)
clns                clns (up, 1986)
ipv4                ipv4 (up, 1500)
mpls                mpls (up, 1512)
ipv6                ipv6_preswitch (up, 1986)
ipv6                ipv6 (up, 1500)
```

Because these changes were only made on a small part of the network, we will make the changes on all nodes in the MPLS core for consistency. I also adjust the IPv4/v6 MTUs on the PE-CE interfaces since they share the same physical interface as the core links. The configurations are not shown, but they set the interface MTU to 2000, MPLS MTU to 1512, and IPv4/v6 MTU to 1500. Now, we can verify that IPv6 connectivity works with 1500 byte packets. We also verify that IPv4 connectivity works with 1500 byte packets without fragmentation, which is ideal.

```
RP/0/0/CPU0:XRv4#ping ::10:0:1:0 source ::10:0:14:1 size 1500
Type escape sequence to abort.
Sending 5, 1500-byte ICMP Echos to ::10:0:1:0, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/185/249 ms
```

```
RP/0/0/CPU0:XRv4#ping 10.0.1.0 source 10.0.14.2 size 1500 df-bit
Type escape sequence to abort.
Sending 5, 1500-byte ICMP Echos to 10.0.1.0, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/75/179 ms
```

We can use EPC inbound on CSR7 to see these packets. The total size is 1526 bytes: 1500 IPv4 + 8 MPLS + 4 dot1q + 14 Ethernet. This packet only has a 2-label stack, which is highlighted. We saw earlier that the labels were {7001 92006} and this confirms it. We technically still have room for one more label since the size of the MPLS packet is 1508 bytes (starting with the topmost label) and the MPLS MTU is 1512 everywhere.

```

```

To ensure the network can support a third label without fragmentation, we build a simple TE tunnel from XRv1 (PE) to CSR8 (P) traversing CSR7. This tunnel will have LDP enabled on it, which triggers a targeted session to CSR8. This is necessary so that the head-end can push an additional label, which will be CSR8's LDP label to reach 211.0.0.12/32, the remote PE. The result will be a 3 label stack that we will verify shortly. We use this tunnel only for traffic going to XRv2, so a static route is appropriate.

```
! XRv1
explicit-path name EP_11_7_8
  index 10 next-address strict ipv4 unicast 211.0.0.7
  index 20 next-address strict ipv4 unicast 211.0.0.8

interface tunnel-te100

```

With the tunnel built properly, we will verify the label stack piece-by-piece for practice. The VPNv4 route uses label 92006 which was allocated by XRv2 to describe reachability to the final destination, 10.0.1.0/32.

```

RP/0/0/CPU0:XRv1#show bgp vpnv4 unicast vrf J 10.0.1.0/32 | begin 211.0.0.12
211.0.0.12 from 211.0.0.13 (211.0.0.12)
  Received Label 92006
    Origin incomplete, metric 0, localpref 100, valid, internal, best,
group-best, import-candidate, imported
    Received Path ID 0, Local Path ID 1, version 25
    Extended community: RT:211:12
    Originator: 211.0.0.12, Cluster list: 211.0.0.13
    Source VRF: J, Source Route Distinguisher: 211:100

```

Next, XRv1 looks up the path to 211.0.0.12 in the global table. It is a static route via a TE-tunnel, and since the tunnel destination is different than the BGP next-hop, the router consults its LDP LIB to find a label for 211.0.0.12/32. CSR8 allocates label 8001 to describe its IGP path to XRv2, which is the remote PE. By exposing this label to CSR8, transport to XRv2 is achieved. XRv1's FIB verifies the 2-label stack so far.

```

```
next hop 211.0.0.12 via 91002/0/21
next hop 0.0.0.0/32 tt100 labels imposed {8001 92006}
```

Last, the TE label is pushed. Because the IGP route was via a TE-tunnel, the RSVP-TE label from CSR7 is used. This describes a path to CSR8 along the TE LSP, and uses value 7003. The full label stack becomes {7003 8001 92006}.

```
RP/0/0/CPU0:XRv1#show mpls traffic-eng tunnels 100 detail | include Label
Outgoing Interface: GigabitEthernet0/0/0/0.571, Outgoing Label: 7003
```

To verify it, we will ping inside the VPN again using 1500-byte packets (DF-bit set) with EPC enabled on CSR7. This reveals the 3-label stack and proves that fragmentation did not occur, confirming our MPLS MTU optimizations. Notice the size is exactly 4 bytes larger than the last test at 1530 bytes. I also highlight the 3-label stack we verified earlier to prove that the TE-tunnel from PE-P is working and traffic is not fragmented. Although EPC only shows the IPv4 packet, we also use ICMPv6 to verify that IPv6 traffic is not being dropped due to MTU violations.

```
RP/0/0/CPU0:XRv4#ping 10.0.1.0 source 10.0.14.2 size 1500 df-bit

```

Next, we will example the MPLS IP minor options. First, we know that LDP will allocate labels for all IGP prefixes by default. The exception is the default route, which LDP excludes from this rule. The idea is that if there is a default route in an MPLS core, chances are it is better to route traffic to the default destination using IP only in case MPLS forwarding is broken. This only makes sense if there is actually a default-route in the network, and in this case, XRv3 originates one inside IS-IS level-2. We verify that it works and that the information is carried inside the IS-IS LSP.

```
! XRv3
router isis 211
```

```
address-family ipv4 unicast
default-information originate
```

```
R7#show isis database level-2 detail XRv3.00-00 | include 0\.0\.0\.0
Metric: 0          IP 0.0.0.0/0
```

Before continuing, note that if you are using the handy “allocate global host-route” feature to only allocate labels for host routes, you must remove it if you want to also enable label switching for the default route. Below is an alternative configuration that only allocates labels for all hosts routes as well as the default route but nothing else. The second permit statement of this prefix-list does nothing until we actually enable the feature, so for now, XE behaves identically as it would with the “host-route” shortcut. Fortunately, XR doesn’t need this workaround since we can add multiple conditions to label advertisement, so the original configuration works (shown again for completeness).

```
! All XE LSRs
ip prefix-list PL_ALLOCATE_LABELS seq 5 permit 0.0.0.0/0 ge 32
ip prefix-list PL_ALLOCATE_LABELS seq 10 permit 0.0.0.0/0

mpls ldp label
allocate global prefix-list PL_ALLOCATE_LABELS

! All XR LSRs
address-family ipv4
label
local
allocate for host-routes
```

By default, both XE and XR actually do allocate labels for the default-route, but that label is a null label in accordance with LDP policies. That is to say, it is normally implicit-null, but could be explicit-null if LDP is configured as such. A quick look on CSR7 and XRv2 confirm this. In reality, the presence of all these null labels effectively means that label switching is disabled for default-routed traffic.

```
R7#show mpls ldp bindings 0.0.0.0 0
lib entry: 0.0.0.0/0, rev 62
local binding: label: imp-null
remote binding: lsr: 211.0.0.12:0, label: imp-null
remote binding: lsr: 211.0.0.6:0, label: imp-null
remote binding: lsr: 211.0.0.8:0, label: imp-null
remote binding: lsr: 211.0.0.11:0, label: imp-null
```

```
RP/0/0/CPU0:XRv1#show mpls ldp bindings 0.0.0.0/0
0.0.0.0/0, rev 28
Local binding: label: ImpNull
Remote bindings: (3 peers)
Peer          Label
-----
211.0.0.6:0   ImpNull
```

```

211.0.0.7:0      ImpNull
211.0.0.8:0      ImpNull

```

We can instruct LDP to allocate labels for the default route as shown below. The XE syntax is less obvious since this is actually a function of LDP, yet it isn't an LDP-related command. XR cleans this up and puts it in a more logical spot. Since XR can have multiple conditions for label allocation, we can add "default-route" along with "allocate for host-routes" and both will work. XE needed to allow the default route in the prefix-list, and enable the feature explicitly.

```

! All XE LSRs
mpls ip default-route

! All XR LSRs
mpls ldp
  address-family ipv4
    label
      local
        default-route

```

When we run the same commands on CSR7 and XRv1, now we see "real" labels for the default route, just like any other prefix. The benefit of this feature is that default-routed traffic can now be steered into TE-tunnels and protected by TE-FRR.

```

R7#show mpls ldp bindings 0.0.0.0 0
  lib entry: 0.0.0.0/0, rev 64
    local binding: label: 7010
    remote binding: lsr: 211.0.0.11:0, label: 91015
    remote binding: lsr: 211.0.0.8:0, label: 8000
    remote binding: lsr: 211.0.0.6:0, label: 6008
    remote binding: lsr: 211.0.0.12:0, label: 92014

```

```

RP/0/0/CPU0:XRv1#show mpls ldp bindings 0.0.0.0/0
0.0.0.0/0, rev 30
  Local binding: label: 91015
  Remote bindings: (3 peers)

    -----
    211.0.0.6:0   6008
    211.0.0.7:0   7010
    211.0.0.8:0   8000

```

One of the most common features that providers configure on their PE routers is TTL-propagation adjustment. Before continuing with these features, I briefly outline MPLS TTL behavior.

1. **Label swap:** The topmost label's TTL is decremented, and this new value is used for the swapped label. This is very similar to normal IP forwarding.

2. **Label push:** The topmost label's TTL is decremented, and this new value is used for the swapped label and any additional pushed labels. This would happen if, for example, a P router was routing traffic into a TE-FRR tunnel and was adding an additional label in the middle of the LSP.
3. **Label pop:** The topmost label's TTL is decremented, and this new value is applied to the inner label that was exposed as a result of the swap. This does not occur if the "new value" from the outer label is greater than the TTL of the inner label. For example, if the inner label has TTL 6 and the outer label has TTL 9, it would not make sense to increase the TTL of the inner packet by setting it to 8 (9 minus 1).

In the vast majority of this book, I use traceroute inside of L3VPNs to verify label stacks and routing paths. It could be highly undesirable/insecure for customers to see the detailed topology information of a provider's network, complete with IP hops and labels, by using a simple traceroute. At the same time, a provider should not prevent a customer from using traceroute to verify L3VPN connectivity between customer sites. By default, when IPv4/v6 packets enter an ingress LSR, their TTL/hop limits are copied onto all labels at imposition. Some other texts indicate that the TTL is only copied to the topmost label, which is false. We will quickly prove the claim that, at imposition, an ingress LSR will copy the IPv4 TTL or IPv6 hop-limit to all imposed labels. We will ping XRv4 to CSR1 again and use EPC inbound and outbound on CSR7 to confirm this. The first two stanzas represent an IPv6 packet and the second two represent an IPv4 packet. The difference in size is 4 bytes (1530 – 1526) and we see one less label in the stack. This is CSR7 performing PHP, but notice the TTLs in the labels is 0x3B, or decimal 59. This is true for all labels. When CSR7 label-switches the packet towards XRv3, it pops the topmost label, decrements TTL on the next label to 58 (0x3A), and forwards the packet. The same is true for the second pair of outputs which represent an IPv4 packet with TTL 254 (0xFE). This is applied to all labels at imposition, and the PHP/TTL reduction process is performed identically regardless of the tunneled protocol. In green, I highlight the original IPv4 TTL and IPv6 hop-limit to illustrate the equality.

```

By copying the TTL from the IPv4/v6 packets, the TTL could potentially expire in the middle of the MPLS core. For example, a packet with TTL=3 would expire at XRv3 along this LSP, which would generate an ICMP time-exceeded unreachable back to the source. We can disable this feature on XRv1 specifically for forwarded packets; we have the option of specifying “forwarded” or “local”, where “local” means locally generated traffic. It would be handy to allow XRv1 to use traceroute inside the MPLS core, but prevent the customers from doing so, which is why I commonly use the “forwarded” option. This is not a function of LDP or any specific protocol.

```

! XRv1
mpls ip-ttl-propagate disable forwarded

```

To verify it, I will send IPv4 and IPv6 pings from XRv4 to CSR1 again. CSR7 is still capturing inbound from XRv1 and outbound to XRv3 so we can see the difference. Notice that despite the command only specifying “ip”, it applies to all versions of IP. The TTL is fixed at 255 (0xFF) for both IPv4 and IPv6, and for all labels at imposition. The IPv4 TTL and IPv6 hop-limit is highlighted in green, which we clearly see is different; earlier it was the same as the MPLS shim-header TTL.

```

 3  fd00:10:1:12::1 0 msec 0 msec 0 msec

```

We demonstrate the benefit of not disabling “local” TTL propagation, because XRv1’s traceroute probe’s can be copied to the MPLS TTL. This means that the core routers can still use traceroute since the traffic was locally originated, so copying the IPv4 TTL or IPv6 hop limit into the MPLS TTL is acceptable.

```
RP/0/0/CPU0:XRv1#traceroute 211.0.0.9 source 211.0.0.11
```

```
Type escape sequence to abort.
```

```
Tracing the route to 211.0.0.9
```

```

 1  211.6.11.6 [MPLS: Label 6000 Exp 0] 0 msec  0 msec  0 msec
 2  211.6.13.13 [MPLS: Label 93002 Exp 0] 0 msec  0 msec  0 msec
 3  211.9.13.9 0 msec  0 msec  0 msec

```

If we also disable local TTL propagation on XRv1, traffic is tunneled inside MPLS all the way to the target, and the traceroute is less valuable inside the provider core network.

```
! XRv1
```

```
mpls ip-ttl-propagate disable local
```

```
RP/0/0/CPU0:XRv1#traceroute 211.0.0.9 source 211.0.0.11

```
Type escape sequence to abort.
```

```
Tracing the route to 211.0.0.9
```

```

 1  211.9.13.9 9 msec  0 msec  0 msec

```

When CSR5 traceroutes to CSR1, the MPLS core is revealed since CSR6 is still copying the customer IP TTL into the MPLS TTL.

```
R5#traceroute 10.0.1.3 source 10.0.5.0
Type escape sequence to abort.
Tracing the route to 10.0.1.3
VRF info: (vrf in name/id, vrf out name/id)
 1 10.5.6.6 6 msec 3 msec 3 msec
 2 211.6.7.7 [MPLS: Labels 7001/92009 Exp 0] 7 msec 7 msec 7 msec
 3 211.7.12.12 [MPLS: Label 92009 Exp 0] 6 msec 11 msec 20 msec
 4 10.1.12.1 19 msec 11 msec 10 msec
```

The command is similar on XE, and we will disable “forwarded” TTL propagation on CSR6 to prevent this. We have the same “forwarded” and “local” options as XR. When the customer devices attempt to traceroute, only the edge LSRs are revealed, along with the VPN label. Note: When TTL propagation is disabled on P-routers, the TTL reduction of the topmost label is not propagated to inner labels. This can effect traceroutes inside the core as it changes the way MPLS handles TTL decrementing.

```
! CSR6
no mpls ip propagate-ttl forwarded
```

```
R5#traceroute 10.0.1.3 source 10.0.5.0
Type escape sequence to abort.
Tracing the route to 10.0.1.3
VRF info: (vrf in name/id, vrf out name/id)
 1 10.5.6.6 5 msec 3 msec 3 msec
 2 211.7.12.12 [MPLS: Label 92009 Exp 0] 5 msec 6 msec 5 msec
 3 10.1.12.1 5 msec 8 msec 10 msec
```

Like XR, we can also disable “local” TTL propagation. Currently, CSR6 can traceroute through the network.

```
R6#traceroute 211.0.0.12 source 211.0.0.6
Type escape sequence to abort.
Tracing the route to 211.0.0.12
VRF info: (vrf in name/id, vrf out name/id)
 1 211.6.7.7 [MPLS: Label 7001 Exp 0] 3 msec 3 msec 3 msec
 2 211.7.12.12 4 msec 3 msec 3 msec
```

When we disable all TTL propagation, this applies to both locally-generated and forwarded traffic, so CSR6 can no longer see the SP network topology via traceroute. The probes are tunneled inside MPLS, so only the first probe reaches the target and an unreachable is returned.

```
! CSR6
no mpls ip propagate-ttl
```

```

R6#traceroute 211.0.0.12 source 211.0.0.6
Type escape sequence to abort.
Tracing the route to 211.0.0.12
VRF info: (vrf in name/id, vrf out name/id)
 1 211.7.12.12 5 msec 3 msec 3 msec

```

From a design perspective, one would normally disable TTL propagation for forwarded traffic on all PE devices that offer L3VPN service. In this design, I leave TTL propagation enabled on XRv2 and CSR9 for variety, though it doesn't make much sense. TTL propagation should be disabled on ingress and egress LSRs; if it isn't, the IP TTL may theoretically exit the network at a larger value than it entered. Cisco safeguards against this, must like it does with the label pop TTL handling, and the MPLS TTL is not copied to the IP TTL if it is greater than the IP TTL. CSR1 can still traceroute across the network and see the SP topology since CSR6 is copying the customer TTL into the MPLS TTL of all labels on imposition.

```

R1#traceroute 10.0.14.1 source 10.0.1.0
Type escape sequence to abort.
Tracing the route to 10.0.14.1

 2 211.9.13.13 [MPLS: Labels 93001/91011 Exp 0] 7 msec 8 msec 8 msec
 3 211.7.8.7 [MPLS: Labels 7000/91011 Exp 0] 8 msec 8 msec 28 msec
 4 211.7.11.11 [MPLS: Label 91011 Exp 0] 20 msec 21 msec 21 msec
 5 10.11.14.14 20 msec 15 msec 14 msec

```

The last MPLS IP-related option is TTL expiration label handling. To understand this command, we first have to understand how traceroute works over MPLS. When an LSP receives an MPLS packet with TTL=1 and the destination is not local, this is considered a time-exceeded event just like with IPv4 or IPv6. We can see this happening on CSR7 if we traceroute from CSR1 to XRv4. We will send a single traceroute probe to reduce the debug output. The debug clearly shows the original destination; because CSR7 is a P router with no context for these VPN addresses, it has no choice but to add the original label stack of {91011} to the ICMP unreachable and send it towards the destination.

```

R7#debug ip icmp
ICMP packet debugging is on

R1#traceroute 10.0.14.1 source 10.0.1.0 probe 1
Type escape sequence to abort.
Tracing the route to 10.0.14.1

 2 211.9.13.13 [MPLS: Labels 93001/91011 Exp 0] 8 msec
 3 211.7.8.7 [MPLS: Labels 7000/91011 Exp 0] 10 msec
 4 211.7.11.11 [MPLS: Label 91011 Exp 0] 9 msec
 5 10.11.14.14 7 msec

```

! CSR7

```
MPLS: ICMP: time exceeded (time to live) sent to 10.0.1.0 (dest was 10.0.14.1)
```

We use EPC on CSR7 outbound towards XRv1 to confirm the actual packet contents. This is an ICMP unreachable message; I assume this because the protocol number is 1, the TTL is 255, and I was not sending any pings in the network during this capture. These fields are highlighted in yellow for clarity. The MPLS label is 91011 and is highlighted in green, which is the full label stack that CSR7 would have used along the original LSP when sending traffic to 10.0.14.1 via XRv1. The ICMP packet encompasses the original traceroute probe with TTL=2 and protocol 17 (grey) with original addresses 10.0.1.0 to 10.0.14.1 (cyan). The magenta addresses are in the ICMP unreachable packet itself, which is 211.7.8.7 to 10.0.1.0; this is a little awkward since the addresses are in two different tables, but is important.

```
R7#show monitor capture CAP buffer dump

0040: 01000A00 0E01C15D 829C0008 98E30000 .....].....
```

When XRv1 receives this packet, it will perform an LFIB lookup and forward the packet to the CE, which is XRv4. XRv4 reverses the source and destination addresses and forwards the packet back into the MPLS network, which makes its way back to CSR1. The pink addresses above are how CSR1 can see that 211.7.8.7 was a hop in the carrier's network since it was carried inside the ICMP unreachable. Thus, if the CE-to-CE connectivity is broken in any way, traceroute will not work for the customer. Even if XRv4's interface was shutdown, CSR1 will get no feedback. We test this quickly, and it is valuable to note that there is no workaround for this within L3VPN. The LSP must be functional end-to-end, including CE routers, for this kind of traceroute to work.

```
R1#traceroute 10.0.14.1 source 10.0.1.0 probe 1
Type escape sequence to abort.
Tracing the route to 10.0.14.1
VRF info: (vrf in name/id, vrf out name/id)
 1 10.1.9.9 6 msec
 2 * [snip]
```

However, addressing within the provider core is all in the same routing table. If, for example, there was a broken LSP in the SP core, the core routers could still communicate using IP. I temporarily disable the link between CSR7 and CSR6 for this example so the LSP is longer (not shown). A traceroute on XRv2 to CSR6 shows us that the network has MPLS transport.

```
RP/0/0/CPU0:XRv2#traceroute 211.0.0.6 source 211.0.0.12
Type escape sequence to abort.
Tracing the route to 211.0.0.6

 1 211.7.12.7 [MPLS: Label 7012 Exp 0] 0 msec 0 msec 0 msec
```

```

2  211.7.8.13 [MPLS: Label 93005] Exp 0] 0 msec  0 msec  0 msec
3  211.6.13.6 0 msec  0 msec  0 msec

```

However, the MPLS process is generally ignorant to the tunneled payload and treats this traceroute just like an L3VPN traceroute. When TTL=1 packets hit CSR7, CSR7 encapsulates the unreachable with the original label stack {93005} (in yellow) and sends the packet towards XRv3. The original source/destination addresses are shown in cyan, which is 211.0.0.12 to 211.0.0.6. In pink, I highlight the TTL=1 and protocol UDP (0x11 or decimal 17) which was the original probe. There isn't a really good reason to send this packet along the original LSP since CSR7 actually does know how to reach 211.0.0.6, the original source.

```
R7#show monitor capture CAP buffer dump
```

```

1
0000:  005056A9 EA540050 56A9EA77 81000DFA  .PV..T.PV..w....

```

We can set a label depth threshold on the routers which allow it to make more intelligent decisions regarding TTL expiration events. If an MPLS packet arrives with less than or equal to the number of labels we specify, the router will use the global routing table for a route lookup. If a packet arrives with more than the number of labels specified, the original label stack is used. By default, the threshold is 0, which means all ICMP unreachables are tunneled to their final destination if they were MPLS encapsulated. By increasing this threshold to 1, we instruct the router to treat things differently for singly-labeled packets. Since XRv2 and CSR6 have only one label at any point in the stack along the path, this is an appropriate value. Other realistic values might be higher if there is a lot of PE-P/P-P TE in the network, CSC or UMPLS, etc. In our case, 1 label generally means global routing table, while 2 or more means L3VPN.

```

! CSR7
mpls ip ttl-expiration pop 1

```

Using traceroute with debugging enabled on CSR7, we can confirm this new behavior. Because the in-label stack was less or equal to the threshold we set, the label stack is removed; the debug reveals this clearly. XRv3 is no longer receiving these packets.

```

! CSR7
MPLS: ICMP: time exceeded (time to live) sent to 211.0.0.12 (dest was
211.0.0.6)
Pop labels: num_in_labels (1) <= ttl_exp_labels (1)

```

The command is nearly identical on XR, and we enable on it XRv3 for completeness. There isn't a good way to verify this with debugs on XR, but it works identically as it does on XE. Also, the link between CSR6 and CSR7 is restored before ending this lab.

```
! XRv3
mpls ip-ttl-expiration-pop 1
```

Additional Reading – Reference configurations “mpls-ip mtu”

8. Describe MPLS advanced features

8.1 Segment Routing

Segment Routing (SR) is a relatively new technology pioneered by Cisco that is meant to reduce state in MPLS core networks. One can use SR to replace LDP and RSVP-TE wholesale provided it is supported. The idea is that individual nodes and adjacencies have segment IDs (SIDs), and each segment has label bindings. This allows traffic to traverse the network encapsulated inside MPLS and individual links can be elected by the headend by way of specifying specific segment labels. There are other SIDs, also, but those are the main two. Right now it is only supported in XR and only for IS-IS IPv4. A SR mapping server can be used for LDP/SR interworking during migrations or pilot scenarios, which is demonstrated later.

You cannot configure prefix-sids on transit links at this time. Support for this feature may be introduced in later code versions.

```
! XRv11
router isis 1
 interface GigabitEthernet0/0/0/0.512
   address-family ipv4 unicast
   prefix-sid index 512
```

!!% Not supported (Success): Nodal Segment configuration is only allowed for Loopback Interfaces

The SRGB (segment routing global block) must not overlap with the global MPLS label range allocation. The SRGB has a specific purpose which is explicitly different than the global MPLS label range and is discussed more later.

```
! XRv11
RP/0/0/CPU0: isis[1006]: %ROUTING-ISIS-4-SRGB_ALLOC_FAIL : SRGB allocation
failed: 'SRGB reservation not successful for [91000,91999], srgb=(91000
91999, SRGB_ALLOC_CONFIG_PENDING, 0x1) (So far 16 attempts). Make sure label
range is free'
```

A basic network diagram is shown below. All XR routers are SR-aware and are also configured for RSVP-TE. The XE routers are LDP-aware; XRv14 will perform the SR-to-LDP interworking.

The ISIS database will show all of the SR information. Some information is harder to see than others, and XRV11's LSP is shown below. Notice that the adjacency SID's are allocated from the global MPLS range, not the SRGB, and are placed in a simple table. The SRGB is designed for node SIDs only while the global MPLS label range supports the adjacency SIDs. The node SID is a little harder to decode; the "Prefix-SID Index" assigned to the router's loopback 11.11.11.11/32 is statically configured under the interface within IS-IS. It can be absolute as a label within the SRGB (like 81011) or a relative index value to be added to the SRGB lower bound (like 11). Every other router, when allocating a label for 11.11.11.11/32, will take its locally configured SRGB lower-bound number and add it to the destination index in question. For example, if XRV13's SRGB is 83000 - 83999 and traffic is destined for XRV11's loopback, XRV13 will allocate a label value of 83011 (83000 + 11) for the prefix 11.11.11.11/32. This process is repeated until labels are allocated for all other routers for which SR is enabled. The network diagram is shown below, along with the initial verifications.

```

The SRGB ranges do not need to be unique across routers, and in many cases should not be. This guarantees that the same label value can be used between pairs of nodes, since everyone adds the prefix-SID index with the SRGB lower bound. Here are two quick examples where XRv12 was configured with the same SRGB as XRv11 (81000 - 81999). Notice the same label value is used for each hop. The routers along the path just perform a swap for the same label value; it is possible there is some hardware optimization to perform no operation at all but this is beyond the scope of our analysis. For troubleshooting, having unique label values with meaningful numbers per node is desirable. This is probably not supportable in a large-scale network, but good for learning and lab use.

```
RP/0/0/CPU0:XRv14#traceroute 13.13.13.13
```

```
Type escape sequence to abort.
```

```
Tracing the route to 13.13.13.13
```

```

 1  24.0.0.12 [MPLS: Label 81013 Exp 0] 19 msec  29 msec  19 msec
 2  12.0.0.11 [MPLS: Label 81013 Exp 0] 19 msec  19 msec  19 msec
 3  13.0.0.13 19 msec  *   39 msec

```

```
RP/0/0/CPU0:XRv13#traceroute 14.14.14.14
```

```
Type escape sequence to abort.
```

```
Tracing the route to 14.14.14.14
```

```

 1  13.0.0.11 [MPLS: Label 81014 Exp 0] 109 msec  39 msec  29 msec
 2  12.0.0.12 [MPLS: Label 81014 Exp 0] 19 msec  29 msec  19 msec
 3  24.0.0.14 29 msec  *   29 msec

```

The prefix-SIDs must be unique based on the way labels are allocated. In this example, XRv14's index has been set to 11, the same as XRv11. Nothing looks wrong from XRv14's perspective, as it has a label for 11.11.11.11/32 via XRv12.

```
RP/0/0/CPU0:XRv14#show cef ipv4 11.11.11.11
```

```
[snip]
```

```

  via 24.0.0.12, GigabitEthernet0/0/0/0.524, 11 dependencies, weight 0,
 class 0 [flags 0x0]

```

```
  path-idx 0 NHID 0x0 [0xa0e87154 0x0]
```

```
  next hop 24.0.0.12
```

```
  local adjacency
```

```
local label 94004      labels imposed {82011}
```

When XRv12 receives traffic with label 82011, PHP is performed, and XRv11 receives the traffic.

```
P/0/0/CPU0:XRv12#sh mpls for labels 82011
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
82011	Pop	No ID	Gi0/0/0/0.512	12.0.0.11	3636

The reverse LSP is broken since XRv12 cannot program the same label value out of multiple interfaces at the same time, so XRv11 has no label to reach XRv14. Normally the label would have to be 82011, which is the same as what was used in the opposite direction. XRv12 allocated the correct label for XRv11 first, so the incorrect label for XRv14 (which should have been 82014) was not allocated.

```
RP/0/0/CPU0:XRv11#show cef ipv4 14.14.14.14
```

```
[snip]

```

RSVP-TE can coexist with SR. In a basic configuration as we have currently, SR has replaced LDP but has not provided any TE capability (called SR-TE). If an RSVP-TE tunnel is built between any pair of routers that does not terminate on the remote PE, then LDP is typically enabled on the tunnel to create a targeted session between the head and tail ends. This is to exchange a label binding for the remote PE's loopback, which ensures the bottom label is not exposed to core routers too early. In this example, we build a basic RSVP-TE tunnel using an explicit path from XRv11 to XRv12 via XRv13. The IGP costs would normally not route this way, which necessitates the use of a TE tunnel.

```
! XRv11
```

```

explicit-path name XRV13
  index 10 next-address strict ipv4 unicast 13.13.13.13
  index 20 next-address strict ipv4 unicast 12.12.12.12

interface tunnel-te18
  ipv4 unnumbered Loopback0
  destination 12.12.12.12
  autoroute announce
  path-option 5 explicit name XRV13

```

XRv12 is the tail end and allocates implicit-null towards XRv13, telling it to perform PHP. This should reveal the SR label for XRv14's loopback, which was learned via IS-IS.

```

RP/0/0/CPU0:XRv12#show mpls traffic-eng tunnels
LSP Tunnel 11.11.11.11 18 [2] is signalled, Signaling State: up
  Tunnel Name: XRv11_t18 Tunnel Role: Tail
  InLabel: GigabitEthernet0/0/0/0.523, implicit-null
  [snip]

```

XRv13 is the midpoint and performs PHP. It allocates label 93003 towards the head end, which is XRv11.

```

RP/0/0/CPU0:XRv13#show mpls traffic-eng tunnels
LSP Tunnel 11.11.11.11 18 [2] is signalled, Signaling State: up
  Tunnel Name: XRv11_t18 Tunnel Role: Mid
  InLabel: GigabitEthernet0/0/0/0.513, 93003
  OutLabel: GigabitEthernet0/0/0/0.523, implicit-null

```

XRv11 is the head and pushes 93003 as the top label in the stack, assuming 14.14.14.14/32 is reachable via the TE tunnel. Notice that the "detail" keyword must be used with the show command to reveal the label on the head end (without looking directly at the RSVP RESV messages).

```

RP/0/0/CPU0:XRv11#sh mpls traffic-eng tunnels detail | begin Current LSP Info
Current LSP Info:
  Instance: 2, Signaling Area: IS-IS 1 level-2
  Uptime: 15:01:40 (since [snip])
  Outgoing Interface: GigabitEthernet0/0/0/0.513, Outgoing Label: 93003

```

Auto-route announce is configured on the tunnel, so the router is gleaned via IS-IS despite the LSPDB not revealing an adjacency.

```

RP/0/0/CPU0:XRv11#show route ipv4 unicast 14.14.14.14/32
Routing entry for 14.14.14.14/32
  Known via "isis 1", distance 115, metric 20, type level-2
  Routing Descriptor Blocks
    12.12.12.12, from 14.14.14.14, via tunnel-te18
    Route metric is 20
  No advertising protos.

```

The FIB shows the SR label for XRv14's loopback, which is the sum of XRv14's prefix SID for its loopback0 and the SRGB lower-bound of XRv12 (tunnel tail). This is the equivalent of an LDP label learned via the TE-tunnel, advertised by XRv12 to represent its label for XRv14's loopback.

```
RP/0/0/CPU0:XRv11#show cef ipv4 14.14.14.14/32
[snip]
  via 12.12.12.12, tunnel-te18, 9 dependencies, weight 0, class 0 [flags
0x0]
    path-idx 0 NHID 0x0 [0xa0fec544 0x0]
    next hop 12.12.12.12
    local adjacency
      local label 91000      labels imposed {82014}
```

When XRv11 sends traffic to XRv14, the SR label is pushed first (to get from XRv12 to XRv14), followed by the TE label (gets from XRv11 to XRv12).

```
RP/0/0/CPU0:XRv11#traceroute 14.14.14.14
Type escape sequence to abort.
Tracing the route to 14.14.14.14

 1  13.0.0.13 [MPLS: Labels 93003/82014 Exp 0] 29 msec  29 msec  29 msec
 2  23.0.0.12 [MPLS: Label 82014 Exp 0] 29 msec  29 msec  29 msec
 3  24.0.0.14 29 msec  *   19 msec
```

We can quickly test VPNv4 traffic also. We expect the label stack to remain the same except now the first label pushed (bottom-most) is the VPNv4 label allocated by XRv14 for its VPN route. The VPNv4 BGP topology is not discussed in detail.

```
RP/0/0/CPU0:XRv11#show bgp vpnv4 unicast vrf A 100.14.14.14/32
BGP routing table entry for 100.14.14.14/32, Route Distinguisher: 1:1
[snip]
 14.14.14.14 (metric 20) from 12.12.12.12 (14.14.14.14)
   Received Label 94007
   Origin incomplete, metric 0, localpref 100, valid, internal, best,
group-best, import-candidate, imported
   Received Path ID 0, Local Path ID 1, version 26
   Extended community: RT:1:1
   Originator: 14.14.14.14, Cluster list: 12.12.12.12
   Source VRF: A, Source Route Distinguisher: 1:1
```

The bottom-most label is 94007 now, with the TE and SR labels remaining in the same sequence. In summary, SR has replaced LDP, and simplifies basic RSVP-TE configuration for TE tunnels not directly configured PE to PE. SR-TE was not made available until XR version 5.3.1, which was released after this was tested and documented.

```
RP/0/0/CPU0:XRv11#traceroute vrf A 100.14.14.14
Type escape sequence to abort.
Tracing the route to 100.14.14.14
```

```

 3  24.0.0.14 89 msec  *   29 msec
```

When the route is learned via the TE tunnel but not via IS-IS (such as using a static route), the SR label cannot be used. Because SR is heavily synchronized with a specific IGP (not generic like LDP), routes from that exact IGP must be used when using TE.

```
RP/0/0/CPU0:XRv11#show route ipv4 unicast 14.14.14.14/32
Routing entry for 14.14.14.14/32
  Known via "static", distance 1, metric 0 (connected)
  Routing Descriptor Blocks
    directly connected, via tunnel-te18
      Route metric is 0
  No advertising protos.
```

```
RP/0/0/CPU0:XRv11#show cef ipv4 14.14.14.14/32
[snip]
  via tunnel-te18, 3 dependencies, weight 0, class 0 [flags 0x8]
    path-idx 0 NHID 0x0 [0xa0fec49c 0xa0fec544]
    local adjacency
      local label 91000      labels imposed {ImplNull}
```

As expected, XRv13 performs PHP of the RSVP-TE label, which will reveal either the raw IP packet or the VPNv4 label to XRv13. VPN connectivity is now broken. This could be considered a limitation of replacing LDP with SR as "autoroute destination" or static routing into a TE tunnel may not always work (autoroute destination is not supported on XRv 5.3.0, but works in XE). I theorize that the reason the CEF entry says implicit-null versus "None" is because the static route references the TE tunnel directly, making it appear attached. The lack of an MPLS at the second entry indicates a broken transport LSP.

```
RP/0/0/CPU0:XRv11#traceroute 14.14.14.14
Type escape sequence to abort.
Tracing the route to 14.14.14.14
```

```

TE forwarding adjacency is an alternative to static routing and autoroute which creates a link in the LSPDB for IS-IS or LSDB for OSPF. It requires TE tunnels on both sides, so a TE tunnel must be added to XRv12 back to XRv11. The paths do not need to be symmetric, though. The IS-IS metric on the tunnel is reduced to 5 so that it is the preferred path between XRv11 and XRv12. This feature is documented in the TE section but is demonstrated here to test SR specifically. Only the tunnel on XRv11 is shown.

```
! XRv11
interface tunnel-te18
 forwarding-adjacency

router isis 1
 interface tunnel-te18
  address-family ipv4 unicast
  metric 5
```

```
RP/0/0/CPU0:XRv11#show isis topology systemid XRv12
IS-IS 1 paths to IPv4 Unicast (Level-2) routers
System Id      Metric  Next-Hop      Interface      SNPA
XRv12          5       XRv12         tt18           *PtoP*
```

```
RP/0/0/CPU0:XRv12#show isis topology systemid XRv11
IS-IS 1 paths to IPv4 Unicast (Level-2) routers
System Id      Metric  Next-Hop      Interface      SNPA
XRv11          5       XRv11         tt18           *PtoP*
```

As expected, VPN traffic works again because the route is learned via IS-IS. As long as the route is IS-IS (forwarding-adjacency or autoroute announce), RSVP-TE with SR will work.

```
RP/0/0/CPU0:XRv11#show route ipv4 unicast 14.14.14.14

```

SR can also use a mapping server to allocate prefix-SIDs. In an SR deployment without a mapping server, prefix-SIDs are locally assigned based on the SRGB by each LSR, much like any other dynamic label allocation. Mappings cannot be shared between IS-IS processes and are not VRF aware (currently). The SR mapping server (SRMS) configuration is straightforward. A range of prefixes is configured starting with the first entry, followed by a starting SID value, followed by a range value. To be clear, the current SRMS support is for prefix-sid only; adjacency-sid is still allocated by each device (using the global MPLS label range) per IS-IS link and not per prefix. A common use case of the SRMS is SR/LDP interworking, where not all routers support SR or a migration is occurring. CSR8 and CSR9 are running LDP in IS-IS L1 behind XRv14, which is the L1/L2 router. So far, these CSRs have not participated in the demonstration. All L2 loopbacks are leaked into L1 and no default route (via AT-bit) exists as all routers share an IS-IS area. Routers in the SR domain still need to label-switch traffic to CSR9. Because XRv14 is running LDP with CSR8, the LSP from CSR9 to XRv11 works fine, but the opposite way does not.

```
CSR9#traceroute 11.11.11.11 source 9.9.9.9
```

```
Type escape sequence to abort.

```

We can configure SRMS on any of the routers, even one that is out of band (kind of like PfR master controllers). Consider this example where XRv11 is the SRMS. Normally if your addresses are contiguous, you can use larger numbers with the "range" keyword to allocate prefix-sid values in bulk fashion rather than by individual prefix, as I did. I wanted to use easy numbers for demonstration. In this case, all

routers now use the indices of 88 and 99 to represent 8.8.8.8/32 and 9.9.9.9/32, respectively, and generate MPLS labels by adding this to their SRGB lower bound. A better example would be that all your loopbacks are /32s in the range of 10.10.10.0/24. You could use the “range 256” modifier to cover the range of 0 – 255, covering prefixes 10.10.10.0/32, 10.10.10.1/32 ... 10.10.10.255/32.

```
! XRv11
segment-routing
mapping-server
prefix-sid-map
address-family ipv4
  8.8.8.8/32 88 range 1
  9.9.9.9/32 99 range 1
```

A key component to SRMS working is configuring ISIS to advertise this information. Without this command on the SRMS, the local LSP will not contain the SID mappings.

```
! XRv11
router isis 1
address-family ipv4 unicast
segment-routing prefix-sid-map advertise-local
```

Likewise on all of the clients, they all must honor these markings. This also must be configured on XRv11 or else it cannot label switch to destinations identified in the SRMS (even though it is the same device).

```
! All SR routers
router isis 1
address-family ipv4 unicast
segment-routing prefix-sid-map receive
```

The mapping server adds these SID bindings to its IS-IS LSP via the prefix-sid Sub-TLV. Everyone else in IS-IS level 2 can see this, which encompasses the entire SR domain. Rather than advertise thousands of SIDs, it takes the mapping values (prefix, start index, and range) and advertises those only. Each router independently can calculate the proper prefix-SIDs based on this, assuming they have the routes. This is why loopback addresses allocated in contiguous blocks improves SR scalability when interworking with LDP.

```
RP/0/0/CPU0:XRv11#show isis database verbose XRv11.00-00 | begin SID Binding
SID Binding:  8.8.8.8/32 F:0 M:0 Weight:0 Range:1
SID: Start:88, R:0 N:0 P:0 E:0 V:0 L:0
SID Binding:  9.9.9.9/32 F:0 M:0 Weight:0 Range:1
SID: Start:99, R:0 N:0 P:0 E:0 V:0 L:0
```

Let's manually trace the LSP from XRv11 to CSR9. First, XRv11 should be using a label allocated by XRv12, since IS-IS routes us that way. 82099 is the SR label generated by XRv12 (82000 + 99, where 82000 is the SRGB lower bound for XRv12 and 99 is the SRMS' manual index for the prefix 9.9.9.9/32).

```
RP/0/0/CPU0:XRv11#show route ipv4 9.9.9.9/32
Routing entry for 9.9.9.9/32
  Known via "isis 1", distance 115, metric 40, type level-2
  Routing Descriptor Blocks
    12.0.0.12, from 14.14.14.14, via GigabitEthernet0/0/0/0.512
    Route metric is 40
  No advertising protos.
```

```
RP/0/0/CPU0:XRv11#show mpls forwarding prefix 9.9.9.9/32
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91012	82099	9.9.9.9/32	Gi0/0/0/0.512	12.0.0.12	768

XRv12 performs a swap to the SR label allocated by XRv14, which is 84099 (84000 + 99). So far, this is basic SR label switching.

```
RP/0/0/CPU0:XRv12#show mpls forwarding labels 82099
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
82099	84099	No ID	Gi0/0/0/0.524	24.0.0.14	2790

Next, XRv14 performs a swap to the LDP label allocated by CSR8. We can see this is an LDP label by verifying the LDP bindings. XRv14 is the point of SR/LDP interworking in this design.

```
RP/0/0/CPU0:XRv14#show mpls forwarding labels 84099
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
84099	8005	No ID	Gi0/0/0/0.548	48.0.0.8	4032

```
RP/0/0/CPU0:XRv14#show mpls ldp bindings 9.9.9.9/32
9.9.9.9/32, rev 26
  Local binding: label: 94011
  Remote bindings: (1 peers)
    Peer          Label
    -----
    8.8.8.8:0     8005
```

Next, CSR8 performs PHP and forwards the traffic to CSR9. This is the end of the LSP.

```
CSR8#show mpls forwarding-table labels 8005
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
8005	Pop Label	9.9.9.9/32	5802	Gi2.589	89.0.0.9

Finally, we perform a trace route from XRv11 to verify the label stack at each hop.

```
RP/0/0/CPU0:XRv11#traceroute 9.9.9.9 source 11.11.11.11
Type escape sequence to abort.
Tracing the route to 9.9.9.9
```

```

 4  89.0.0.9  79 msec   *    49 msec
```

SR has some minor options related to the prefix-SID that are worth mentioning. When enabling “prefix-sid” under a loopback, you can specify how to treat the node flag (n-flag) and explicit null e-flag). Explicit null is used for long pipe and uniform QoS models and is documented elsewhere in this book. LDP, BGP, and RSVP-TE all support explicit-null for this purpose as well. The N-flag is specific to SR and, if set, identifies the router itself. It's normally set on loopback interfaces and is meant to differentiate nodes from links. The mapping server seems to clear all flags and does not give options to set any (at this time), so adjusting these options with LDP interworking appears limited. The P-flag stands for “no-PHP” flag and does not appear directly configurable, and seems a little redundant since if exp-null is set, then no-PHP should also be set. If exp-null is clear, no-PHP should be clear. The output below shows a second loopback configured on XRv14 with the E-flag set and the N-flag clear (neither setting is a default). An interesting note about the N-flag is that the routers must ignore the N-flag if it is set on a prefix that is not /32 (IPv4) or /128 (IPv6), as it is meant to represent a stable transport address for LSPs.

```
! XRv14
router isis 1
 interface Loopback1
   address-family ipv4 unicast
     prefix-sid index 1 explicit-null n-flag-clear
```

A quick look at the database reveals the differences between the default-configuration on 14.14.14.14/32 versus the customized configuration on 14.14.14.1/32. The R, V, and L flags are defined in the draft RFCs and do not appear directly configurable in XR version 5.3.0. We also see a correlation between the P-flag and E-flag as discussed above.

```
RP/0/0/CPU0:XRv14#show isis database verbose XRv14.00-00
[snip]
Metric: 0          IP-Extended 14.14.14.1/32
Prefix-SID Index: 1, R:0 N:0 P:1 E:1 V:0 L:0
Metric: 0          IP-Extended 14.14.14.14/32
Prefix-SID Index: 14, R:0 N:1 P:0 E:0 V:0 L:0
```

Let's quickly trace the LSP to see if exp-null is being used when sending traffic toXRv14's new loopback. XRv11 shows the SR label for 14.14.14.1/32 via XRv12 (82000 + 1). The number 1 is the index used to identify that loopback (the prefix-sid index).

```
RP/0/0/CPU0:XRv11#show mpls forwarding prefix 14.14.14.1/32
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91008	82001	14.14.14.1/32	Gi0/0/0/0.512	12.0.0.12	192

XRv12 performs a swap to label explicit-null (label 0 for IPv4), thus delivering the topmost EXP markings intact to XRv14 at the end of the LSP.

```
RP/0/0/CPU0:XRv12#show mpls forwarding labels 82001
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
82001	Exp-Null-v4	No ID	Gi0/0/0/0.524	24.0.0.14	654

Additional Reading – Reference configurations "sr"

8.2 Generalized MPLS (GMPLS)

GMPLS is an extension of the MPLS concept whereby any path attribute that can identify a flow can be specified. Specifically, GMPLS (sometimes called Multiprotocol Lambda Switching) targets optical networks for its use.

Given an all-optical network, traffic is often carried over these fibers in multiple different wavelengths. These different light waves are multiplexed (mux'ed) at the head-end and demultiplexed (demux'ed) at the tail end of the path. The links have enormous capacity as a single fiber strand can carry several wavelengths using Wavelength Division Multiplexing (WDM). It comes in Coarse and Dense (CWDM and DWDM) varieties, with the only difference being how closely two adjacent wavelengths are together. Dense means they are more tightly packed (smaller gaps) and is the only model deployed widely today in large carrier networks. CWDM is less expensive and might be appropriate in smaller networks. Note: The RF world calls this Frequency Division Multiplexing (FDM), but the two terms are identical. Changing frequency means changing wavelength no matter what. WDM technologies were discussed in a dedication chapter earlier in the book.

GMPLS seeks to provide a mechanism to set up "light paths" from end to end based on a set of constraints. Just like regular MPLS-TE, a specific amount of bandwidth or set of link colors might be preferred. GMPLS extends the idea to include anything else that might be relevant, including layer 1 components such as wavelength, fiber strand, etc. Provided the mechanism by which labels are allocated is aware of these characteristics, GMPLS labels can steer traffic accordingly. The main motivation for selecting an end-to-end wavelength is to guarantee connectivity. For example, each optical transport device in the network is certainly smart enough to dynamically determine which

available wavelengths exist on its links and select one accordingly. This is done using some kind of waveform assignment algorithm. Insufficient network resources may cause a light-path not to be established. Selecting a lambda explicitly for certain flows can simplify troubleshooting and also ensure the signal doesn't have to be "changed" multiple times in the network. The signal quality degrades over distance and time, but if the signal needed to be totally "changed" at each optical network device, it would be less efficient for the network to manage this than the occasional signal "clean up".

Another benefit of GMPLS is that it supports bidirectional LSPs, which is not supported in normal IP/MPLS networks. If using this feature, the requirements for the LSP are the same in both directions, which reduces latency during setup time. Explicit-paths can also be used to specify each hop/wavelength to use along the path in the optical network. There are some draft RFCs that discuss extending OSPF and IS-IS to flood this TE information, but I do not see Cisco claiming support for this on any platform.

XE has the command syntax for GMPLS interface but does not appear well-documented or widely used at the time of this writing. XR has a basic configuration guide but it does not mention using IGP to carry the TED.

8.3 MPLS Transport Profile (MPLS-TP)

MPLS TP is a mechanism to adjust typical MPLS behavior (technically IP/MPLS) to better emulate TDM networks. Carriers liked the idea of MPLS and saw obvious benefits, but wanted the additional OAM features and circuit-oriented approach within TDM and SONET/SDH architectures. MPLS TP supplants transport label allocation mechanisms, such as RSVP-TE, LDP, BGP, and SR. It stands in contrast to IP/MPLS in three key areas since these features are NOT supported in MPLS-TP:

1. **PHP:** Because the transport labels define the path, and MPLS-TP paths are statically configured and highly explicit, the PHP cannot remove the transport label. MPLS-TP is like extending a layer 2 circuit over an MPLS network, which includes all of the alarm signaling contained therein.
2. **ECMP:** MPLS-TP requires all paths to be congruent (symmetric) which is not a requirement in IP/MPLS. In IP/MPLS, paths can be asymmetric (non-congruent), LSPs can be unidirectional, etc. MPLS-TP requires congruence with bi-directional LSPs, much like a TDM/SONET/SDH circuit.
3. **Label merge:** When two LSPs reach a common LSR and have a common next-hop, their LSPs can be merged by using a single outgoing-label. In LDP, this is how MP2P trees can form and is highly efficient. This is not allowed in MPLS-TP since every LSP is entirely different, again, like a traditional circuit.

Despite not supporting these features, MPLS-TP supports several benefits over IP/MPLS.

1. **No need to configure IP:** There is no concept of binding labels to IP prefixes in MPLS-TP. While MPLS-TP can use IP addresses on a per-link basis for building its paths, this is optional. The lab shown later demonstrates this.
2. **Advanced OAM:** Rich set of tools to monitor and manage the MPLS-TP and the PWs that run through it. This includes the Generic Alert Label (GAL) and the Generic Associated Channel (G-ACH). The purpose of the GAL is to alert the router to the presence of the G-ACH within the

header. This is similar to the PC-ACH seen in the VCCV section and is discussed in detail later. In summary, this provides SONET/SDH-like features such as automatic protection switching (APS) and data communications channel (DCC). These are not available in IP/MPLS.

3. **Fault reporting:** As a component of OAM, there are 3 main message types used for fault management and reporting with MPLS-TP. Within the scope of the labs in this book, these are very similar in concept/behavior to Ethernet CFM (specifically ITU-T Y.1371 enhancements).
 - a. **Link Down Indicator (LDI):** Generated by a midpoint router when a failure occurs. Since the failure will break connectivity towards one end of the circuit, the message is sent back to the end that is still reachable. This will cause a switch from working to protect LSPs.
 - b. **Lock Report (LKR):** Generated by a midpoint router when an interface is administratively shutdown. Like the LDI, this message is sent back to the end that is still reachable. This will also cause a switch from working to protect LSPs.
 - c. **Alarm Indication Signal (AIS):** Not generated by Cisco, but is used to report general alarms along the LSP. Receipt of this message will NOT cause a switch from working to protect LSPs.

The network diagram is shown below. Since MPLS-TP is not supported in XRv, we use only CSR1000v routers in this lab. There is no IP routing configured anywhere. CSR5 and CSR6 are the PE routers while all other routers are P routers. CSR5 and CSR6 will provide AToM services for a number of VCs to connect customer routers CSR8 and CSR9. Below is quick proof that we cannot test MPLS-TP on XRv.

```
! XRv1
mpls traffic-eng
tp
node-id 11.11.11.11
```

!!% The requested operation is not supported: MPLS-TP is not supported on this platform

The link configurations are tedious but very simple. Here is an example from CSR5; note that only physical interfaces support MPLS-TP (no virtual interfaces, not even dot1q subinterfaces). Each link eligible to carry MPLS-TP LSPs must have a link number that must be unique on each router. You can specify the next-hop one of three ways:

1. **Next-hop MAC address:** On Ethernet networks, this is necessary since the router needs to know how to encapsulate the MPLS packet. I use this commonly throughout the lab and each interface has simple MAC addresses to facilitate easy reading (Gig1 and Gig2).
2. **Next-hop IPv4 address:** Assuming IPv4 is running in the network and is configured on a particular interface, you can specify the IP next-hop versus the MAC address. I only did this on the link between CSR5 and CSR4 for demonstration, nowhere else (Gig3).
3. **Treat as P2P link:** On P2P links, or Ethernet links identified as P2P using “medium p2p”, you can simply assign a TP link number without specifying any kind of next-hop (Gig7). As we will see later, this uses the destination MAC address of 0180.c200.0000, which is an IEEE reserved MAC typically used for STP. The idea is that there can be no STP-aware switches in the network between a pair of nodes, since MPLS-TP can’t really be sure these two routers are directly connected. You can obviously “hack” this by using switches that just flood frames sent to this multicast MAC address, but that defeats the purpose of MPLS-TP. Because my lab routers move between different physical hosts, there could be STP-aware switches in between, which will consume these frames. This method doesn’t work in my particular setup, which is why I use the next-easiest MAC address method.

For consistency I use the “tx-mac” method on all other links in the topology. We can immediately begin to see that MPLS-TP is very strict and non-dynamic. Thought it can interwork with targeted LDP and G-MPLS, that is beyond the scope of this test. The snippet below shows all three methods of enabling MPLS-TP on a link; no matter which method is used, you must specify a link ID.

```
! CSR5
interface GigabitEthernet1
  description TO R1
  mac-address 0000.0015.0005
  mpls tp link 1 tx-mac 0000.0015.0001

interface GigabitEthernet2
  description TO R7
  mac-address 0000.0057.0005
  mpls tp link 7 tx-mac 0000.0057.0007

interface GigabitEthernet3
  description TO R4
  ip address 10.4.5.5 255.255.255.0
  mpls tp link 4 ipv4 10.4.5.4
```

```

interface GigabitEthernet7
  description TO NOWHERE
  medium p2p
  mpls tp link 999

```

To verify this configuration, we can use a special show command. Notice that Gig1 and Gig2 identify a next-hop MAC and nothing else. Gig3 identifies a next-hop IP address, which implies ARP will be used to resolve the next-hop MAC address. Gig7 shows the reserved IEEE MAC 0180.c200.0000 as discussed earlier, which I show here just for demonstration.

```
R5#show mpls tp link-numbers
```

```
MPLS-TP Link Numbers:
```

Link	Interface	Next Hop	RX Macs
1	GigabitEthernet1	0000.0015.0001	
4	GigabitEthernet3	10.4.5.4	
7	GigabitEthernet2	0000.0057.0007	
999	GigabitEthernet7	0180.c200.0000	0180.c200.0000

```
R5#show ip arp 10.4.5.4
```

Protocol	Address	Age (min)	Hardware Addr	Type	Interface
Internet	10.4.5.4	88	0050.56a9.c765	ARPA	GigabitEthernet3

MPLS-TP also requires a static label range because the LSPs are manually (statically) provisioned. Each router has a static range equal to its dynamic range divided by ten. Below, CSR5 uses 5000 – 5999 for dynamic labels and 500 – 599 for static labels. In addition, an IP-like router-ID is required for each MPLS-TP node, although like OSPF, it does not have to be routable. This is required on all routers, to include P routers.

```

! CSR5
mpls label range 5000 5999 static 500 599
mpls tp
  logging events
  router-id 5.5.5.5

```

We can quickly verify these configurations by checking the MPLS-TP summary and MPLs label range. The MPLS-TP summary shows the router-ID, but all of the other fields are zero since we haven't configured any profiles or LSPs. Using similar terminology seen with SONTE/SDH, we can see the concepts of “working” and “protect” used in this context as well.

```
R2#show mpls tp summary
```

```

MPLS-TP: 0::5.5.5.5
  Path protection mode: 1:1 revertive
  PSC: Disabled
  Timers:  Fault OAM: 20 seconds  Wait-to-Restore: 10 seconds
           PSC: Fast-Timer: 1000 milli seconds, 3 messages

Platform max TP interfaces: 65536

```

```

R5#show mpls label range
Downstream Generic label region: Min/Max label: 5000/5999
Range for static labels: Min/Max label: 500/599

```

As a best practice, we will configure a basic single-hop BFD template for our MPLS-TP tunnels. This will allow MPLS-TP to determine when individual tunnels fails, which is important for failover to work correctly. This is required on all MPLS-TP endpoints, which include CSR5 and CSR6. I use a slow BFD timer to avoid the 100 kbps rate-limit on the CSR1000v.

```

! CSR5 and CSR6
bfd-template single-hop BT_MPLS_TP
  interval min-tx 900 min-rx 900 multiplier 3

```

Next, we will configure an MPLS-TP tunnel. This is somewhat like an MPLS-TE tunnel except it can have two tail ends. Specifically, the concepts of “working” and “protect” are carried over from other circuit-based protocols and configured here. This feels like manually building an LFIB since we are identifying local labels, remote labels, and outgoing interfaces. In this case, we will force traffic for the working LSP towards CSR7 with the protect LSP routing via CSR1. The difficult part is that you must track the label values manually, so I tried to use easy values. Traffic to CSR1 uses label 105 (protect) and traffic to CSR7 uses label 705 (working). The in-labels specified here are for the reverse LSP, which by definition MUST come from the same direction since congruence is required. The LSP numbers are used just to differentiate the paths, and the global-ID is used to make the MPLS-TP router-ID unique in a multi-provider environment. It isn’t necessary in this architecture but I demonstrate it anyway. Both router-ID and global-ID are carried in fault messages to assist the operator in finding the fault areas. BFD is applied directly to this profile while implies it is enabled for both working and protect LSPs.

```

! CSR5
interface Tunnel-tp56
  no ip address
  no keepalive
  tp source 5.5.5.5 global-id 0
  tp destination 6.6.6.6 global-id 0
  bfd BT_MPLS_TP
  working-lsp
    out-label 705 out-link 7
    in-label 507
    lsp-number 0
  protect-lsp
    out-label 105 out-link 1
    in-label 501

```

```
lsp-number 1
```

The configuration on CSR6 is nearly identical to CSR5 with reversed source/destination and a different set of labels and out-links. CSR6 sends traffic with label 607 towards CSR7 (working) and traffic with label 603 to CSR3 (protect).

```
! CSR6
interface Tunnel-tp56
  no ip address
  no keepalive
  tp source 6.6.6.6 global-id 0
  tp destination 5.5.5.5 global-id 0
  bfd BT_MPLS_TP
  working-lsp
    out-label 706 out-link 7
    in-label 607
    lsp-number 0
  protect-lsp
    out-label 306 out-link 3
    in-label 603
    lsp-number 1
```

Next, we have to manually configure every midpoint router. CSR7 is shown first, and remember that the MPLS-TP link numbers, router-ID, and static label range must be configured first (on all routers). The MPLS-TP on CSR5 indicates that label 705 is the out-label from CSR5, which means it is the in-label on CSR7. CSR7 connects this to label 607 outbound to CSR6, which is identified as the in-label on CSR6's MPLS-TP for the working LSP. You can see how this can get very tedious, which makes MPLS-TP a good target for automation. The reverse-LSP follows the same logic except in the opposite direction. The reverse LSP will swap labels in this sequence: 706 > 507.

```
! CSR7
mpls tp lsp source 5.5.5.5 tunnel-tp 56 lsp working destination 6.6.6.6
tunnel-tp 56
  forward-lsp
    in-label 705 out-label 607 out-link 6
  reverse-lsp
    in-label 706 out-label 507 out-link 5
```

Next, we quickly configure the protect path, which has two P routers, CSR1 and CSR3. The same logic applies, except we have to account for the additional routers. Following the forward LSP, the label swapping will be 105 > 301 > 603. The reverse LSP will be 306 > 103 > 501.

```
! CSR1
mpls tp lsp source 5.5.5.5 tunnel-tp 56 lsp protect destination 6.6.6.6
tunnel-tp 56
  forward-lsp
```

```

    in-label 105 out-label 301 out-link 3
reverse-lsp
    in-label 103 out-label 501 out-link 5

! CSR3
mpls tp lsp source 5.5.5.5 tunnel-tp 56 lsp protect destination 6.6.6.6
tunnel-tp 56
    forward-lsp
        in-label 301 out-label 603 out-link 6
    reverse-lsp
        in-label 306 out-label 103 out-link 1

```

Since these routers are just normal LSRs, we can check the LFIB to ensure these labels were programmed correctly. We need to verify the LSPs are correct along with the MAC next-hops. Once the LSPs are operational, we will also see byte counters increase as traffic flows along these LSPs.

```

R1#show mpls forwarding-table labels 100 - 199

```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
103	501	0::6.6.6.6::56::1::0::5.5.5.5	1016836	Gi1	0000.0015.0005
105	301	0::5.5.5.5::56::1::0::6.6.6.6	1014838	Gi2	0000.0013.0003

```

R3#show mpls forwarding-table labels 300 - 399

```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
301	603	0::5.5.5.5::56::1::0::6.6.6.6	1010152	Gi1	0000.0036.0006
306	103	0::6.6.6.6::56::1::0::5.5.5.5	1017086	Gi2	0000.0013.0001

Assuming everything was configured correctly, both the protect and working LSPs should come up. The debugs for MPLS-TP are verbose but not terribly useful. For completeness, we will analyze a few of them, specifically the LSP-endpoint and general event debugs.

```

! CSR5
debug mpls tp lsp-ep
debug mpls tp event

```

The first valuable piece of information we see is MPLS-TP trying to start building the working and protect paths using labels 705 and 105, respectively.

```

! CSR5
mpls_tp_forwarding_headend_update: tun 56 = 0x7FD99A5FA6B8: searching for
adjacencies for if (12)

```

```

mpls_tp_forwarding_headend_update: doing the adj walk? working 0x7FD99A620CF8

success

```

Next, we can see MPLS-TP is bound to BFD and OAM. This applies to both LSP 0 and LSP 1, which we configured to be our working and protect LSPs, respectively. OAM in this context refers to the fault signaling that is exchanged between the MPLS-TP LSRs.

```

! CSR5
mpls_tp_lsp_ep_add_bfd_session: LSP added in BFD db if 12 tun 56 lsp 0
session handle 1
mpls_tp_lsp_ep_add_bfd_session: LSP added in BFD db if 12 tun 56 lsp 1
session handle 2
mpls_tp_lsp_ep_add_fault_session: Fault OAM added for EP LSP: tun 56 lsp 0
session hdl 2600468486
mpls_tp_lsp_ep_add_fault_session: Fault OAM added for EP LSP: tun 56 lsp 1
session hdl 1677721607

```

```
mpls_tp_bfd_session_notify_callback: BFD session notify event ADJ UP
Received for handle 1
mpls_tp_bfd_session_notify_callback: BFD session notify event ADJ UP
Received for handle 2
```

Filtering some of the unnecessary debugs, we ultimately see both the working and protect LSPs are fully up. As you can see, these debugs are difficult to read and aren't very telling.

```
! CSR5
mpls_tp_get_pp_event_and_run_pp_fsm: tunnel:56 lsp:working
lsp_fsm_event:BFD_UP sending pp_fsm_event:WRK_UP

mpls_tp_get_pp_event_and_run_pp_fsm: tunnel:56 lsp:protect
lsp_fsm_event:BFD_UP sending pp_fsm_event:PROT_UP
```

We can verify this by looking at the MPLS-TP tunnel. The summary form is shown first, followed by the detailed form. We can see that the working LSP is being used along the LSP with out-label 705. The details indicate there are no OAM faults as well.

```
R5#show mpls tp tunnel-tp 56
```

Tunnel Number	Peer global-id::node-id::tun	Active LSP	Local Label	Out Label	Out Interface	Oper State
56	0::6.6.6.6::56	work	507	705	Gi2	up

```
R5#show mpls tp tunnel-tp 56 detail
MPLS-TP tunnel 56:
  src global id: 0      node id: 5.5.5.5  tunnel: 56
  dst global id: 0      node id: 6.6.6.6  tunnel: 56
  description:

```

Tunnel-tp56	Protect	7/4	Up	Up
Registered protocols: MPLS-TP				
Tunnel-tp56	Working	6/3	Up	Up
Registered protocols: MPLS-TP				

We have our standard OAM options like ping and traceroute as well. The default is non-IP encapsulated messages within the G-ACH (ending in 0x0023) which is different than some of the PW-ACH formats we saw earlier (ending in 0x0021). Because we are not routing IP in this network, we will use the default G-ACH channel type, but I show the options below.

```
R5#ping mpls tp tunnel-tp 56 lsp working channel ?
```

```
cv use non-ip encapsulation with GACH channel 0x0025
```

```
ip use ip encapsulation with GACH channel 0x0021
```

First, we will check the working LSP. The keywords “working” and “protect” allow us to select which path to test. Notice that traceroute shows us the static LSP we provisioned which the labels hop-by-hop.

```
R5#ping mpls tp tunnel-tp 56 lsp working
Sending 5, 72-byte MPLS Echos to Tunnel-tp56,
    timeout is 2 seconds, send interval is 0 msec:
[snip]
```

Type escape sequence to abort.

!!!!

```
Success rate is 100 percent (5/5), round-trip min/avg/max = 4/4/8 ms
Total Time Elapsed 24 ms
```

```
R5#traceroute mpls tp tunnel-tp 56 lsp working
Tracing MPLS TP Label Switched Path on Tunnel-tp56, timeout is 2 seconds
[snip]
```

Type escape sequence to abort.

```
0 0::5.5.5.5 MRU 1500 [Labels: 705 Exp: 0]
L 1 0::7.7.7.7 MRU 1500 [Labels: 607 Exp: 0] 7 ms
! 2 0::6.6.6.6 4 ms
```

We can also explicitly check the protect LSP as well. This should be a totally independent path from the working LSP. This LSP routes from CSR1 to CSR3 to CSR6 as expected.

```
R5#ping mpls tp tunnel-tp 56 lsp protect
Sending 5, 72-byte MPLS Echos to Tunnel-tp56,
    timeout is 2 seconds, send interval is 0 msec:

We will use EPC to look at the BFD packets being sent down the LSPs by capturing on both out-links at the same time from CSR5. Although BFD was configured once under the template, it is technically two independent sessions, so the sending of BFD packets may not be at exactly the same moment. The

working LSP timestamps are highlighted in green and the protect LSP timestamps are highlighted in yellow (the MAC addresses make it easy to tell). The MPLS label stacks are interesting since we have a new label 13 (0xD), which is the GAL label. The first label in the stack is the MPLS-TP label, which is 105 (0x69) or 705 (0x2C1) depending on which LSP is used. The bottom label is the GAL label, and notice that both labels carry EXP 6 (110). Following the label stacks is the G-ACH, like the PW-ACH. The presence of the GAL indicates that the G-ACH will follow. It begins with bits 0001 to show it is an associated channel, except has a new value of 0x0007. I assume this is specific to MPLS-TP; notice there is no IP traffic anywhere in this packet which means 0x0021 isn't used, and this isn't a G-ACH OAM test packet (like a ping) so 0x0025 isn't used either.

We will perform another capture, except this time we will look at the OAM packets. I sent one 500-byte OAM packet so that it stands out amongst the BFD packets. The G-ACH is highlighted in yellow and now shows 0x0025 as the channel header, which is correct. The GAL is highlighted in green and serves an identical purpose as before except the EXP is 0 since we did not specify a custom value in the MPLS ping.

```

```

Now that we have verified the MPLS-TP transport LSPs, we can configure a basic PW over this profile. Both legacy and L2VPN syntaxes are supported, but we will begin with the legacy syntax. I also define a static-OAM class which identifies a timeout setting for OAM messages. The PW-class enables the CW and disables LDP as a signaling protocol. It applies the OAM-class for status in lieu of LDP and assigns the MPLS-TP interface as a preferred path. This is similar to using MPLS-TE for PW support, except this time we use MPLS-TP.

```
! CSR5
pseudowire-static-oam class OAM_CLASS
    timeout refresh send 20

pseudowire-class PW_CLASS
    encapsulation mpls
    control-word
    protocol none
    preferred-path interface Tunnel-tp56
    status protocol notification static OAM_CLASS
```

The AC configuration is identical to a normal static PW. We define the labels and specify the neighbor ID (again, not reachable via IP, but just the remote MPLS-TP router-ID). The configurations are nearly identical on CSR6 and are not shown here.

```
! CSR5
interface GigabitEthernet6
    description CUSTOMER AC
    service instance 56 ethernet
    encapsulation dot1q 3558 second-dot1q 100
    rewrite ingress tag pop 2 symmetric
    xconnect 6.6.6.6 100 encapsulation mpls manual pw-class PW_CLASS
    mpls label 506 605
    mpls control-word
```

We verify that the PW comes up. The detailed view looks identical to a normal PW, but the details show that MPLS-TP is used as the preferred path. It also shows us the transport label of 705 which is used for the working LSP.

```
R5#show mpls l2transport vc 100
```

Local intf	Local circuit	Dest address	VC ID	Status
Gi6	Eth VLAN 3558/100	6.6.6.6	100	UP

```
R5#show mpls l2transport vc 100 detail | section Destination
Destination address: 6.6.6.6, VC ID: 100, VC status: up
Output interface: Tp56, imposed label stack {705 605}
Preferred path: Tunnel-tp56, active
Default path:
Next hop: point2point
```

Testing this LSP with OAM is tricky. If we use a basic MPLS ping syntax, it won't work. This may lead you to think (as I did) that the PW was somehow misconfigured despite it being UP.

```
R5#ping mpls pseudowire 6.6.6.6 100
Sending 5, 72-byte MPLS Echos to 6.6.6.6,
    timeout is 2 seconds, send interval is 0 msec:

```

The reason is because there is no IP routing in the network. When using MPLS OAM, the replies are IPv4 by default. Debugging on CSR6 can help reveal this.

```

```

```
LSPV: Reply sent via IP
```

In the OAM section, I demonstrate different reply options. When the CW is negotiated, the reply can be carried in the associated channel, and this technique does work. We will use EPC inbound on CSR5 to look at the reply packet. Just like in the OAM section, we see 0x0021 in the CW to identify this as an IPv4 packet, which is fine since it is being processed locally. The significant part is that the packet is MPLS-encapsulated inside the ACH on the way back. Without MPLS-TP, this was never an issue since IP routing guaranteed reachability between PW endpoints.

```

```

We can also test the failover from working to protect LSP. If we administratively shutdown CSR7's Gig4, this will break the working LSP, and the protect LSP should become active after BFD detects the failure. Our definitions earlier suggest that CSR7 should send a Lock Report (LKR) back to CSR5 but not to CSR6. Both CSR5 and CSR6 show log messages to indicate these changes, since both of them are running BFD and will detect the failure that way. We can clearly see that the issue is with CSR7, TP link 6. The code of CC (continuity check) represents a BFD failure since CSR6 didn't get the detailed OAM alert. If we had multiple PWs, they could all be using this transport profile, which effectively becomes a FEC.

```
! CSR5
%MPLS_TP_LSP-3-UPDOWN: Working LSP 0::5.5.5.5::56::0::6.6.6.6::56::0 is down:
LKR:0::7.7.7.7::6
%MPLS_TP-5-REDUNDANCY: Tunnel-tp56, switched to Protect LSP as active

! CSR6
%MPLS_TP_LSP-3-UPDOWN: Working LSP 0::6.6.6.6::56::0::5.5.5.5::56::0 is down:
CC
%MPLS_TP-5-REDUNDANCY: Tunnel-tp56, switched to Protect LSP as active
```

Looking at the LSP details for this MPLS-TP instance, we can see that the protect LSP is now "active". This failover process took less than 3 seconds as we can see by the pings sent within the customer network between CSR8 and CSR9. Failure detection takes 2.7 seconds (900 ms times 3) which is consistent with the output below. In a production environment, BFD would have detected the failure much more quickly, which better approximates SONET/SDH failure detection behavior.

```
R5#show mpls tp lsps 5.5.5.5 tunnel-tp 56
MPLS-TP Endpoint LSPs:
```

!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!!
Success rate is 99 percent (303/305), round-trip min/avg/max = 3/22/31 ms

```

In case logging was disabled or we simply didn't see the message, we can see the fault OAM code by looking at the MPLS-TP details. CSR6 doesn't show the fault code since CSR7 has no reachability to CSR6 along this LSP anymore, so all faults appear "clear". The working LSP is still down thanks to BFD, so connectivity is restored using the protect LSP.

```

R5#show mpls tp tunnel-tp 56 detail
MPLS-TP tunnel 56:
  src global id: 0      node id: 5.5.5.5  tunnel: 56
  dst global id: 0      node id: 6.6.6.6  tunnel: 56
  description:

```

We can verify that the protect LSP is active by using OAM with the "active" keyword. This could be either the working or protect LSP, depending on which one is currently active. We can see that the LSP traverses through CSR1 and CSR3 as expected.

```
R5#traceroute mpls tp tunnel-tp 56 lsp active
Tracing MPLS TP Label Switched Path on Tunnel-tp56, timeout is 2 seconds
[snip]
```

Type escape sequence to abort.

```
0 0::5.5.5.5 MRU 1500 [Labels: 105 Exp: 0]
L 1 0::1.1.1.1 MRU 1500 [Labels: 301 Exp: 0] 8 ms
L 2 0::3.3.3.3 MRU 1500 [Labels: 603 Exp: 0] 4 ms
! 3 0::6.6.6.6 5 ms
```

Bringing CSR7's interface back up causes the working LSP to become active again, since the failover process is "revertive" by default. However, the reversion timer is 10 seconds, which is used to protect against flaps in the network. It is better to continue using a stable protect LSP rather than switch to the working LSP too quickly after a failure. This is loosely analogous to the LDP IGP sync-delay timer.

```
! CSR5
19:56:17.007: %MPLS_TP_LSP-3-UPDOWN: Working LSP
0::5.5.5.5::56::0::6.6.6.6::56::0 is up

19:56:37.609: %MPLS_TP-5-REDUNDANCY: Tunnel-tp56, switched to Working LSP as
active
```

For completeness, we can verify this behavior again using the summary show command. The wait-to-restore (WTR) timer is 10 seconds by default and is controlled globally. The context-sensitive help is shown below as well.

```
R5#show mpls tp summary
MPLS-TP:      0::5.5.5.5
Path protection mode: 1:1 revertive
PSC: Disabled
Timers: Fault OAM: 20 seconds Wait-to-Restore: 10 seconds
        PSC: Fast-Timer: 1000 milli seconds, 3 messages
            Slow-Timer: 5 seconds

          Protect: 1      up: 1      down: 0
Midpoints: 0      working: 0      protect: 0
Platform max TP interfaces: 65536
```

```
R5(config-mpls-tp)#wtr-timer ?
<0-2147483647> Time in seconds to wait before restoring from protect to
```

working

We can use show commands along with OAM to confirm this change. Using the “active” option, we now see that the working LSP is active for this transport profile.

```
R5#show mpls tp lsp 6.6.6.6 tunnel-tp 56
MPLS-TP Endpoint LSPs:
```

LSP Identifier	Role	Local Label	Out Label	Out Interface	Oper State
0::5.5.5.5::56::0::6.6.6.6::56::0	actv	507	705	Gi2	up
0::5.5.5.5::56::0::6.6.6.6::56::1	stby	501	105	Gi1	up

```
R5#traceroute mpls tp tunnel-tp 56 lsp active
Tracing MPLS TP Label Switched Path on Tunnel-tp56, timeout is 2 seconds
[snip]
```

Type escape sequence to abort.

```
0 0::5.5.5.5 MRU 1500 [Labels: 705 Exp: 0]
L 1 0::7.7.7.7 MRU 1500 [Labels: 607 Exp: 0] 8 ms
! 2 0::6.6.6.6 4 ms
```

We will quickly demonstrate the LDI condition which occurs when a link actually goes down (not including admin-shut). We demonstrate this by disconnecting CSR7’s vNIC to CSR6 from within VMware so that the interface appears unplugged. While the log message shows CC as the error, the TP details show it (correctly) as LDI. Before continuing, we reconnect CSR7’s vNIC to CSR6.

```
R5#show mpls tp tunnel-tp 56 detail | begin working
      working-lsp: Standby      lsp num 0
      BFD State: Down
      Lockout : Clear
      Fault OAM: LDI
      protect-lsp: Active      lsp num 1
      BFD State: Up
      Lockout : Clear
      Fault OAM: Clear
```

Next, we will configure another MPLS-TP tunnel along the path CSR5 > CSR4 > CSR2 > CSR6. This will carry a second PW using VCID 200. It is possible to bind multiple PWs to a single MPLS-TP, which basically follows the logic of a FEC as mentioned earlier. However, we will map the second PW to a new MPLS-TP tunnel for variety. This TP will request 4 Mbps of bandwidth as well; the interesting part is that we must configure IP RSVP at the endpoints, but not the midpoints.

```
! CSR5 and CSR6
interface GigabitEthernet3
 ip rsvp bandwidth 5000
```

The MPLS-TP configurations are near identical on CSR5 and CSR6, so only CSR5 is shown. This requests 4 Mbps of bandwidth and also has a custom TP name. There is no protect LSP (not required) for brevity, but I would have configured it over one of the other 2 paths in the network not associated with this MPLS-TP. We can re-use the BFD template as well.

```
! CSR5
interface Tunnel-tp560
  no ip address
  no keepalive
  tp bandwidth 4000
  tp tunnel-name COOL_NAME
  tp source 5.5.5.5 global-id 0
  tp destination 6.6.6.6 global-id 0
  bfd BT_MPLS_TP
  working-lsp
    out-label 405 out-link 4
    in-label 504
    lsp-number 2
```

The midpoints of CSR4 and CSR2 are very similar to CSR1 and CSR3. They just connect the LSP together, and RSVP is not required on them since there isn't actually any RSVP signaling. The endpoints just look at their local egress interfaces for admission control, which isn't very comprehensive. The forward LSP uses labels 405 > 204 > 602. The reverse LSP uses labels 206 > 402 > 504.

```
! CSR4
mpls tp lsp source 5.5.5.5 tunnel-tp 560 lsp working destination 6.6.6.6
tunnel-tp 560
  forward-lsp
    in-label 405 out-label 204 out-link 2
  reverse-lsp
    in-label 402 out-label 504 out-link 5
```

```
! CSR2
mpls tp lsp source 5.5.5.5 tunnel-tp 560 lsp working destination 6.6.6.6
tunnel-tp 560
  forward-lsp
    in-label 204 out-label 602 out-link 6
  reverse-lsp
    in-label 206 out-label 402 out-link 4
```

We verify the tunnel is up by checking the TP summary and seeing a new working LSP (but no new protect LSPs).

```
R5#show mpls tp summary
MPLS-TP:      0::5.5.5.5
```

```

Path protection mode: 1:1 revertive
PSC: Disabled
Timers:  Fault OAM: 20 seconds  Wait-to-Restore: 10 seconds
        PSC: Fast-Timer: 1000 milli seconds, 3 messages
            Slow-Timer: 5 seconds
Endpoints: 2      up: 2      down: 0      shut: 0
Working: 2      up: 2      down: 0
Protect: 1      up: 1      down: 0
Midpoints: 0      working: 0      protect: 0
Platform max TP interfaces: 65536

```

We can also check the MPLS-TP LSPs. We can clearly see the TP number is 560 and the LSP is 2, which clearly differentiates it from the existing LSPs from earlier. The details for this new TP show that there is no protect LSP and that the working LSP is fully operational. It also shows the 4 Mbps bandwidth reservation.

```

R5#show mpls tp lsp
MPLS-TP Endpoint LSPs:

```

LSP Identifier	Local Role	Out Label	Out Interface	Oper State
0::5.5.5.5::56::0::6.6.6.6::56::0	actv	507	Gi2	up
0::5.5.5.5::56::0::6.6.6.6::56::1	stby	501	Gi1	up
0::5.5.5.5::560::0::6.6.6.6::560::2	actv	504	Gi3	up

```

R5#show mpls tp tunnel-tp 560 detail

```

```

MPLS-TP tunnel 560:
  src global id: 0      node id: 5.5.5.5  tunnel: 560
  dst global id: 0      node id: 6.6.6.6  tunnel: 560
  description:
  Admin: up            Oper: up

Tun  Dest                                     Out

```

Num	Global-id::Node-id	LSP	Intf	BW (kbps)
56	0::6.6.6.6	working-lsp:num 0	Gi2	0
56	0::6.6.6.6	protect-lsp:num 1	Gi1	0
560	0::6.6.6.6	working-lsp:num 2	Gi3	4000

When using OAM to trace this LSP from CSR5, we get some interesting output. The MPLS TP router-IDs aren't prefixed with the global-ID (specifically the string "0::") and one of the entries is marked as "unknown upstream index". The reason for this is because IPv4 is enabled on the link between CSR4 and CSR5. As such, the router assumes it can use the IP-encapsulated G-ACH (0x0021) versus the non-IP one (0x0025). The ping still works but gives us odd results. To clean up the output, we explicitly specify the "CV" mode.

```
R5#traceroute mpls tp tunnel-tp 560 lsp working
Tracing MPLS TP Label Switched Path on Tunnel-tp560, timeout is 2 seconds
```

```
Codes: '!' - success, 'Q' - request not sent, '.' - timeout,
'R' - transit router, 'I' - unknown upstream index,
```

```
Type escape sequence to abort.
 0 10.4.5.5 MRU 1500 [Labels: 405 Exp: 0]

I 2 2.2.2.2 MRU 1500 [Labels: 602 Exp: 0] 6 ms
! 3 6.6.6.6 5 ms
```

```
R5#traceroute mpls tp tunnel-tp 560 lsp working channel cv
Tracing MPLS TP Label Switched Path on Tunnel-tp560, timeout is 2 seconds
[snip]
```

```
Type escape sequence to abort.
 0 0::5.5.5.5 MRU 1500 [Labels: 405 Exp: 0]
L 1 0::4.4.4.4 MRU 1500 [Labels: 204 Exp: 0] 8 ms
L 2 0::2.2.2.2 MRU 1500 [Labels: 602 Exp: 0] 3 ms
! 3 0::6.6.6.6 5 ms
```

Now that the LSP is working, we will create a PW to use it. For this, we can use the new L2VPN syntax, but the logic is the same. Only CSR5 is shown since CSR6 is nearly identical.

```
! CSR5
template type pseudowire PW_TEMP
 encapsulation mpls
 vc type ethernet
 signaling protocol none
 preferred-path interface Tunnel-tp560

interface pseudowire65
 source template type pseudowire PW_TEMP
```

```

encapsulation mpls
neighbor 6.6.6.6 200
signaling protocol none
label 516 615
pseudowire type 5

interface GigabitEthernet6
service instance 65 ethernet
encapsulation dot1q 3558 second-dot1q 200
rewrite ingress tag pop 2 symmetric

l2vpn xconnect context ATOM
member GigabitEthernet6 service-instance 65
member pseudowire65

```

Once the PW is configured, we can verify it is operational, along with revealing its full label stack. The PW label was statically configured as 615 and the MPLS-TP label used to send traffic to CSR4 is 405 (like the FEC). The PW uses MPLS-TP tunnel560 as configured in the PW template above.

```

R5#show l2vpn atom vc vcid 200 detail | section Destination
Destination address: 6.6.6.6 VC ID: 200
Output interface: Tp560, imposed label stack {405 615}
Preferred path: Tunnel-tp560, active
Default path:
Next hop: point2point

```

We can verify that the PW works using OAM. Again, remember to specify the control-channel (PW-ACH) for LSPV replies or else it will not work since IP routing is not enabled in this architecture.

```

R5#ping mpls pseudowire 6.6.6.6 200 reply mode control-channel
Sending 5, 72-byte MPLS Echos to 6.6.6.6,
    timeout is 2 seconds, send interval is 0 msec:
[snip]

Type escape sequence to abort.
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 5/7/10 ms
Total Time Elapsed 36 ms

```

A quick check in the customer network (CSR8 to CSR9) shows that this new VC works.

```

R8#ping 20.8.9.9
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 20.8.9.9, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 6/9/20 ms

```

8.4 Inter-AS MPLS

This section discusses many options for providing MPLS services across AS boundaries. This includes L3VPN, L2VPN, MVPN, and TE functionality. Not all features are supported for all inter AS options; these details are discussed in subsequent sections. The network diagram includes two ASes. There are 3 transit links between the ASes and the exact configuration of these links changes with each option. There are 3 L3VPN customers, each one using a different routing protocol (OSPFv3, EIGRP, and BGP). The BGP customer is a central services VPN representing the Internet (CSR10). The EIGRP customer has an intra-AS backdoor link as well as a single remote site (CSR3, CSR1, and XRv3). The OSPFv3 customer has an inter-AS backdoor link and is singly-attached to each MPLS provider independently (CSR4/CSR9).

For the majority of tests, the eBGP topology shown above is used. Some of the inter-AS MPLS options support BGP confederations as well. The diagram is almost identical, except that the confederation ASN is 42518 and the existing ASes become sub-ASes. The diagram is shown here for reference but is only relevant for the confederation variations discussed later.

The intra-AS IGP, LDP, TE, and multicast infrastructure configurations don't change much between options so they are verified quickly. The intra-AS configurations are very basic so they are not shown here. Beginning with AS 13, we will view the OSPF database to ensure all links are properly formed. For brevity, I omit the router LSA entries not relevant for this verification. The summary view shows 4 router LSAs within area 0, which is correct. We see 14 opaque-area (type 10) LSAs which make up the TED. Each router creates one of these LSAs for its own node, which totals 4. Then, each node creates another for each link enabled for TE: 3 for CSR8, 2 for CSR5, 2 for XRV2, and 3 for XRV1, for a total of 10. Thus, the total of 14 type-10 LSAs is correct. Since all network types are point-to-point, there are no designated routers (network LSA).

```
R8#show ip ospf 13 0 database database-summary
```

```
OSPF Router with ID (13.0.0.8) (Process ID 13)
```

```
Area 0 database summary
```

LSA Type	Count	Delete	Maxage
Router	4	0	0
Network	0	0	0
Summary Net	0	0	0
Summary ASBR	0	0	0
Type-7 Ext	0	0	0
Prefixes redistributed in Type-7 0			
Opaque Link	0	0	0
Opaque Area	14	0	0
Subtotal	18	0	0

Each router has the proper point-to-point connections within the area as verified below. Although this output is long, it is a very fast and accurate way of checking the OSPF connectivity within an area.

```

R8#show ip ospf 13 0 database router | include Advertising|Neighboring_Router
Advertising Router: 13.0.0.5
  (Link ID) Neighboring Router ID: 13.0.0.11
  (Link ID) Neighboring Router ID: 13.0.0.8
Advertising Router: 13.0.0.8
  (Link ID) Neighboring Router ID: 13.0.0.11
  (Link ID) Neighboring Router ID: 13.0.0.12
  (Link ID) Neighboring Router ID: 13.0.0.5

  (Link ID) Neighboring Router ID: 13.0.0.12
  (Link ID) Neighboring Router ID: 13.0.0.5
  (Link ID) Neighboring Router ID: 13.0.0.8
Advertising Router: 13.0.0.12
  (Link ID) Neighboring Router ID: 13.0.0.11
  (Link ID) Neighboring Router ID: 13.0.0.8

```

We will also verify that the link between XRv1 and XRv2 has a higher cost. This will influence the traffic forwarding patterns for the LSPs tested later.

```

R8#show ip ospf 13 0 database router 13.0.0.11 | begin 13.0.0.12
(Link ID) Neighboring Router ID: 13.0.0.12
(Link Data) Router Interface address: 13.11.12.11
Number of MTID metrics: 0
TOS 0 Metrics: 50
[snip]

```

```

R8#show ip ospf 13 0 database router 13.0.0.12 | begin 13.0.0.11
(Link ID) Neighboring Router ID: 13.0.0.11
(Link Data) Router Interface address: 13.11.12.12
Number of MTID metrics: 0
TOS 0 Metrics: 50
[snip]

```

Next, we can verify that OSPF is carrying the loopbacks between the routers. We will look at the OSPF RIB to see them. From CSR8's perspective, one prefix is connected while the other 3 are OSPF-learned.

```

R8#show ip ospf rib | section /32
*> 13.0.0.5/32, Intra, cost 2, area 0
    via 13.5.8.5, GigabitEthernet2.558
*   13.0.0.8/32, Intra, cost 1, area 0, Connected
    via 13.0.0.8, Loopback0
*> 13.0.0.11/32, Intra, cost 2, area 0
    via 13.8.11.11, GigabitEthernet2.581
*> 13.0.0.12/32, Intra, cost 2, area 0
    via 13.8.12.12, GigabitEthernet2.582

```

Reachability to these loopbacks implies that LDP neighbors can form, assuming it is enabled. We ensure that LDP is enabled on all interfaces on XRv1 and CSR8 routers, then verify the LDP peers. Since XRv1

and CSR8 have the most interfaces (connect to all other nodes in the area), we will assume LDP is fully functional in verifying only those routers.

```
R8#show mpls interfaces
```

Interface	IP	Tunnel	BGP	Static	Operational
GigabitEthernet2.582	Yes (ldp)	Yes	No	No	Yes
GigabitEthernet2.558	Yes (ldp)	Yes	No	No	Yes
GigabitEthernet2.581	Yes (ldp)	Yes	No	No	Yes

```
RP/0/0/CPU0:XRv1#show mpls interfaces
```

Interface	LDP	Tunnel	Static	Enabled
GigabitEthernet0/0/0/0.521	Yes	Yes	No	Yes
GigabitEthernet0/0/0/0.551	Yes	Yes	No	Yes
GigabitEthernet0/0/0/0.581	Yes	Yes	No	Yes

```
R8#show mpls ldp neighbor | include Peer_LDP
```

```
Peer LDP Ident: 13.0.0.5:0; Local LDP Ident 13.0.0.8:0
Peer LDP Ident: 13.0.0.12:0; Local LDP Ident 13.0.0.8:0
Peer LDP Ident: 13.0.0.11:0; Local LDP Ident 13.0.0.8:0
```

```
RP/0/0/CPU0:XRv1#show mpls ldp neighbor brief
```

Peer	GR	NSR	Up Time	Discovery		Addresses		Labels	
				ipv4	ipv6	ipv4	ipv6	ipv4	ipv6
13.0.0.12:0	N	N	12:37:23	1	0	3	0	8	0
13.0.0.5:0	N	N	12:37:23	1	0	3	0	9	0
13.0.0.8:0	N	N	12:37:23	1	0	4	0	10	0

A quick look at the CSR8 and XRv1 LFIBs shows that labels have been learned for all remote loopbacks. Most of the time, the label is implicit-null, but this is dependent upon IGP. Since XRv1 routes to XRv2 via CSR8, CSR8's local label for 13.0.0.12/32 is used.

```
RP/0/0/CPU0:XRv1#show mpls forwarding | include Pop
```

91000	Pop	13.0.0.5/32	Gi0/0/0/0.551	13.5.11.5	86546
91001	Pop	13.0.0.8/32	Gi0/0/0/0.581	13.8.11.8	86456

```
RP/0/0/CPU0:XRv1#show mpls forwarding prefix 13.0.0.12/32
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91002	8012	13.0.0.12/32	Gi0/0/0/0.581	13.8.11.8	701073

```
R8#show mpls forwarding-table | include Pop
```

8003	Pop Label	13.0.0.5/32	866602	Gi2.558	13.5.8.5
8012	Pop Label	13.0.0.12/32	1761822	Gi2.582	13.8.12.12
8014	Pop Label	13.0.0.11/32	835899	Gi2.581	13.8.11.11

We can see label 8012 being used when XRv1 sends traffic towards XRv2. This quick check shows us that MPLS forwarding is operational.

```
RP/0/0/CPU0:XRv1#traceroute 13.0.0.12 source 13.0.0.11
Type escape sequence to abort.
Tracing the route to 13.0.0.12
 1 13.8.11.8 [MPLS: Label 8012 Exp 0] 9 msec 0 msec 0 msec
 2 13.8.12.12 29 msec 0 msec 0 msec
```

Next, we will verify the TED. Like OSPF, we will look at the significant topology components such as vertices and edges. Since there is no fancy TE at this time, we don't need to perform a detailed verification. We simply need to ensure TE is enabled on all nodes and all links within the AS. The output is very similar to the OSPF database information we saw earlier, where we have 4 vertices and 10 edges (if you count each edge unidirectionally). These 14 lines of output map to the 14 type-10 LSAs we counted earlier.

```
R8#show mpls traffic-eng topology brief | include IGP_Id
IGP Id: 13.0.0.5, MPLS TE Id:13.0.0.5 Router Node (ospf 13 area 0)
  link[0]: Point-to-Point, Nbr IGP Id: 13.0.0.8, nbr_node_id:18, gen:71
  link[1]: Point-to-Point, Nbr IGP Id: 13.0.0.11, nbr_node_id:20, gen:71
IGP Id: 13.0.0.8, MPLS TE Id:13.0.0.8 Router Node (ospf 13 area 0)
  link[0]: Point-to-Point, Nbr IGP Id: 13.0.0.5, nbr_node_id:19, gen:62
  link[1]: Point-to-Point, Nbr IGP Id: 13.0.0.11, nbr_node_id:20, gen:62
  link[2]: Point-to-Point, Nbr IGP Id: 13.0.0.12, nbr_node_id:21, gen:62
IGP Id: 13.0.0.11, MPLS TE Id:13.0.0.11 Router Node (ospf 13 area 0)
  link[0]: Point-to-Point, Nbr IGP Id: 13.0.0.5, nbr_node_id:19, gen:68
  link[1]: Point-to-Point, Nbr IGP Id: 13.0.0.8, nbr_node_id:18, gen:68
  link[2]: Point-to-Point, Nbr IGP Id: 13.0.0.12, nbr_node_id:21, gen:68
IGP Id: 13.0.0.12, MPLS TE Id:13.0.0.12 Router Node (ospf 13 area 0)
  link[0]: Point-to-Point, Nbr IGP Id: 13.0.0.8, nbr_node_id:18, gen:69
  link[1]: Point-to-Point, Nbr IGP Id: 13.0.0.11, nbr_node_id:20, gen:69
```

We also verify that RSVP is enabled so that TE LSPs can be properly signaled. I limit the verification to CSR8 and XRv1 as they have the most links.

```
RP/0/0/CPU0:XRv1#show rsvp interface
*: RDM: Default I/F B/W % : 75% [default] (max resv/bc0), 0% [default] (bc1)
Interface    MaxBW (bps)    MaxFlow (bps)    Allocated (bps)    MaxSub (bps)
-----
Gi0/0/0/0.521    200M          200M          0 ( 0%)          0
Gi0/0/0/0.551    200M          200M          0 ( 0%)          0
Gi0/0/0/0.581    200M          200M          0 ( 0%)          0
```

```
R8#show ip rsvp interface
interface    rsvp    allocated    i/f max    flow max    sub max    VRF
Gi2          ena      0           750M       750M       0
Gi2.558      ena      0           200M       200M       0
```

Gi2.581	ena	0	200M	200M	0
Gi2.582	ena	0	200M	200M	0

Next, we verify the intra-AS multicast network. XRv2 and CSR2 are the RPs for all groups, and each AS uses BSR internally to disseminate RP information. For brevity, I simply verify CSR8 and XRv1 PIM neighbors to ensure they are up. Since PIM neighbors can form unidirectionally, I verify PIM neighbors on all devices but only show output from two routers.

```
R8#show ip pim neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime/Expires	Ver	DR Prio/Mode
13.5.8.5	GigabitEthernet2.558	12:05:52/00:01:36	v2	1 / S P G
13.8.11.11	GigabitEthernet2.581	12:03:33/00:01:40	v2	1 / DR P G
13.8.12.12	GigabitEthernet2.582	12:02:58/00:01:21	v2	1 / DR P G

```
RP/0/0/CPU0:XRv1#show pim neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime	Expires	DR pri	Flags
13.11.12.11*	GigabitEthernet0/0/0/0.521	12:04:30	00:01:29	1	B P E
13.11.12.12	GigabitEthernet0/0/0/0.521	12:03:50	00:01:36	1 (DR)	B P
13.5.11.5	GigabitEthernet0/0/0/0.551	12:04:24	00:01:33	1	P
13.5.11.11*	GigabitEthernet0/0/0/0.551	12:04:30	00:01:22	1 (DR)	B P E
13.8.11.8	GigabitEthernet0/0/0/0.581	12:04:25	00:01:17	1	P
13.8.11.11*	GigabitEthernet0/0/0/0.581	12:04:30	00:01:18	1 (DR)	B P E
13.0.0.11*	Loopback0	12:04:30	00:01:26	1 (DR)	B P E

For brevity, I also ensure that the RP information is being distributed. Both CSR8 and XRv4 learn the RP information via BSR within their respective ASes.

```
R8#show ip pim rp mapping
```

Before looking at the BGP topology related to VPNs, we will perform the same set of verifications in AS 24. Beginning with IS-IS, we look at the LSP details to see each vertex and its associated edges in the SPF graph. Unlike OSPFv2 in AS 13, IS-IS is running multi-topology IPv6 routing as well. It doesn't contribute to the inter-AS testing but is enabled for any future excursions using this topology. As such, the IS-IS LSPs

are larger to account for the multi-topology (MT) links for IPv6. CSR2 and CSR6 have 2 IPv4 peers, 2 IPv6 peers, and one loopback address. CSR7 and XRv4 have 3 IPv4 peers, 3 IPv6 peers, and one loopback address. We also see that for IPv4 only, the link between CSR2 and CSR7 has a high cost. With this single command, we can verify the most critical parts of the IS-IS topology from a single router. With OSPF, we used multiple commands for variety.

```
RP/0/0/CPU0:XRv4#show isis database detail | utility egrep '^[RX]|Extended'
```

```

  remote binding: lsr: 24.0.0.14:0, label: 94009

```

A quick traceroute shows a small LSP within the network, which shows that MPLS imposition works.

R2#traceroute 24.0.0.7 source 24.0.0.2

Type escape sequence to abort.

Tracing the route to 24.0.0.7

VRF info: (vrf in name/id, vrf out name/id)

```

 1 24.2.14.14 [MPLS: Label 94010 Exp 0] 5 msec 4 msec 4 msec

```

2 24.7.14.7 5 msec 4 msec 5 msec

Next, I verify the TED using the same technique we used earlier. The command is identical on XR and we use XRv4 for this verification. The IGP IDs are IS-IS NETs versus OSPF RIDs. The TE ID is still a dotted-decimal number derived from the loopback0 assigned to TE. CSR2 and CSR6 have 2 links while CSR7 and XRv4 have 3 links, which is correct.

```
RP/0/0/CPU0:XRv4#show mpls traffic-eng topology brief | include IGP Id
IGP Id: 0000.0000.0002.00, MPLS TE Id: 24.0.0.2 Router Node (IS-IS 24 level-2)
  Link[0]:Point-to-Point, Nbr IGP Id:0000.0000.0007.00, Nbr Node Id:4, gen:9668

    Uptime: 12:26:15, expires: 00:02:12

```

The BGP topology varies significantly between the options so we only verify the most basic configurations now. XRv2 and CSR2 are the route-reflectors for all AFIs within their respective ASes for all labs. The RT policies will also change quite a bit, but initially, I identify export-only RTs for the BGP VRF on CSR8. The BGP configuration on CSR8 is a basic RR-client that peers to XRv2 and no other devices. VPNv4/v6 are negotiated as a base configuration; VPLS/MVPN AFIs are used as needed for specific options. Within the VPN, CSR8 peers with CSR10 to receive some Internet routes.

```

! CSR8
vrf definition BGP
  rd 13:1
  address-family ipv4
    route-target export 13:1
  address-family ipv6
    route-target export 13:1

router bgp 13
  no bgp default ipv4-unicast
  neighbor 13.0.0.12 remote-as 13

```

```

neighbor 13.0.0.12 password IBGP13
neighbor 13.0.0.12 update-source Loopback0
neighbor 13.0.0.12 timers 10 40

address-family vpnv4
  neighbor 13.0.0.12 activate

address-family vpnv6
  neighbor 13.0.0.12 activate

address-family ipv4 vrf BGP
  neighbor 10.8.10.10 remote-as 100
  neighbor 10.8.10.10 activate

address-family ipv6 vrf BGP
  neighbor FD00:10:8:10::10 remote-as 100
  neighbor FD00:10:8:10::10 activate

```

The RR configuration is also straightforward. I only show the configuration to CSR8, but the other routers in the AS use an identical configuration.

```

! XRv2
router bgp 13
  bgp cluster-id 13.0.0.12

```

CSR8 learns several IPv4/v6 Internet routes. Checking the details of one IPv4 and one IPv6 route, we can see the proper export RT has been applied. All of the routes are reachable via CSR10, the Internet peering point. This proves that the basic PE-CE routing with CSR10 is functional.

```

XRv2, as the RR, will learn and maintain these routes. Since they have not been imported into a VRF, we can reference them by RD since that is the mechanism by which BGP differentiates VPN routes. This proves that the intra-AS VPNv4/v6 advertisement is functional.

```

RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 13:1 | begin Network

Next, we look at XRv4. The PE-CE configuration is similar to CSR2 where RT:24:3 is exported and nothing is imported. The routes are exchanged with BGP via redistribution and XRv4 peers with CSR2 inside the VPNv4/v6 AFIs.

```

XRv4 learns EIGRP routes locally from XRv3 within VRF EIGRP and advertises them to CSR2. Looking at a single route from each AFI, RT:24:3 was applied.

```

CSR2 retains them within the RD table, but they are not imported into VRF EIGRP on CSR2 yet. We can confirm that CSR2 received these routes from XRv4. The RT values were properly received, but since VRF EIGRP isn't importing this value, MPLS L3VPN connectivity doesn't exist yet.

```

The last component to configure/verify are the L2VPN pieces. Since the L2VPN topology will change many timers between the options, I limit this to just the PE-CE access configurations. The VRF for VPLS on the CE routers is just used for ping testing so that there is no interference with the L3VPN/MVPN verification.

```
! CSR3
interface GigabitEthernet2.538
 encapsulation dot1Q 3538
 vrf forwarding VPLS
 ip address 10.0.0.3 255.255.255.0
 ipv6 address FE80::3 link-local

! CSR8
interface GigabitEthernet2
 service instance 3 ethernet
 encapsulation dot1q 3538 exact
 rewrite ingress tag pop 1 symmetric
```

On the other side of the network, the configuration is similar except different dot1q tags are used.

```
! CSR1
interface GigabitEthernet2.5123
 encapsulation dot1Q 3512 second-dot1q 3
 vrf forwarding VPLS
 ip address 10.0.0.1 255.255.255.0
 ipv6 address FE80::1 link-local

! CSR2
interface GigabitEthernet2
 service instance 3 ethernet
 encapsulation dot1q 3512 second-dot1q 3
 rewrite ingress tag pop 2 symmetric
```

A quick check shows that the service instances were configured correctly and are operational.

```
R2#show ethernet service instance
Identifier  Type      Interface      State      CE-Vlans
3           Static    GigabitEthernet2 Up
```

```
R8#show ethernet service instance
Identifier  Type      Interface      State      CE-Vlans
```

The following configuration is generic and is applied to any L2VPN PW termination point. The template enables the control word and sequence numbers. L2VPN logging is always nice to enable as well. This is on CSR2 and CSR8 initially, but may be added to other routers depending on the test.

```
! CSR2 and CSR8, others in the future
template type pseudowire TMP_VPLS
  encapsulation mpls
  sequencing both
  control-word include

l2vpn
  logging pseudowire status
```

The transit links have not been configured at this point. Like the VPN details, these change based on the option used.

8.4.1 Option A (Back to back VRF exchange)

Option A permits inter-AS MPLS connectivity by treating the ASBRs as ordinary PEs. These PEs will impose labels for ingress traffic and remote labels for egress traffic, just like a normal PE. The inter-AS traffic is therefore not MPLS encapsulated, which implies the ASBRs just treat one another as CE routers. VRF-aware BGP for IPv4/v6 exchanges allow routes to be exchanged back and forth, and extended-communities could be exchanged to keep certain attributes (OSPF/EIGRP custom communities, RTs, etc) intact during this exchange. The inter-AS traffic could be MPLS encapsulated for certain CSC architecture, which is a variation of this design discussed later.

There are many benefits to Option A. It is the simplest inter-AS MPLS option as it does not require any coordination of RDs, RTs, or other VPN information between providers. It is used in the vast majority of real-life deployments for this reason as it “just works”. It introduces no new technology into the SP network and works for all MPLS services (L3VPN, L2VPN, etc). The drawbacks of this option are that it scales poorly; for each customer VPN requiring inter-AS service, a new VRF (mapped to a specific interface) must be created on the ASBRs. This reduces the transparency of Option A and makes it very configuration-intensive. Many routers also have a limit on the number of BGP sessions they can support since each inter-AS connection is a new BGP peer. It also implies that LSPs are not end-to-end since the inter-AS transit traffic is regular IPv4/v6 (unless CSC variations are applied).

Additional Reading – Reference configurations “inter-as-mpls-a”

8.4.1.1 L3VPN

Before configuring Option A L3VPN, we will add basic import RTs to the existing VRFs. I added export-only RTs earlier just to demonstrate VRF-to-BGP route exports. Because this is a very basic task, I show a few examples for brevity. The exported RTs are identical to the imported RTs with option A since the RT

values don't need to be exchanged between ASes. CSR8 shows the central services RT being imported into VRF OSPF and the OSPF/EIGRP RT being imported into the central services VRF.

```

As a quick test, this means that CSR1 and XRv3 should have reachability over MPLS to one another (the backdoor link is currently down). CSR2 shows an iBGP route for 10.13.13.13/32 via XRv4's loopback using VPN label 94006. These routers had VPNv4/v6 configured in the basic configuration earlier and it is not related to inter-AS MPLS at all.

```
R2#show bgp vpnv4 unicast vrf EIGRP 10.13.13.13/32
BGP routing table entry for 24:3:10.13.13.13/32, version 36
Paths: (1 available, best #1, table EIGRP)
```

Advertised to update-groups:

24.0.0.14 (metric 10) (via default) from 24.0.0.14 (24.0.0.14)
Origin incomplete, metric 10752, localpref 100, valid, internal, best
Extended Community: RT:24:3 Cost:pre-bestpath:128:10752 0x8800:32768:0
0x8801:3:282 0x8802:65281:2560 0x8803:1:1500 0x8806:0:168627469
Connector Attribute: count=1
type 1 len 12 value 24:3:24.0.0.14
mpls labels in/out nlabel/94006
rx pathid: 0, tx pathid: 0x0

The route to the BGP next-hop is an IGP route, so an LDP label is used. The routers are directly connected, making CSR2 the ingress LSR and PHP LSR, so only the VPN label is imposed.

R2#show ip route 24.0.0.14

Routing entry for 24.0.0.14/32

Known via "isis", distance 115, metric 10, type level-2

Redistributing via isis 24

Last update from 24.2.14.14 on GigabitEthernet2.524, 18:09:15 ago

Routing Descriptor Blocks:

* 24.2.14.14, from 24.0.0.14, 18:09:15 ago, via GigabitEthernet2.524
Route metric is 10, traffic share count is 1

R2#show mpls ldp bindings 24.0.0.14 32 neighbor 24.0.0.14

lib entry: 24.0.0.14/32, rev 15

remote binding: lsr: 24.0.0.14:0, label: imp-null

Thanks to the EIGRP extended communities, this is seen as an internal route on CSR1. The MPLS network collapses into a single, logical EIGRP router in this way. Traceroute reveals the VPN label of 94006 and the sites have reachability over MPLS. For brevity, I only one direction.

```

We will continue with the inter-AS configurations next. To support Option A with our baseline network, we must accomplish these general tasks:

1. Configure ASBRs as PEs for all VRFs that require inter-AS service; adjust RTs as needed
2. Create a new subinterface for each customer VRF to be exchanged
3. Configure IPv4/v6 BGP sessions between ASBRs within the VRF
4. Configure BGP VPNv4/v6 to all ASBRs within each AS

None of these tasks are particularly difficult and no new features are introduced. Beginning with the first task, we must configure VRFs OSPF and EIGRP on XRv1, CSR5, CSR6, and CSR7 (ASBRs). We could optionally configure VRF BGP inside AS 24 as well, but there is a simpler way to do inter-AS option A central services; this is discussed later. For simplicity, each AS uses RT's in the format RT:ASN:X where ASN is the BGP AS number and X is a number based on the VRF. BGP is 1, OSPF is 2, and EIGRP is 3. The RT's could be the same, but since I am exchanging extended-communities between the ASes to demonstrate other features, I make them different for clarity. For brevity, I only show CSR6 and XRv1, since the configurations on the other ASBRs are almost identical. Notice that XRv1 imports the central services RT into each VRF; this effectively allows the remote EIGRP and OSPF routers in AS 24 to access the central service networks. We do not have to extend VRF BGP into AS 24, which adds complexity.

```

Once these VRFs are defined, we can configure the transit links. Since we are extending 2 different VPNs across ASes, we must create 2 VRF-aware transit links between each set of neighbors. For brevity, I only show XRv1 and CSR6. Notice that CSR6 has 4 new interfaces as it has two inter-AS peers, and for redundancy, configures a link to each peer for each VRF. I use QinQ for VLAN conservation as well, but this is not a requirement. I also overlap IPv4/v6 addresses on the transit links to minimize configuration changes. Since we want to test MVPN later, we also enable PIM on all of these transit links.

```

```

Since we haven't configured BGP yet and it would make sense to ensure the links were configured correctly, we can verify all the PIM neighbors. This is a slow process but we need to verify it eventually, and it also implies that the VLAN tagging was done correctly. To speed things up, I verify this on CSR5 and CSR6 only since they have multiple inter-AS links.

```
R5#show ip pim vrf EIGRP neighbor | begin ^Neigh

Next, I will configure the BGP sessions between pairs of routers across these transit links. This is very basic so I only show XRv1 and CSR6. Again, CSR6 has two sets of peers per VRF as it is multi-homed to AS 13. Extended communities are explicitly enabled on all peers so that specific EIGRP and OSPF information can be exchanged; this is not going to impact any RT policies between ASes.

```
! XRv1

```

Ideally, this should complete the basic Option A configuration for L3VPN. Before introducing the complexities of backdoor connections, we will trace the LSP from CSR3 to XRv3. First, CSR3 has an internal EIGRP route to XRv3; right away we can see that the extended-communities used by EIGRP over MPLS were maintained between AS boundaries. We will prove this later as well.

```

R3#show ip route 10.13.13.13

  Loading 1/255, Hops 2

```

Upon receiving traffic for this destination, XRv2 has multiple matching BGP routes with associated VPN labels. One path is from CSR5 and one is from XRv1. The routes are equal in every way so the tie is broken based on the BGP RID; CSR5 is the best path. The label is 5008; this was not exchanged across AS boundaries as this is a local label from CSR5. Additionally, the RT:13:3 is the RT specific to AS 13, so the RT was also not carried over. However, all of the important EIGRP information was transmitted, which is valuable for inter-AS backdoor links. This is true for both routes from XRv1 and CSR5.

```

In addition to label 5008, XRv2 adds a transport label. The route to the BGP next-hop is an IGP route via a non-TE interface, so an LDP label is added. The IGP routes via CSR8 to reach 13.0.0.5/32, so we consult

the LIB to find CSR8's local label for 13.0.0.5/32 and add it to the stack. The label stack becomes {8003 5008}.

```

CSR6 performs an ordinary MPLS label imposition as a PE could. CSR5 looks like a CE from its perspective as raw IPv4/v6 packets are received. The VPNv4 route uses remote label 94006 from XRv4, the remote PE. The transport label is not imposed since CSR6 is also the penultimate hop, shown below.

```

When XRv4 receives packets with label 94006, it removes the label stack and forwards the packets to XRv3 inside VRF EIGRP. In summary, there were two different and totally independent L3VPN processes we verified. Using traceroute on CSR3, we can verify the entire path. Notice that the PE-CE links at the beginning and the end of the traceroute are unlabeled as usual. The inter-AS transit link is also unlabeled since the ASBRs both consider this a PE-CE link. At each labeled hop, we confirm that the labels revealed by traceroute match the labels we verified above.

```

We will repeat the exercise for VRF OSPF using IPv6 in the opposite direction. CSR9 will be sending packets to CSR6 (backdoor link is down). CSR9 sees the route to CSR4 as inter-area, which like the EIGRP internal route on CSR3, immediately tells us that the OSPF extended-communities were correctly carried across the AS boundary. Had they not been, this route would have been external.

```
R9#show ipv6 route ::10:4:4:4
Routing entry for ::10:4:4:4/128
  Known via "ospf 2", distance 110, metric 2, type inter area
  Route count is 1/1, share count 0
  Routing paths:
    FE80::2, GigabitEthernet2.529
    Last updated 00:01:30 ago
```

As the ingress LSR, CSR2 will be imposing at least 1 label for L3VPN. It learns a pair VPNv6 routes from CSR6 and CSR7. CSR6 wins due to having a lower BGP RID, so label 6027 is pushed first. We also confirm that both routes carry the OSPF extended communities that were passed from AS 13.

```
R2#show bgp vpnv6 unicast vrf OSPF ::10:4:4:4/128

```

Since 6VPE is in use, the BGP next-hop is an IPv4 route so the router will perform a lookup in the IPv4 FIB. The route is IGP with a next-hop of XRv4, so XRv4's LDP label for 24.0.0.6/32 is pushed. The FIB shows this as label 94008. The full label stack is also revealed for this VPNv6 prefix as {94008 6027}.

```

```

Next, we will verify central services connectivity. I will trace the LSPs much more quickly since the process is identical; again, no new technologies are introduced. As a sanity check, we ensure that intra-AS central services is working. In order to get these BGP routes into EIGRP, we must define a redistribution metric. We don't need to do this when the BGP route carries the EIGRP extended communities, but these routes are actually external. Rather than reset EIGRP metrics for all prefixes, I use a parameterized RPL for the XR PEs. Only the Internet routes have their metrics set, while other routes are allowed to pass transparently. The RPL can consume IPv4 or IPv6 prefix-sets as well.

```
! XRv1 and XRv2
prefix-set PS_INTERNET_ROUTES
  110.0.0.0/8 le 32
end-set

prefix-set PS_INTERNET_ROUTES_V6
  ::110:0:0:0/80 le 128
end-set

route-policy RPL_BGP_TO_EIGRP($PS)
  if destination in $PS then
    set eigrp-metric 100000 10 255 1 1500
  else
    pass
  endif
end-policy

router eigrp EIGRP
  vrf EIGRP
    address-family ipv4
      redistribute bgp 13 route-policy RPL_BGP_TO_EIGRP(PS_INTERNET_ROUTES)
    address-family ipv6
      redistribute bgp 13 route-policy RPL_BGP_TO_EIGRP(PS_INTERNET_ROUTES_V6)
```

On XRv2, we can verify this worked by checking the EIGRP topology inside the VRF. The VPNv4 sourced routes are clearly different than the truly external ones, as shown below. The metric values also differ which validates the RPL configuration.

```
RP/0/0/CPU0:XRv2#show eigrp vrf EIGRP topology 10.13.13.13/32
IPv4-EIGRP VR(EIGRP) AS(3) VRF EIGRP: Topology entry for 10.13.13.13/32

        External protocol is BGP, external metric is 0
        Administrator tag is 0 (0x00000000)
```

Moving back to AS 13, we will verify the intra-AS central services connectivity now. XRv2 has a VPN route for 100.0.0.0/32 which pushes a single VPN label allocated by CSR8. In the opposite direction, CSR8 pushes a label from XRv2 to reach CSR3's loopback.

```
RP/0/0/CPU0:XRv2#show cef vrf EIGRP 110.0.0.0/32
110.0.0.0/32, version 7, internal 0x5000001 0x0 (ptr 0xa142dc74) [1], 0x0
(0x0), 0x208 (0xa15a1140)
```

```

```

AS 24 has no knowledge of VRF BGP or RT:13:1 at all. Using CSR5 and XRv1, we saw earlier how RT:13:1 was imported into VRFs OSPF and EIGRP at these ASBRs. This allows CSR6 and CSR7 to learn the prefixes as normal “customer” routes without caring that it’s actually a central services extension. As an example, CSR5 imports the regular OSPF RT:13:2 from BGP into VRF OSPF, as well as RT:13:1 which represents the shared serviced VPN.

```
R5#show vrf detail OSPF | include ^Address|port_VPN|RT
Address family ipv4 unicast (Table ID = 0x2):
  Export VPN route-target communities
    RT:13:2
  Import VPN route-target communities
    RT:13:2 RT:13:1
Address family ipv6 unicast (Table ID = 0x1E000002):
  Export VPN route-target communities
    RT:13:2
  Import VPN route-target communities
    RT:13:2 RT:13:1
```

A quick look at the VPNv4 tables for VRFs OSPF and EIGRP on CSR5 shows that the routes have been correctly imported. We can verify their RTs as well.

```
R5#show bgp vpnv4 unicast vrf OSPF 110.0.0.0/32
BGP routing table entry for 13:2:110.0.0.0/32, version 31
Paths: (1 available, best #1, table OSPF)

      mpls labels in/out nolabel/8016
      rx pathid: 0, tx pathid: 0x0
```

When these are received by AS 24 ASBRs and exported from the VRF to BGP, the RT is overwritten. AS 24 is none the wiser, and it doesn't matter. CSR7, for example, learns an eBGP path from CSR5 and an iBGP path from CSR6, but both have identical attributes.

```
R7#show bgp vpnv4 unicast vrf OSPF 110.0.0.0/32
BGP routing table entry for 24:2:110.0.0.0/32, version 35
Paths: (2 available, best #2, table OSPF)
  Advertised to update-groups:

  Extended Community: RT:24:2
  mpls labels in/out 7019/nolabel
  rx pathid: 0, tx pathid: 0x0

```

Earlier, we cleaned up the BGP to EIGRP redistribution to ensure that both internal routes (inside the EIGRP VPN) and external routes (Internet, extranets, etc) could be redistributed properly. CSR1 and XRv3 both have EIGRP external routes to the Internet which shows that the central services control plane is operational.

```

R1#show ipv6 route ::110:0:0:3
Routing entry for ::110:0:0:3/128

    Route metric is 107520
  No advertising protos.

```

We have already traced several LSPs, so I will use traceroute to verify connectivity instead. As always with option A, the inter-AS transit link traffic is unlabeled. This proves that central services is supported with option A.

```

R1#traceroute ipv6
Target IPv6 address: ::110:0:0:3
Source address: ::10:1:1:1
[snip]
Type escape sequence to abort.
Tracing the route to ::110:0:0:3

 1 FD00:10:1:2::2 4 msec 4 msec 3 msec

 6 FD00:10:8:10::10 23 msec 15 msec 15 msec

```

```
RP/0/0/CPU0:XRv3#traceroute ::110:0:0:3 source ::10:13:13:13
Type escape sequence to abort.
Tracing the route to ::110:0:0:3
```

```
 1  fd00:10:13:14::14 0 msec 0 msec 0 msec
 2  fd00:10:5:6::6 [MPLS: Label 6018 Exp 0] 0 msec 0 msec 0 msec
 3  fd00:10:5:6::5 9 msec 0 msec 0 msec
 4  fd00:10:8:10::8 [MPLS: Label 8008 Exp 0] 0 msec 0 msec 0 msec
 5  fd00:10:8:10::10 9 msec 0 msec 0 msec
```

Next, I will enable the backdoor links. The EIGRP backdoor isn't particularly interesting since it is intra-AS, so I will cover it quickly. I add new interfaces for this link and increase the delay so EIGRP does not prefer it.

```
! CSR1
interface GigabitEthernet2.513
 encapsulation dot1q 3513
 ip address 10.1.13.1 255.255.255.0
 ip pim sparse-mode
 delay 10000
 ipv6 address FE80::1 link-local
 ipv6 address FD00:10:1:13::1/64

router eigrp CUST
 address-family ipv4 unicast autonomous-system 3
  network 10.1.13.1 0.0.0.0

! XRv3
interface GigabitEthernet0/0/0/0.513
 ipv4 address 10.1.13.13 255.255.255.0
 ipv6 address fe80::13 link-local
 ipv6 address fd00:10:1:13::31/64
 encapsulation dot1q 3513

router eigrp CUST
 address-family ipv4
  interface GigabitEthernet0/0/0/0.513
   metric delay 10000
 address-family ipv6
  interface GigabitEthernet0/0/0/0.513
   metric delay 10000
```

I verify that EIGRP neighbors are up on CSR1 for both AFIs, then use traceroute to ensure MPLS is still preferred. Because extended-communities are in use, no loops can form when all links are operational, and the existing inter-AS/central services design is unaffected.

```
R1#show eigrp address-family ipv4 neighbors
```

```
EIGRP-IPv4 VR(CUST) Address-Family Neighbors for AS(3)

1 ::10:13:13:13 2 msec 3 msec 2 msec
```

Of greater interest is the OSPF backdoor. The configuration is shown below and is very basic. After applying this configuration, the backdoor link is preferred over the MPLS link despite the high cost. This is the classic use-case for the sham-link so that the MPLS-reachable routes are also OSPF intra-area. I only show CSR4 for brevity since the interfaces are identical, IPv4/v6 addresses notwithstanding.

```
! CSR4
interface GigabitEthernet2.549
 encapsulation dot1Q 3549
 ip address 10.4.9.4 255.255.255.0
 ip pim sparse-mode
 ipv6 address FE80::4 link-local
 ipv6 address FD00:10:4:9::4/64
 ospfv3 network point-to-point
 ospfv3 2 cost 500
 ospfv3 2 ipv4 area 0
 ospfv3 2 ipv6 area 0
```

```
R4#show ip route 10.9.9.9
Routing entry for 10.9.9.9/32
  Known via "ospfv3 2", distance 110, metric 500, type intra area
  Last update from 10.4.9.9 on GigabitEthernet2.549, 00:00:49 ago
  Routing Descriptor Blocks:

 1 10.4.9.9 4 msec 3 msec 3 msec
```

Since we already have ordinary MPLS service between AS boundaries, creating a sham-link requires no new steps. I apply route-maps to the redistribution points to ensure that the sham-link endpoints don't get exposed to the customer. This is not necessary for IPv4 since the sham-link endpoints are IPv6 addresses. This topic is covered in detail in the multi-VRF CE chapter. I only show the configuration for CSR2 since CSR8 is identical, except for minor details like BGP AS, loopback IPv6 address, and sham-link source/destination.

```
! CSR2
interface Loopback2
```

```

vrf forwarding OSPF
ipv6 address FD00::2/128

ipv6 prefix-list PL_SHAM seq 5 permit FD00::/124 ge 128

route-map RM_BGP_TO_OSPF deny 10
  match ipv6 address prefix-list PL_SHAM
route-map RM_BGP_TO_OSPF permit 100

router ospfv3 2
  address-family ipv4 unicast vrf OSPF
  redistribute bgp 24
  area 0 sham-link FD00::2 FD00::8

address-family ipv6 unicast vrf OSPF
  redistribute bgp 24 route-map RM_BGP_TO_OSPF
  area 0 sham-link FD00::2 FD00::8

router bgp 13
  address-family ipv6 vrf OSPF
  network FD00::2/128

```

Since OSPFv3 IPv4 and IPv6 are two separate protocol instances, we created two separate sham-links. On CSR2, I verify that they are both operational. Unlike virtual-links, sham-links are just ordinary P2P adjacencies in the OSPF graph. I verify this by looking at CSR2's local router LSA; it reveals a direct connection to CSR8 and CSR9. The default sham-link cost is 1 but this is adjustable.

```

R2#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::8 is up
Sham Link OSPFv3_SL1 to address FD00::8 is up

R2#show ospfv3 vrf OSPF ipv4 database router adv-router 10.2.9.2
[snip]
  Number of Links: 2

    Link connected to: another Router (point-to-point)
      Link Metric: 1
      Local Interface ID: 18
      Neighbor Interface ID: 32
      Neighbor Router ID: 10.4.8.8

    Link connected to: another Router (point-to-point)
      Link Metric: 1
      Local Interface ID: 14
      Neighbor Interface ID: 27
      Neighbor Router ID: 10.4.9.9

```

We can verify that BGP is transporting these prefixes correctly (it must be, or else the sham-link would be down). CSR2 sees both its locally originated endpoint and the BGP-learned endpoint representing CSR8.

```
R2#show bgp vpnv6 unicast vrf OSPF FD00::/124 longer-prefixes | begin Network
      Network          Next Hop          Metric LocPrf Weight Path

8.4.1.2 L2VPN

L2VPN over option A is very similar to L3VPN in terms of the general logic. Traffic enters the PE and the layer 2 frame is wrapped inside MPLS. The end of the virtual circuit is the ASBR, which like L3VPN, simply removes the labels and forwards the frame out of the access circuit (AC). The ASBR on the other end of the AC treats this incoming frame like it came from a customer and encapsulates it inside MPLS as expected. Like option A, the two providers can use totally different L2VPN mechanisms. In this example, AS 13 uses LDP signaled VPLS via BGP auto-discovery while AS 24 uses BGP signaled VPLS via BGP auto-discovery. Any kind of EVPN variations or static VPLS configurations are also acceptable. The basic PE-CE access configurations were validated earlier, so we will add the specific L2VPN details. First, we configure LDP-based VPLS on CSR8. This includes activating the proper AFI towards XRv2, the RR for AS 13. The bridge-domain ties the VFI to the service-instance. L2VPN has a dedicated chapter which covers the operational details.

```

! CSR8
l2vpn vfi context VPLS
  vpn id 3
  autodiscovery bgp signaling ldp template TMP_VPLS
  rd 13:30

bridge-domain 3
  member GigabitEthernet2 service-instance 3
  member vfi VPLS

router bgp 13
  address-family l2vpn vpls
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 prefix-length-size 2

```

To avoid creating a bridging loop, the L2VPN traffic will only use one of the inter-AS links. Specifically, I will configure the L2VPN ASBRs to be CSR5 and CSR6. CSR5 terminates the PW inside AS 13 using an almost identical configuration to CSR8. I use dot1q tag 30 to demonstrate that the tags can be different at every layer 2 hop since the EFPs are stripping all tags before MPLS encapsulation occurs. This access circuit was not verified earlier since CSR5 wasn't initially considered an L2VPN PE. Using the option A model, it would be.

```

! CSR5
interface GigabitEthernet2

```

```

service instance 30 ethernet
  encapsulation dot1q 3556 second-dot1q 30
  rewrite ingress tag pop 2 symmetric

l2vpn vfi context VPLS
  vpn id 3
  autodiscovery bgp signaling ldp template TMP_VPLS
  rd 13:30

bridge-domain 3
  member GigabitEthernet2 service-instance 30
  member vfi VPLS

router bgp 13
  address-family l2vpn vpls
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 prefix-length-size 2

```

Last, we will configure XRv2 as the RR for the L2VPN-VPLS AFI. It doesn't do any local processing; it only needs to reflect the L2VPN AD routes and disable BGP signaling as LDP should be used.

```

! XRv2
router bgp 13
  address-family l2vpn vpls-vpws

  af-group L2VPN address-family l2vpn vpls-vpws
    route-reflector-client
    Signalling bgp disable

  neighbor 13.0.0.5
    address-family l2vpn vpls-vpws
    use af-group L2VPN

  neighbor 13.0.0.8
    address-family l2vpn vpls-vpws
    use af-group L2VPN

```

Once this is complete, we can verify that the L2VPN BGP routes were properly exchanged. Notice that there are no labels associated with these routes. BGP is only used for discovery while tLDP is used for signaling, so no labels need to be exchanged. XRv2 learns both routes via iBGP and reflects them appropriately.

```

RP/0/0/CPU0:XRv2#show bgp l2vpn vpls rd 13:30 | begin Network
  Network          Next Hop          Rcvd Label          Local Label
Route Distinguisher: 13:30
*>i13.0.0.5/32      13.0.0.5          nolabel             nolabel
*>i13.0.0.8/32      13.0.0.8          nolabel             nolabel

```

Upon receiving the peer route, both CSR5 and CSR8 are able to create the tLDP session. We verify that the tLDP neighbor comes up and that the MPLS PW follows. Don't be fooled by the RT:13:3 value; although the same set of numbers used for EIGRP L3VPN, this is auto-generated. The 13 is the BGP ASN and the 3 is the VPN ID. I did this intentionally to make the lab tricky. The MPLS labels are zeroed out as well (explicit null is 0x00000).

```
R5#show bgp l2vpn vpls rd 13:30 13.0.0.8

```
R5#show l2vpn atom vc
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw100002	13.0.0.8	3	vfi	VPLS	UP

Next, we will configure VPLS auto-discovery and signaling using BGP inside AS 24. The configuration is very similar. Since CSR2 is the RR, we only have to enable the session directly between CSR2 and CSR6.

```
! CSR2
l2vpn vfi context VPLS
  vpn id 3
  autodiscovery bgp signaling bgp template TMP_VPLS
  ve id 2
  rd 24:30

bridge-domain 3
  member GigabitEthernet2 service-instance 3
  member vfi VPLS

router bgp 24
  address-family l2vpn vpls
    neighbor 24.0.0.6 activate
    neighbor 24.0.0.6 suppress-signaling-protocol ldp
```

Like CSR5, CSR6 needs to define an EFP for the inter-AS Ethernet frames. Otherwise, the configuration is almost identical to CSR2.

```
! CSR6
interface GigabitEthernet2
  service instance 30 ethernet
  encapsulation dot1q 3556 second-dot1q 30
  rewrite ingress tag pop 2 symmetric

l2vpn vfi context VPLS
  vpn id 3
  autodiscovery bgp signaling bgp template TMP_VPLS
  ve id 6
  rd 24:30

bridge-domain 3
  member GigabitEthernet2 service-instance 30
  member vfi VPLS

router bgp 24
  address-family l2vpn vpls
  neighbor 24.0.0.2 activate
  neighbor 24.0.0.2 suppress-signaling-protocol ldp
```

BGP-based VPLS signaling is much more complex than LDP in terms of mathematical evaluation. The labels are not carried in the BGP route, but a series of parameters are used to compute the label. This process is covered in detail in the L2VPN section. In short, CSR6 receives the route from CSR2, builds the PW, and derives a label from the information carried in the BGP route.

```
R6#show bgp l2vpn vpls rd 24:30 ve-id 2 block-offset 1
BGP routing table entry for 24:30:VEID-2:Blk-1/136, version 10

```
R6#show l2vpn atom vc
```

		Service			
Interface	Peer ID	VC ID	Type	Name	Status
pw100002	2	3	vfi	VPLS	UP

Tracing the path from CSR3 to CSR1 over L2VPN, we can see the label that CSR8 imposes is 5019. this is the PW label allocated by CSR5 via tLDP.

```
R8#show l2vpn atom binding 13.0.0.5
Destination Address: 13.0.0.5, VC ID: 3
Local Label: 8017
  Cbit: 1, VC Type: Ethernet, GroupID: n/a
  MTU: 1500, Interface Desc: n/a
  VCCV: CC Type: RA [2], TTL [3]
        CV Type: LSPV [2]
Remote Label: 5019
  Cbit: 1, VC Type: Ethernet, GroupID: n/a
  MTU: 1500, Interface Desc: n/a
  VCCV: CC Type: RA [2], TTL [3]
        CV Type: LSPV [2]
```

Since CSR8 and CSR5 are directly connected, no LDP label is imposed (imp-null is signaled). The MPLS PW details show a single label being imposed which is the PW label.

```
R8#show l2vpn atom vc vcid 3 detail | include label_stack
Output interface: Gi2.558, imposed label stack {5019}
```

```
R8#show mpls ldp bindings 13.0.0.5 32
lib entry: 13.0.0.5/32, rev 8
local binding: label: 8002
remote binding: lsr: 13.0.0.5:0, label: imp-null
remote binding: lsr: 13.0.0.11:0, label: 91000
remote binding: lsr: 13.0.0.12:0, label: 92004
```

When CSR5 receives labeled packets, it removes all labels and sends the traffic onto the service-instance tied to CSR6.

```
R5#show mpls forwarding-table labels 5019
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
5019	No Label	l2ckt(1)	902	none	point2point

```

CSR6 is the ingress LSR and receives the Ethernet frame as if it came from the customer. Two labels are imposed: the bottom label was derived from BGP to represent the PW, and the top label was derived from LDP. Specifically, the top label is XRv4's local label for 24.0.0.2/32 as shown below.

```

R6#show l2vpn atom vc vcid 3 detail | include label_stack
Output interface: Gi2.564, imposed label stack {94009 2031}

R6#show mpls ldp bindings 24.0.0.2 32 neighbor 24.0.0.14
lib entry: 24.0.0.2/32, rev 14
remote binding: lsr: 24.0.0.14:0, label: 94009

```

XRv4 is a P router along this LSP and performs PHP to expose label 2031 to CSR2.

```

RP/0/0/CPU0:XRv4#show mpls forwarding labels 94009
Local   Outgoing   Prefix           Outgoing   Next Hop        Bytes
Label   Label       or ID           Interface  Next Hop        Switched
-----
94009 Pop          24.0.0.2/32     Gi0/0/0/0.524 24.2.14.2      3552757

```

Upon receipt, CSR2 removes all labels and forwards the frame to CSR1, the end customer.

```

R2#show mpls forwarding-table labels 2031
Local   Outgoing   Prefix           Bytes Label   Outgoing   Next Hop
Label   Label       or Tunnel Id     Switched      interface
2031    No Label    lbl-blk-id(2:5)  1090          none       point2point

```

Using MPLS OAM, we can quickly verify the data plane for each PW individually before attempting to test end-to-end connectivity.

```

R8#ping mpls pseudowire 13.0.0.5 3
Sending 5, 72-byte MPLS Echos to 13.0.0.5,
    timeout is 2 seconds, send interval is 0 msec:
[snip]

Type escape sequence to abort.
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 2/4/8 ms
Total Time Elapsed 21 ms

```

Since the CW is not supported over BGP signaled PWs within XE, we can use the IPv4 FEC to at least trace the transport path inside AS 24.

```
R2#ping mpls ipv4 24.0.0.6/32 source 24.0.0.2
Sending 5, 72-byte MPLS Echos to Target FEC Stack TLV descriptor,
    timeout is 2 seconds, send interval is 0 msec:
[snip]

Type escape sequence to abort.
!!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 4/5/8 ms
Total Time Elapsed 28 ms
```

Last, we can verify that CSR3 and CSR1 can communicate over the inter-AS L2VPN. Traceroute reveals that the two routers are one hop away (directly connected at layer 3), which is the design goal.

```
R3#traceroute vrf VPLS 10.0.0.1
Type escape sequence to abort.
Tracing the route to 10.0.0.1
VRF info: (vrf in name/id, vrf out name/id)
 1 10.0.0.1 11 msec 9 msec 9 msec
```

8.4.1.3 MVPN – GRE (Profile 0) and mLDP (Profile 1)

As we have seen in the L3VPN and L2VPN sections, the two ASes can use completely different mechanisms for transporting traffic between their PE and AS boundary routers. For this test, we will transport multicast traffic within VRFs EIGRP and OSPF between customer sites. AS 13 will use MVPN profile 0 which relies on PIM for c-mcast signaling and data-plane encapsulation. AS 24 will use MVPN profile 1 which relies on PIM for c-mcast signaling but uses MPLS for transporting label switched multicast (LSM). This is a simple MVPN profile that doesn't require BGP auto-discovery as the LSM root is hard-coded for the MP2MP tree. These delivery trees are build using mLDP; all of these MVPN technologies are covered in detail later. Initially, we will not enable data MDT support in AS 13 nor P2MP S-PMSI support in AS 24; all multicast transport will follow the default MDT.

First, I define default MDT groups for VRFs OSPF and EIGRP. Using ASM obviates the need for IPv4 MDT or IPv4 MVPN AFI negotiation with BGP, but adds more complexity to the MVPN. I will use the ASM method as it is less common and more difficult. VRF OSPF will use ASM group 225.0.0.2 while VRF EIGRP uses ASM group 225.0.0.3.

```
! CSR8 and CSR5
vrf definition OSPF
  address-family ipv4
    mdt default 225.0.0.2
  address-family ipv6
    mdt default 225.0.0.2
```

```

! CSR5 only
vrf definition EIGRP
  address-family ipv4
    mdt default 225.0.0.3
  address-family ipv6
    mdt default 225.0.0.3

! XRv2 and XRv1
multicast-routing
vrf EIGRP
  address-family ipv4
    mdt default ipv4 225.0.0.3
  address-family ipv6
    mdt default ipv4 225.0.0.3

! XRv1 only
multicast-routing
vrf OSPF
  address-family ipv4
    mdt default ipv4 225.0.0.2
  address-family ipv6
    mdt default ipv4 225.0.0.2

```

We can do a quick spot-check to ensure the default MDTs are built properly. On CSR5, we look at 225.0.0.2 with XRv1 and CSR8 as sources. Both of them are inside VRF OSPF, but XRv2 is not. This makes sense as XRv2 is not a PE for the OSPF VPN.

```

R5#show ip mroute 225.0.0.2 13.0.0.11 | begin \
(13.0.0.11, 225.0.0.2), 00:06:16/00:02:37, flags: JTZ
  Incoming interface: GigabitEthernet2.551, RPF nbr 13.5.11.11
  Outgoing interface list:
    MVRF OSPF, Forward/Sparse, 00:06:16/00:02:43

```

```

R5#show ip mroute 225.0.0.2 13.0.0.8 | begin \
(13.0.0.8, 225.0.0.2), 00:12:14/00:01:05, flags: JTZ
  Incoming interface: GigabitEthernet2.558, RPF nbr 13.5.8.8
  Outgoing interface list:
    MVRF OSPF, Forward/Sparse, 00:12:14/00:02:45

```

The same set of checks applies to 225.0.0.3 which services VRF EIGRP, but the members include XRv1 and XRv2 now (not CSR8). Each loopback joined the proper (*,G) tree rooted at XRv2, but once the c-mcast PIM signaling was sent, the SPT switchover occurred for all multicast state. That is why the 'J' flag is set on all of these entries.

```

R5#show ip mroute 225.0.0.3 13.0.0.11 | begin \
(13.0.0.11, 225.0.0.3), 00:09:26/00:02:13, flags: JTZ
  Incoming interface: GigabitEthernet2.551, RPF nbr 13.5.11.11

```

Outgoing interface list:

MVRF EIGRP, Forward/Sparse, 00:09:26/00:02:33

```
R5#show ip mroute 225.0.0.3 13.0.0.12 | begin \  
(13.0.0.12, 225.0.0.3), 00:14:35/00:02:42, flags: JTZ  
Incoming interface: GigabitEthernet2.558, RPF nbr 13.5.8.8  
Outgoing interface list:  
MVRF EIGRP, Forward/Sparse, 00:14:35/00:00:24
```

With the MDTs properly built, we will verify c-mcast PIM neighbors within each VPN. For EIGRP, we expect to see XRv1 and XRv2. For OSPF, we expect to see XRv1 and CSR8.

```
R5#show ip pim vrf EIGRP neighbor | begin ^Neigh  
Neighbor      Interface      Uptime/Expires  Ver  DR  
Address                               Prio/Mode  
10.5.6.6      GigabitEthernet2.5563  01:37:08/00:01:28 v2    1 / DR S P G  
10.5.7.7      GigabitEthernet2.5573  01:37:08/00:01:33 v2    1 / DR S P G  
13.0.0.11     Tunnel5               00:11:13/00:01:20 v2    1 / P G

::FFFF:13.0.0.11     Tunnel5       00:09:05  00:01:32 B G    1  
::FFFF:13.0.0.12     Tunnel5       00:09:03  00:01:44 B G    DR 1
```

```
R5#show ipv6 pim vrf OSPF neighbor | begin ^Neigh  
Neighbor Address      Interface      Uptime    Expires  Mode  DR pri  
FE80::6              Gi2.5562      01:37:22  00:01:39 B G    DR 1  
FE80::7              Gi2.5572      01:37:22  00:01:36 B G    DR 1  
::FFFF:13.0.0.8      Tunnel4       00:09:10  00:01:27 B G    1  
::FFFF:13.0.0.11     Tunnel4       00:09:09  00:01:22 B G    DR 1
```

Next, I will configure AS 24 with mLDP. XRv4 is the root for all VPNs within the AS. The mLDP configuration is identical on CSR2, CSR6, and CSR7 as all three routers host both VRF EIGRP and OSPF. The critical step to configuring mLDP is to identify a VPN ID. Without it, mLDP will not work, and there isn't an error message to help reveal it.

```
! CSR2, CSR6, CSR7
vrf definition EIGRP
  vpn id 24:3
  address-family ipv4
    mdt preference mldp
    mdt default mpls mldp 24.0.0.14
  address-family ipv6
    mdt preference mldp
    mdt default mpls mldp 24.0.0.14

vrf definition OSPF
  vpn id 24:2
  address-family ipv4
    mdt preference mldp
    mdt default mpls mldp 24.0.0.14
  address-family ipv6
    mdt preference mldp
    mdt default mpls mldp 24.0.0.14
```

XRv4 is the MP2MP root and also a PE. Since XRv doesn't support LSM in the PE role, the configuration below does nothing (reference only).

```
! XRv4
vrf EIGRP
  vpn id 24:3

multicast-routing
  vrf EIGRP
    address-family ipv4
      mdt default mldp ipv4 24.0.0.14
    address-family ipv6
      mdt default mldp ipv4 24.0.0.14
```

A quick way to verify the mLDP configuration is to check the root. It has no upstream peers; the root of the tree never does. For the 24:2 VPN (OSPF), it has 3 downstream peers. These would be CSR2, CSR6, and CSR7. For 24:3 (EIGRP), it has 4 downstream peers. This includes the 3 routers plus the VPN customer interface (PMSI), generally speaking.

```
RP/0/0/CPU0:XRv4#show mpls mldp database brief
```

LSM ID	Type	Root	Up	Down	Decoded	Opaque	Value
0x00002	MP2MP	24.0.0.14	0	3	[mdt	24:2	0]
0x00001	MP2MP	24.0.0.14	0	4	[mdt	24:3	0]

Since MP2MP trees are bidirectional, we can use OAM to verify the MDT from any PE. From CSR2, we can use this as a discovery mechanism to find all members of a given MVPN instance. Inside of VPN 24:2, only the ASBRs respond, since the third member is CSR2 (the source). Inside of VPN 24:3, the ASBRs and XRv4 respond, because all of them are PEs for this MVPN instance.

```
R2#ping mpls mldp mp2mp 24.0.0.14 mdt 24:2 0

As a final check, we verify that the PEs have PIM neighbors within their respective VPNs. From CSR7's perspective, there are 2 neighbors in VPN 24:2 (OSPF) which include CSR2 and CSR6 only. VPN 24:3 (EIGRP) includes XRv4 as well, for a total of 3.

```
R7#show ip pim vrf OSPF neighbor | begin ^Neigh
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
10.5.7.5           GigabitEthernet2.5572  02:00:38/00:01:37 v2      1 / S P G
24.0.0.6           Lspvif1              00:15:15/00:01:16 v2      1 / S P G
24.0.0.2           Lspvif1              00:15:15/00:01:44 v2      1 / S P G

R7#show ip pim vrf EIGRP neighbor | begin ^Neigh

To prepare for customer ASM testing, we will configure CSR3 as the RP inside the EIGRP VPN for IPv4 and IPv6. Because XRv4 cannot support LSM PE functions, we also must modify RPF on XRv3 so that it can learn the RP information from CSR1. Without the static multicast route per AFI, the BSR messages from CSR1 are dropped due to RPF failure.

```
! CSR3
ip pim bsr-candidate Loopback0 0
ip pim rp-candidate Loopback0
ipv6 pim bsr candidate bsr ::10:3:3:3
ipv6 pim bsr candidate rp ::10:3:3:3
```

```
! XRv3

```

Just by virtue of the BSR messages being passed from CSR3 to CSR1/XRv3 means that the inter-AS MVPN is probably working. However, we will test actual data traffic as well to ensure all PIM signaling functions (join, prune, etc) are working between ASes. XRv3 will be a receiver for group 225.13.13.13 on its loopback interface. This is an ASM membership report as the mode is EXCLUDE and no sources are specified.

```
! XRv3
router igmp
  interface Loopback0
    join-group 225.13.13.13
```

```
RP/0/0/CPU0:XRv3#show igmp groups 225.13.13.13 detail

Group:          225.13.13.13
Uptime:         00:00:52
Router mode:    EXCLUDE (Expires: never)
Host mode:      EXCLUDE
Last reporter:  10.13.13.13
Source list is empty
```

XRv3 originates the C(*,G) join towards the RP towards CSR3 (RP) via CSR1. The static multicast route identifies CSR1 as the RPF neighbor towards 10.3.3.3/32, and we can confirm this by checking the RPF details.

```
RP/0/0/CPU0:XRv3#show pim topology 225.13.13.13 | begin 13\13
(*,225.13.13.13) SM Up: 00:00:25 RP: 10.3.3.3

  Loopback0                                00:00:25 fwd LI II LH
```

```
RP/0/0/CPU0:XRv3#show pim rpf 10.3.3.3
Table: IPv4-Multicast-default
* 10.3.3.3/32 [1/0]
    via GigabitEthernet0/0/0/0.513 with rpf neighbor 10.1.13.1
```

CSR1 sends the C(*,G) join to CSR2, the PE, as its RPF is based on the unicast EIGRP route to 10.3.3.3/32.

```
R1#show ip mroute 225.13.13.13 | begin \
(*, 225.13.13.13), 00:00:18/00:03:11, RP 10.3.3.3, flags: S
    Incoming interface: GigabitEthernet2.512, RPF nbr 10.1.2.2
    Outgoing interface list:
        GigabitEthernet2.513, Forward/Sparse, 00:00:18/00:03:11
```

```
R1#show ip rpf 10.3.3.3
RPF information for ? (10.3.3.3)
    RPF interface: GigabitEthernet2.512
    RPF neighbor: ? (10.1.2.2)
    RPF route/mask: 10.3.3.3/32
    RPF type: unicast (eigrp 3)
    Doing distance-preferred lookups across tables
    RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

CSR2 receives the C(*,G) join in the VPN and sends it over the default MP2MP tree towards CSR6. Since the MVPN instances are confined to each AS, CSR2 is not aware that XRv2 is the egress PE, and instead views CSR6 as having this role.

```
R2#show ip mroute vrf EIGRP 225.13.13.13 | begin \
(*, 225.13.13.13), 00:00:59/00:03:29, RP 10.3.3.3, flags: S
    Incoming interface: Lspvif0, RPF nbr 24.0.0.6
    Outgoing interface list:
        GigabitEthernet2.512, Forward/Sparse, 00:00:59/00:03:29
```

CSR6 receives the C(*,G) join and forwards it towards XRv1. CSR5 was not selected due to XRv1's eBGP route being older as shown below.

```
R6#show ip mroute vrf EIGRP 225.13.13.13 | begin \
(*, 225.13.13.13), 00:02:12/00:03:14, RP 10.3.3.3, flags: S
    Incoming interface: GigabitEthernet2.5613, RPF nbr 10.6.11.11
    Outgoing interface list:
        Lspvif0, Forward/Sparse, 00:02:12/00:03:14
```

```

XRv1 views this C(*,G) join as if it came from a CE device, so it is wrapped inside the default MDT and signaled towards XRv2. When XRv2 receives it, the join is passed back into the customer network towards CSR3.

```
RP/0/0/CPU0:XRv1#show pim vrf EIGRP topology 225.13.13.13 | begin 225
(*,225.13.13.13) SM Up: 00:05:05 RP: 10.3.3.3

  mdtEIGRP 00:05:56 fwd Join(00:02:35)
```

In the customer network, CSR3 is the RP and therefore the root of the customer shared tree. This shows the correct C(*,G) construction.

```
R3#show ip mroute 225.13.13.13 | begin \
(*, 225.13.13.13), 00:06:44/00:02:43, RP 10.3.3.3, flags: S
  Incoming interface: Null, RPF nbr 0.0.0.0
  Outgoing interface list:
    GigabitEthernet2.532, Forward/Sparse, 00:06:44/00:02:43
```

For simplicity, the host address 10.3.3.3 will also be the source of the multicast traffic. This will allow XRv3 to issue C(S,G) joins towards CSR1 as we added RPF fix-up routes on XRv3. The PIM registration and SPT switchover processes are not evaluated in detail as this is documented in many other places.

```
R3#ping ip
Target IP address: 225.13.13.13
Repeat count [1]: 100000
Datagram size [100]:
```

```

Timeout in seconds [2]: 1
Extended commands [n]: y
Interface [All]: loopback0
Time to live [255]:
Source address or interface: loopback0
[snip]

```

XRv3 gets the first few packets along the C(*,G) tree and then performs the SPT switchover. XRv3 shows no OIL interfaces but we know the traffic is being delivered to the loopback (process switched).

```

RP/0/0/CPU0:XRv3#show pim topology 225.13.13.13 10.3.3.3 | begin 3,225
(10.3.3.3,225.13.13.13)SPT SM Up: 00:02:25
JP: Join(00:00:24) RPF: GigabitEthernet0/0/0/0.513,10.1.13.1 Flags:
KAT(00:01:05) RA
No interfaces in immediate olist

```

Looking briefly at the packet counters, we see exactly 1 100-byte packet received along the C(*,G) tree which triggered the SPT switchover. All future packets arrive along the C(S,G) tree. The size of each packet is exactly 100 bytes as expected. Seeing packets here is a sign that the test is working. For practice, we will verify the entire path though we know the signaling must be correct.

```

RP/0/0/CPU0:XRv3#show mfib route 225.13.13.13 | begin 225

  GigabitEthernet0/0/0/0.513 Flags:  A, Up:00:03:06

```

CSR1 has the proper C(S,G) state and its packet counters are incrementing along this tree. Again, only one packet traversed the C(*,G) tree. XE accounts for the layer 2 encapsulation (14 bytes Ethernet + 4 bytes dot1q) in its packet counters, where XR does not. Otherwise, we can see the packet is exactly 100 bytes as expected.

```

R1#show ip mroute 225.13.13.13 10.3.3.3 | begin \

```

```
(10.3.3.3, 225.13.13.13), 00:05:12/00:02:22, flags: T

```

A quick EPC on the link to XRv4 shows singly-labeled multicast packets entering CSR2. CSR2 removes the labels and forwards the raw IP multicast towards CSR1 as a “replication client”. The packet is 122 bytes which accounts for the 18 bytes of Ethernet/dot1q encapsulation and a single MP2MP label. The label value 2011 (0x7DB) is shown in yellow with the IP source/destination shown in green.

```
R2#show monitor capture CAP buffer detailed

0030: 03100000 00008575 FBF9ABCD ABCDABCD .....u.....
```

As the ASBR, CSR6 receives IP multicast from AS 13 and encapsulates it inside MPLS along the MP2MP tree. This uses label 94012 towards XRv4 as this traffic is being sent upstream towards the root.

```
R6#show ip mroute vrf EIGRP 225.13.13.13 10.3.3.3 | begin \((
(10.3.3.3, 225.13.13.13), 00:19:56/00:03:25, flags: T

0030:  03FA0000 00008579 8E83ABCD ABCDABCD  .....y.....
```

Like CSR2, XRv1 receives traffic from the PMSI and forwards it towards the “customer” router CSR6. The traffic is following the default MDT since data MDTs were not configured for this test. This uses the P(S,G) of (13.0.0.2, 225.0.0.3) from XRv2. The packet counters indicate 0 packets in and many packets out; this is because traffic technically arrives on a global P-multicast group and goes out on a VPN c-multicast group. Only 1 100-byte packet was seen on the shared customer tree as expected.

```

Looking at the P(S,G) for the default MDT, we see the opposite effect. Many packets come in but nothing goes out. The reason this number is much greater than the C(S,G) counters is because this accounts for all of the PIM signaling messages plus all other VPN flows.

```

XRv2 has the C(S,G) join for this group and receives packets from the CE, CSR3. Packets sent to the PMSI on the ingress PE are accounted for in the in and out directions as shown below. This is just the way XR accounts for packets; the egress PE only showed the outbound packet counter increasing.

```

Since VRF OSPF has no RP to support ASM, we will use SSM there. CSR4 will issue an MLDv2 report to receive traffic from group FF33::9 from CSR9's loopback. We verify the details of the MLDv2 join to see it is operating in INCLUDE mode with source ::10:9:9:9.

```

! CSR4
interface Loopback0
ipv6 mld join-group FF33::9 ::10:9:9:9

```

```

R4#show ipv6 mld groups ff33::9 detail
Interface: Loopback0

```

Since CSR4 is also an IPv6 multicast router, it issues the C(S,G) join towards CSR8, which is in the reverse path towards CSR9. This implies the OSPFv3 sham-link tested earlier is still operational so that traffic prefers the MPLS network over the slow backdoor link.

```
R4#show ipv6 mroute ff33::9 ::10:9:9:9 | begin \  
(::10:9:9:9, FF33::9), 00:03:00/never, flags: sLTI

Immediate Outgoing interface list:  
Loopback0, Forward, 00:03:00/never
```

CSR8 receives this C(S,G) join and sends it onward towards CSR5. At this point, it isn't exactly clear why CSR8 selected CSR5 over XRv1, so we check the BGP table to only find one route for ::10:9:9:9.

```
R8#show ipv6 mroute vrf OSPF ff33::9 ::10:9:9:9 | begin \

```

The reason for this reduced visibility within the AS is the route-reflector. XRv2 receives both paths but selects CSR5 over XRv1 due to a lower BGP RID. Only this path is advertised by the RR because add-path is not in use. This isn't specific to inter-AS MVPN but is worth noting that the unicast VPN routing influences the MVPN routing heavily.

```

CSR6 sends the C(S,G) join to CSR2 over the mLDP MP2MP tree. This uses the same MP2MP tree we traced earlier, so we know the transit path is across XRv4. CSR2 receives the C(S,G) join and sends it to CSR9, which is the CE.

```
R6#show ipv6 mroute vrf OSPF ff33::9 ::10:9:9:9 | begin \  
(::10:9:9:9, FF33::9), 00:12:26/00:03:03, flags: sT

Immediate Outgoing interface list:  
Lspvif1, Forward, 00:12:57/00:02:35
```

CSR9 is the root of the C-SPT and expects to see traffic enter from loopback0.

```
R9#show ipv6 mroute ff33::9 ::10:9:9:9 | begin \  
(::10:9:9:9, FF33::9), 00:13:58/00:02:31, flags: sT  
Incoming interface: Loopback0  
RPF nbr: FE80::21E:E5FF:FEA2:5700  
Immediate Outgoing interface list:  
GigabitEthernet2.529, Forward, 00:13:58/00:02:31
```

One benefit of SSM is that once the delivery tree is built, there is no more signaling. We don't need to trace the control path again since we know the SPT is built; there was never a C(*,G) tree or RP, implying no need for the registration or SPT switchover processes. We can originate traffic on CSR9 as shown below.

```
R9#ping ipv6  
Target IPv6 address: ff33::9  
Repeat count [5]: 100000  
Datagram size [100]:  
Timeout in seconds [2]: 1  
Extended commands? [no]: y  
Source address or interface: ::10:9:9:9  
[snip]  
Output Interface: loopback0
```

For brevity, I will verify a few key routers. The ingress PE is CSR2 and is showing packets received from the customer. These are being MPLS-encapsulated and sent towards XRv4 along the MP2MP mLDP tree. The label used is 94005 since traffic is flowing upstream.

```

```

We confirm this using EPC on CSR2. Of note, there is always an IPv6-exp-null label (value 2) as the bottom label. I assume this is used as a shim to indicate that the packet is IPv6. Since IPv4 and IPv6 would otherwise use the same (and only) MP2MP mLDP labels, this can be used to identify an MPLS packet as carrying IPv6 so the proper MFIB lookup can occur. The labels are in green; the length is 126 bytes which is 4 bytes larger than the IPv4 packets; this is a result of exp-null being imposed. This is shown in yellow.

```

R2#show monitor capture CAP buffer detail

```

To see the encapsulation on CSR8, we use EPC inbound from CSR5. This shows IPv6 multicast tunneled inside IPv4 multicast (default MDT). The GRE encapsulation is shown in yellow which specifies the IPv4 source/destination addresses. The IPv6 ethertype and first nibble of the IPv6 packet is shown in green, which shows IPv6 inside IPv4. The packet is 142 bytes long (cyan) which accounts for 14 bytes Ethernet, 4 bytes dot1q, and 24 bytes GRE.

```
R8#show monitor capture CAP buffer detail

```

Finally, we check CSR4 who is receiving the packets. This shows that IPv6 multicast can also work across option A.

```
R4#show ipv6 mroute ff33::9 ::10:9:9:9 count | begin ^Group
Group: FF33::9
Source: ::10:9:9:9,
SW Forwarding: 0/0/0/0, Other: 0/0/0
HW Forwarding: 1181/1/118/0, Other: 0/0/0
Totals - Source count: 1, Packet count: 1181
```

8.4.1.4 MPLS TE

TE with option A is not very interesting as the tunnels are confined to their own ASes. This will be a brief test to ensure the feature works with option A. This is somewhat similar to using TE with CSC since you can only move traffic between PE, P, and ASBR routers within the AS. I will build a tunnel in each AS to

demonstrate the feature. First, I build a basic TE tunnel to CSR5 that traverses XRv1 directly, which is a high-cost path the OSPF did not select. I add a bandwidth reservation as well although it is not significant. This uses a simple explicit-path; once configured, we verify the tunnel is up.

```
! XRv2
explicit-path name EP_12_11_5
  index 10 next-address strict ipv4 unicast 13.0.0.11
  index 20 next-address strict ipv4 unicast 13.0.0.5

interface tunnel-te100
  ipv4 unnumbered Loopback0
  logging events all
  signalled-bandwidth 5000
  autoroute announce
  destination 13.0.0.5
  path-option 10 explicit name EP_12_11_5
```

```
RP/0/0/CPU0:XRv2#show mpls traffic-eng tunnels brief
```

TUNNEL NAME	DESTINATION	STATUS	STATE
tunnel-te100	13.0.0.5	up	up

Displayed 1 (of 1) heads, 0 (of 0) midpoints, 0 (of 0) tails
Displayed 1 up, 0 down, 0 recovering, 0 recovered heads

Before continuing, we expect to see some multicast issues as a result of building this tunnel. With auto-route, the path to 13.0.0.5/32 is now via this tunnel which is not PIM enabled. This will break the MDT in use by AS 13.

```
RP/0/0/CPU0:XRv2#show pim rpf 13.0.0.5
Table: IPv4-Unicast-default
* 13.0.0.5/32 [110/3]
  via Null with rpf neighbor 0.0.0.0
```

We can fix this by telling IGP to keep the multicast topology intact by effectively ignoring TE tunnels as RPF interfaces. This repairs RPF and allows the GRE traffic to flow following the ordinary IGP paths. These considerations are not specific to inter-AS VPN service, but are general issues. This handy feature is only supported when the TE tunnel uses “autoroute announce”.

```
! XRv2
router ospf 13
  mpls traffic-eng multicast-intact
```

```
RP/0/0/CPU0:XRv2#show pim rpf 13.0.0.5
Table: IPv4-Multicast-default
* 13.0.0.5/32 [110/3]
  via GigabitEthernet0/0/0/0.582 with rpf neighbor 13.8.12.8
```

We verify the outgoing label, which was allocated by XRv1. This allows XRv2 to tunnel traffic towards XRv1 inside the TE LSP.

```
RP/0/0/CPU0:XRv2#show mpls traffic-eng tunnels 100 detail | include Label
    Outgoing Interface: GigabitEthernet0/0/0/0.521, Outgoing Label: 91017
```

Any traffic that normally relied on 13.0.0.5/32 as a next-hop will now use this tunnel. Specifically, this will affect VRF EIGRP traffic traversing ASes. Traffic to CSR1's loopback will be sent towards CSR5, which means the existing LDP label is no longer used.

```
RP/0/0/CPU0:XRv2#show route vrf EIGRP 10.1.1.1

 7 10.1.2.1 15 msec 9 msec 9 msec
```

Since CSR5 is preferring CSR6 due to it advertising the oldest eBGP route (verified earlier), we also build a tunnel from CSR6 to CSR2. This tunnel will route via CSR7 and CSR2, also using the high cost path not chosen by IS-IS. We verify that the tunnel comes up correctly.

```
! CSR6
ip explicit-path name EP_6_7_2 enable
  next-address 24.0.0.7
  next-address 24.0.0.2

interface Tunnel100
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 24.0.0.2
  tunnel mpls traffic-eng autoroute announce
  tunnel mpls traffic-eng path-option 10 explicit name EP_6_7_2

R6#show mpls traffic-eng tunnels tunnel 100 brief | begin TUNNEL
TUNNEL NAME                DESTINATION        UP IF      DOWN IF
STATE/PROT
R6_t100                    24.0.0.2          -          Gi2.567    up/up
```

Following the route recursion, BGP points to 24.0.0.2 as the next-hop. The RIB says this is reachable via a TE tunnel, so the RSVP label is used. The label stack becomes {7064 2012}.

```

Traffic is now tunnel across CSR7 to CSR2 in AS 24. Using TE tunnels in this way, we can influence left-to-right traffic to use high cost paths, as an example. There are no multicast concerns with mLDP in AS 24 as we never configured mLDP to use TE tunnels in the first place. If we had, LDP would need to be configured on those tunnels so mLDP can exchange labels via those paths.

```

8.4.1.5 Confederation variation

Inter-AS MPLS option A also works with BGP confederations. This might occur when one SP acquires or merges with another. In this case, sub-ASes 13 and 24 form into confederation AS 42518. The configuration is very simple on all 8 LSRs. The configurations for XE and XR are identical as well. Only the ASBRs need to enumerate the confederation peers, as the true iBGP peers just need to identify the confederation ASN.

```
! CSR2 and XRv4
router bgp 24
  bgp confederation identifier 42518
```

```
! CSR6 and CSR7
router bgp 24
  bgp confederation identifier 42518
  bgp confederation peers 13
```

```
! CSR8 and XRv2
router bgp 13
  bgp confederation identifier 42518
```

```
! CSR5 and XRv1
router bgp 13
  bgp confederation identifier 42518
  bgp confederation peers 24
```

If we make the changes quickly enough, the BGP peers may not even flap. I quickly check all 4 ASBRs for brevity to ensure the BGP sessions are operational. This will include the iBGP links to the sub-AS RRs and the intraconfederation (inter-subAS) links utilizing option A. All I do here is scan the last column for any number, indicating some prefix exchanges. Of note, to view VRF-aware BGP peers in XR that are not actually running VPNv4, you must use the specific VRF/AFI show command. This is technically more correct than the way XE does it, but takes longer to verify.

```

Since only one router, CSR10, was running BGP as the PE-CE protocol, only that one router needs its BGP configuration updated. The remote-AS is now 42518 which represents the entire confederation. Checking CSR2, we can see that it's PE-CE eBGP peer is up, as well as the iBGP peer to the RR, XRv2.

```
! CSR10
router bgp 100
 neighbor 10.8.10.8 remote-as 42518
 neighbor FD00:10:8:10::8 remote-as 42518
```

```

FD00:10:8:10::10	4	100	23	27	260	0	0	00:16:58	4

Checking the neighbor details for the IPv4 session inside VRF OSPF between CSR6 and XRv1, we see some additional information. The output says the neighbors are “under common administration”, which is displayed only when the external peer is a confed-external peer. The output is consistent across both XE and XR platforms.

```
RP/0/0/CPU0:XRv1#show bgp vrf OSPF ipv4 unicast neighbors 10.6.11.6
BGP neighbor is 10.6.11.6, vrf OSPF
 Remote AS 24, local AS 13, external link
 Remote router ID 24.0.0.6
 Neighbor under common administration
 BGP state = Established, up for 00:26:57
[snip]
```

```
R6#show bgp vpnv4 unicast vrf OSPF neighbors 10.6.11.11
```

```
BGP neighbor is 10.6.11.11, vrf OSPF, remote AS 13, external link
BGP version 4, remote router ID 13.0.0.11
Neighbor under common administration
BGP state = Established, up for 00:27:15
[snip]
```

Another benefit of using confederations with XR is that the mandatory eBGP RPL filters are no longer required. Since it is assumed that these peers are under a “common administrator”, such filtering may not be appropriate. XR also automatically sends communities to confed-external peers, following the same logic. I quickly clean up the configuration on XRv1 as a result. The filters were harmless since they passed everything, and the sending of communities was also implied, but removing these commands from the configuration is preferred as they add no value.

```
! XRv1
router bgp 13
vrf OSPF
neighbor 10.6.11.6
address-family ipv4 unicast
no route-policy RPL_PASS in
no route-policy RPL_PASS out
no send-extended-community-ebgp

neighbor fd00:10:6:11::6
address-family ipv6 unicast
no route-policy RPL_PASS in
no route-policy RPL_PASS out
no send-extended-community-ebgp

vrf EIGRP
neighbor 10.6.11.6
address-family ipv4 unicast
no route-policy RPL_PASS in
no route-policy RPL_PASS out
no send-extended-community-ebgp

neighbor fd00:10:6:11::6
address-family ipv6 unicast
no route-policy RPL_PASS in
no route-policy RPL_PASS out
no send-extended-community-ebgp
```

Checking a VPN route on CSR6, we can see that it is successfully receiving routes, along with extended communities, from XRv1 and CSR5. This proves that the RPL/community configurations removed above were indeed unnecessary. The configurations below also reveal a problem. Confed-external peers behave similar to iBGP peers with respect to next-hop adjustments. That is to say, routes exchanged intraconfederation (inter-subAS) have their next-hops left intact. Most of the time, sub-ASes will run their own IGPs, so this default behavior is often undesirable. The exception to this would be if both ASes

were in a common IGP domain and confederations were only used to minimize iBGP full mesh requirements in lieu of route-reflection.

```
R6#show bgp vpnv4 unicast vrf OSPF 110.0.0.2/32
BGP routing table entry for 24:2:110.0.0.2/32, version 293

      rx pathid: 0, tx pathid: 0
  Refresh Epoch 1
  (13) 100
    13.0.0.8 (inaccessible) (via vrf OSPF) from 10.5.6.5 (13.0.0.5)
      Origin incomplete, metric 0, localpref 100, valid, confed-external
      Extended Community: RT:24:2
      mpls labels in/out 6040/nolabel
      rx pathid: 0, tx pathid: 0
```

Within the context of VPNv4, we cannot advertise addresses like 13.0.0.8 into the VPN since these are global routes used for VPN next-hop recursion. Next-hop-self is the best option, and I configure it on all ASBRs. For brevity, I show the configuration on CSR5 and XRv1.

```
! XRv1
router bgp 13
  vrf OSPF
    neighbor 10.6.11.6
      address-family ipv4 unicast
      next-hop-self

    neighbor fd00:10:6:11::6
      address-family ipv6 unicast
      next-hop-self

  vrf EIGRP
    neighbor 10.6.11.6
      address-family ipv4 unicast
      next-hop-self

    neighbor fd00:10:6:11::6
      address-family ipv6 unicast
      next-hop-self

! CSR5
router bgp 13
```

```

address-family ipv4 vrf EIGRP
  neighbor 10.5.6.6 next-hop-self
  neighbor 10.5.7.7 next-hop-self

address-family ipv6 vrf EIGRP
  neighbor FD00:10:5:6::6 next-hop-self
  neighbor FD00:10:5:7::7 next-hop-self

address-family ipv4 vrf OSPF
  neighbor 10.5.6.6 next-hop-self
  neighbor 10.5.7.7 next-hop-self

address-family ipv6 vrf OSPF
  neighbor FD00:10:5:6::6 next-hop-self
  neighbor FD00:10:5:7::7 next-hop-self

```

At this point, the routes learned inside the transit link VRFs are now showing valid next-hop values. The network should be logically identical to option A with eBGP now. The only exception is that the AS paths now contain the sub-ASes in parenthesis to indicate that they are part of the same confederation.

```

R6#show bgp vpnv4 unicast vrf OSPF 10.4.4.4/32
BGP routing table entry for 24:2:10.4.4.4/32, version 311

      rx pathid: 0, tx pathid: 0x0

```

The existing sham-link automatically forms once there is VPN connectivity between the PEs participating in the sham-link. This is a good indication that MPLS forwarding will work for the customer traffic as well.

```
R8#show ospfv3 vrf OSPF sham-links | include ^Sham
```

```
Sham Link OSPFv3_SL0 to address FD00::2 is up
Sham Link OSPFv3_SL1 to address FD00::2 is up
```

Tracing the path from CSR4 to CSR9, we see that CSR4 has both the PE-CE and backdoor links up. The route to 10.9.9.9/32 is an intra-area route via the MPLS network, proving that the sham-link is working.

```
R4#show ospfv3 neighbor
```

```

CSR6 adds two labels to the incoming traffic from CSR5. 2015 is the VPN label allocated by CSR2 and 94009 is XRv4's label towards 24.0.0.2/32, bound by LDP. XRv4 is a P router that performs PHP to expose label 2015 to CSR2. CSR2 removes all labels and delivers the packet to CSR9 inside the OSPF VPN.

```

    Originator: 24.0.0.6, Cluster list: 24.0.0.2
    Source VRF: EIGRP, Source Route Distinguisher: 24:3
```

On the other side of the network, CSR10 shows only AS 42518 in the path. The entire confederation AS path list collapses into the confederation ID once the route is advertised to a true eBGP peer. From CSR8's perspective, the ASN of 100 is a true external AS and the prefixes from that AS are labeled as such. This is not specific to inter-AS MPLS but is the general behavior of BGP confederations.

```

```

As a quick MVPN test, we can see that the BSR information inside VRF EIGRP has traversed the network. If any of the default MDTs were broken in either AS, this would not be possible, so this cursory check implies the default MDTs are still operational from the option A configuration. Once the intraconfederation BGP next-hops are set to “self” on the ASBRs, everything “just works” when migrating from eBGP to confederations.

```
RP/0/0/CPU0:XRv3#show pim rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4

Additional Reading – Reference configurations “inter-as-mpls-a-confed”

8.4.1.6 Carrier Supporting Carrier (CSC) variation

This variation uses the original option A lab (no confederations) to demonstrate how to have an end-to-end MPLS forwarding path. Like option B, the LSPs change frequently along the path as the VPN label is swapped, but this can be used for CSC support. For example, if VRF OSPF and VRF EIGRP were renamed to CUST_CARRIER1 and CUST_CARRIER2, VPN routes could be exchanged between two core carriers that team up to provide CSC services. Since options B and C already support MPLS paths end-to-end, this is not a consideration for them as CSC support is inherent in those designs. Option AB, discussed later, has a specific CSC feature as well. Using basic IPv4 labeled-unicast can be used to enhance option A, making it a viable solution for inter-AS MPLS encapsulation between two core carriers. The configuration changes are very simple and are shown below. All we must do is enable labeled-unicast where CSC is required. In this example, VRF OSPF requires CSC (MPLS on transit link) while VRF EIGRP does not (IP on transit link, classic design). As such, there is no reason to exchange BGP labels inside the EIGRP VPN. This assumes that the configuration baseline begins with the standard eBGP option A design.

```
! XRv1
router bgp 13
  vrf OSPF
    address-family ipv4 unicast
      allocate-label all

  neighbor 10.6.11.6
    no address-family ipv4 unicast
    address-family ipv4 labeled-unicast
    route-policy RPL_PASS in
    route-policy RPL_PASS out
    send-extended-community-ebgp

! CSR6
router bgp 24

  address-family ipv4 vrf OSPF
    neighbor 10.5.6.6 send-label
    neighbor 10.5.7.7 send-label
```

```
! CSR7
router bgp 24
  address-family ipv4 vrf OSPF
    neighbor 10.5.7.5 send-label
```

Once the BGP sessions comes up, we see the usual syslog message about “mpls bgp forwarding” being configured on the transit links on XE routers. This is a good sign that BGP IPv4 labeled-unicast has been successfully negotiated.

```
! CSR5 and CSR6
%BGP_LMM-6-AUTOGEN1: The mpls bgp forwarding command has been configured on
interface: GigabitEthernet2.5562
```

We quickly verify that labeled-unicast was negotiated with all peers by checking CSR5 and CSR6 only. Since they peer with all remote ASBRs, this is faster than checking all 4 routers. Technically, XE calls this VPNv4 labeled-unicast since the labels are exchanged inside of a VPN, but the configuration is still similar to IPv4 labeled-unicast on all platforms; this is not the same as VPNv4 unicast. The capability is advertised and received on all routers, which implies bidirectionally capability negotiation.

```
R5#show bgp vpnv4 unicast vrf OSPF neighbors 10.5.6.6 | include
^BGP|vpnv4_MPLS
BGP neighbor is 10.5.6.6, vrf OSPF, remote AS 24, external link
vpnv4 MPLS Label capability: advertised and received
```

```
R5#show bgp vpnv4 unicast vrf OSPF neighbors 10.5.7.7 | include

```

```
R6#show bgp vpnv4 unicast vrf OSPF neighbors 10.6.11.11 | include
^BGP|vpnv4_MPLS
BGP neighbor is 10.6.11.11, vrf OSPF, remote AS 13, external link
vpnv4 MPLS Label capability: advertised and received
```

Although this new CSC configuration has nothing to do with the OSPF sham-links, we verify that they are up. This will allow traffic between CSR4 and CSR9 to prefer to MPLS network over the low-speed backdoor link.

```
R2#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::8 is up
```

Sham Link OSPFv3_SL1 to address FD00::8 is up

We will trace the LSP from CSR9 to CSR4 using IPv4. The focus is on the ASBRs so the intra-AS trace will be fast. CSR2's best VPN route is via CSR6 using label 6025 with a transport label of 94008.

```

XRv4 removes label 94008 to expose label 6025 to CSR6. CSR6 swaps this for label 5054, which was received from CSR5 for prefix 10.4.4.4/32 inside the OSPF VPN, and forwards traffic towards CSR5 in that same VPN. MPLS traffic essentially moves from the global table to a customer VPN, just like CSC. Although the LFIB gives us all the details we require for a trace, I show the BGP route for comparison. This is the primary difference between traditional option A and CSC-supported option A. Normally label 6205 would be removed and raw IPv4 traffic would be forwarded towards 10.5.6.5.

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94008
```

```

Of note, since the central services routes were merged with the OSPF VPN routes inside AS 13, CSC is supported towards CSR10 as well. This may not be particularly useful, especially if CSR10 actually is a “central services” router, but certain CSC architectures may require something similar.

```

```

Quickly using traceroute inside the EIGRP VPN, we can see the traffic on the transit links is still raw IP. This is by design as BGP labels were not exchanged within the EIGRP VPN. This allows option A to remain flexible on a per-customer basis, which can preserve labels on the ASBRs as CSC can be selectively enabled.

```
RP/0/0/CPU0:XRv3#traceroute 10.3.3.3 source 10.13.13.13
Type escape sequence to abort.

```

Regarding IPv6, it will remain raw IPv6 across both VPNs at this point. We did not explicitly configure IPv6 labeled-unicast inside of the OSPF VPN. Using traceroute inside the OSPF VPN proves this.

```
R4#traceroute ipv6
```

```
Target IPv6 address: ::10:9:9:9
```

```
Source address: ::10:4:4:4
```

```
[snip]
```

```

1 FD00:10:4:8::8 5 msec 4 msec 1 msec
2 FD00:10:5:6::5 [MPLS: Label 5049 Exp 0] 4 msec 5 msec 4 msec
3 FD00:10:5:6::6 23 msec 13 msec 16 msec
4 ::FFFF:24.6.7.7 [MPLS: Labels 7010/2032 Exp 0] 15 msec 24 msec 27 msec
5 FD00:10:2:9::2 [MPLS: Label 2032 Exp 0] 22 msec 22 msec 22 msec
6 FD00:10:2:9::9 23 msec 16 msec 13 msec

```

Below are snippets that would probably work if XE supported VPNv6 labeled-unicast exchange. It is not currently supported, so this configuration is for demonstration only. This is generally acceptable since the CSC endpoints would normally be IPv4 loopbacks, and the customer carrier could run 6VPE inside of the existing MPLS tunnel. XR appears to support the feature, though.

```
! XRv1 (future testing)
```

```
router bgp 13
```

```
vrf OSPF
```

```
address-family ipv6 unicast
```

```
allocate-label all
```

```
neighbor fd00:10:6:11::6
```

```
no address-family ipv6 unicast
```

```
address-family ipv6 labeled-unicast
```

```
route-policy RPL_PASS in
```

```
route-policy RPL_PASS out
```

```
send-extended-community-ebgp
```

```

! CSR6 (future testing)
router bgp 24
  address-family ipv6 vrf OSPF
    neighbor fd00:10:5:6::5 send-label
    neighbor fd00:10:6:11::11 send-label

! CSR5 (future testing)
router bgp 13
  address-family ipv6 vrf OSPF
    neighbor fd00:10:5:6::6 send-label
    neighbor fd00:10:5:7::7 send-label

! CSR7 (future testing)
router bgp 24
  address-family ipv6 vrf OSPF
    neighbor fd00:10:5:7::5 send-label

```

Applying these configurations to CSR7, as an example, generate the following error message. I suspect this will be supported in the future as IPv6 becomes common in the carrier IGP domains, along with LDPv6.

```

R7(config-router-af)#neighbor fd00:10:5:7::5 send-label
%BGP-4-BGP_LABELS_NOT_SUPPORTED: BGP neighbor FD00:10:5:7::5 does not support
sending labelsend

```

8.4.2 Option B (ASBR VPNv4/v6 eBGP)

Inter-AS Option B uses direct VPNv4/v6 sessions between ASBRs to exchange VPN routes. This means that the VPN sessions are eBGP and exist in the global table; thus, a single global transit link can be used. This greatly enhances the scalability of inter-AS VPNs over Option A as all ASBRs no longer need to define VRFs locally or configure per-customer BGP sessions. It also means that inter-AS traffic can be MPLS-encapsulated implying that technologies like TE, mLDP, and CSC can be extended across AS boundaries. In terms of configuration, the ASBRs still must run VPNv4/v6 for L3VPN, so those intra-AS BGP sessions shown in option A are still needed. I do not show the basic intra-AS VPNv4/v6 configurations again for these AFIs here. The same is true for the L2VPN AFI, except that now the two ASes must agree on the auto-discovery and signaling methods. One of the biggest downsides to option B is that the providers must agree on the exact RT policies per customer as these values are exchanged between ASes. This additional coordination, in real life, can be very burdensome and problematic. Failing to do this would require manual RT rewriting at the ASBRs which scales poorly and is considered a workaround in many cases. The common configuration for option B for all MPLS services is the transit link configuration. These configurations are incomplete in terms of MPLS TE but that is discussed later as appropriate. First we begin with the AS 13 transit links. Two of them connect to CSR6 and one of them connects to CSR7. These are basic interfaces with no new technologies; BSR-border is required so that

RP information does not leak between AS boundaries. This was not a concern in option A since the transit links were in separate VRFs.

```
! XRv1
interface GigabitEthernet0/0/0/0.561
  ipv4 address 10.6.11.11 255.255.255.0
  ipv6 address fe80::11 link-local
  ipv6 address fd00:10:6:11::11/64
  encapsulation dot1q 3561

router pim
  address-family ipv4
    interface GigabitEthernet0/0/0/0.561
      bsr-border

! CSR5
interface GigabitEthernet2.556
  encapsulation dot1Q 3556
  ip address 10.5.6.5 255.255.255.0
  ip pim bsr-border
  ip pim sparse-mode
  ipv6 address FE80::5 link-local
  ipv6 address FD00:10:5:6::5/64
  ip rsvp bandwidth 200000
  no ipv6 pim

interface GigabitEthernet2.557
  encapsulation dot1Q 3557
  ip address 10.5.7.5 255.255.255.0
  ip pim bsr-border
  ip pim sparse-mode
  ipv6 address FE80::5 link-local
  ipv6 address FD00:10:5:7::5/64
  no ipv6 pim
```

Next, the transit links in AS 24 are shown. There is nothing special here either; the configurations are for reference only.

```
! CSR6
interface GigabitEthernet2.556
  encapsulation dot1Q 3556
  ip address 10.5.6.6 255.255.255.0
  ip pim bsr-border
  ip pim sparse-mode
  ipv6 address FE80::6 link-local
  ipv6 address FD00:10:5:6::6/64
  no ipv6 pim
```

```

interface GigabitEthernet2.561
  encapsulation dot1Q 3561
  ip address 10.6.11.6 255.255.255.0
  ip pim bsr-border
  ip pim sparse-mode
  ipv6 address FE80::6 link-local
  ipv6 address FD00:10:6:11::6/64
  no ipv6 pim

! CSR7
interface GigabitEthernet2.557
  encapsulation dot1Q 3557
  ip address 10.5.7.7 255.255.255.0
  ip pim bsr-border
  ip pim sparse-mode
  ipv6 address FE80::7 link-local
  ipv6 address FD00:10:5:7::7/64
  no ipv6 pim

```

To verify that the transit links were configured correctly, we can use the same method we used for option A. Checking the PIM neighbors is a two-fold benefit: it ensures there is IP reachability between ASes and also verifies the PIM neighbors (required for multicast). I limit the verification to CSR5 and CSR6 since they have neighbors with all peer AS routers.

```

R5#show ip pim neighbor | begin ^Neighbor
Neighbor      Interface      Uptime/Expires    Ver    DR

8.4.2.1 L3VPN

With the transit links properly configured, we will verify that the VPNv4/v6 sessions are enabled between the RR and each PE/ASBR. Like option A, we still need to extend VPNv4/v6 to each PE/ASBR as the ASBRs are now exchanging these routes directly with the peer AS. We will verify XRv2 (AS 13) and

CSR2 (AS 24) to ensure the VPNv4/v6 sessions are up. As expected, no VPN routes are received from the ASBRs presently for either AFI.

```

```

After receiving VPN routes from the PE routers in each AS (and locally originated, since each RR is also a PE for at least one VPN), these are advertised to the ASBRs. This is true for all RDs. On CSR2, we see that all of the routes with RD 24:2 and RD 24:3 are advertised to CSR6 as an example.

```
R2#show bgp vpnv4 unicast all neighbors 24.0.0.6 advertised-routes | begin
Network

      Network      Next Hop      Metric LocPrf Weight Path

```

However, CSR6 does not have any of these routes. If the ASBR doesn't learn the VPN routes, there is no possible way that they can be advertised across the AS boundary. The same issue exists on all ASBRs; I show a few other ASBRs as well, along with VPNv6 AFI outputs. This isn't an AS-specific or router-specific problem at this point.

```
R6#show bgp vpnv4 unicast all  
[no output]
```

```
RP/0/0/CPU0:XRv1#show bgp vpnv6 unicast  
[no output]
```

```
R5#show bgp vpnv4 unicast all  
[no output]
```

```
R7#show bgp vpnv6 unicast all  
[no output]
```

To troubleshoot the issue, I enable BGP update debugging for VPNv4 on CSR6. We can see routes arriving from both the OSPF and EIGRP VPNs (RD 24:2 and 24:3 respectively) and both are rejected. This output means that the RTs were not imported into any local VRF on CSR6, so there is no logical reason for CSR6 to retain these prefixes. Doing so, in the majority of cases, is a waste of memory.

```
R6#debug bgp vpnv4 unicast updates in  
BGP updates debugging is on (inbound) for address family: VPNv4 Unicast
```

```

```

There are three solutions to this problem, and we will demonstrate all three. The first and most obvious solution is to configure the VRFs locally on the ASBRs. This reduces scalability and it introduces some of the limitations present in option A. While there need not be any interfaces inside of the VRF, having the VRF locally to import the RTs in question will permit BGP to retain the routes. We will configure this on CSR6; note that no RTs are exported. The VRFs are essentially importing routes just to appease BGP filtering policies.

```

! CSR6
vrf definition EIGRP
  rd 24:3
  address-family ipv4
    route-target import 24:3
  address-family ipv6
    route-target import 24:3

vrf definition OSPF
  rd 24:2
  address-family ipv4
    route-target import 24:2
  address-family ipv6
    route-target import 24:2

```

To confirm proper operation, we look at all of the VPN routes received. We now see VPN routes inside VRF EIGRP and OSPF, which is exactly what the RR saw. This is true for IPv4 and IPv6 and is a valid solution for option B. Note that, since the VRFs are configured on the ASBR, BGP is able to identify an RD to a VRF and displays the VRF name in the output below.

```

R6#show bgp vpnv4 unicast all | begin Network

```

Network	Next Hop	Metric	LocPrf	Weight	Path
Route Distinguisher: 24:2 (default for vrf OSPF)					
*>i 10.2.9.0/24	24.0.0.2	0	100	0 ?

```
*>i FD00:10:13:14::/64
::FFFF:24.0.0.14
0      100      0 ?
```

The second option is to configure the ASBR as a route-reflector. Specifically, the ASBR would identify the RR as an RR-client, which seems awkward since ASBRs have no iBGP routes to reflect. Since RRs for VPNv4/v6 are required to distribute VPN routes to all iBGP peers within the AS, they cannot be selective (unless a specific RT constraint advertise feature is enabled, which it presently is not) on which VPN routes are advertised. VPN routes from an RR-client are installed in the BGP table and the best path within each RD is advertised onward. CSR7 only has one iBGP peer, so making it an RR doesn't have any negative network effects in this particular topology. The drawback of approach is revealed when multiple RRs are present in each AS, which is very common. The ASBR will be reflecting VPN routes back towards the RRs; although the originator-ID or the cluster-ID will eventually break the advertisement loop, it is a sloppy design and wastes memory. It is, however, a valid solution for configuring option B.

```
! CSR7
router bgp 24
 address-family vpnv4
   neighbor 24.0.0.2 route-reflector-client
 address-family vpnv6
   neighbor 24.0.0.2 route-reflector-client
```

After configuring this and waiting for BGP to converge, CSR7 now has all of the VPN routes for IPv4/v6. Unlike the previous option of configuring each VRF locally, this solution scales better. The output does not list the VRF alongside the RD because CSR7 has no idea what the VRF names are; it only sees the RD. This solution is more scalable than configuring every VRF locally on the option B ASBRs.

```
R7#show bgp vpnv4 unicast all | begin Network

The third and most preferred option is to simply instruct the ASBRs to retain all VPN routes regardless of whether the RTs are imported or not. This feature is specific to option B and has little value outside of an option B ASBR. We will configure this option on CSR5 for both VPNv4/v6. The command effectively instructs the router to not automatically filter RTs that are not locally imported. The double-negative in XE syntax means that all routes are retained.

```
! CSR5
router bgp 13
 address-family vpnv4
   no bgp default route-target filter
 address-family vpnv6
   no bgp default route-target filter
```

Unlike the other solutions, this requires a soft route refresh to take effect since the configuration is local-only. AS 13 has three VRFs, but CSR5 is not aware of them. Like the second option, the VRFs are not defined locally, so CSR5 only has RD-level visibility. Compared to the other solutions, this option has no limitations in terms of scalability or loops. A general limitation of option B is that the ASBRs must always retain these VPN routes, which means they must be large routers with abundant memory. They also need to explicitly negotiate every AFI that must be supported between ASes (VPNv4, VPNv6, L2VPN, IPv4 MDT, etc). Normally these requirements were only relevant for RRs but the requirement is extended to ASBRs. This is not specific to the three options discussed and is basic option B architecture.

```
R5#clear bgp vpnv4 unicast * soft
R5#clear bgp vpnv6 unicast * soft
```

```
R5#show bgp vpnv4 unicast all | begin Network
```

We have not yet looked at IOS XR and how the same problem is solved. All three options still exist, but we will only configure the third. Configuring the VRFs locally or making XRv1 an RR is nothing new in terms of configuration, and logically, we know it will work identically as it does on XE. Instead, we configure XRv1 to retain VPN routes for VPNv4 and VPNv6. The command syntax in XR is easier than XE, removing the double negative and simply saying “retain the routes” rather than “don’t disallow the routes”. XR also introduces an RPL attach point; we can specify which routes we want to retain based on RT, or simply specify all routes. XE does not have this capability. I demonstrate both techniques below.

```

! XRv1
extcommunity-set rt RT_OSPF
  13:2
end-set

route-policy RPL_RETAIN_RT_V6
  if extcommunity rt matches-any RT_OSPF then
    drop
  else
    pass
  endif
end-policy

router bgp 13
  address-family vpnv4 unicast
    retain route-target all
  address-family vpnv6 unicast
    retain route-target route-policy RPL_RETAIN_RT_V6

```

For VPNv4, we see routes from all three RDs in the VPNv4 table. For VPNv6, we only see routes from RDs 13:1 and 13:2; this implies that XRv1 cannot be an ASBR for VRF OSPF. We cannot match the RD at this attach point, but since I matched the RT to the RD artificially, I am effectively removing all routes

from an entire VPN by filtering route targets. This can be used for traffic engineering since the OSPF VPN traffic must always traverse CSR5.

```

Now that the ASBRs have the VPN routes, we must configure eBGP VPNv4/v6 peers. This is a straightforward process and introduces no new technologies or techniques. For brevity, I only show the configurations for CSR5 and XRv1 inside AS 13.

```
! CSR5
router bgp 13
 neighbor 10.5.6.6 remote-as 24
 neighbor 10.5.7.7 remote-as 24
 address-family vpnv4
  neighbor 10.5.6.6 activate
  neighbor 10.5.7.7 activate
 address-family vpnv6
  neighbor 10.5.6.6 activate
  neighbor 10.5.7.7 activate

! XRv1
router bgp 13
 neighbor 10.6.11.6
  remote-as 24
```

```

address-family vpnv4 unicast
  route-policy RPL_PASS in
  route-policy RPL_PASS out
address-family vpnv6 unicast
  route-policy RPL_PASS in
  route-policy RPL_PASS out

```

As soon as the BGP peers come up, the XE routers will display a new syslog message on every interface that establishes a VPN eBGP peer. Below is a message from CSR5 as an example. It states that a new command was automatically configured on the transit links to support BGP-based MPLS forwarding. This is explained in more detail later.

```

! CSR5
%BGP_LMM-6-AUTOGEN1: The mpls bgp forwarding command has been configured on
interface: GigabitEthernet2.556

```

To verify it, we check the interface configuration and see this new command. We also check the MPLS interfaces to see that it has been enabled for BGP forwarding as well. When we verify the data plane, we will be relying on BGP to perform label-swaps of the VPN label between ASes, which effectively changes the LSP.

```

! CSR5
interface GigabitEthernet2.556
  encapsulation dot1Q 3556
  ip address 10.5.6.5 255.255.255.0
[snip]
mpls bgp forwarding

```

```
R5#show mpls interfaces
```

Interface	IP	Tunnel	BGP	Static	Operational
GigabitEthernet2.551	Yes (ldp)	Yes	No	No	Yes
GigabitEthernet2.558	Yes (ldp)	Yes	No	No	Yes
GigabitEthernet2.556	No	No	Yes	No	Yes
GigabitEthernet2.557	No	No	Yes	No	Yes

Before we do any data-plane verifications with BGP forwarding, we will ensure the VPNv4/v6 neighbors came up on all routers. A quick check on CSR5 and CSR6 confirms this, and we should see a number greater than zero for all inter-AS VPN peers. CSR6 does not appear to be receiving any inter-AS VPN routes, so this indicates a problem.

```

```

Debugging BGP updates for VPNv4 reveals the problem. This is the same issue we noticed when CSR6 was trying to learn intra-AS routes when it was not importing the RTs locally. Since all other ASBRs are either configured as RRs or to retain RTs, CSR6 must import AS 13's RTs for each VPN. Hopefully this illustrates why the option B ASBR solution on CSR6 is not a good choice; in addition to scaling poorly, it is difficult to maintain.

```
R6#debug bgp vpnv4 unicast updates in
```

BGP updates debugging is on (inbound) for address family: VPNv4 Unicast

```
BGP(4): 10.6.11.11 rcvd UPDATE w/ attr: nexthop 10.6.11.11, origin ?, merged
path 13, AS_PATH , extended community RT:13:2 OSPF ROUTER ID:10.4.8.8:0 OSPF
RT:0.0.0.0:2:0
```

```
BGP(4): 10.6.11.11 rcvd 13:2:10.9.9.9/32, label 91009 -- DENIED due to:
extended community not supported;
```

```
BGP(4): 10.6.11.11 rcvd UPDATE w/ attr: nexthop 10.6.11.11, origin ?, merged
path 13, AS_PATH , extended community RT:13:3 0x8800:32768:0 0x8801:3:288
0x8802:65281:2560 0x8803:1:1500 0x8806:0:167971843
```

```
BGP(4): 10.6.11.11 rcvd 13:3:10.3.3.3/32, label 91010 -- DENIED due to:
extended community not supported;
```

We quickly import these AS 13 RTs into VRFs OSPF and EIGRP for both AFIs. Then, we see the routes are accepted from the eBGP peer.

```
! CSR6
vrf definition EIGRP
  address-family ipv4
    route-target import 13:3
  address-family ipv6
    route-target import 13:3
```

```
vrf definition OSPF
  address-family ipv4
    route-target import 13:2
  address-family ipv6
    route-target import 13:2
```

```
R6#show bgp vpnv6 unicast all summary | begin ^Neighbor
```

Neighbor	V	AS	MsgRcvd	MsgSent	TblVer	InQ	OutQ	Up/Down	State/PfxRcd
10.5.6.5	4	13	97	78	950	0	0	00:22:59	5

extended community not supported;
BGP(4): 10.5.6.5 rcvd 13:1:110.0.0.2/32, label 5014 -- DENIED due to:
extended community not supported;
BGP(4): 10.5.6.5 rcvd 13:1:110.0.0.3/32, label 5015 -- DENIED due to:
extended community not supported;
```

Even worse, CSR6 now has to worry about the central services VPN. We can configure the central service VPN locally so that it can import those RTs, which is highly undesirable. The best way to salvage this situation is to import RT:13:1 into VRFs OSPF and EIGRP rather than create a new VRF. Now, we can see that CSR6 is importing all of the routes from AS 13. Clearly this approach is undesirable but might be the only option if the (low-end) ASBR does not support RT retention or RR capabilities.

```
! CSR6
vrf definition EIGRP
  address-family ipv4
    route-target import 13:1
  address-family ipv6
    route-target import 13:1
```

```
vrf definition OSPF
  address-family ipv4
    route-target import 13:1
  address-family ipv6
    route-target import 13:1
```

```

24.0.0.2       4      24    8623    8480     979    0    0 21:37:28      8
```

Upon receiving the VPN routes, the ASBRs ultimately need to advertise the routes to the remote PEs where the customers attach. In both ASes, this is done via the RRs. I select a VPN route and check the RR in AS 24 for its presence; we are immediately presented with next-hop reachability problems.

```
R2#show bgp vpnv4 unicast rd 13:1 110.0.0.0/32
BGP routing table entry for 13:1:110.0.0.0/32, version 0
Paths: (2 available, no best path)
  Not advertised to any peer
  Refresh Epoch 3
  13 100, (Received from a RR-client)
```

```

10.5.6.5 (inaccessible) (via default) from 24.0.0.6 (24.0.0.6)

  Extended Community: RT:13:1
  mpls labels in/out nolabel/5021
  rx pathid: 0, tx pathid: 0

```

This is the classic iBGP behavior of not modifying the next-hop of any BGP routes by default. The transit links were never advertised into IGP and the BGP routers never used “next-hop-self” towards the RR. Either solution is valid for option B but the LSPs change slightly depending on which option we use. Inside AS 24, I will advertise the transit links into IGP. CSR6 uses IS-IS passive interfaces and CSR7 uses redistribution for variety.

```

! CSR6
router isis 24
  passive-interface GigabitEthernet2.556
  passive-interface GigabitEthernet2.561

! CSR7
ip prefix-list PL_R5R7 seq 5 permit 10.5.7.0/24

route-map RM_CONN_TO_ISIS permit 10
  match ip address prefix-list PL_R5R7

router isis 24
  redistribute connected route-map RM_CONN_TO_ISIS

```

To confirm the IS-IS advertisement was successful, I check the LSP details. This is done locally on each ASBR.

```

```

Now CSR2 has valid routes for remote VPN destinations. CSR2 selects the route via CSR6 as best due to having a lower BGP RID and advertises it only XRv4. It would also be used for redistribution into EIGRP/OSPF since this is a central services route. Because CSR6 and CSR7 did not adjust the VPN next-hop, the VPN label of 5021 remains unchanged as allocated by CSR5.

```

R2#show bgp vpnv4 unicast rd 13:1 110.0.0.0/32

```

When we check XRv4 for this central services route, it has nothing from RD 13:1. This is because it is not importing RT:13:1, which is an AS 13 route target. This is one of the option B limitations; the providers must agree on the RT policies.

```

RP/0/0/CPU0:XRv4#show bgp vpnv4 unicast rd 13:1
[no output]

```

If we expect the AS 24 VPN customers to have reachability to the AS 13 VPN customers, AS 24 must import the RTs exported by AS 13. On XRv4, this means importing RT:13:3 for EIGRP VPN reachability as well as RT:13:1 for central services reachability. Once we import these AS 13 route targets, we quickly check XRv4 to ensure it imports the EIGRP VPN and central services routes from AS 13.

```

! XRv4
vrf EIGRP
  address-family ipv4 unicast
    import route-target
      13:1
      13:3

  address-family ipv6 unicast

*>i10.3.12.0/24	10.5.6.5	0	100	0	13 ?

We must do the same thing on CSR2 for both the EIGRP and OSPF VPNs. Don't be fooled; just because CSR2 is an RR and retains all VPN routes, this does not automatically mean the customer VPNs on the RR have reachability. The output below proves it as CSR2 is preferring CSR1 (CE) as the next-hop towards the remote EIGRP VPN. If CSR2 actually had a BGP route in its VRF for this, the BGP-learned route would be preferred (this one is BGP originated).

```
R2#show bgp vpnv4 unicast vrf EIGRP 10.3.3.3/32
```

```

```
      mpls labels in/out 2072/nolabel
```

```
      rx pathid: 0, tx pathid: 0x0
```

Below are the updated RT policies on CSR2 needed to enable inter-AS reachability. Both EIGRP and OSPF VPNs import the central services RT of 13:1, along with their specific VPN RTs per VPN. Notice that the OSPF VPN no longer needs to import RT:24:2 as CSR2 is the only router exporting it. For cleanup, we remote this from the RT policy, although leaving it there has no operational effect.

```
! CSR2
vrf definition EIGRP
  address-family ipv4
    route-target import 13:3
    route-target import 13:1
  address-family ipv6
    route-target import 13:3
    route-target import 13:1

vrf definition OSPF
  address-family ipv4
    route-target import 13:2
    route-target import 13:1
    no route-target import 24:2
  address-family ipv6
    route-target import 13:2
    route-target import 13:1
    no route-target import 24:2
```

Using the same example as above, we can now see the VPN routes pointing in the right direction.

```
R2#show bgp vpnv4 unicast vrf EIGRP 10.3.3.3/32

    Connector Attribute: count=1
      type 1 len 12 value 13:3:13.0.0.12
    mpls labels in/out nolabel/5020
    rx pathid: 0, tx pathid: 0x0
```

We quickly check the EIGRP VPN to see the routes being populated for IPv4 and IPv6. We will do more detailed verification once AS 13 has been properly configured. The EIGRP extended communities that allow the VPN routes to appear internal are transitive as seen earlier in option A tests. The route to CSR3

is an internal route, but the central services routes as external as these are BGP originated. This is true for IPv4 and IPv6 and is the expected result.

```
R1#show ip route eigrp | begin Gate
Gateway of last resort is not set
```

```
10.0.0.0/8 is variably subnetted, 9 subnets, 2 masks

```

Shifting our attention to AS 13's RR, we expect to see next-hop inaccessibility for the VPN routes on XRv2. In AS 24, we corrected this by advertising the transit links into IGP.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 24:2 10.9.9.9 | begin 24,
24, (Received from a RR-client)
10.5.6.6 (inaccessible) from 13.0.0.5 (13.0.0.5)
Received Label 6036
Origin incomplete, metric 0, localpref 100, valid, internal, not-in-vrf
Received Path ID 0, Local Path ID 0, version 0

Extended community: OSPF router-id:10.2.9.2 OSPF route-type:0:2:0x0
RT:24:2
```

The AS 24 approach is less desirable than “next-hop-self”, at least in this context, as we will discover later when it comes to MPLS forwarding limitations on certain platforms. AS 13 will use the simpler “next-hop-self” approach on XRv1 and CSR5.

```
! CSR5
router bgp 13
 address-family vpnv4
   neighbor 13.0.0.12 next-hop-self
 address-family vpnv6
   neighbor 13.0.0.12 next-hop-self
```

```
! XRv1
router bgp 13
 neighbor 13.0.0.12
 address-family vpnv4 unicast
   next-hop-self
 address-family vpnv6 unicast
   next-hop-self
```

Checking XRv2, we can now see that the VPN routes are reachable. Because CSR5 and XRv1 changed the VPN next-hops, they also allocated new local labels.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 24:2 10.9.9.9 | begin 24,
24, (Received from a RR-client)
 13.0.0.5 (metric 3) from 13.0.0.5 (13.0.0.5)
   Received Label 5037
   Origin incomplete, metric 0, localpref 100, valid, internal, best,
group-best, import-candidate, not-in-vrf
   Received Path ID 0, Local Path ID 1, version 334
   Extended community: OSPF router-id:10.2.9.2 OSPF route-type:0:2:0x0
RT:24:2
  Path #2: Received by speaker 0
  Not advertised to any peer
 24, (Received from a RR-client)
 13.0.0.11 (metric 3) from 13.0.0.11 (13.0.0.11)
   Received Label 91021
   Origin incomplete, localpref 100, valid, internal, import-candidate,
not-in-vrf
   Received Path ID 0, Local Path ID 0, version 0
   Extended community: OSPF router-id:10.2.9.2 OSPF route-type:0:2:0x0
RT:24:2
```

We will also run into the same inter-AS RT issue observed in AS 24. CSR8, for example, is a PE for the OSPF VPN. Looking at the BGP table, we do see a route, but upon further inspection we see that it was locally originated. This is because of the inter-AS OSPF backdoor; the route was learned from CSR4 and redistributed into BGP, which is not ideal. There are many ways to see this: the next-hop is CSR4, the MED is 501 (backdoor plus transit link), the route is sourced, the weight is 32,768, and the MPLS label is a local label (should be an outbound label from the ASBR). The route was not iBGP learned as it is not marked with “internal” as we would expect.

```
R8#show bgp vpnv4 unicast vrf OSPF 10.9.9.9/32
BGP routing table entry for 13:2:10.9.9.9/32, version 125
Paths: (1 available, best #1, table OSPF)
  Advertised to update-groups:
    2
  Refresh Epoch 1
  Local
    10.4.8.4 (via vrf OSPF) from 0.0.0.0 (13.0.0.8)
      Origin incomplete, metric 501, localpref 100, weight 32768, valid,
sourced, best
      Extended Community: RT:13:2 OSPF ROUTER ID:10.4.8.8:0
        OSPF RT:0.0.0.0:2:0
        mpls labels in/out 8009/nolabel
      rx pathid: 0, tx pathid: 0x0
```

Below are the VRF RT updates on CSR8. For the shared services VPN, we must import the AS 24 routes for both EIGRP and OSPF VPNs. For the OSPF VPN, there is no need to import RT:13:2 since CSR8 is the only router exporting this RT now. Instead, we must import RT:24:2 which was exported by CSR2. This is the same cleanup we performed on CSR2. The RT policies become more complex when they are coordinated across AS boundaries.

```
! CSR8
vrf definition BGP
  address-family ipv4
    route-target import 24:2
    route-target import 24:3
  address-family ipv6
    route-target import 24:2
    route-target import 24:3

vrf definition OSPF
  address-family ipv4
    no route-target import 13:2
    route-target import 24:2
  address-family ipv6
    no route-target import 13:2
    route-target import 24:2
```

BGP shows the iBGP route now learned in the VPN table for OSPF, but there is a routing issue. We will resolve this later, but for now, we can see the proper path was imported across AS boundaries. The iBGP route is not preferred over the backdoor-originated route due to the weight attribute.

```
R8#show bgp vpnv4 unicast vrf OSPF 10.9.9.9/32
BGP routing table entry for 13:2:10.9.9.9/32, version 125
Paths: (2 available, best #2, table OSPF)
  Advertised to update-groups:
    2
  Refresh Epoch 1
    24, imported path from 24:2:10.9.9.9/32 (global)
      13.0.0.5 (metric 2) (via default) from 13.0.0.12 (13.0.0.12)
        Origin incomplete, metric 0, localpref 100, valid, internal
        Extended Community: RT:24:2 OSPF ROUTER ID:10.2.9.2:0
          OSPF RT:0.0.0.0:2:0
          Originator: 13.0.0.5, Cluster list: 13.0.0.12
          mpls labels in/out 8009/5037
          rx pathid: 0, tx pathid: 0
    Refresh Epoch 1
  Local
    10.4.8.4 (via vrf OSPF) from 0.0.0.0 (13.0.0.8)
      Origin incomplete, metric 501, localpref 100, weight 32768, valid,
sourced, best
      Extended Community: RT:13:2 OSPF ROUTER ID:10.4.8.8:0
        OSPF RT:0.0.0.0:2:0
        mpls labels in/out 8009/nolabel
        rx pathid: 0, tx pathid: 0x0
```

XRv2 is a PE servicing the EIGRP VPN and it must import RT:24:3 and stop importing RT:13:3 as a result of the new architecture.

```
! XRv2
vrf EIGRP
  address-family ipv4 unicast
    import route-target
    no 13:3
    24:3

  address-family ipv6 unicast
    import route-target
    no 13:3
    24:3
```

At this point, we will manually trace the path from CSR3 to XRv3 before sending any traffic. We just configured XRv2 to import the EIGRP VPN routes, so CSR3 should have an EIGRP internal route to XRv3's loopback.

```

R3#show ip route 10.13.13.13
Routing entry for 10.13.13.13/32
  Known via "eigrp 3", distance 90, metric 15880, type internal

  Remote bindings: (2 peers)
    Peer          Label
    -----
    13.0.0.8:0    8002

```

CSR8 performs PHP to expose label 5032 to CSR5.

```
R8#show mpls forwarding-table labels 8002
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
8002	Pop Label	13.0.0.5/32	1390704	Gi2.558	13.5.8.5

CSR5 receives label 5032 and performs a label swap to 6030. Notice that the prefix shows the full 96-bit VPN prefix including the RD. This is BGP VPNv4 influencing a label swap, which is something we have not seen yet.

```
R5#show mpls forwarding-table labels 5032
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
5032	6030	24:3:10.13.13.13/32	\		
			0	Gi2.556	10.5.6.6

CSR5 learned two eBGP VPNv4 paths to 10.13.13.13/32 within RD 24:3. CSR6 is preferred as it is the older eBGP route, so CSR6's label is used as the outgoing label.

```

No additional transport label is needed because the route to the next-hop is connected. Oddly, the route is a /32; this is the result of the "mpls bgp forwarding" command that was automatically added to the configuration when the eBGP VPN neighbor came up. The logic is that routers must have a /32 route to the BGP next-hop. Some IOS platforms/versions will still forward traffic when VPN next-hops are not host routes, but XR never will. This is revealed later.

```

XRv4 receives packets labeled 94006, removes all labels, and forwards the traffic to the customer. The LSP appears to be operational.

```
RP/0/0/CPU0:XRv4#show mpls forwarding vrf EIGRP prefix 10.13.13.13/32
```

Local	Outgoing	Prefix	Outgoing	Next Hop	Bytes

Label	Label	or ID	Interface	Switched
94006	Unlabelled	10.13.13.13/32 [V]	Gi0/0/0/0.534	10.13.14.13
				5882

A quick ping test shows that bidirectional connectivity does not exist. Debugging on XRv3 reveals that traffic is at least working in one direction, which is the LSP we just verified. XRv3 receives the echo request and sends a reply back to 10.3.3.3, but the reply is not making it back.

```
R3#ping 10.13.13.13 so 10.3.3.3
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.13.13.13, timeout is 2 seconds:
Packet sent with a source address of 10.3.3.3
.....
Success rate is 0 percent (0/5)
```

```
RP/0/0/CPU0:XRv3#debug icmp ipv4
ipv4_io[264]: IPv4 ICMP: GigabitEthernet0/0/0/0.534: Received echo request
from 10.3.3.3
ipv4_io[264]: IPv4 ICMP: GigabitEthernet0/0/0/0.534: Sending echo reply to
10.3.3.3
```

We will trace the LSP from XRv3 to CSR3, which could potentially follow a very different path. XRv3 has an EIGRP internal route to CSR3 as expected. The next-hop is via XRv4, which is the ingress LSR. Since the routes have been exchanged end-to-end, it is likely a data-plane issue.

```
RP/0/0/CPU0:XRv3#show route 10.3.3.3

      Route metric is 16000
  No advertising protos.
```

XRv4 has a VPN route for 10.3.3.3/32 which is via 10.5.6.5 using label 5020, which was allocated by CSR5. CSR5 is the remote ASBR, not the local one; since CSR6 did not change the VPN next-hop, it did not allocate a new label for this prefix. This makes sense as this behavior is observed in intra-AS VPNs all the time. It only makes sense for BGP to allocate a label for a prefix, and perform a label swap, if the BGP next-hop changes.

```
RP/0/0/CPU0:XRv4#show bgp vpnv4 unicast vrf EIGRP 10.3.3.3/32 | begin 13$

```

When we perform a route lookup for 10.5.6.5, we find a matching /24. However, there are no labels allocated for this prefix. This is because all of the routers, due to my personal configuration habits, are only allocating labels for host routes.

```

RP/0/0/CPU0:XRv4#show route 10.5.6.5

```

```

RP/0/0/CPU0:XRv4#show mpls ldp bindings 10.5.6.0/24
[no output]

```

We can see the error in the FIB as well. Only a single label is imposed and the FIB marks this as an “unresolved” entry. There is no possible way XRv4 will be able to forward traffic along this LSP.

```

RP/0/0/CPU0:XRv4#show cef vrf EIGRP 10.3.3.3
10.3.3.3/32, version 8379, internal 0x5000001 0x0 (ptr 0xa142d974) [1], 0x0

  next hop VRF - 'default', table - 0xe0000000
  unresolved
  labels imposed {5020}

```

I quickly disable the host-route label filters on all AS 24 routers. I could have been more elegant and used a prefix-list, but for brevity I simply allocate labels for all prefixes. The configuration removal is not shown, but instead I show that a valid LDP label has been bound to prefix 10.5.6.0/24 by all LDP peers. Since CSR6 is connected, it allocated implicit null, but the other routers allocate non-null labels as they are IGP-learned.

```

RP/0/0/CPU0:XRv4#show mpls ldp bindings 10.5.6.0/24
10.5.6.0/24, rev 38
  Local binding: label: 94003

    Peer          Label

```

-----	-----
24.0.0.2:0	2100
24.0.0.6:0	ImpNull
24.0.0.7:0	7082

Despite the label resolution, the FIB remains dysfunctional. The single label stack is correct but CEF is still unable to forward packets. At this point, one would never know how to solve this problem without referencing Cisco's documentation on IOS XR. It clearly states that there must be a /32 route to the BGP next-hop for VPN routes. This is true whether the BGP route is iBGP or eBGP learned. The output hints at this issue since XRv4 claims it is trying to perform "recursion-via-/32" but the longest-match route to 10.5.6.5 is a /24.

```
RP/0/0/CPU0:XRv4#show cef vrf EIGRP 10.3.3.3
10.3.3.3/32, version 8379, internal 0x5000001 0x0 (ptr 0xa142d974) [1], 0x0
(0x0), 0x208 (0xa156d488)
Prefix Len 32, traffic index 0, precedence n/a, priority 3

path-idx 0 NHID 0x0 [0xa0f67254 0x0]
recursion-via-/32
next hop VRF - 'default', table - 0xe0000000
unresolved
labels imposed {5020}
```

Solving this problem is a bit awkward. Next-hop-self would be the most obvious solution, but we already used that successfully in AS 13. Recall that XE routers have installed a connected /32 on their transit links for which there is an eBGP VPN peer. Both CSR6 and CSR7 have these peer host routes (somewhat similar to the result of PPP neighbor routes) on each transit link.

```
R6#show ip route connected | include ^C.*/32
C      10.5.6.5/32 is directly connected, GigabitEthernet2.556
C      10.6.11.11/32 is directly connected, GigabitEthernet2.561
C      24.0.0.6/32 is directly connected, Loopback0

R7#show ip route connected | include ^C.*/32
C      10.5.7.5/32 is directly connected, GigabitEthernet2.557
C      24.0.0.7/32 is directly connected, Loopback0
```

Rather than advertise the transit /24, CSR6 and CSR7 could advertise the peer /32 instead. This would satisfy the requirement that the BGP next-hop is a host route. On CSR6, this means removing the passive-interface configuration and adding new route-maps/prefix-lists for redistribution. On CSR7, it means simply adjusting the existing prefix-list. The other benefit is that we can re-add our label filter to only allocate labels for host routes (which is a good practice). The configuration for the label filtering is not shown, but it is enabled again.

! CSR6

```

ip prefix-list PL_R5R6 seq 5 permit 10.5.6.5/32
ip prefix-list PL_R6XRv1 seq 5 permit 10.6.11.11/32

route-map RM_CONN_TO_ISIS permit 10
  match ip address prefix-list PL_R6XRv1

route-map RM_CONN_TO_ISIS permit 20
  match ip address prefix-list PL_R5R6

router isis 24
  no passive-interface GigabitEthernet2.556
  no passive-interface GigabitEthernet2.561
  redistribute connected route-map RM_CONN_TO_ISIS

! CSR7
no ip prefix-list PL_R5R7 seq 5 permit 10.5.7.0/24
ip prefix-list PL_R5R7 seq 5 permit 10.5.7.5/32

```

We can verify this by checking the IS-IS LSPs as we did before to ensure the host routes are being advertised properly. Now, they have a length of 32 which satisfies XR's forwarding constraints.

```

```

Interestingly, the label stack changes. Despite this being a “connected” route on CSR6, it is not a “local” route. As such, CSR6 cannot allocate a null-label for it. Recall that XRv4's VPN label for 10.3.3.3/32 was allocated by CSR5; we cannot expose this to CSR6 or else traffic will be dropped. CSR6 is not performing a swap of the VPN label since it did not change the BGP next-hop, so the top-most label allows CSR6 to pass the VPN label to CSR5 intact. If a null-label were allocated for this preferred, CSR6 would be indicating that it wants to see the next label in the stack, which would break the LSP.

```
RP/0/0/CPU0:XRv4#show mpls ldp bindings 10.5.6.5/32
10.5.6.5/32, rev 50
```

```
Local binding: label: 94018
```

```

```

Peer	Label
24.0.0.2:0	2103
24.0.0.6:0	6035
24.0.0.7:0	7087

Most importantly, XRv4's FIB entry for this VPN route is now fully operable. We see two labels in the stack and a valid next-hop. The entry is no longer flagged as "unresolved". XRv4 now passes traffic to CSR6 using label stack {6035 5020}.

```
RP/0/0/CPU0:XRv4#show cef vrf EIGRP 10.3.3.3
10.3.3.3/32, version 8533, internal 0x5000001 0x0 (ptr 0xa142ef74) [1], 0x0

```

The LSP is now operational. Using traceroute from CSR3, we confirm the label stack we verified first. Technically, this is considered 3 separate LSPs since the VPN label changes 3 times. The first LSP connects XRv2 and CSR5, the second connects CSR5 and CSR6 between ASes, and the third connects CSR6 to XRv4. The three VPN labels are highlighted; these are BGP-swap actions.

```

R3#traceroute 10.13.13.13 source 10.3.3.3
Type escape sequence to abort.

```

The return path consists of only two LSPs since the BGP label was swapped once, not twice. Since CSR6, as the egress ASBR, did not change the BGP next-hop, it does not swap the VPN label. Thus, the two LSPs connect XRv4 to CSR5, and CSR5 to XRv2. Notwithstanding MPLS-TR, all LSPs are unidirectional and can be non-congruent. This means each AS can treat the eBGP next-hops according to local policies, provided reachability is maintained.

```

```

Despite this pair of LSPs being functional, there is still an issue lurking in the network. To demonstrate it, we will use VPNv6 prefixes exchanged between ASes. Currently, XRv2 prefers CSR5 over XRv1 as the egress ASBR towards ::10:3:3:3/128 since it has a lower BGP RID.

```

RP/0/0/CPU0:XRv2#show bgp vpnv6 unicast rd 24:3 ::10:13:13:13/128 | begin 24,
24, (Received from a RR-client)
 13.0.0.5 (metric 3) from 13.0.0.5 (13.0.0.5)
    Received Label 5024
    Origin incomplete, metric 0, localpref 100, valid, internal, best,
group-best, import-candidate, not-in-vrf
    Received Path ID 0, Local Path ID 1, version 339
    Extended community: EIGRP route-info:0x8000:0 EIGRP AD:3:282 EIGRP
RHB:255:1:2560 EIGRP LM:0x0:1:1500 EIGRP VRR:0x0:13.13.13.10 RT:24:3
    Path #2: Received by speaker 0
    Not advertised to any peer
24, (Received from a RR-client)
 13.0.0.11 (metric 3) from 13.0.0.11 (13.0.0.11)
    Received Label 91035

```

```

    Origin incomplete, localpref 100, valid, internal, import-candidate,
not-in-vrf
    Received Path ID 0, Local Path ID 0, version 0
    Extended community: EIGRP route-info:0x8000:0 EIGRP AD:3:282 EIGRP
RHB:255:1:2560 EIGRP LM:0x0:1:1500 EIGRP VRR:0x0:13.13.13.10 RT:24:3

```

We can adjust this in many ways. I will use inbound local-preference on XRv1 to increase its preference as an egress ASBR for that VPNv6 prefix only. I use a parameterized RPL in case I need to reuse it later.

```

! XRv1
prefix-set PS_XRV3_V6
::10:13:13:13/128
end-set

route-policy RPL_SET_LOCAL_PREF($PS, $LPREF)
  if destination in $PS then
    set local-preference $LPREF
  else
    pass
  endif
end-policy

router bgp 13
neighbor 10.6.11.6
address-family vpnv6 unicast
  route-policy RPL_SET_LOCAL_PREF(PS_XRV3_V6, 200) in

```

Now, the RR only sees one route because CSR5 has accepted this local-preference 200 prefix as best. Since XRv2 is also the PE, it cares about the received label which is 91035. This is the first label added to the stack.

```

RP/0/0/CPU0:XRv2#show bgp vpnv6 unicast rd 24:3 ::10:13:13:13/128 | begin 24,
24, (Received from a RR-client)
13.0.0.11 (metric 3) from 13.0.0.11 (13.0.0.11)
  Received Label 91035
    Origin incomplete, localpref 200, valid, internal, best, group-best,
import-candidate, not-in-vrf
    Received Path ID 0, Local Path ID 1, version 375
    Extended community: EIGRP route-info:0x8000:0 EIGRP AD:3:282 EIGRP
RHB:255:1:2560 EIGRP LM:0x0:1:1500 EIGRP VRR:0x0:13.13.13.10 RT:24:3

```

A transport label is also added since XRv2 routes via CSr8 to reach XRv1. The route is IGP-learned so CSR8's LDP label of 8001 is pushed atop the stack. The label stack is now {8001 91035}.

```

RP/0/0/CPU0:XRv2#show route 13.0.0.11

13.8.12.8, from 13.0.0.11, via GigabitEthernet0/0/0/0.582

Route metric is 3

No advertising protos.

```
RP/0/0/CPU0:XRv2#show mpls ldp bindings 13.0.0.11/32 neighbor 13.0.0.8
13.0.0.11/32, rev 14
```

Local binding: label: 92006

Remote bindings: (2 peers)

Peer	Label
13.0.0.8:0	8001

CSR8 is an ordinary P-router and performs PHP to expose label 91035 to XRv1.

```
R8#show mpls forwarding-table labels 8001
```

Local	Outgoing	Prefix	Bytes	Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched		interface	
8001	Pop Label	13.0.0.11/32	1667433		Gi2.581	13.8.11.11

XRv1's LFIB has a seemingly valid entry for this VPN prefix with a next-hop of 10.5.6.5. We see 0 bytes being label switched, which is an indication of a potential issue. The FIB does not mark the entry as unresolved; in fact, it shows as a /32 local adjacency since IPv4 ARP resolution occurred for this IP address. The problem with the FIB entry is that it makes no mention of MPLS labels or MPLS forwarding.

```
RP/0/0/CPU0:Xshow mpls forwarding labels 91035
```

Local	Outgoing	Prefix	Outgoing	Next Hop	Bytes
Label	Label	or ID	Interface		Switched
91035	6014	24:3:::10:13:13:13/128	\	10.6.11.6	0

```
RP/0/0/CPU0:XRv1#show cef 10.6.11.6
```

10.6.11.6/32, version 0, internal 0x1020001 0x0 (ptr 0xa14487f4) [1], 0x0 (0xa1413ab8), 0x0 (0x0)

local adjacency 10.6.11.6

Prefix Len 32, traffic index 0, Adjacency-prefix, precedence n/a, priority 15

via 10.6.11.6, GigabitEthernet0/0/0/0.561, 3 dependencies, weight 0, class 0 [flags 0x0]

path-idx 0 NHID 0x0 [0xa10853a0 0x0]

next hop 10.6.11.6

local adjacency

However, the FIB has derived this /32 based on ARP, not based on the RIB. The RIB only shows a /24 for this prefix. Again, there is not a good way to troubleshoot this other than to know that XR requires a /32 route to the BGP next-hop, period.

```
RP/0/0/CPU0:XRv1#show route 10.6.11.6
Routing entry for 10.6.11.0/24
  Known via "connected", distance 0, metric 0 (connected)
  Routing Descriptor Blocks
    directly connected, via GigabitEthernet0/0/0/0.561
      Route metric is 0
  No advertising protos.
```

To repair this, we can configure a static /32 to the BGP peer. There is no rule that says the host route must be appear as “connected” in the RIB, but it must exist. Since this is a host-route, specifying a next-hop makes no sense, so we specify the outgoing interface. A “static” route will meet XR’s forwarding requirement.

```
! XRv1
router static
  address-family ipv4 unicast
    10.6.11.6/32 GigabitEthernet0/0/0/0.561
```

Despite us fixing the problem, XR gives us a warning message about using this technique. When the prefix length is shorter than /32, this will cause the router proxy-ARP for all destinations matching that network, so the log message is well-founded and sensible. It is interesting to see it displayed when it is actually fixing an XR limitation in the first place.

```
! XRv11
ipv4_static[1040]: %ROUTING-IP_STATIC-4-CONFIG_NEXTHOP_ETHER_INTERFACE :
Route for 10.6.11.6 is configured via ethernet interface without nexthop,
Please check if this is intended
```

Now, the RIB has a /32 and the FIB reports some MPLS label activity. This is indicative of a working system. Also notice that because this is a host route, LDP allocates a label for it. The label is useless since XRv1 changes the BGP next-hop, but if it didn’t, we could also use the redistribution technique used in AS 24 provided an LDP label was allocated for the transit link (and it is).

```
RP/0/0/CPU0:XRv1#show route 10.6.11.6
Routing entry for 10.6.11.6/32
  Known via "static", distance 1, metric 0 (connected)

    path-idx 0 NHID 0x0 [0xa10853a0 0xa10854f0]
    local adjacency
      local label 91009      labels imposed {ImplNull}

```

Without tracing the entire LSP, we perform a ping test from XRv3. After this is done, we can see 520 bytes of traffic matching this LFIB entry which we didn't see initially. This accounts for 5 104-byte packets, which includes the VPN label for inter-AS operations.

```

RP/0/0/CPU0:XRv3#ping ::10:3:3:3 source ::10:13:13:13
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to ::10:3:3:3, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 19/29/69 ms

```

```

RP/0/0/CPU0:XRv1#show mpls forwarding labels 91035

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91035	6014	24:3::10:13:13:13/128	Gi0/0/0/0.561	10.6.11.6	520

Now that the entire transport network has been correctly configured, we will establish the inter-AS sham-link using option B. The configuration is identical to that used in option A since the sham-link endpoints have not changed; VPNv4/v6 eBGP peers are already exchanged extended communities as well. We also know that the OSPF special communities are transitive so building the sham-links should be no issue. In fact, with the network properly verified, the sham-links just “come up”.

```

R8#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::2 is up
Sham Link OSPFv3_SL1 to address FD00::2 is up

```

Checking CSR8, we can see the local and remote sham-link endpoints inside of VRF OSPF as expected. Once these two addresses can exchange targeted OSPF hellos, the sham-link can form.

```

R8#show bgp vpnv6 unicast vrf OSPF | include FD00::
*>i FD00::2/128      ::FFFF:13.0.0.5      0      100      0 24 i
*>  FD00::8/128      ::                    0      32768 i

```

To show the transitivity of the OSPF extended communities, we check CSR5 for the route to CSR9's loopback. From both CSR6 and CSR7, it learns the route with the communities intact, which allows OSPF to treat the MPLS network as an area 0 link.

```

R5#show bgp vpnv6 unicast rd 24:2 ::10:9:9:9/128 | begin 24$
[snip]

  rx pathid: 0, tx pathid: 0x0

```

To test its operation, I perform a quick traceroute from CSR4 to CSR9 and CSR9 to CSR10. The first output shows the OSPF-to-OSPF communication over MPLS, which is preferred over the backdoor. Notice that 3 separate LSPs (3 VPN labels) are required since the AS 13 ASBRs use iBGP next-hop-self. The second shows OSPF-to-central-services over the inter-AS boundary, which is the result out of RT policy. Only 2 LSPs (2 VPN labels) are required since AS 24 ASBRs redistribute the BGP next-hops into IGP.

```

```

One final note about this design is that there is no exchange of IGP networks between ASes. Similar to option A, only VPN routes are exchanged. Even though the VPNv4/v6 peers exist in the global table, the IGP routes are not leaked. This keeps network integrity between the ASes and is an added benefit of option B.

8.4.2.2 L2VPN

L2VPN service over option B is very complex. Unlike option A, we cannot simply terminate the L2VPN on the ASBRs and pipe the frames across a transit link. The expectation is that traffic is label-switched for the entire path. Unlike option C (discussed later), we cannot directly peer the PEs since IGP routes are not leaked across AS boundaries. The solution involves multi-segment PWs (MSPW). This topic is covered in detail in a dedicated section, but the idea is to create many PWs that are stitched together. Similar to having or 2 or 3 different VPN labels for option B L3VPN, this design requires 3 stitched PWs for inter-AS over option B. Statically configuring these PWs is shown in the dedicated section elsewhere in this book; for variety, this test will use BGP auto-discovery between AS boundaries. Before we configure any VPLS instances, we need to build the BGP infrastructure. There are additional limitations on L2VPN: specifically, we must use BGP next-hop-self and we must retain all routes on the ASBR. The alternatives demonstrated in L3VPN, such as RR configuration and local VRF configuration, are not applicable here. Technically, the RR approach could work but Cisco does not recommend it. CSR2 and CSR6 peer directly in AS 24 while XRv2 is used as an RR in AS 13. On CSR5 and CSR6 are L2VPN-capable ASBRs; this is a limitation of the feature as only one inter-AS link can exist. We also must configure an eBGP L2VPN VPLS session between CSR5 and CSR6.

```
! CSR2
router bgp 24
  address-family l2vpn vpls
    neighbor 24.0.0.6 activate

! CSR6
router bgp 24
  address-family l2vpn vpls
    no bgp default route-target filter
    neighbor 10.5.6.5 activate
    neighbor 24.0.0.2 activate
    neighbor 24.0.0.2 next-hop-self
```

The configuration in AS 13 is very similar. The prefix-length size increase is an XR interoperability option and is described in the dedicated L2VPN section. So far, the configuration is very similar to L3VPN except using a different AFI. The same RT retention and next-hop-self design goals are in effect as those are fundamental tenants of option B.

```
! CSR8
router bgp 13
```

```

address-family l2vpn vpls
  neighbor 13.0.0.12 activate
  neighbor 13.0.0.12 prefix-length-size 2

! CSR5
router bgp 13
  address-family l2vpn vpls
    no bgp default route-target filter
    neighbor 10.5.6.6 activate
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 prefix-length-size 2
    neighbor 13.0.0.12 next-hop-self

! XRv2
router bgp 13
  af-group L2VPN address-family l2vpn vpls-vpws
    route-reflector-client
    Signalling bgp disable

neighbor 13.0.0.5
  address-family l2vpn vpls-vpws
  use af-group L2VPN

neighbor 13.0.0.8
  address-family l2vpn vpls-vpws
  use af-group L2VPN

```

For brevity, I check the BGP peers XRv2 and CSR6. Assuming these routers see all their peers, we can be confident all routers have L2VPN VPLS BGP configured properly.

```

RP/0/0/CPU0:XRv2#show bgp l2vpn vpls summary | begin ^Neighbor
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.5      0     13   18326    17397      25     0    0    1d01h    0
13.0.0.8      0     13   18100    17389      25     0    0    1d01h    0

R6#show bgp l2vpn vpls all summary | begin ^Neighbor
Neighbor      V      AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down  State/PfxRcd
10.5.6.5      4     13    72       74         56     0    0  00:27:51    0
24.0.0.2      4     24   363      320         56     0    0  00:43:48    0

```

Next, we will configure the L2VPNs and bind them to the bridge-domain. These tie the VFI to the ACs. The VPN configurations are incomplete but we can at least verify BGP advertisement by configuring a VFI. I intentionally configure different VPN IDs because these might be intra-AS VPLS instances as well. We can pretend there are other clients within each AS that all agree on the VPN ID.

```

! CSR8
l2vpn vfi context VPLS
  vpn id 13
  autodiscovery bgp signaling ldp template TMP_VPLS

```

```

! CSR2
l2vpn vfi context VPLS
  vpn id 24
  autodiscovery bgp signaling ldp template TMP_VPLS

```

Additionally, in order for this design to work, we must enable PW routing. This allows PWs to be stitched together. The TPE tie-breaker is discussed more later.

```

! All ASBRs and PEs
l2vpn
  logging pseudowire status
  pseudowire routing
  terminating-pe tie-breaker

```

Since we only expect to see 2 routes, we look at all the details for all routes across all RDs. CSR6 has both routes which is a good sign that the route exchange is occurring. We can immediately see a mismatch in the route-target values and L2VPN attachment group ID (AGI). Both of them are automatically derived from the BGP ASN and VPN IN, which explains the values RT:13:13 and RT:24:24. The ASBRs are able to retain these prefixes because, as option B requires, the default RT filter has been disabled.

```

R6#show bgp l2vpn vpls all detail

```

To clean this up, I will use a different set of RTs to achieve inter-AS connectivity. We can leave “auto-route-target” enabled because I am pretending other members of this VPN instance exist within the VRF. Thus, I will add additional RT import statements to each VFI instance. To minimize changes, I configure CSR2 to import RT:13:13 and CSR8 to import RT:24:24. No new RTs need to be defined in this case and no new RTs are attached to the existing routes.

Bridge-Domain 3 attachment circuits:
Pseudo-port interface: pseudowire100009
Interface          Peer Address      VC ID      Discovered Router ID  S
```

```
R8#show l2vpn vfi name VPLS
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: VPLS, state: up, type: multipoint, signaling: LDP
VPN ID: 13, VPLS-ID: 13:13
RD: 13:13, RT: 13:13, import 24:24
Bridge-Domain 3 attachment circuits:
Pseudo-port interface: pseudowire100014
Interface          Peer Address      VC ID      Discovered Router ID  S
```

Despite these changes, the L2VPN routes are still being rejected. The debug output tells us the extended community is not supported, and normally this indicates an RT issue. However, the AGI is also an extended community. This is specifically used to determine if two VFIs are in the same VPLS instance. The BGP output above clearly shows different values.

```
R2#debug bgp l2vpn vpls updates in
BGP updates debugging is on (inbound) for address family: L2VPN Vpls

BGP(9): 24.0.0.6 rcvd 13:13:13.0.0.8/96 -- DENIED due to: extended community
not supported;
```

We adjust this VPLS ID on both CSR2 and CSR8 so that they are in the same VPN again. Other intra-AS clients would also have to agree on this value in order for VPLS to operate as well.

```

! CSR2 and CSR8
l2vpn vfi context VPLS
  autodiscovery bgp signaling ldp template TMP_VPLS
  vpls-id 13:24

```

Checking CSR2, we can see that the remote L2VPN route from AS 13 was accepted. The route-targets still differ, but since those are being imported on opposing VFIs, it doesn't matter.

```

```

Checking CSR2, we can see that it sees 13.0.0.2 as the remote PW endpoints. Of course, we know these two IP addresses don't have reachability to one another. Checking the details of the PW, we can see that the BGP next-hop is identified as 24.0.0.6. This means that CSR2 will try to build the PW to this endpoint knowing that the VPLS is inter-AS.

```

R2#show l2vpn atom vc

[snip]
```

One of the challenges of dealing with MSPW is that if one of the circuit legs is down, the entire MSPW is down. Examining the details on CSR6, we discover LDP trying to establish a session across the ASBR link. This makes sense as the VPLS is LDP-signaled, yet LDP is not enabled on the transit link.

```

[snip]
```

The TPE command we entered earlier is a requirement for auto-discovered VPLS over option B. A terminating PE is one of the remote PEs, not an ASBR, that terminates an MSPW. By default, all PEs are in the active state in terms of tLDP sessions. One of them MUST be in the passive state in order for this feature to work. The device with the numerically higher L2VPN RID (based on the highest loopback by default) is the active device. Before continuing, we will enable passive reception of tLDP sessions on all devices except the active TPE. Looking at the XC details below, we see that CSR2 has a higher L2VPN RID and CSR8 is marked as passive.

```
R8#show xconnect rib detail
Local Router ID: 13.0.0.8
VPLS-ID: 13:24, Target ID: 24.0.0.2
  iBGP Peer

```

```
NLRI handle: 38000004
```

As a result of this, we configure CSR8, CSR5, and CSR6 to accept tLDP sessions. We could also configure CSR2, but it technically is not required.

```
! CSR8, CSR5, and CSR6
mpls ldp discovery targeted-hello accept
```

Now, we can see LDP trying to establish a session over the transit link with targeted hellos, but with LDP disabled, a peer can never form. CSR6 can communicate directionally with CSR2, which shows good intra-AS communications. CSR5 claims it has no route to CSR6's loopback, which is its LDP ID. This is true, especially with LDP being totally disabled on the link. Notice that CSR6 is active for this session and CSR5 is passive; the session was initiated from CSR2 and the active-ness of a session is transitive from one TPE to the other.

```
R6#show mpls ldp discovery | begin Target
```

```
Targeted Hellos:
```

```
10.5.6.6 -> 10.5.6.5 (ldp): active, xmit
```

```
24.0.0.6 -> 24.0.0.2 (ldp): active/passive, xmit/recv
```

```
LDP Id: 24.0.0.2:0
```

```
R5#show mpls ldp discovery | begin Target
```

```
Targeted Hellos:
```

```
10.5.6.5 -> 10.5.6.6 (ldp): passive, xmit/recv
```

```
LDP Id: 24.0.0.6:0; no route
```

First, let's enable LDP on the link and see if it makes a difference. So far, it doesn't. We would still have the problem of CSR5 not having a route to CSR6's loopback, and vice versa.

```
! CSR5 and CSR6
interface GigabitEthernet2.556
mpls ip
```

The most obvious fix for this problem is some patchwork with static routes, or maybe IGP/BGP. This goes against the spirit of option B, so I will use a more elegant solution. We can configure LDP to use a different TCP transport address on a per-interface basis which is very useful in situations like this. I configure both CSR5 and CSR6 to use their connected interface addresses for the TCP session. This would apply to any neighbors discovered on that interface.

```
! CSR5 and CSR6
interface GigabitEthernet2.556
 mpls ldp discovery transport-address interface
```

The PW immediately comes up. While CSR5 still has no route to CSR6's loopback, the LDP neighbor forms as expected. The active/passive monikers seem to disappear as the MSPW is formed since the active formation of the MSPW occurs only during setup.

```
R5#show mpls ldp discovery | begin Targeted
Targeted Hellos:
  10.5.6.5 -> 10.5.6.6 (ldp): active/passive, xmit/recv
    LDP Id: 24.0.0.6:0; no route
  13.0.0.5 -> 13.0.0.8 (ldp): active/passive, xmit/recv
    LDP Id: 13.0.0.8:0
```

Checking the PW details on CSR2, we can see the PW is operational. The two-label stack shows a PW label (tLDP) and a transport label (LDP) in use. The targeted hellos are directed at the next-hop PE, not the target, as this MSPW is smart enough to know that there isn't reachability between the endpoints. When the BGP next-hop changes, rather than swap a label as in L3VPN, a PW is terminated. This ensures that inter-AS connectivity can work when BGP adjusts next-hops.

```
R2#show l2vpn atom vc vcid 24 detail

  [snip]
```

MPLS OAM is very useful to verify the integrity of the MSPW. Rather than trace intra-AS LSPs again, we will use this tool. Since we know there are 3 segments, we can use traceroute to reveal all of the PW

labels in use across the different PWs. We cannot use ordinary MPLS or IP-based traceroutes since we don't have connectivity between AS loopbacks. The customers are in a L2VPN and are totally unaware of any MPLS presence. OAM also reveals the PE/ASBR devices along the path that are making label adjustments. CSR2 uses label 6073 along the PW to CSR6. CSR6 swaps it for label 5040 towards CSR5, and CSR5 swaps it for label 8015 towards CSR8.

```
R2#traceroute mpls pseudowire 13.0.0.8 24 segment 3
Tracing MS-PW segments within range [1-3] peer address 13.0.0.8 and timeout 2
seconds

    local 24.0.0.6 remote 13.0.0.5 vc id 1001

! 3 13.5.8.8 6 ms [Labels: 8015 Exp: 0]
    local 13.0.0.5 remote 13.0.0.8 vc id 1001
```

MPLS ping gives us useful results as well. The capital 'L' means that the traffic would have used a labeled path, but expired in transit. It is rare to see this in a ping message, but if we don't specify the proper number of segments in the MSPW, we will see this. This can be valuable for testing a certain number of segments in the MSPW if necessary.

```
R2#ping mpls pseudowire 13.0.0.8 24 segment 1
Sending 5, 72-byte MPLS Echos to 13.0.0.8,
    timeout is 2 seconds, send interval is 0 msec:

Success rate is 100 percent (5/5), round-trip min/avg/max = 10/10/12 ms

```
R3#traceroute vrf VPLS 10.0.0.1
```

Type escape sequence to abort.

Tracing the route to 10.0.0.1

VRF info: (vrf in name/id, vrf out name/id)

```
 1 10.0.0.1 8 msec 10 msec 9 msec
```

Some additional verifications on the ASBRs are valuable. The L2VPN RIB is a nicely organized view of all PWs in the network. We can see each of the L2VPN routes along with their targets, next-hops, and other details. The output is similar on CSR5 and CSR6 as they each have one iBGP and one eBGP route. The eBGP route is targeted for the TPE loopback but has a next-hop that is the ASBR peer, as expected.

```
R6#show l2vpn rib
```

e N N N	13:24	24.0.0.2	10.5.6.6	24:24

As a best practice, I would recommend some inter-AS LDP “cleanup” activities on CSR5 and CSR6. Since they are running LDP with one another, they are exchanging all of their LDP-allocated labels. On CSR6, we can see these labels. Since CSR6 has no routes to any of these networks, the labels are useless and waste memory.

```
R6#show mpls ldp bindings neighbor 13.0.0.5
lib entry: 10.5.6.6/32, rev 62
    remote binding: lsr: 13.0.0.5:0, label: 5022
lib entry: 10.5.7.7/32, rev 63
    remote binding: lsr: 13.0.0.5:0, label: 5039
lib entry: 13.0.0.5/32, rev 58
    remote binding: lsr: 13.0.0.5:0, label: imp-null
lib entry: 13.0.0.8/32, rev 61
    remote binding: lsr: 13.0.0.5:0, label: 5002
lib entry: 13.0.0.11/32, rev 60
    remote binding: lsr: 13.0.0.5:0, label: 5001
lib entry: 13.0.0.12/32, rev 59
    remote binding: lsr: 13.0.0.5:0, label: 5000
```

To fix it, we perform outbound LDP label filtering. This is covered in detail in the LDP section. The XE configuration for this is somewhat involved, but the logic of the snippets below indicate that labels for all prefixes can be advertised to any internal peer; I use ACLs matching 13.0.0.0/24 and 24.0.0.0/24 to signify “internal”. Otherwise, no other peers can have any labels for any IP prefixes. This does not affect tLDP label advertisement for PWs as the inter-AS VPLS is still operational.

```
! CSR5
no mpls ldp advertise-labels
mpls ldp advertise-labels for ACL_ANY to ACL_INTERNAL_PEERS
ip access-list standard ACL_ANY
    permit any
ip access-list standard ACL_INTERNAL_PEERS
    permit 13.0.0.0 0.0.0.255
```

```
! CSR6
no mpls ldp advertise-labels
mpls ldp advertise-labels for ACL_ANY to ACL_INTERNAL_PEERS
ip access-list standard ACL_ANY
    permit any
ip access-list standard ACL_INTERNAL_PEERS
    permit 24.0.0.0 0.0.0.255
```

When we check for remote label bindings on each ASBR from the other ASBR, we see no output. This is the expected result.

```
R6#show mpls ldp bindings neighbor 13.0.0.5  
[no output]
```

```
R5#show mpls ldp bindings neighbor 24.0.0.6  
[no output]
```

8.4.2.3 mVPN – GRE (Profile 0)

When using option B, MVPN using GRE is supported between ASes as well. This presents many unique challenges since the only route exchanges that occur are VPN based. For example, this could include VPNv4, VPNv6, L2VPN, etc. Ordinary IPv4/v6 unicast routes are not exchanged which can be considered a benefit of option B as addresses can overlap and remain uncoordinated between providers. Only VPN details, such as RD, RT, VPLS-ID, etc must be coordinated between ASes. We will use VRF EIGRP to test this feature between ASes. I will use PIM-SSM for the default MDT along with BGP IPv4 MDT for signaling. Beginning with AS 24, I configure these basic parameters.

```
! CSR2  
vrf definition EIGRP  
  address-family ipv4  
    mdt default 232.13.24.255  
  address-family ipv6  
    mdt default 232.13.24.255  
  
router bgp 24  
  address-family ipv4 mdt  
  neighbor 24.0.0.14 activate  
  
! XRv4  
multicast-routing  
vrf EIGRP  
  address-family ipv4  
    mdt default ipv4 232.13.24.255  
  address-family ipv6  
    mdt default ipv4 232.13.24.255  
  
router bgp 24  
  address-family ipv4 mdt  
  neighbor 24.0.0.2  
  address-family ipv4 mdt
```

With two PEs in that AS, we should see the default MDT form between XRv4 and CSR2. Checking CSR2, it has the MDT route from XRv4. This carries the default MDT multicast group and the MDT source. Effectively, this is the P(S,G) information needed to build the MDT towards a peer. We can ensure the

default MDTs match by checking the details for both routes on CSR2. There is no concept of RTs for these routes which is why exchanging extended communities is not required for the IPv4 MDT AFI. The P-sources and P-groups are highlighted below.

```
R2#show bgp ipv4 mdt vrf EIGRP detail
BGP routing table entry for 24:3:24.0.0.2/32          version 2

      MDT group address: 232.13.24.255
      rx pathid: 0, tx pathid: 0x0
```

Checking the P(S,G) information on CSR2 and XRv4, we can see the SPTs built between the peers. Since the routers are directly connected, the tree exists only on one link for now. CSR2 marks this with the big 'Z' flag to signify a multicast tunnel.

```
R2#show ip mroute 232.13.24.255 24.0.0.14 | begin \

router bgp 24
 address-family ipv4 mdt
  neighbor 24.0.0.2 activate
```

On CSR2, we quickly verify all of the sessions come up. We also verify that CSR6 and CSR7 learn the MDT routes from CSR2. CSR6 and CSR7 are not sending any new routes into the network, so we expected to see 0 prefixes received. There is no concept of RT retention for this AFI, so the option B ASBRs do not need to worry about filtering the routes not used locally.

```
R2#show bgp ipv4 mdt all summary | begin ^Neighbor
Neighbor      V      AS MsgRcvd MsgSent      TblVer  InQ  OutQ  Up/Down  State/PfxRcd

```

```
R7#show bgp ipv4 mdt all | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 24:3 (default for vrf EIGRP)
*>i 24.0.0.2/32      24.0.0.2          0     100      0 ?
*>i 24.0.0.14/32     24.0.0.14         100    0 i
```

Before configuring the eBGP IPv4 MDT connections to AS 13, I will configure the intra-AS parameters inside AS 13. Since there is only 1 PE, there won't be any MDT construction to verify. We will build the BGP sessions and ensure the MDT route from CSR8 is present on XRv1 and CSR5 (ASBRs). Note that there is no reason for XRv2 to negotiate this AFI with CSR8; VRF OSPF will not be using PIM/GRE for MVPN. It is required that the default MDT group match between ASes, so this must be coordinated between providers.

```
! XRv2
router bgp 13
  address-family ipv4 mdt

  af-group MDT address-family ipv4 mdt
  route-reflector-client

neighbor 13.0.0.5
  address-family ipv4 mdt
  use af-group MDT

neighbor 13.0.0.11
  address-family ipv4 mdt
  use af-group MDT

multicast-routing
vrf EIGRP
  address-family ipv4
    mdt default ipv4 232.13.24.255
  address-family ipv6
    mdt default ipv4 232.13.24.255

! XRv1
router bgp 13
  address-family ipv4 mdt
  neighbor 13.0.0.12
  address-family ipv4 mdt

! CSR5
Router bgp 13
  address-family ipv4 mdt
  neighbor 13.0.0.12 activate
```

Checking XRv2, we can see the IPv4 MDT peers are up; no routes are received from the ASBRs as expected. Both XRv1 and CSR5 have XRv2's MDT route. I show the summary on CSR5 and the details on XRv1 to ensure the P(S,G) information is correct. This verifies all of the BGP auto-discovery signaling.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mdt summary | begin ^Neighbor
Neighbor      Spk    AS MsgRcvd MsgSent  TblVer  InQ  OutQ  Up/Down  St/PfxRcd
```

13.0.0.5	0	13	24593	23511	2	0	0	00:00:15	0
13.0.0.11	0	13	23250	23470	2	0	0	00:00:14	0

```
R5#show bgp ipv4 mdt all | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 13:3
*>i 13.0.0.12/32    13.0.0.12      100      0 i
```

```
RP/0/0/CPU0:XRv1#show bgp ipv4 mdt rd 13:3 13.0.0.12
BGP routing table entry for 13.0.0.12/96, Route Distinguisher: 13:3
[snip]
Local
  13.0.0.12 (metric 3) from 13.0.0.12 (13.0.0.12)
    Origin IGP, localpref 100, valid, internal, best, group-best
    Received Path ID 0, Local Path ID 1, version 2
    MDT group address: 232.13.24.255
```

Next, we configure the eBGP IPv4 MDT peers. Unlike MPLS L3VPN and L2VPN, there is no reliance on MPLS here, so any kind of label operations need not occur on the transit links. The configuration is very basic so I only show XRv1 and CSR6 for brevity. Since all of these eBGP neighbors were already defined, we only need to activate the new AFI rather than redefine the general session parameters.

```
! XRv1
router bgp 13
  neighbor 10.6.11.6
  address-family ipv4 mdt
    route-policy RPL_PASS in
    route-policy RPL_PASS out

! CSR6
router bgp 24
  address-family ipv4 mdt
  neighbor 10.5.6.5 activate
  neighbor 10.6.11.11 activate
```

Checking CSR6 and CSR5 for neighbors, we can see that all peers are up. CSR6 receives 1 prefix from CSR5 and XRv1 which represents XRv2's MDT route. CSR5 learns 2 prefixes from CSR6 and CSR7 which represent MDT routes from CSR2 and XRv4. So far, everything looks good.

```
R6#show bgp ipv4 mdt all summary | begin ^Neighbor
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd
10.5.6.5      4      13      57      48      4      0   0 00:01:13      1
10.6.11.11    4      13      14      34      4      0   0 00:00:23      1
24.0.0.2      4      24     466     196      4      0   0 00:16:58      2

R5#show bgp ipv4 mdt all summary | begin ^Neighbor
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd
10.5.6.6      4      24      49      58      4      0   0 00:02:02      2
10.5.7.7      4      24      47      43      4      0   0 00:01:50      2
```

```
13.0.0.12      4      13      228      136      4      0      0 00:08:14      1
```

Next, we will verify that the RRs in each AS have received these MDT routes. CSR2 shows two copies of the route from CSR6 and CSR7. The routes appear valid since the transit link host routes were redistributed into IS-IS earlier.

```
R2#show bgp ipv4 mdt rd 13:3 13.0.0.12
BGP routing table entry for 13:3:13.0.0.12/32          version 6
Paths: (2 available, best #2, table IPv4-MDT-BGP-Table)
  Advertised to update-groups:
    2
  Refresh Epoch 1
  13, (Received from a RR-client)
    10.5.7.5 from 24.0.0.7 (24.0.0.7)
      Origin IGP, metric 0, localpref 100, valid, internal,
      MDT group address: 232.13.24.255

      rx pathid: 0, tx pathid: 0
  Refresh Epoch 1
  13, (Received from a RR-client)
    10.5.6.5 from 24.0.0.6 (24.0.0.6)
      Origin IGP, metric 0, localpref 100, valid, internal, best,
      MDT group address: 232.13.24.255
      rx pathid: 0, tx pathid: 0x0
```

XRv2 cannot install these BGP routes since the next-hop is inaccessible. For L3VPN tests, AS 13 ASBRs used next-hop-self rather than advertise the transit links. With inter-AS PIM/GRE using option B, we can use either method.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mdt rd 24:3 24.0.0.2
BGP routing table entry for 24.0.0.2/96, Route Distinguisher: 24:3
Versions:
  Process          bRIB/RIB  SendTblVer
  Speaker          0          0
Paths: (2 available, no best path)
  Not advertised to any peer
  Path #1: Received by speaker 0
  Not advertised to any peer
  24, (Received from a RR-client)
    10.5.6.6 (inaccessible) from 13.0.0.5 (13.0.0.5)
      Origin incomplete, metric 0, localpref 100, valid, internal
      Received Path ID 0, Local Path ID 0, version 0
      MDT group address: 232.13.24.255

  Path #2: Received by speaker 0
  Not advertised to any peer
  24, (Received from a RR-client)
    10.6.11.6 (inaccessible) from 13.0.0.11 (13.0.0.11)
```

```
Origin incomplete, localpref 100, valid, internal
Received Path ID 0, Local Path ID 0, version 0
MDT group address: 232.13.24.255
```

Correcting this problem is simple; we apply next-hop-self on the ASBRs towards the RR and the next-hops become accessible again. Now, iBGP speakers inside of each AS can process the BGP routes.

```
! XRv1
router bgp 13
 neighbor 13.0.0.12
  address-family ipv4 mdt
  next-hop-self
```

```
! CSR5
router bgp 13
 address-family ipv4 mdt
 neighbor 13.0.0.12 next-hop-self
```

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mdt rd 24:3 24.0.0.2 | begin 24,
24, (Received from a RR-client)

  Origin incomplete, metric 0, localpref 100, valid, internal, best,
group-best
  Received Path ID 0, Local Path ID 1, version 5
  MDT group address: 232.13.24.255
```

```
Path #2: Received by speaker 0
Not advertised to any peer
24, (Received from a RR-client)
 13.0.0.11 (metric 3) from 13.0.0.11 (13.0.0.11)
  Origin incomplete, localpref 100, valid, internal
  Received Path ID 0, Local Path ID 0, version 0
  MDT group address: 232.13.24.255
```

With the routes properly advertised and installed, ideally the inter-AS MDT would be built. A quick check of all three PEs shows that something is wrong. Every single PE for every single P(S,G) has the same issue; there is no route back to the P-source. This makes sense since these loopbacks were never exchanged across AS boundaries. This is somewhat similar to the L2VPN problem we solved with MSPW as building an end-to-end PW is not possible.

```
RP/0/0/CPU0:XRv4#show pim topology 232.13.24.255 13.0.0.12 | begin 232

```

The fact that each router is actively trying to build the MDTs is a good sign that BGP is configured properly. We now must adjust PIM so that it can build trees between ASes by somehow fixing RPF. The normal RPF fix-up techniques, such as static multicast routes or BGP IPv4/v6 multicast AFI, are not appropriate here. A specific feature known as PIM proxy vector was invented specifically to solve this problem. This is configured on the PEs which encode the BGP next-hop inside of the PIM joins; this allows routers to compute RPF towards the vector address rather than the root address. To demonstrate the basic functionality, I enable this on CSR2. I also include the RD which is required for using this feature with MPLS VPNs.

```
! CSR2
ip multicast vrf EIGRP rpf proxy rd vector
```

To verify that the vector has been originated, we can check the MRIB for proxy entries. The P(S,G) for the inter-AS PE is shown below. The RD of 13:3 is encoded along with the BGP next-hop of the best route. The assigner is local to CSR2.

```
R2#show ip mroute proxy
(13.0.0.12, 232.13.24.255)
Proxy          Assigner      Origin      Uptime/Expire
13:3/10.5.6.5  0.0.0.0      BGP MDT     00:03:10/stopped
```

The ability to communicate this new PIM TLV is a special PIM capability negotiated during neighbor formation. The 'P' flag in the PIM neighbors shows which peers can support it. At a glance, it appears all neighbors can from CSR2's perspective. We have used this PIM show command many times but never paid attention to the 'P' flag until now.

```
R2#show ip pim neighbor | begin ^Neigh
Neighbor      Interface      Uptime/Expires  Ver  DR
Address
24.2.14.14    GigabitEthernet2.524  2d13h/00:01:44  v2   1 / DR P G
24.2.7.7      GigabitEthernet2.527  2d13h/00:01:25  v2   1 / DR S P G
```

Looking at the MRIB, we can see that the proxy information is revealed here per (S,G). The big 'V' flag means both the PIM vector and RD are encoded in the PIM joins. When the vector is present, PIM routers will use that for RPF rather than the root of the tree. All routers in AS 24 should have a route to 10.5.6.5, but none of them have a route to 13.0.0.12. Now, CSR2 appears to have a valid P(S,G) entry for this group.

```
R2#show ip mroute 232.13.24.255 13.0.0.12 | begin \  
(13.0.0.12, 232.13.24.255), 01:12:57/stopped, flags: STIZV  
  Incoming interface: GigabitEthernet2.524, RPF nbr 24.2.14.14, vector  
10.5.6.5  
  Outgoing interface list:  
    MVRP EIGRP, Forward/Sparse, 01:12:57/00:02:43  
  
R2#show ip rpf 10.5.6.5  
RPF information for ? (10.5.6.5)  
  RPF interface: GigabitEthernet2.524  
  RPF neighbor: ? (24.2.14.14)  
  RPF route/mask: 10.5.6.5/32  
  RPF type: unicast (isis 24)  
  Doing distance-preferred lookups across tables  
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

```
R2#show ip rpf 13.0.0.12  
failed, no route exists
```

With debugging enabled, we can see CSR2 originate the P(S,G) join towards XRv4 which is in the reverse path towards 10.5.6.5. The RD and vector are both included in the PIM join.

```
R2#debug ip pim 232.13.24.255  
PIM debugging is on  
  
PIM(0): Insert (13.0.0.12,232.13.24.255) join in nbr 24.2.14.14's queue  
PIM(0): Building Join/Prune packet for nbr 24.2.14.14  
PIM(0): Adding v2 (13.0.0.12/32, 232.13.24.255), S-bit Join MDT proxy  
13:3/10.5.6.5  
PIM(0): Send v2 join/prune to 24.2.14.14 (GigabitEthernet2.524)
```

When XRv4 receives the join, it claims the proxy vector is disabled towards CSR2 (and reveals a spelling error).

```
RP/0/0/CPU0:XRv4#debug pim protocol join-prune  
pim[1160]: [13] VRF : default Received J/P on Gi0/0/0/0.524 from 24.2.14.2  
target: 24.2.14.14 (to us) containing 1 group size:46  
pim[1160]: [13] J/P group 232.13.24.255 found grange in vrf default  
pim[1160]: [13] VRF : default J/P Group 232.13.24.255 includes 1 joins  
pim[1160]: [13] VRF : default J/P recvieved when proxy is disabled to  
13.0.0.12
```

```
pim[1160]: [13] VRF : default J/P Group 232.13.24.255 includes 0 prunes
```

We can enable the feature under XRv4, taking note that we enable it under the global AFI rather than the EIGRP VPN. We are trying to get XRv4 to at least understand the P(S,G) from CSR2 first.

```
! XRv4
router pim
  address-family ipv4
    rpf-vector
```

With debugging still enabled, we are now presented with another error. Although cryptic, this message effectively says that XR does not understand the PIM vector + RD join message. XR makes no attempt to read the vector address by itself, even if it cannot understand the RD. A component of the PIM join for (13.0.0.12, 232.13.24.255) from CSR2 cannot be understood. As a result, XR totally ignores the PIM join.

```
RP/0/0/CPU0:XRv4#debug pim protocol join-prune
pim[1160]: [13] VRF : default Received J/P on Gi0/0/0/0.524 from 24.2.14.2
target: 24.2.14.14 (to us) containing 1 group size:46
pim[1160]: [13] J/P group 232.13.24.255 found grange in vrf default
pim[1160]: [13] VRF : default J/P Group 232.13.24.255 includes 1 joins
pim[1160]: [13] VRF : default J/P with unknown proxy type 2 forwarding...
pim[1160]: [13] VRF : default, RECV J/P entry: Join, root: 13.0.0.12 proxy
0.0.0.0, grp: 232.13.24.255, tgt: 24.2.14.14, flags: S , on intf
Gi0/0/0/0.524, sender: 24.2.14.2
```

Until testing this feature, I was not aware that XR has no support for the PIM vector with RD. It only supports the PIM vector by itself, which means XR cannot be used in an option B environment for inter-AS MVPN. Not supporting RD means that inter-AS multicast support is still possible but not within the scope of MPLS VPNs. XRv4 has no RPF interface for this P(S,G) and cannot build the tree.

```
RP/0/0/CPU0:XRv4#show pim topology 232.13.24.255 13.0.0.12 | begin 232
(13.0.0.12,232.13.24.255)SPT SSM Up: 01:26:49 Vector: 0.0.0.0
JP: Join(00:00:38) RPF: Null,0.0.0.0 proxy-disabled, Flags:
  Loopback0 00:18:25 fwd LI LH
  GigabitEthernet0/0/0/0.524 00:05:07 fwd Join(00:03:16)
```

In an attempt to demonstrate the operation of the PIM vector with RD, I will make an RPF adjustment on CSR2. Using a static multicast route, I will assign CSR7 as the RPF neighbor for 10.0.0.0/8 which will cover the transit interfaces. I verify that the multicast route is properly installed and active.

```
! CSR2
ip mroute 10.0.0.0 255.0.0.0 24.2.7.7
```

```
R2#show ip static route multicast | begin Static
Static multicast local RIB for multicast
MC 10.0.0.0/8 [1/0] via 24.2.7.7 [A]
```

Debugging on CSR2, we can see the PIM join with vector + RD is now being sent to CSR7, who understands the message. We can also confirm this by checking the MRIB. We can see the vector is still applied, but the RPF neighbor has been adjusted via an “Mroute”. The only reason this is a decent solution is because we can easily bypass the only XR router in the AS. If there were other XR routers, the static multicast routes would be needed anywhere the RPF interfaces would transit XR routers. This is extremely sloppy and even using BGP IPv4 multicast is a poor option since we are effectively bypassing entire sets of routers.

```
R2#debug ip pim 232.13.24.255
PIM debugging is on
PIM(0): Insert (13.0.0.12,232.13.24.255) join in nbr 24.2.7.7's queue
PIM(0): Building Join/Prune packet for nbr 24.2.7.7
PIM(0): Adding v2 (13.0.0.12/32, 232.13.24.255), S-bit Join MDT proxy
13:3/10.5.6.5
PIM(0): Send v2 join/prune to 24.2.7.7 (GigabitEthernet2.527)
```

```
R2#show ip mroute 232.13.24.255 13.0.0.12 | begin \
(13.0.0.12, 232.13.24.255), 01:31:13/stopped, flags: sTIZV
Incoming interface: GigabitEthernet2.527, RPF nbr 24.2.7.7, Mroute, vector
10.5.6.5
Outgoing interface list:
MVRFP EIGRP, Forward/Sparse, 01:31:13/00:02:27
```

Checking CSR7, we can see the PIM vector from CSR2. Rather than being locally originated and assigned by BGP, this vector was PIM-learned from CSR2. CSR7’s RPF route for 10.5.6.5 will be IGP-learned from CSR6, so no RPF fixup is needed.

```
R7#show ip mroute proxy
(13.0.0.12, 232.13.24.255)

| Proxy         | Assigner | Origin | Uptime/Expire     |
|---------------|----------|--------|-------------------|
| 13:3/10.5.6.5 | 24.2.7.2 | PIM    | 00:05:26/00:02:16 |

```

```
R7#show ip mroute 232.13.24.255 13.0.0.12 | begin \
(13.0.0.12, 232.13.24.255), 00:06:14/00:02:57, flags: sTV
Incoming interface: GigabitEthernet2.567, RPF nbr 24.6.7.6, vector 10.5.6.5
Outgoing interface list:
GigabitEthernet2.527, Forward/Sparse, 00:06:14/00:02:57
```

CSR7 passes the PIM join to CSR6 who has a similar set of outputs. The incoming interface is via CSR5 due to being the oldest eBGP route.

```
R6#show ip mroute proxy

  rx pathid: 0, tx pathid: 0x0

```

We are fortunate that CSR5 was selected over XRv1 since we know XRv1 cannot understand the PIM vector + RD. Checking CSR5 quickly, we can see the PIM vector was learned. The actual vector gets removed at this point as it no longer serves its purpose; everyone in AS 13 has a route to 13.0.0.12. CSR5 makes no mention of the vector when the PIM is sent to CSR8. I prove this with show and debug commands as the PIM vector + RD is received but not forwarded.

```

R5#show ip mroute proxy
(13.0.0.12, 232.13.24.255)

PIM(0): Insert (13.0.0.12,232.13.24.255) join in nbr 13.5.8.8's queue

PIM(0): Building Join/Prune packet for nbr 13.5.8.8

PIM(0): Adding v2 (13.0.0.12/32, 232.13.24.255), S-bit Join

PIM(0): Send v2 join/prune to 13.5.8.8 (GigabitEthernet2.558)

To demonstrate what happens when XRv1 is the best ingress point into AS 13, I will clear CSR6's BGP session to CSR5. CSR6 now selects XRv1 as the best route as it is the oldest.

```
R6#clear bgp ipv4 mdt 10.5.6.5
```

```
R6#show bgp ipv4 mdt rd 13:3 13.0.0.12
```

```
BGP routing table entry for 13:3:13.0.0.12/32          version 9

```

This is acceptable since CSR2 has an RPF fixup for all of 10.0.0.0/8, so the RPF interface is still towards CSR7. CSR7 receives the join from CSR2 and passes it to CSR6. CSR6 then passes it to XRv1 along with the PIM vector + RD.

```
R2#show ip mroute 232.13.24.255 13.0.0.12 | begin \  
(13.0.0.12, 232.13.24.255), 01:49:46/00:02:30, flags: sTIZV

```

Debugging PIM on XRv1, we can see the PIM join received from CSR6 but is rejected. Even though XRv1 has a perfectly valid RPF to 13.0.0.2, the reception of a join with an unknown TLV is grounds for ignoring it entirely. It builds P(S,G) state but the RPF remains null.

```
RP/0/0/CPU0:XRv1#debug pim protocol join-prune  
  
pim[1160]: [13] VRF : default (13.0.0.12,232.13.24.255) J/P processing  
pim[1160]: [13] VRF : default(13.0.0.12,232.13.24.255) No RPF neighbor to  
send J/P  
pim[1160]: [13] VRF : default Received J/P on Gi0/0/0/0.561 from 10.6.11.6  
target: 10.6.11.11 (to us) containing 1 group size:46  
pim[1160]: [13] J/P group 232.13.24.255 found grange in vrf default  
pim[1160]: [13] VRF : default J/P Group 232.13.24.255 includes 1 joins  
pim[1160]: [13] VRF : default J/P with unknown proxy type 2 forwarding...  
pim[1160]: [13] VRF : default, RECV J/P entry: Join, root: 13.0.0.12 proxy  
0.0.0.0, grp: 232.13.24.255, tgt: 10.6.11.11, flags: S , on intf  
Gi0/0/0/0.561, sender: 10.6.11.6  
pim[1160]: [13] VRF : default J/P Group 232.13.24.255 includes 0 prunes
```

We can confirm the P(S,G) creation and valid RPF using ordinary PIM show commands.

```
RP/0/0/CPU0:XRv1#show pim topology 232.13.24.255 | begin 232  
(13.0.0.12,232.13.24.255)SPT SSM Up: 00:05:28 Vector: 0.0.0.0

```

```
RP/0/0/CPU0:XRv1#show pim rpf 13.0.0.12
```

```
Table: IPv4-Unicast-default
```

```
* 13.0.0.12/32 [110/3]
```

```
via GigabitEthernet0/0/0/0.581 with rpf neighbor 13.8.11.8
```

As expected, XR cannot support this architecture. Rather than leave CSR6's bestpath decision to chance, I will configure MED outbound on XRv1 so that CSR5 is always the preferred ingress point. This way, when routers reboot or BGP sessions are cleared, inter-AS MVPN can still work by bypassing XRv1.

```
! XRv1
route-policy RPL_MDT_MED_OUT($MED)
  set med $MED
end-policy

router bgp 13
  neighbor 10.6.11.6
  address-family ipv4 mdt
  route-policy RPL_MDT_MED_OUT(1111) out
```

We check CSR6 to ensure the MED was set correctly and that CSR6 selects CSR5 as the best-path.

```
R6#show bgp ipv4 mdt rd 13:3 13.0.0.12
BGP routing table entry for 13:3:13.0.0.12/32          version 10
Paths: (2 available, best #1, table IPv4-MDT-BGP-Table)
  Advertised to update-groups:
    1          2
Refresh Epoch 2

    rx pathid: 0, tx pathid: 0x0

```

We will pick up our verification on CSR5 where we left off. CSR5 passes the join to CSR8 using the normal RPF rules (no need for PIM vector) and CSR8 passes the join to XRv2.

```

R5#show ip mroute 232.13.24.255 13.0.0.12 | begin \
(13.0.0.12, 232.13.24.255), 00:02:14/00:03:06, flags: sT
  Incoming interface: GigabitEthernet2.558, RPF nbr 13.5.8.8
  Outgoing interface list:
    GigabitEthernet2.556, Forward/Sparse, 00:02:14/00:03:06

```

```

R8#show ip mroute 232.13.24.255 13.0.0.12 | begin \
(13.0.0.12, 232.13.24.255), 00:02:43/00:02:44, flags: sT
  Incoming interface: GigabitEthernet2.582, RPF nbr 13.8.12.12
  Outgoing interface list:
    GigabitEthernet2.558, Forward/Sparse, 00:02:43/00:02:44

```

Since there is no need for PIM vector or RD for this right-to-left MDT, XRv2 simply adds CSR8 to its OIL. This means that multicast signaling within the VPN can technically flow from left-to-right as XRv2 is capable of forwarding traffic down the MDT. The design is dysfunctional but it's better than having no connectivity.

```

RP/0/0/CPU0:XRv2#show pim topology 232.13.24.255 13.0.0.12 | begin 232
(13.0.0.12,232.13.24.255)SPT SSM Up: 02:09:58
JP: Join(never) RPF: Loopback0,13.0.0.12* Flags:
  Loopback0                02:09:58  fwd LI LH
  GigabitEthernet0/0/0/0.582 00:04:03  fwd Join(00:03:24)

```

To prove this, we can check the PIM neighbors on XRv2 and CSR2. CSR2 sees XRv2 as a VPN PIM neighbor but not vice versa. This is because XRv2's PIM hellos are traversing the inter-AS MDT and being received by CSR2. The opposite is not true since CSR2 cannot join XRv2's SPT.

```

RP/0/0/CPU0:XRv2#show pim vrf EIGRP neighbor | begin ^Neigh
Neighbor Address      Interface                Uptime    Expires  DR pri  Flags

```

Since XRv4 is incapable of originating the PIM vector + RD, we can use a static multicast route for the remote SPT root. This is worse than what we did on CSR2, which was simply to change the RPF to the transit links; we still used PIM vector + RD. On XRv4, we are reducing the scalability of option B since XRv4 needs to identify the remote loopbacks specifically. Other than using BGP IPv4 multicast for RPF fixup, this is the most logical way to fix the problem. For variety, I will use CSR7 as the RPF interface. CSR7 will be the replication point for intra-AS multicast as the links to XRv4 and CSR2 will be downstream interfaces in the OIL. I also remove the PIM configuration that enables RPF vector as it is just clutter.

```

! XRv4
no router pim

router static
 address-family ipv4 multicast
  13.0.0.0/8 24.7.14.7

```

XRv4 can now issue a PIM join towards 13.0.0.2 using CSR7. There is no PIM proxy involved on XRv4 and CSR7 treats this like a normal PIM join. It adds another interface to the OIL, and the rest of the MDT upstream remains unchanged. CSR6 is still CSR7's RPF neighbor and is the ASBR from which the EIGRP VPN multicast will arrive.

```

RP/0/0/CPU0:XRv4#show pim topology 232.13.24.255 13.0.0.12 | begin 232
(13.0.0.12,232.13.24.255)SPT SSM Up: 02:12:02

```

We see an angry syslog message on XRv4 generated by LPTS. Packets are being dropped but no details are revealed. The signaling appears to be functional so this may not be an issue. We will investigate this briefly to see if this will totally break the MVPN traffic or not.

```
! XRv4
%OS-LPTS-3-BAD_LISTENER_TAG : 'bad listener tag detected on the packet,
dropping packet'
```

With debugging, I try to find the reason for the drops. With an entry absent from the iFIB, this might be the reason why LPTS is dropping packets. The VRF ID maps to the default VRF, which means this is probably MDT related.

```
RP/0/0/CPU0:XRv4#debug lpts packet fast-path drops
RP/0/0/CPU0:XRv4#debug lpts packet slow-path drops

netio[309]: lpts decaps [0xb0c0eb14/124 md ?L3] IFIB lookup failed, dropping
VRF 0x60000000

RP/0/0/CPU0:XRv4#show lpts vrf
VRF-ID      VRF-NAME
0x00000001  *
0x60000000  default
0x60000001  **nVSatellite
0x60000002  EIGRP
```

Debugging LPTS packets on the slow-path, we can see this in an IPv6 PIM message. The output is verbose so be sure to send this to the log buffer. The packet is sourced from XRv2's MDT source towards the all-PIM-routers IPv6 multicast group of FF02::D. This occurs within the MDT, so XRv4 should have an iFIB entry to permit this traffic.

```
RP/0/0/CPU0:XRv4#debug lpts packet slow-path
netio[309]: lpts sub ifib/pifib [0xb0c0eb14/82 md VRF 0x60000000 IP6
::ffff:13.0.0.12 -> ff02::d p10] lookup successful IFH/VRF: 0x00001480 opcode
DELIVER, flow_type PIM-mcast-known, local flag 0, listener tag IPv6_STACK,
deliver
netio[309]: lpts pifib [0xb0c0eb14/82 md VRF 0x60000000 IP6 ::ffff:13.0.0.12
-> ff02::d p10] to local IPv6_STACK
```

```
netio[309]: lpts decaps [0xb0c0eb14/82 md VRF 0x60000000 IP6 ::ffff:13.0.0.12
-> ff02::d p10] to local stack (listener tag = IPv6_STACK)
netio[309]: %OS-LPTS-3-BAD_LISTENER_TAG : 'bad listener tag detected on the
packet, dropping packet'
netio[309]: lpts decaps [0xb0c0eb14/124 md ?L3] IFIB lookup failed, dropping
VRF 0x60000000
```

Checking the iFIB, we can clear see that PIM traffic destined to FF02::D is allowed from any source inside the MDT.

```
RP/0/0/CPU0:XRv4#show lpts ifib type raw6 brief | include PIM

```

XRv4 also has a PIMv6 neighbor with XRv2 inside the VPN, which means the IPv6 PIM signaling is working properly as expected. I will assume this log message is the result of a lack of XRv support since everything appears functional.

```
RP/0/0/CPU0:XRv4#show pim vrf EIGRP ipv6 neighbor | begin ^mdt
mdtEIGRP
Neighbor Address                Uptime    Expires    DR pri    DR    Flags
::ffff:13.0.0.12                01:20:47  00:01:43  1          P
::ffff:24.0.0.2                 02:02:58  00:01:20  1

```

XRv2 is still unable to join the trees of XRv2 and CSR2 as it has no route to those MDT endpoints. XR's inability to support PIM vector + RD means that XRv2 will need to perform RPF lookups for these endpoints. The same is true for core routers like CSR8 since there is no PIM vector coming from the PE anymore. To solve this semi-dynamically, I use BGP IPv4 multicast. I enable it between all neighbors inside AS 24 to start. No routes have been advertised into this AFI yet. This is definitely not within the spirit of option B but is a valid, dynamic workaround.

```
! XRv2
router bgp 13
 address-family ipv4 multicast

 af-group MCAST_V4 address-family ipv4 multicast
   route-reflector-client

 neighbor 13.0.0.5
   address-family ipv4 multicast
   use af-group MCAST_V4

 neighbor 13.0.0.8
```

```

address-family ipv4 multicast
  use af-group MCAST_V4

neighbor 13.0.0.11
  address-family ipv4 multicast
  use af-group MCAST_V4

! CSR5 and CSR8
router bgp 13
  address-family ipv4 multicast
  neighbor 13.0.0.12 activate

! XRv1
router bgp 13
  address-family ipv4 multicast
  neighbor 13.0.0.12
  address-family ipv4 multicast

```

Checking the RR, we can see that the AFI was successfully negotiated with all peers. No routes have been exchanged yet, as expected.

```

RP/0/0/CPU0:XRv2#show bgp ipv4 multicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down  St/PfxRcd

```

I will use CSR5 as the ingress ASBR and CSR7 as the egress ASBR for this tree. As such, CSR5 will configure a static multicast route for 24.0.0.0/8 and advertise it into multicast BGP. This also implies we need to adjust the next-hop on CSR5 as the route is advertised towards XRv2 since AS 13 does not have reachability to the transit links.

```

! CSR5
ip mroute 24.0.0.0 255.0.0.0 10.5.7.7
router bgp 13
  address-family ipv4 multicast
  network 24.0.0.0
  neighbor 13.0.0.12 next-hop-self

```

```

R5#show ip route multicast static | begin Gate
Gateway of last resort is not set
S    24.0.0.0/8 [1/0] via 10.5.7.7

```

```

R5#show bgp ipv4 multicast | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
*>  24.0.0.0      10.5.7.7          0         32768 i

```

Quickly checking RPF on CSR8 and XRv2, we can see they now have a valid lookup for 24.0.0.2 and 24.0.0.14 inside AS 24. I use XRv14 as an example.

```
RP/0/0/CPU0:XRv2#show pim rpf 24.0.0.14
Table: IPv4-Multicast-default
* 24.0.0.14/32 [200/3]
    via GigabitEthernet0/0/0/0.582 with rpf neighbor 13.8.12.8

R8#show ip rpf 24.0.0.14
RPF information for ? (24.0.0.14)
  RPF interface: GigabitEthernet2.558
  RPF neighbor: ? (13.5.8.5)
  RPF route/mask: 24.0.0.0/8
  RPF type: multicast (bgp 13)
  Doing distance-preferred lookups across tables
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

Next, we trace the P(S,G) tree. XRv2 originates the P(S,G) join towards CSR8, who forwards it to CSR5. CSR8 clearly shows this as a multicast BGP RPF lookup. CSR7 shows it as a static multicast route as it was the originator of the BGP route for the rest of the AS. If PIM vector + RD is not supported, this would be the next best option, with intra-AS static multicast routes being the least preferred method.

```
P/0/0/CPU0:XRv2#show pim topology 232.13.24.255 24.0.0.14 | begin 232
(24.0.0.14,232.13.24.255)SPT SSM Up: 00:07:28

Outgoing interface list:
GigabitEthernet2.557, Forward/Sparse, 00:04:31/00:02:54
```

Checking XRv4, it is the root of one tree, and a transit router for the other. CSR2 is the root of the second tree, so the MDT appears to be fully signaled now. Some of this multicast state already existed since CSR2 and XRv4 were already in the MDT together, but we verify it again for completeness.

```
RP/0/0/CPU0:XRv4#show pim topology 232.13.24.255 24.0.0.14 | begin 232

```

To test it, we can re-use the ASM group configured on XRv3 from earlier sections. XRv3 is joining 225.13.13.13 on its loopback and sending the C(*,G) join towards the RP, which is CSR3. The fact that XRv3 is learning the RP is a good indication that the default MDT is operational.

```
RP/0/0/CPU0:XRv3#show pim rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4
```

Outgoing interface list:

GigabitEthernet2.532, Forward/Sparse, 00:14:14/00:03:12

CSR3 is also the source for the group. We will not detail the entire c-mcast signaling process, to include PIM registration and SPT switchover. Instead, we will focus on the P(S,G) which has already been signaled and will not change as no data MDTs are configured.

```

R3#ping ip
Target IP address: 225.13.13.13
Repeat count [1]: 1000000
Datagram size [100]:
Timeout in seconds [2]: 1
Extended commands [n]: y
Interface [All]: loopback0
Time to live [255]:
Source address or interface: loopback0

```

CSR3 sends its first packet down the shared tree across the MDT, and XRv3 immediately switches to the SPT. For brevity, we will not verify packet counters at every single hop. Instead, we can look at XRv3's C(S,G) state. It now has a C(*,G) and C(S,G) for the group in question. The traffic is being processed locally so the OIL is empty.

```

RP/0/0/CPU0:XRv3#show pim topology 225.13.13.13 | begin 225
(*,225.13.13.13) SM Up: 1d05h RP: 10.3.3.3
JP: Join(00:00:05) RPF: GigabitEthernet0/0/0/0.513,10.1.13.1 Flags: LH
    Loopback0                1d05h      fwd LI II LH

(10.3.3.3,225.13.13.13) SPT SM Up: 00:01:43
JP: Join(00:00:05) RPF: GigabitEthernet0/0/0/0.513,10.1.13.1 Flags:
KAT(00:01:47) RA
    No interfaces in immediate olist

```

Checking the packet counters on XRv3, we can see one packet along the shared tree and several more along the SPT. This is because XRv3 immediately joined the SPT, which doesn't introduce any efficiencies in this topology.

```

RP/0/0/CPU0:XRv3#show mfib route 225.13.13.13 * | begin 225

```

GigabitEthernet0/0/0/0.513 Flags: A, Up:00:02:35

There is one key component we have overlooked during this data transfer. When MVPN is enabled for a VRF, BGP will add a “connector attribute” to each VPN route. This allows the customer multicast traffic to pass RPF. For example, CSR2 is the egress MVPN router that decapsulates traffic along the MDT and forwards it to the CE. CSR2 uses the BGP route for RPF shown below. **The RPF rule of MDT states that the BGP next-hop MUST equal the MDT endpoint.** In this case, 10.5.6.5 is not the same as 13.0.0.12, so RPF would normally fail. Since this VPN route was originated by XRv2, there must be some mechanism to carry the original PE address as the BGP next-hop (and MPLS label) changes at the ASBR. The connector attribute is transitive for this reason and serves to carry the originating PE address.

```
R2#show bgp vpnv4 unicast vrf EIGRP 10.3.3.3/32
BGP routing table entry for 24:3:10.3.3.3/32, version 5646
Paths: (1 available, best #1, table EIGRP)
  Not advertised to any peer
  Refresh Epoch 1
  13, (Received from a RR-client), imported path from 13:3:10.3.3.3/32
(global)
  10.5.6.5 (metric 20) (via default) from 24.0.0.6 (24.0.0.6)
    Origin incomplete, metric 0, localpref 100, valid, internal, best
    Extended Community: RT:13:3 0x8800:32768:0 0x8801:3:288
      0x8802:65281:2560 0x8803:1:1500 0x8806:0:167971843
    Connector Attribute: count=1
      type 1 len 12 value 13:3:13.0.0.12
    mpls labels in/out nlabel/5072
    rx pathid: 0, tx pathid: 0x0
```

When this attribute is present, it is used instead of the BGP next-hop for the RPF check. Fortunately, this behavior is easy and automatic and requires no configuration. If the connector attribute was somehow stripped in transit, RPF would fail, and customer multicast traffic would be dropped at the egress PE. Note that this attribute is meaningless within an AS (assuming the next-hop does not change) since the BGP next-hop equals the originating PE anyway.

```
R2#show ip rpf vrf EIGRP 10.3.3.3
RPF information for ? (10.3.3.3)
  RPF interface: Tunnel5
  RPF neighbor: ? (13.0.0.12)
  RPF route/mask: 10.3.3.3/32
  RPF type: unicast (bgp 24)
  Doing distance-preferred lookups across tables
  BGP originator: 13.0.0.12
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

This concludes the PIM/GRE inter-AS option B lab. In summary, always plan to live without PIM vector + RD in this design if XR is in the multicast shortest path.

8.4.2.4 MVPN – mLDP (Profile 17)

To test mLDP between ASes, I will use profile 17. This uses BGP for auto-discovery, default MDTs using P2MP trees, and PIM for customer multicast signaling. First, we will prepare VRF OSPF on CSR2 and CSR8 for mLDP profile 17, ignoring the inter-AS requirement for now (which means the configuration is incomplete). As with all mLDP trees, the VPN ID must match as this is part of what is carried in the opaque field.

```
! CSR2 and CSR8
vrf definition OSPF
  vpn id 1300:2400
  address-family ipv4
    mdt preference mldp
    mdt auto-discovery mldp
    mdt default mpls mldp p2mp
  address-family ipv6
    mdt preference mldp
    mdt auto-discovery mldp
    mdt default mpls mldp p2mp
```

Since this profile relies on BGP MVPN AFI, we must configure those as well. The configuration is very simple but somewhat involved as we will configure it between PEs, RRs, and ASBRs. In this network, only XRv4 doesn't need to run these AFIs. We begin with AS 24.

```
! CSR2
router bgp 24
  address-family ipv4 mvpn
    neighbor 24.0.0.6 activate
    neighbor 24.0.0.6 send-community extended
    neighbor 24.0.0.6 route-reflector-client
    neighbor 24.0.0.7 activate
    neighbor 24.0.0.7 send-community extended
    neighbor 24.0.0.7 route-reflector-client
  address-family ipv6 mvpn
    neighbor 24.0.0.6 activate
    neighbor 24.0.0.6 send-community extended
    neighbor 24.0.0.6 route-reflector-client
    neighbor 24.0.0.7 activate
    neighbor 24.0.0.7 send-community extended
    neighbor 24.0.0.7 route-reflector-client
```

```
! CSR6 and CSR7
router bgp 24
  address-family ipv4 mvpn
    neighbor 24.0.0.2 activate
    neighbor 24.0.0.2 send-community extended
  address-family ipv6 mvpn
    neighbor 24.0.0.2 activate
```

```
neighbor 24.0.0.2 send-community extended
```

Once these are configured, we quickly verify the AFIs are properly negotiated with both ASBRs for IPv4 and IPv6. No routes are being received from the ASBRs yet.

```
R2#show bgp ipv4 mvpn all summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent   TblVer   InQ OutQ Up/Down   State/PfxRcd
24.0.0.6      4      24      27     68       1    0    0 00:00:57      0
24.0.0.7      4      24      21     47       1    0    0 00:00:36      0
```

```
R2#show bgp ipv6 mvpn all summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent   TblVer   InQ OutQ Up/Down   State/PfxRcd
24.0.0.6      4      24      28     69       1    0    0 00:01:02      0
24.0.0.7      4      24      22     48       1    0    0 00:00:40      0
```

CSR2 is currently originating a single type-1 Intra-AS I-PMSI route. This is used to build the default MDTs with other PEs in a given MVPN instance. One is created for both IPv4 and IPv6.

```
R2#show bgp ipv4 mvpn all | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 24:2 (default for vrf OSPF)
*>  [1] [24:2] [24.0.0.2]/12
      0.0.0.0      32768 ?
```

```
R2#show bgp ipv6 mvpn all | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 24:2 (default for vrf OSPF)
*>  [1] [24:2] [24.0.0.2]/12
      ::      32768 ?
```

We can confirm that CSR6 and CSR7 learn these prefixes. Since CSR6 has VRF OSPF configured locally, we can reference the route via the VRF table to view the details. These routes have RTs just like VPNv4 routes, so the option B consideration of ASBR RT retention matter for MVPN AFIs. Notice that the community of no-export is also set, which effectively makes this an intra-AS or intra-confederation AD route. PMSI tunnel type 2 represents mLDP P2MP and the tunnel root is 24.0.0.2, which is carried in the tunnel parameters.

```
R6#show bgp ipv4 mvpn vrf OSPF route-type 1 24.0.0.2
BGP routing table entry for [1][24:2][24.0.0.2]/12, version 4

rx pathid: 0, tx pathid: 0x0
```

For variety, we check CSR7 for the IPv6 MVPN I-PMSI route. It does not exist; CSR7 must retain the routes somehow. This was not a consideration with IPv4 MDT since the MDT address is what really determines MVPN membership in that design.

```
R7#show bgp ipv6 mvpn rd 24:2 route-type 1 24.0.0.2
% Network not in table
```

Since CSR7 configured CSR2 as an RR-client for other AFIs as a workaround, we will use that technique again for this AFI. We could have also configured the VRFs locally or instructed the ASBR to disable the default RT-filter.

```
! CSR7
router bgp 24
 address-family ipv4 mvpn
   neighbor 24.0.0.2 route-reflector-client
 address-family ipv6 mvpn
   neighbor 24.0.0.2 route-reflector-client
```

When the session comes back up, CSR7 has the proper MVPN routes. The IPv6 route has identical characteristics as the IPv4 route, but I display the details for completeness.

```
R7#show bgp ipv6 mvpn rd 24:2 route-type 1 24.0.0.2

```

Next, we will configure AS 13 similarly. Both ASBRs will retain all RTs rather than use the workarounds employed in AS 24. XRv2 negotiates this capability with all routes in AS 13. This is configuration intensive but very simple.

```
! XRv2
```

```

router bgp 13
  address-family ipv4 mvpn
  address-family ipv6 mvpn

  af-group MVPNV4 address-family ipv4 mvpn
    route-reflector-client
  af-group MVPNV6 address-family ipv6 mvpn
    route-reflector-client

    neighbor 13.0.0.12 activate

! XRv1
router bgp 13
  address-family ipv4 mvpn
    retain route-target all

  address-family ipv6 mvpn

```

```
retain route-target all

neighbor 13.0.0.12
address-family ipv4 mvpn
address-family ipv6 mvpn
```

Quickly checking XRv2, we can see that all sessions are up. XRv2 learns 2 routes from CSR8, which is odd as we would expect it to only learn one.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mvpn summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down    St/PfxRcd
13.0.0.5       0    13   26773    25781       3     0     0  00:04:16      0
13.0.0.8       0    13   26388    25790       3     0     0  00:04:43      2
13.0.0.11      0    13   25392    25736       3     0     0  00:02:52      0

RP/0/0/CPU0:XRv2#show bgp ipv6 mvpn summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down    St/PfxRcd
13.0.0.5       0    13   26773    25781       3     0     0  00:04:19      0
13.0.0.8       0    13   26389    25790       3     0     0  00:04:46      2
13.0.0.11      0    13   25392    25736       3     0     0  00:02:55      0
```

The reason for learning two I-PMSI routes is because of the central-services VPN. VRF OSPF imports VRF BGP's exported RT, which means that it will create an I-PMSI route with VRF BGP's RD. This is harmless.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mvpn | begin Network
Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 13:1
*>i[1][13.0.0.8]/40  13.0.0.8      0      100      0 ?
Route Distinguisher: 13:2
*>i[1][13.0.0.8]/40  13.0.0.8      0      100      0 ?
```

Both XRv1 and CSR5 successfully learn these routes, thanks to the RT filter being disabled. The key details, such as the BGP next-hop, communities, tunnel type (mLDP P2MP) and tunnel root (13.0.0.8) are all highlighted. These messages look almost identical to the ones in AS 24 except with different IP addressing.

```

```

Next, we will configure the inter-AS peers. For brevity, I only show the configuration on XRv1 and CSR6.

```

! XRv1
router bgp 13
neighbor 10.6.11.6
address-family ipv4 mvpn
route-policy RPL_PASS in
route-policy RPL_PASS out
address-family ipv6 mvpn
route-policy RPL_PASS in
route-policy RPL_PASS out

! CSR6
address-family ipv4 mvpn
neighbor 10.5.6.5 activate
neighbor 10.6.11.11 activate
address-family ipv6 mvpn
neighbor 10.5.6.5 activate
neighbor 10.6.11.11 activate

```

Once all the peers are configured, we perform a quick verification on CSR5 and CSR6 to ensure all peers come up. The problem at this point is clear; no MVPN routes are being exchanged between ASes. The type-1 I-PMSI routes are intra-AS only which is why BGP automatically applies to no-export community.

We saw this earlier on both IPv4 and IPv6 MVPN routes, and this explains why there is no eBGP MVPN route exchange.

```
R6#show bgp ipv4 mvpn all summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd
10.5.6.5      4      13      53     49       4    0   0 00:00:38      0

```

To solve this, we can add the optional “inter-as” modifier to the BGP AD configuration under the VRF. From the PEs perspective, this actually does not create a different I-PMSI route; it simply removes the “no-export” community from the type-1 route. Checking CSR2’s local route, the lack of the “no-export” community is the only difference. Only the RT remains.

```
! CSR2 and CSR8
vrf definition OSPF

rx pathid: 0, tx pathid: 0x0

```

CSR2 also has the remote I-PMSI route from CSR8 with RD 13:2. This has been successfully imported into VRF OSPF. The fact that it received a copy from both CSR6 and CSR7 indicates that both ASBRs are passing routes properly. Notice their neither CSR6 nor CSR7 changed the eBGP next-hop when advertising it to CSR (iBGP peer), which is expected.

```

R2#show bgp ipv4 mvpn rd 13:2 route-type 1 13.0.0.8

      rx pathid: 0, tx pathid: 0

```

CSR8 does not have CSR2's I-PMSI routes. Checking XRv2, we can see this is the result (again) of failing to set next-hop-self on the ASBRs. Neither path is the bestpath as a result.

```

R8#show bgp ipv4 mvpn rd 24:2
[no output]

```

```

RP/0/0/CPU0:XRv2#show bgp ipv4 mvpn rd 24:2 | begin Network
      Network                Next Hop                Metric LocPrf Weight Path
Route Distinguisher: 24:2
* i [1][24.0.0.2]/40        10.5.6.6                0      100      0 24 ?
* i                          10.6.11.6                100     100      0 24 ?

```

After making the adjustment on XRv1 and CSR5, CSR8 learns one copy of the route (the bestpath from the RR).

```

! CSR5

```

```

address-family ipv4 mvpn
  neighbor 13.0.0.12 next-hop-self
address-family ipv6 mvpn
  neighbor 13.0.0.12 next-hop-self

```

```

! XRv1
router bgp 13
  neighbor 13.0.0.12
    address-family ipv4 mvpn
      next-hop-self
    address-family ipv6 mvpn
      next-hop-self

```

```

R8#show bgp ipv4 mvpn rd 24:2 | begin Network
      Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 24:2
*>i [1][24:2][24.0.0.2]/12
      13.0.0.5          0          100          0 24 ?

```

When we check the mLDP database, we see several dynamically-discovered P2MP trees. I will look at the first tree rooted in CSR8. CSR2 should be a leaf in this tree, and the upstream client should point towards 13.0.0.8.

```

R2#show mpls mldp database summary

```

LSM ID Cnt.	Type	Root	Decoded Opaque Value	Client
B	P2MP	13.0.0.8	[gid 131072 (0x00020000)]	1
5	P2MP	24.0.0.2	[gid 131072 (0x00020000)]	1
6	P2MP	24.0.0.2	[gid 196608 (0x00030000)]	1
C	P2MP	13.0.0.8	[gid 262144 (0x00040000)]	1

However, we see no output for the upstream client. CSR2 has no idea how to reach 13.0.0.8, the root of the tree, and this cannot send label mapping messages towards it. The same is true for CSR8 trying to reach 24.0.0.2.

```

R2#show mpls mldp database id B
LSM ID : B   Type: P2MP   Uptime : 00:08:26
  FEC Root      : 13.0.0.8
  Opaque decoded : [gid 131072 (0x00020000)]
  Opaque length  : 4 bytes
  Opaque value   : 01 0004 00020000
  Upstream client(s) :
    None
    Expires      : N/A          Path Set ID   : B
  Replication client(s):
    MDT (VRF OSPF)
    Uptime       : 00:08:26     Path Set ID   : None

```

Interface : Lspvif1

```
R8#show ip cef 24.0.0.2
0.0.0.0/0
no route
```

```
R2#show ip cef 13.0.0.8
0.0.0.0/0
no route
```

A temporary static route shows what the “proper” output would look like. A downstream label is allocated on CSR2 and advertised to CSR7 so that LSM can be received along this P2MP tree. The static route is immediately removed after this output is displayed.

```
! CSR2
ip route 13.0.0.8 255.255.255.255 24.2.7.7

R2#show mpls mldp database id B

    Interface    : Lspvif1
```

Inter-AS option B with non-segmented (that is, end-to-end) mLDP trees is not supported on XE at this time. The “proper” way to do this configuration would be to use segmented trees with the ASBRs as the stitching points, much like L2VPN. On real XR platforms (not XRV), this is supported and is the point at which the type-2 inter-AS I-PMSI routes are created. Even though the type-1 I-PMSI routes were exchanged, the core trees cannot be built. The routers need real unicast routes (not just RPF fixup) towards the FEC root per tree. Of course, we know this is very bad design for option B. Introducing loopback leaking this late in the option B test will invalidate many of the other tasks we have accomplished. However, we will complete this style of design when testing option C since leaking PE loopbacks is required for all MPLS services. Cisco recommends using profile 0 as we demonstrated earlier, along with the PIM vector + RD, to support inter-AS MVPN on XE routers with option B. In the event the feature is ever supported, one can continue this lab based on the partial configuration.

8.4.2.5 MPLS TE

This section details how to configure inter-AS TE with option B. Somewhat like the failed MVPN mLDPLab for option B, MPLS TE is a little unwieldy because it assumes the ASes are aware of one another's loopbacks. It does technically "work" with option B, but from a design perspective, it makes more sense in option C. TE LSPs can be signaled but their utility is very limited. The operation of inter-AS TE is almost identical to inter-area/inter-level TE examined in the Unified MPLS section. It is covered in detail here as well, but essentially, loose hop path expansion is used on each ASBR to stitch a patch from head to tail.

The configuration is very simple. First, we must enable MPLS TE on the transit interfaces on all routers. On the XE routers, we identify the remote ASBR peer as a "passive" neighbor. This feature is not supported on XR and we will use an alternative approach discussed later.

```
! CSR6
interface GigabitEthernet2.556
  mpls traffic-eng tunnels
  mpls traffic-eng passive-interface nbr-te-id 13.0.0.5 nbr-if-addr 10.5.6.5
  ip rsvp bandwidth 200000

interface GigabitEthernet2.561
  mpls traffic-eng tunnels
  mpls traffic-eng passive-interface nbr-te-id 13.0.0.11 nbr-if-addr
10.6.11.11
  ip rsvp bandwidth 200000

! XRv1
rsvp
  interface GigabitEthernet0/0/0/0.561
    bandwidth 200000

mpls traffic-eng
  interface GigabitEthernet0/0/0/0.561

! CSR5
interface GigabitEthernet2.556
  mpls traffic-eng tunnels
  mpls traffic-eng passive-interface nbr-te-id 24.0.0.6 nbr-if-addr 10.5.6.6
  ip rsvp bandwidth 200000

interface GigabitEthernet2.557
  mpls traffic-eng tunnels
  mpls traffic-eng passive-interface nbr-te-id 24.0.0.7 nbr-if-addr 10.5.7.7
  ip rsvp bandwidth 200000

! CSR7
interface GigabitEthernet2.557
  mpls traffic-eng tunnels
  mpls traffic-eng passive-interface nbr-te-id 13.0.0.5 nbr-if-addr 10.5.7.5
  ip rsvp bandwidth 200000
```

Once this is configured, we can verify the TED in each AS. Beginning with AS 24, we will use the same cursory check seen in the initial option B verification. There are three new links in the TED that are a result of the MPLS TE passive-interfaces configured on the ASBRs. The links are highlighted below; there is no internal neighbor node ID for these peers, so the value is sent to $2^{32} - 1$ as a way of signaling a null value. The IS-IS system ID within the NET is the peer TE ID encoded into the first 4 bytes of the system ID. Since these are valid links in the graph, PCALC can consider them for TE LSPs.

```
R2#show mpls traffic-eng topology brief | include IGP Id

```

Inside AS 13, we now see 16 opaque-area LSAs versus 14 from before. Ideally, we would have seen 17; this is where XR fails to support inter-AS TE. The transit link between XRv1 and CSR6 is not visible to AS 13 as a result of this XR limitation.

```
R8#show ip ospf 13 0 database database-summary
```

```
OSPF Router with ID (13.0.0.8) (Process ID 13)
```

```
Area 0 database summary
```

LSA Type	Count	Delete	Maxage
Router	4	0	0
Network	0	0	0
Summary Net	0	0	0
Summary ASBR	0	0	0
Type-7 Ext	0	0	0
Prefixes redistributed in Type-7 0			
Opaque Link	0	0	0
Opaque Area	16	0	0

```

Just like with inter-area TE, we can accomplish inter-AS TE with two different mentalities. The first is tunnel stitching, which similar to the L2VPN MSPW, would result in intra-AS TE tunnels that terminate on the ASBRs. We would optionally configure a one-hop tunnel between ASBRs but that doesn't make much sense. To demonstrate this capability, I will create a TE tunnel from CSR2 to CSR6 over the high-cost path via CSR7. This will fully replace the LDP label normally imposed by CSR2 for transport across AS 24. The reason the tunnel should go to CSR6 and not CSR7 is because CSR2's VPN routes prefer CSR6 as the egress ASBR. CSR2 selected CSR6 due to having a lower BGP RID, so tunneling traffic to CSR7 would not be effective. We will test connectivity to a central services route.

```
R2#show bgp vpnv4 unicast vrf OSPF 110.0.0.0
BGP routing table entry for 24:2:110.0.0.0/32, version 6424
Paths: (1 available, best #1, table OSPF)
  Not advertised to any peer
  Refresh Epoch 1
  13 100, (Received from a RR-client), imported path from 13:1:110.0.0.0/32
(global)
  10.5.6.5 (metric 20) (via default) from 24.0.0.6 (24.0.0.6)
    Origin incomplete, metric 0, localpref 100, valid, internal, best
    Extended Community: RT:13:1
    mpls labels in/out nolabel/5008
    rx pathid: 0, tx pathid: 0x0
```

The tunnel configuration is very straightforward using explicit-paths and autoroute. Remember that this will place all IP traffic towards 24.0.0.6/32 into the tunnel, which may include L2VPN traffic.

```
! CSR2
ip explicit-path name EP_2_7_14_6 enable
```

```
next-address 24.0.0.7
next-address 24.0.0.14
next-address 24.0.0.6
```

```
interface Tunnel200
description INTRA-AS TO CSR6
ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 24.0.0.6
tunnel mpls traffic-eng autoroute announce
tunnel mpls traffic-eng path-option 10 explicit name EP_2_7_14_6
```

We quickly check the status of the tunnel to ensure it is up, then use MPLS traceroute to check the data plane. For additional details on MPLS TE, check the dedicated chapter. These TE examples will focus only on the inter-AS components.

```
R2#show mpls traffic-eng tunnels tunnel 200 brief | begin TUNNEL
TUNNEL NAME          DESTINATION          UP IF    DOWN IF    STATE/PROT
INTRA-AS TO CSR6     24.0.0.6             -        Gi2.527    up/up
```

```
R2#traceroute mpls traffic-eng tunnel 200
Tracing MPLS TE Label Switched Path on Tunnel200, timeout is 2 seconds
[snip]
Type escape sequence to abort.
 0 24.2.7.2 MRU 1500 [Labels: 7041 Exp: 0]
L 1 24.2.7.7 MRU 1500 [Labels: 94003 Exp: 0] 8 ms
L 2 24.7.14.14 MRU 1500 [Labels: implicit-null Exp: 0] 2 ms
! 3 24.6.14.6 4 ms
```

As soon as we build this tunnel, VPN connectivity inside both VPNs is broken. Both VPNs are ultimately depending on CSR6 as their egress point, but the tunnel is “unusable”.

```
R2#show ip cef vrf EIGRP 10.3.3.3
10.3.3.3/32
  nexthop 24.0.0.6 Tunnel200 unusable: no label
```

```
R2#show ip cef vrf OSPF 10.4.4.4
10.4.4.4/32
  nexthop 24.0.0.6 Tunnel200 unusable: no label
```

The output is a bit misleading because clearly the tunnel has an associated RSVP label; we proved it with MPLS OAM. If we follow the route recursion more closely, we can reveal the error via a manual tracing procedure. Inside the EIGRP VPN as an example, the VPN next-hop is XRv1’s transit link interface towards CSR6. This is because CSR6 did not adjust the next-hop and instead redistributed the host route 10.6.11.11/32 into IGP.

```

R2#show bgp vpnv4 unicast vrf EIGRP 10.3.3.3

    mpls labels in/out nlabel/91010
    rx pathid: 0, tx pathid: 0x0

```

The route is learned via a TE tunnel, so one might think the RSVP label can be imposed now. This is false and is explained below.

```

R2#show ip route 10.6.11.11
Routing entry for 10.6.11.11/32
  Known via "isis", distance 115, metric 20, type level-2

  Routing Descriptor Blocks:
    * 24.0.0.6, from 24.0.0.6, 00:06:31 ago, via Tunnel200
      Route metric is 20, traffic share count is 1

```

When we first configured CSR6 to redistribute those transit links, we noticed that CSR6 allocated non-null labels for them. Despite being connected host-routes, they are not local routes, so LDP treats them as if they were IGP learned. As such, the BGP next-hop is not the same LSR as the tunnel destination. To solve this, we require a third label between the transport RSVP label and the BGP VPN label. This is normally achieved with tLDP running across the TE tunnel. If CSR2 can learn CSR6's local label for 10.6.11.11/32, it can push that label second in the stack, which allows CSR6 to switch the packet to XRv1. CSR6 cannot swap the BGP label since it did not allocate it (did not change the BGP next-hop). Instead, this third label allows us the tunnel the VPN label outside of the AS so that XRv1 can perform the swap. CSR6 must accept LDP targeted sessions (it already is to support VPLS but I show the configuration again) and CSR2 must enable tLDP on the tunnel.

```

! CSR6
mpls ldp discovery targeted-hello accept

! CSR2
interface Tunnel200
  mpls ip

```

When the tLDP session forms, CSR2 can learn CSR6's label for 10.6.11.11/32 and push it onto the label stack above the VPN label. The TE label is added last and is not shown in the CEF output. The tunnel is now usable and unicast connectivity should be restored.

```
R2#show mpls ldp bindings 10.6.11.11 32 neighbor 24.0.0.6
  lib entry: 10.6.11.11/32, rev 43
    remote binding: lsr: 24.0.0.6:0, label: 6005
```

```
R2#show ip cef vrf EIGRP 10.3.3.3
10.3.3.3/32
  nexthop 24.0.0.6 Tunnel200 label 6005 91010
```

```
R2#show ip cef vrf OSPF 10.4.4.4
10.4.4.4/32
  nexthop 24.0.0.6 Tunnel200 label 6005 91007
```

A traceroute inside VRF EIGRP proves this; we can see 3 labels in the stack while the packet transits CSR7 and XRv4. We can see that label 91010, the VPN label for 10.3.3.3/32, is tunneled all the way to XRv1.

```
R1#traceroute 10.3.3.3 source 10.1.1.1
Type escape sequence to abort.
Tracing the route to 10.3.3.3
VRF info: (vrf in name/id, vrf out name/id)

 8 10.3.12.3 16 msec 12 msec 11 msec
```

Upon receipt, XRv1 may want to put this traffic into a TE tunnel as well. Below is a basic TE tunnel to stitch traffic from the ASBR to the egress PE.

```
! XRv1
explicit-path name EP_11_5_8_12
  index 10 next-address strict ipv4 unicast 13.0.0.5
  index 20 next-address strict ipv4 unicast 13.0.0.8
  index 30 next-address strict ipv4 unicast 13.0.0.12

interface tunnel-te300
  description INTRA AS TO XRv2
  ipv4 unnumbered Loopback0
  autoroute announce
  destination 13.0.0.12
  path-option 10 explicit name EP_11_5_8_12
```

Unlike AS 24, XRv1 does not have to worry about running tLDP over this TE tunnel. Since the final destination is the tunnel target (that is to say, the LDP label would have been a null-label anyway), a third label is not required. We verify that the tunnel comes up on XRv1, then verify the data plane with MPLS traceroute.

```
RP/0/0/CPU0:XRv1#show mpls traffic-eng tunnels brief
              TUNNEL NAME          DESTINATION      STATUS  STATE

```

This kind of inter-AS TE approach is very simple but does not take advantage of the new inter-AS links. It's similar to option A with the added complexity of a third MPLS label in certain instances. With option B, actually having PE-PE tunnels across AS boundaries does not make sense. Below, I demonstrate such an example. Using loose-hop path expansion, we can specify the ASBRs along the path. This information is written to the RSVP PATH ERO with a special flag so the loose-hops know to "expand" the ERO to replace a single loose hop with several strict hops. We must use some form of static route here as

autoroute announce and forwarding adjacency are unsupported; this seems to violate the option B design as it requires routers to know about one other's TE IDs.

```
! CSR2
ip explicit-path name EP_LOOSE_2_7_5_11_12 enable
  next-address loose 24.0.0.7
  next-address loose 13.0.0.5
  next-address loose 13.0.0.12

interface Tunnel201
  description INTER-AS TO XRV2
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 13.0.0.12
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng path-option 10 explicit name EP_LOOSE_2_7_5_11_12
```

To understand the process, we will enable PCALC debugging on CSR2, CSR7, and CSR5. This will reveal what the PCALC algorithm is doing behind the scenes to build the loose path.

```
! CSR2, CSR7, and CSR5
debug mpls traffic-eng path lookup
```

CSR2 begins the PCALC process by feeding the explicit-path into the PCALC algorithm. The hops are all identified as loose hops. CSR2 immediately realizes it does not have TE ID 13.0.0.12 in its TED; because of loose-hop expansion, CSR2 assumes that if it can compute the path to CSR7, then CSR7 can continue to compute partial paths towards the final destination. This is not typical for RSVP-TE since normally only the headend executes CPF and involves PCALC while the middle/tail routers only interact via the signaling protocol, RSVP. CSR2's best dynamic path to CSR7 is via XRv4, so the first loose-hop of 24.0.0.7 is expanded into a series of strict hops.

```

```

The ERO that CSR2 sends to XRv4 contains this refinement computed above. From XRv4's perspective, it doesn't have to do any loose hop expansion since it is just following a strict path to CSR7.

```

R2#show ip rsvp sender detail filter session-type 7 destination 13.0.0.12 |
section outgoing
  ERO: (outgoing)
    24.2.14.14 (Strict IPv4 Prefix, 8 bytes, /32)
    24.7.14.7 (Strict IPv4 Prefix, 8 bytes, /32)
    24.0.0.7 (Strict IPv4 Prefix, 8 bytes, /32)
    13.0.0.5 (Loose IPv4 Prefix, 8 bytes, /32)
    13.0.0.12 (Loose IPv4 Prefix, 8 bytes, /32)

```

CSR7's debug output isn't very useful, likewise due to the next loose-hop being inter-AS. CSR7 invokes the LSP expand algorithm based on the loose hop of 13.0.0.5 inside the PATH ERO from XRv4. Also note that nodes CSR2 and XRv4 are "exclude nodes"; this guarantees that, while computing the loose path, CSR7 does not consider those nodes in the path to create a loop. The reason it knows about these nodes is the RSVP PATH RRO, which tracks the hops in the forward direction (seen later).

```

! CSR7

```

The debug output makes it look like the process failed, but it didn't. Instead, CSR7 just failed to expand the loose hop, so it removes its own addresses from the ERO and sends the PATH message onward to CSR5 without expanding 13.0.0.5.

```

R7#show ip rsvp sender detail filter session-type 7 destination 13.0.0.12 |
section ERO
  ERO: (incoming)
    24.7.14.7 (Strict IPv4 Prefix, 8 bytes, /32)
    24.0.0.7 (Strict IPv4 Prefix, 8 bytes, /32)
    13.0.0.5 (Loose IPv4 Prefix, 8 bytes, /32)
    13.0.0.12 (Loose IPv4 Prefix, 8 bytes, /32)
  ERO: (outgoing)

    13.0.0.5 (Loose IPv4 Prefix, 8 bytes, /32)
    13.0.0.12 (Loose IPv4 Prefix, 8 bytes, /32)

```

To show the PATH RRO, we look at the same detailed output with a different filter. Using this, we can see all the hops in the path to prevent loose-hop expansion loops. It also details any FRR within the network.

```

R7#show ip rsvp sender detail filter session-type 7 destination 13.0.0.12 |
section RRO
  RRO:
    24.7.14.14/32, Flags:0x0 (No Local Protection)

```

24.2.14.2/32, Flags:0x0 (No Local Protection)

When CSR5 receives the PATH message, it needs to expand the path to XRv2. It ignores the hop to 13.0.0.5 since that is its local TE ID and begins processing the next-hop in the ERO. Several error messages are displayed since CSR5 has no idea how to interpret the RSVP PATH RRO; the three highlighted IP addresses aren't in the TED (passive interfaces don't count) and so the router warns us that it cannot guarantee a loop free path as a result. CSR5 expands the loose path to XRv2 to include CSR8 as a strict hop.

```

```

We cannot use traceroute to verify the LSP since routers in AS 13 has no reachability back to CSR2, so the traceroute replies will not return. This is part of the reason why inter-AS option B is awkward. However, we can prove that the traceroute probes are reaching XRv2 using some debug. OAM LSP verification (LSPV) reports packets from RID 13.0.0.2, which means the unidirectional LSP is functional. XRv2 reports there is no reverse LSP, so there is no ability to reply.

```

When we traceroute inside the VPN, the traffic flows through. Looking carefully at the first few labels of the TE tunnel above, we can clearly see that VPN traffic isn't even going inside the TE tunnel at all. For example, XRv4 is the next-hop after CSR2, but it uses label 94017 versus label 94005.

```

R1#traceroute 10.3.3.3 source 10.1.1.1

```

Following the route recursion, this makes perfect sense. CSR2 is going to push a BGP label allocated by XRv1 (10.6.11.11) and tunnel traffic towards the ASBR, CSR6. Having an end-to-end tunnel does nothing for us because the BGP next-hop isn't 13.0.0.12. It doesn't matter that CSR2 tries to route VPN traffic to XRv2 directly over the TE tunnel because the BGP topology doesn't enable this. The VPN traffic must pass through the ASBR that advertised the best-path or else the label swapping cannot occur properly.

```

    Route metric is 20, traffic share count is 1
```

If we try to forcefully move traffic into the tunnel, everything breaks. I add a temporary bogus static route below to prove it. Suddenly the route recursion looks correct at a glance. This is why it is important to track the actual label values and not just count the number of labels in the stack.

```
R2#show ip route 10.6.11.11
Routing entry for 10.6.11.11/32
  Known via "static", distance 1, metric 0 (connected)
  Routing Descriptor Blocks:
  * directly connected, via Tunnel201
    Route metric is 0, traffic share count is 1
```

```
R2#show ip cef vrf EIGRP 10.3.3.3
10.3.3.3/32
  nexthop 10.6.11.11 Tunnel201 label 91010
```

Using ping and traceroute, we can clearly see VPN connectivity is broken. VPN label 91010 is still being added to the stack but XRv1 has been totally bypassed. This VPN label will be exposed to XRv2 and the traffic will be dropped as a result.

```
R1#ping 10.3.3.3 source 10.1.1.1
Type escape sequence to abort.

```

Using EPC outbound on CSR8 towards XRv2, we can see this failure. CSR8 performs PHP along the TE LSP as it should, exposing the incorrect VPN label to XRv2. This proves that the TE tunnel and static route on CSR2 are functioning properly, but the lack of synchronization with the BGP topology means option B is broken. Label 0x16382 is 91010 in decimal, and XRv2 drops this traffic as there is no corresponding LFIB entry. This label should have been exposed to XRv1.

```
R8#show mpls traffic-eng tunnels role middle | include Label

RP/0/0/CPU0:XRv2#show mpls forwarding labels 91010
[no output]
```

In summary, inter-AS TE does technically work (PCALC completes and the LSP can be signaled) over an option B network. It is not very useful because the ASBRs will adjust the BGP next-hops at least once, so tunneling traffic across ASes in a single LSP is not compatible with the option B design. This feature would make more sense for UMPLS or inter-AS option C architectures where MPLS service next-hops (L3VPN, L2VPN, etc) are unchanged. For MPLS-TE in an option B environment, I would recommend the tunnel stitching method as used for option A.

8.4.2.6 Confederation variation

Confederations with option B are a little more interesting than with option A. With option A, we only had to adjust the BGP configurations slightly: confederation ASN/peer specification, next-hop processing on ASBRs, and filter removal. We will have to do these things for option B, but the configuration is more involved on XR as new commands are introduced for intraconfederation (inter-subAS) MPLS forwarding. First, I begin by changing the BGP ASNs as was done with option A. This configuration will be identical for all confederation variations. This also includes adjusting CSR10, a CE router, to peer with AS 42518 rather than AS 24.

```
! CSR2 and XRv4
router bgp 24
  bgp confederation identifier 42518

! CSR6 and CSR7
router bgp 24
  bgp confederation identifier 42518
  bgp confederation peers 13

! CSR8 and XRv2
router bgp 13
  bgp confederation identifier 42518

! CSR5 and XRv1
router bgp 13
  bgp confederation identifier 42518
  bgp confederation peers 24

! CSR10
router bgp 100
  neighbor 10.8.10.8 remote-as 42518
  neighbor FD00:10:8:10::8 remote-as 42518
```

For brevity, I check CSR5 and CSR6 for their VPNv4/v6 sessions between ASes. This check ensures that the confed-internal connections to the RRs are operational. It also validates the confed-external connections between all sets of ASBRs. Quickly scanning the last column, we can see the peers are still up. This verification is easier than with option A since there were per-VRF peers across the intraconfederation (inter-subAS) boundaries.

```

    no route-policy RPL_PASS in
    no route-policy RPL_PASS out
```

To review from earlier, CSR5 and XRv1 are configured to retain all RTs (the preferred approach for option B ASBRs), CSR7 is a route-reflector, and CSR6 imports the routes locally into VRFs. Checking CSR5, we can see routes received from CSR6 and CSR7 with RD 24:2 (represents OSPF VPN). These are confed-external as expected, and like option A, the next-hops are inaccessible. Like option A, these sub-AS loopbacks are not supposed to leak between AS boundaries, so next-hop-self is the best option to resolve this.

```
R5#show bgp vpnv4 unicast rd 24:2 10.9.9.9/32

Similar to option A, applying this configuration seems to “fix” everything. This is mostly because it restores the traditional option B eBGP behavior at the AS boundaries. As a very fast verification, we can see the OSPF sham-links are up, and XRv3 learns the C-PIM RP information. This quickly tests us, with some degree of confidence, that unicast and multicast connectivity are operable between sub-ASes.

```

R8#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::2 is up
Sham Link OSPFv3_SL1 to address FD00::2 is up

```

I quickly trace the LSP from CSR9 to CSR10 inside of the central services VPN using IPv6. CSR9 has an external route via CSR2. This is an indication that the sham-link is working since CSR9 is going to prefer the shortest path to the originating ASBR, which is 10.4.8.8 (CSR8). The shortest path to CSR8 is via the MPLS network and the path is intra-area. Just because the shared services route is external does not mean the sham-link cannot influence forwarding towards it.

```

```

CSR2's VPNv4 route originates from AS 100 and transits sub-AS 13. RT:13:1 is imported locally by both VRF EIGRP and OSPF, and label 5030 is used to forward traffic to CSR5. This implies that CSR2 has an IGP route to CSR5, also implying that CSR6 did not set "next-hop-self" for this AFI. Label 94032 is used since the IGP route points through XRv4, requiring XRv4's LDP label be imposed. The label stack becomes {94032 5030}.

XRv4 and CSR6 are P routers along this LSP, performing label swap/pop operations as shown below. Although CSR6 is an ASBR, it must tunnel the VPNv4-labeled traffic to CSR5 as it did not set a new VPN next-hop (and thus did not allocate a new VPN label).

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94032
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94032	6069	10.5.6.5/32	Gi0/0/0/0.564	24.6.14.6	12944

```
R6#show mpls forwarding-table labels 6069
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
6069	Pop Label	10.5.6.5/32	14224	Gi2.556	10.5.6.5

CSR5 performs the function of a classic option B ASBR by swapping the VPN label for the original VPN label of 8004, allocated by CSR8. Since CSR5 did change the next-hop (result of next-hop-self during this confederation test), the VPN label must be swapped. CSR8 receives traffic with VPN label 8004, removes all labels, and delivers the traffic to CSR10 inside the VPN.

```
R5#show mpls forwarding-table labels 5030
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
5030	8004	[13:1]::110:0:0:2/128	\	Gi2.558	13.5.8.8

```
R8#show mpls forwarding-table labels 8004 detail
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
8004	No Label	::110:0:0:2/128[V]	\	Gi2.580	FE80::10

MAC/Encaps=18/18, MRU=1504, Label Stack{}

005056A9F961005056A9FB1C81000DFC86DD

VPN route: BGP

No output feature configured

Traceroute on CSR9 confirms this operation and the label stack. So far, this is identical behavior to what was observed in option B.

```
R9#traceroute ipv6
```

```

```

Next, I will simulate CSR5 going down for maintenance. The router remains online, but its intraconfederation links are inoperable. The only connection between sub-ASes is between XRv1 and CSR6. CSR6 now learns the central services routes from XRv1 only. Everything appears correct. CSR6 does not adjust the next-hop and so does not allocate a local label, nor perform a VPNv6 label swap. The route is confed-external and originates from AS 100, transiting through sub-AS 13.

```
R6#show bgp vpnv6 unicast vrf OSPF ::110:0:0:2/128
```

```

```

```
Extended Community: RT:13:1
```

```
mpls labels in/out nlabel/91009
```

```
rx pathid: 0, tx pathid: 0x0
```

CSR2 correct imposes a transport label from XRv4 towards 10.6.11.11 (VPN next-hop) along with the VPN label of 91009 above.

```
R2#show ipv6 cef vrf OSPF ::110:0:0:2
```

```
::110:0:0:2/128
```

```
nexthop 24.2.14.14 GigabitEthernet2.524 label 94034 91009
```

XRv1 appears to perform the correct VPN label swapping as well, just as CSR5 did.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91009
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91009	8004	13:1:::110:0:0:2/128	\	13.0.0.8	2220

Traceroute on CSR9 indicates proper connectivity from CSR9 to CSR10.

```
R9#traceroute ipv6
Target IPv6 address: ::110:0:0:2
Source address: ::10:9:9:9
[snip]

 1 FD00:10:2:9::2 4 msec 4 msec 4 msec
 2 2024:24:2:14::14 [MPLS: Labels 94034/91009 Exp 0] 7 msec 7 msec 10 msec

 6 FD00:10:8:10::10 29 msec 15 msec 14 msec
```

Using traceroute in the opposite direction, we notice a very undesirable effect. Traffic is preferring the backdoor link over the MPLS network. This is a result of the weight being higher for locally-originated routes. CSR8 should not be preferring the backdoor link to CSR9 anyway; this is an indication that the sham-links have failed. This issue is not specific to option B confederations, but we did not examine this exact case in the original option B L3VPN section.

```
R10#traceroute ipv6

Tracing the LSP between sham-link endpoints (necessary for the targeted OSPF hello exchange), we see that CSR8 has a valid VPNv6 route with associated label from XRv1. The route to the BGP next-hop is IGP, so the LDP label is used, which is implicit-null.

```

R8#show bgp vpnv6 unicast vrf OSPF fd00::2/128

```

Routing paths:

receive via Loopback2

Last updated 17:30:28 ago

Debugging OSPFv3 packets on CSR2 for IPv4 and IPv6, we can clearly see CSR2 receiving packets along both sham-links. This implies that connectivity from CSR8 to CSR2 is functioning correctly.

```
R2#debug ospfv3 vrf OSPF ipv6 packet
OSPFv3 packet debugging is on for process 2, IPv6, vrf OSPF
```

```
OSPFv3-2-IPv6-OSPF PAK    SL1: Sham link packet: interface VRF ID 0, packet
VRF ID 2
OSPFv3-2-IPv6-OSPF PAK   : SL1: IN: FD00::8->FD00::2: ver:3 type:1 len:36
rid:10.4.8.8 area:0.0.0.0 chksum:EECE inst:0
```

```
R2#debug ospfv3 vrf OSPF ipv4 packet
OSPFv3 packet debugging is on for process 2, IPv4, vrf OSPF
```

```
OSPFv3-2-IPv4-OSPF PAK    SL0: Sham link packet: interface VRF ID 0, packet
VRF ID 2
OSPFv3-2-IPv4-OSPF PAK   : SL0: IN: FD00::8->FD00::2: ver:3 type:1 len:36
rid:10.4.8.8 area:0.0.0.0 chksum:ADD0 inst:64
```

The output does not indicate any attempt to send packets out of the sham-links towards FD00::8/128. CSR2 does not have a VPN route to this destination in its OSPF VPN table, or in any table at all. The same is true for CSR6, which likely indicates some kind of routing problem inside sub-AS 13.

```
R2#show bgp vpnv6 unicast vrf OSPF fd00::8/128
% Network not in table
```

```
R2#show bgp vpnv6 unicast all fd00::8/128
% Network not in table
```

```
R6#show bgp vpnv6 unicast all FD00::8/128
% Network not in table
```

XRv1 doesn't even have it. XRv2 does, and reports that it advertises it to XRv1 as well.

```

```

This issue actually has nothing to do with confederations, but is good practice for solving a “non-issue”. In the option B section, we configured XRv1 not to be a candidate ASBR for the OSPF VPN using an RPL to selectively retain RTs. This behavior is the result of design decisions we made earlier for demonstration purposes. For this test, I will remove this configuration by retaining all RTs on XRv1. The sham-links immediately come up and proper connectivity is restored.

```

! XRv1
router bgp 13
  address-family vpnv6 unicast
    retain route-target all

```

As a side note, Cisco clearly states that some additional commands are necessary when using inter-AS option B with confederations under certain conditions. Specifically, the documentation states that the “mpls activate” stanza, complete with a list of transit links, must be configured under BGP. **This is only required when the BGP next-hop is learned through IGP or static; that is, if the next-hop is not connected.** I suspect that this would be required for ordinary eBGP peers as well given the multi-hop condition and is not specific to BGP confederations. I quickly configure XRv1 to peer with a new loopback on CSR6. CSR6 still peers with XRv1’s directly connected interface, but sources it’s BGP session from the new loopback. XRv1 no longer needs a host-route to CSR6’s connected interface, but does need one to the loopback for the BGP peer to form. We can also assume that it is needed for MPLS forwarding to work. You can use eBGP-multihop or ignore the connected check. Both of these qualify as “multi-hop” in terms of Cisco’s documentation of this feature.

```

XRv1 successfully learns the remote sham-link endpoint in AS 24, which is FD00::2/128. Traffic arriving to XRv1 for this VPN route would have label 91022 which XRv1 should swap to label 6059.

```

RP/0/0/CPU0:XRv1#show bgp vpnv6 unicast rd 24:2 FD00::2/128

XRv1 has a /32 route to the BGP next-hop, which meets the MPLS forwarding requirement in XR. Since the route is learned via static, it also expects an LDP label for this destination. A local label is allocated, but a remote label remains unbound. There is no LDP neighbor with 10.6.11.6 at all.

```

RP/0/0/CPU0:XRv1#show route 10.6.110.110
Routing entry for 10.6.110.110/32
  Known via "static", distance 1, metric 0
  Routing Descriptor Blocks

RP/0/0/CPU0:XRv1#show mpls ldp bindings 10.6.110.110/32
10.6.110.110/32, rev 17
  Local binding: label: 91037
  No remote bindings

```

Despite this lack of a new label binding, the LFIB does not appear to indicate an obvious fault. The label swap looks like it should be working, but we see 0 bytes switched. The sham-links are actively trying to form, so this number should be increasing if XRv1 was functioning properly. XRv1, at this point, is not able to send traffic as there is no transport label binding.

```

RP/0/0/CPU0:XRv1#show mpls forwarding labels 91022

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91022	6059	24:2:fd00::2/128		10.6.110.110	0

CSR6 doesn't have this problem as its architecture is different. It is not adjusting the VPNv4 next-hop and it redistributes the connected host-route into IGP. As such, it can tunnel traffic to XRv1 without issue. Traffic with VPN label 91017 is tunneled to XRv1 through CSR6.

```

R6#show bgp vpnv6 unicast rd 13:2 FD00::8/128

    Origin IGP, metric 0, localpref 100, valid, confed-external, best

```

```
Extended Community: RT:13:2
mpls labels in/out nlabel/91017
rx pathid: 0, tx pathid: 0x0
```

```
R6#show mpls forwarding-table 10.6.11.11 32
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Outgoing interface	Next Hop
6074	Pop Label	10.6.11.11/32	28546	Gi2.561	10.6.11.11

XRv1 is able to receive these packets. It then performs the appropriate VPN label swap and transport label push operations as necessary. The byte counters increase, so we theorize that CSR2 can send traffic to CSR8, but not vice versa.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91017
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91017	8016	13:2:fd00::8/128		13.0.0.8	24064

OSPFv3 debugging on CSR2 and CSR8 reveal this is true. CSR2 only shows LAN-side OSPFv3 exchanges with no sham-link activity. This indicates a problem with XRv1 forwarding MPLS traffic towards CSR6 as a result of the multi-hop BGP peer.

```

The most obvious solution to this problem would be to somehow inform XRv1 that it can use a null label in the stack as transport to reach 10.6.110.110/32. We know that it is connected to CSR6 so no long-range transport is necessary. Although sloppy, we can enable LDP between the peers to accomplish this. I use some intelligent outbound LDP label filtering on both XRv1 and CSR6. On CSR6, the sequence of filters does matter, so the more specific filter towards XRv1 is placed first. This allows CSR6 to only advertise the implicit-null label for 10.6.110.110/32 towards XRv1, while the internal peers can get all labels. XRv1 advertises no labels at all to CSR6, effectively making it a receive-only peer.

```
! CSR6
interface GigabitEthernet2.561
  mpls ip
  mpls ldp discovery transport-address interface

no mpls ldp advertise-labels
mpls ldp advertise-labels for ACL_BGP_LOOP to ACL_XRV1
mpls ldp advertise-labels for ACL_ANY to ACL_INTERNAL_PEERS

ip access-list standard ACL_ANY
  permit any
ip access-list standard ACL_BGP_LOOP
  permit 10.6.110.110
ip access-list standard ACL_INTERNAL_PEERS
  permit 24.0.0.0 0.0.0.255
ip access-list standard ACL_XRV1
  permit 13.0.0.11

! XRv1
ipv4 access-list ACL_DENY
  10 deny ipv4 any any

mpls ldp
  address-family ipv4
  label
  local
  advertise
  to 24.0.0.6:0 for ACL_DENY

interface GigabitEthernet0/0/0.561
  address-family ipv4
  discovery transport-address interface
```

We check XRv1 to see that the peer is up and exactly 1 IPv4 label was received. The label is imp-null and is bound to prefix 10.6.110.110/32. CSR6 receives no labels from XRv1 at all, as expected.

```
RP/0/0/CPU0:XRv1#show mpls ldp neighbor brief
```

Peer	GR	NSR	Up Time	Discovery	Addresses	Labels

				ipv4	ipv6	ipv4	ipv6	ipv4	ipv6
13.0.0.12:0	N	N	14:33:17	1	0	3	0	4	0
13.0.0.5:0	N	N	14:33:17	1	0	5	0	4	0
13.0.0.8:0	N	N	02:43:39	1	0	4	0	5	0

```

```
Remote bindings: (1 peers)
```

Peer	Label
24.0.0.6:0	ImpNull

```
R6#show mpls ldp bindings neighbor 13.0.0.11
[no output]
```

Now, we can verify XRv1's LFIB entry along the sham-link transit path to see bytes being switched. This fixes the MPLS forwarding problem that confederations (or any multi-hop eBGP session) may create on the transit links. Since the next-hop is recursive (not connected), it is acceptable to not have an outgoing interface in the LFIB.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91022
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91022	6059	24:2:fd00::2/128		10.6.110.110	3188

We quickly check the sham-links to ensure they are up, then use traceroute within the VPN to verify it. This proves that XRv1 is now able to swap VPN labels between the sub-ASes.

```
R8#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::2 is up
Sham Link OSPFv3_SL1 to address FD00::2 is up
```

```

 6 10.2.9.9 20 msec 11 msec 13 msec
```

The LDP solution was very configuration-intensive and is generally a bad practice. Instead, Cisco built the “mpls activate” XR command stanza discussed briefly earlier. This instructs BGP to perform a null label (implicit-null) rewrite on traffic going towards a multi-hop external or confed-external peer, rather than rely on LDP. To test this, I disable LDP on CSR6’s interface (not shown) but leave the existing LDP filters in place for reference. The LDP neighbor goes down on XRv1, and forwarding is broken again. Traceroute inside of a customer VPN confirms this. Once the sham-link fails, the OSPF VPN will have a backdoor link available, but since the sham-link is a demand circuit, it may never fail without some other OSPF/BGP reconvergence event as a catalyst. Since the VPNv4/v6 control-plane is working, this can be a dangerous situation as traffic is blackholed and the backdoor link cannot be utilized.

```
RP/0/0/CPU0:XRv1#show mpls ldp bindings neighbor 24.0.0.6
[no output]
```

```
R4#traceroute 10.9.9.9 source 10.4.4.4

Tracing the route to 10.9.9.9
VRF info: (vrf in name/id, vrf out name/id)
 1 10.4.8.8 6 msec 4 msec 3 msec
 2 * * *
```

We can see the result of having this broken by checking the global FIB. There is no label for this prefix, so all labels are removed from the stack. This is the fundamental problem seen earlier, now reintroduced as a result of disabling LDP.

```
RP/0/0/CPU0:XRv1#show cef 10.6.110.110
10.6.110.110/32, version 3991, internal 0x1000001 0x0 (ptr 0xa14476f4) [1],
0x0 (0xa14139bc), 0xa20 (0xa156d708)
local adjacency 10.6.11.6

via 10.6.11.6, GigabitEthernet0/0/0/0.561, 5 dependencies, weight 0, class
0 [flags 0x0]
path-idx 0 NHID 0x0 [0xa1085100 0x0]
next hop 10.6.11.6
local adjacency
local label 91037 labels imposed {None}
```

On XRv1, we simply enable the feature under BGP to specify the null label rewrite. This is a purpose-built command introduced specifically for this purpose, which makes it more wieldy than the LDP solution. It allows BGP to assume implicit-null for the multi-hop peer without relying on LDP at all. This is a way to bypass the typical MPLS label imposition process. Although BGP technically has no concept of “interfaces” per se, this feature simply allows BGP to shortcut the label stacking process intelligently.

```
! XRv1
router bgp 13
mpls activate
```

```
interface GigabitEthernet0/0/0/0.561
```

Checking the FIB, we can see implicit-null is now bound to this prefix, despite it not being LDP learned. Connectivity has been restored across the VPNs now that XRv1 can label-switch traffic between sub-ASes again.

```
RP/0/0/CPU0:XRv1#show cef 10.6.110.110

From CSR6's perspective, nothing terribly interesting has happened. We can test XE as well to ensure that, when recursively looking up remote BGP next-hops, confederations are still supported. I shut down XRv1's BGP session to CSR6 to force traffic across CSR5. CSR5 is reconfigured to peer with 10.6.110.110 much like XRv1. CSR6 just changes the update-source to loopback611.

```
! CSR6
router bgp 24
  neighbor 10.5.6.5 update-source Loopback611

! CSR5
router bgp 13
  no neighbor 10.5.6.6
  neighbor 10.6.110.110 remote-as 24
  neighbor 10.6.110.110 disable-connected-check

  neighbor 10.6.110.110 next-hop-self
```

```
address-family l2vpn vpls
  neighbor 10.6.110.110 activate
  neighbor 10.6.110.110 next-hop-self
```

```
ip route 10.6.110.110 255.255.255.255 GigabitEthernet2.556 10.5.6.6
```

Checking CSR5's VPNv6 route to CSR2 for the sham-link, we can see it is reachable via CSR6's new loopback address. CSR5 has a static route for this peer just like Xrv1 did, which would suggest that CSR5 would have the same label binding problems.

```
R5#show bgp vpnv6 unicast rd 24:2 FD00::2/128
BGP routing table entry for [24:2]FD00::2/128, version 676

```

```
R5#show ip route 10.6.110.110
Routing entry for 10.6.110.110/32
  Known via "static", distance 1, metric 0
  Routing Descriptor Blocks:
  * 10.5.6.6, via GigabitEthernet2.556
    Route metric is 0, traffic share count is 1
```

Checking the LFIB, we can see that label swap occurring with some byte counts. The next-hop automatically recurses to 10.5.6.6, which is different than XR. As long as the interface is configured for MPLS BGP forwarding, XE does not require any special configuration to support this architecture. A quick traceroute proves that the label switching is functional.

```
R5#show mpls forwarding-table labels 5038
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
5038	6059	[24:2]FD00::2/128	2044	\	Gi2.556	10.5.6.6

```
R9#traceroute 10.4.4.4 source 10.9.9.9

 6 10.4.8.4 20 msec 11 msec 11 msec
```

If we temporarily remove “mpls bgp forwarding” from CSR5’s link to CSR6, forwarding does not work. This command is loosely equivalent to XR’s “mpls activate” except that XE requires it for options B and C for single and multi-hop BGP peers. XR only requires “mpls activate” for multi-hop peers. In any event, VPN traffic fails, and CSR5’s LFIB drops traffic since the VPN next-hop 10.6.110.110 is not reachable via an MPLS-enabled interface. Note: LDP is enabled on this transit link to support VPLS and has no effect on the BGP forwarding.

```
R9#traceroute 10.4.4.4 source 10.9.9.9
Type escape sequence to abort.
Tracing the route to 10.4.4.4
VRF info: (vrf in name/id, vrf out name/id)
 1 10.2.9.2 3 msec 3 msec 3 msec
 2 * * *
```

```
R5#show mpls forwarding-table labels 5038
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
5038	6059	[24:2]FD00::2/128	2236	\	drop	

Before continuing, I restore all BGP sessions in the network. A quick check on CSR6 and CSR5 will show that all sessions have been restored. I scan the right-most column for any positive integer, indicating that prefixes are being received from each peer.

10.6.11.11	4	13	20	37	1262	0	0	00:00:33	8
24.0.0.2	4	24	2184	1688	1262	0	0	03:50:00	6

MVPN works the same as it does in option B. Because mLDP is not supported across XE-based ASBRs, we will focus on PIM/GRE inside the EIGRP VPN. The default MDT uses P-group 232.13.24.255 and is exchanged across the intraconfederation links. CSR2, for example, receives the intra-AS route from XRv4 and two intraconfederation routes from CSR6 and CSR7. The next-hops for the intraconfederation routes are CSR5's connected interfaces, which is acceptable as CSR2 has IGP routes to these host addresses.

```
R2#show bgp ipv4 mdt all | begin Network
```

Network	Next Hop	Metric	LocPrf	Weight	Path
Route Distinguisher: 13:3					
* i 13.0.0.12/32	10.5.7.5	0	100	0	(13) i
*>i	10.5.6.5	0	100	0	(13) i
Route Distinguisher: 24:3 (default for vrf EIGRP)					
*> 24.0.0.2/32	0.0.0.0			0	?
*>i 24.0.0.14/32	24.0.0.14		100	0	i

Looking at the routes from the ASBRs, the most significant component of the MDT update is the default group address. This address must match within a confederation for the MVPN to form.

```

```

CSR2 sees both XRv2 and XRv4 as neighbors, which shows that it can receive traffic along the MDT. A more thorough verification would involve checking the other neighbors as well, but the architecture is identical to option B.

```

R2#show ip pim vrf EIGRP neighbor | begin ^Neigh
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
10.1.2.1          GigabitEthernet2.512    20:06:07/00:01:34 v2      1 / S P G

24.0.0.14         Tunnel17                 04:02:38/00:01:42 v2      1 / DR G

```

The BGP connector attribute is used to ensure that traffic arriving from the PMSI comes from the originator of the VPN route. In this case, that is 13.0.0.12, which matches the PIM neighbor above. RPF should pass for traffic arriving at CSR2. When the BGP connector attribute is present, it is evaluated in place of the BGP next-hop. Since 10.5.6.5 is not a PIM neighbor nor the MDT source of the traffic, the connector attribute helps forms the VPN end-to-end across an option B deployment.

```

R2#show bgp vpnv4 unicast vrf EIGRP 10.3.3.3/32

The PIM vector is still in play so that any core routers in AS 24 can successfully perform RPF lookups for the P-source 13.0.0.12. The P(S,G) join moves from CSR2 > CSR7 > CSR6 as shown below by way of the PIM vector.

```
R2#show ip mroute proxy
(13.0.0.12, 232.13.24.255)
  Proxy          Assigner      Origin      Uptime/Expire

  Proxy          Assigner      Origin      Uptime/Expire
  13:3/10.5.6.5   24.6.7.7     PIM         00:59:05/00:02:44
```

CSR7 cannot perform an RPF lookup for 13.0.0.12, so it uses the PIM vector instead. This is originated by the PE, CSR2, via BGP MDT. The PIM vector is the BGP next-hop which all routers in the AS should be able to reach. All of this information is the same as in option B.

```
R7#show ip mroute 232.13.24.255 13.0.0.12 | begin \
(13.0.0.12, 232.13.24.255), 03:39:30/00:02:44, flags: sTV
  Incoming interface: GigabitEthernet2.567, RPF nbr 24.6.7.6, vector 10.5.6.5
  Outgoing interface list:

```

Additional Reading – Reference configurations "inter-as-mpls-b-confed"

8.4.3 Option C (ASBR eBGP + Label, RR VPNv4 eBGP)

Option C is a highly scalable but highly complex inter-AS VPN solution. The VPN advertisement logic is similar to CSC or UMPLS since the MPLS service label never changes. That is, there is no ASBR performing a VPNv4/v6 or PW label swap as seen in option B. Instead, BGP labeled-unicast is used between the ASBRs so that labels can be allocated for remote PE loopbacks, which implies PE loopbacks are leaked between ASes. This is considered highly insecure and requires very close coordination between providers, but in doing this, the MPLS services are truly end-to-end. BGP imposes a second label over the transit links so that the bottom-most label is never swapped. For maximum scalability, the RRs in each AS are peered so the PEs need not run inter-AS eBGP sessions. As a result, the total number of new BGP sessions to configure is the sum of the RRs and ASBRs, which is a small number compared to options A and B. Continuing from option B, our ASBRs have very complex BGP configurations since they are supporting every “service” AFI we tested between ASes.

8.4.3.1 L3VPN

The first thing to do in this configuration is to establish the basic VPNv4/v6 peers within an AS between the PEs and RRs. Technically there is no need for the RRs to identify their single VPNv4/v6 peer as an RR-client, but I will do it as a best practice since it becomes significant if there are more PEs later. We will begin with AS 24; I do not show the basic peer-session parameters again.

```
! CSR2
router bgp 24
  address-family vpnv4
    neighbor 24.0.0.14 activate
    neighbor 24.0.0.14 route-reflector-client
  address-family vpnv6
    neighbor 24.0.0.14 activate
    neighbor 24.0.0.14 route-reflector-client

! XRv4
router bgp 24
  address-family vpnv4 unicast
  address-family vpnv6 unicast

  neighbor 24.0.0.2
    address-family vpnv4 unicast
    address-family vpnv6 unicast
```

From CSR2, we verify the session comes up. In the basic inter-AS verification, we also configured all of the PE-CE interactions, to include redistribution. We do not need to verify this again as it is basic and unrelated to option C.

```
R2#show bgp vpnv4 unicast all summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ  OutQ Up/Down  State/PfxRcd
24.0.0.14     4      24      32      41      6563   0    0 00:02:48      3

R2#show bgp vpnv6 unicast all summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ  OutQ Up/Down  State/PfxRcd
24.0.0.14     4      24      33      42      6065   0    0 00:02:56      4
```

A quick traceroute from CSR1 to XRv3 shows that the L3VPN within AS 24 is functional. The LSP is very short but this verifies the core MPLS components like VPNv4, CEF, LDP, and redistribution.

```
R1#traceroute 10.13.13.13 source 10.1.1.1
Type escape sequence to abort.
Tracing the route to 10.13.13.13
VRF info: (vrf in name/id, vrf out name/id)
 1 10.1.2.2 4 msec 4 msec 4 msec
 2 24.2.14.14 [MPLS: Label 94006 Exp 0] 5 msec 3 msec 4 msec
```

```
3 10.13.14.13 4 msec 12 msec 13 msec
```

Next, I will configure the same features in AS 13. XRv2 is a PE for the EIGRP VPN and also the RR for the AS.

```
! XRv2
router bgp 13
  bgp cluster-id 13.0.0.12
  address-family vpnv4 unicast
  address-family vpnv6 unicast

  af-group VPNV4 address-family vpnv4 unicast
    route-reflector-client
  af-group VPNV6 address-family vpnv6 unicast
    route-reflector-client

neighbor 13.0.0.8
  address-family vpnv4 unicast
    use af-group VPNV4
  address-family vpnv6 unicast
    use af-group VPNV6

! CSR8
router bgp 13
  address-family vpnv4
    neighbor 13.0.0.12 activate
  address-family vpnv6
    neighbor 13.0.0.12 activate
```

We verify that all of the BGP AFIs were successfully negotiated on XRv2.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.8      0     13   33429   32516    1620    0    0  00:05:08      7

RP/0/0/CPU0:XRv2#show bgp vpnv6 unicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.8      0     13   33429   32516    1695    0    0  00:05:11      7
```

Next, I configure the RT policies on VRF EIGRP and VRF BGP so that VRF BGP is the central services VPN. We did this earlier for all other labs so this is nothing new. I only do this in order to quickly verify the local L3VPN connectivity within AS 13 before continuing.

```
! CSR8
vrf definition BGP
  address-family ipv4
    route-target export 13:1
    route-target import 13:3
```

```

address-family ipv6
  route-target export 13:1
  route-target import 13:3

! Xrv2
vrf EIGRP
  address-family ipv4 unicast
    import route-target
      13:1
    export route-target
      13:3

  address-family ipv6 unicast
    import route-target
      13:1
    export route-target
      13:3

```

Using traceroute from CSR2 to CSR10, we can see that the intra-AS L3VPN is operational.

```

R3#traceroute 110.0.0.0 source 10.3.3.3
Type escape sequence to abort.
Tracing the route to 110.0.0.0
VRF info: (vrf in name/id, vrf out name/id)
 1 10.3.12.12 3 msec 3 msec 1 msec
 2 10.8.10.8 [MPLS: Label 8003 Exp 0] 5 msec 3 msec 3 msec
 3 10.8.10.10 4 msec 4 msec 4 msec

```

Next, we will prepare the ASBRs by configuring their transit links. I include the inter-AS TE configurations as well since these commands were discussed in the option B section. Like option B, there is a single transit link in the global table, so the configuration is straightforward. PIM is enabled with BSR-border to enable GRE-encapsulated multicast between both ASes without the RP information leaking across. There is nothing new about these interface configurations but I show them for reference.

```

! CSR6
interface GigabitEthernet2.556

```

Next, we will configure the eBGP labeled-unicast sessions. BGP should be configured to allocate labels only for internal loopback addresses in each AS as a best practice. This is valuable when these routers are also exchanging Internet routing tables and allocating labels for them is a waste of resources. In this test, I ensure that only these loopbacks can be exchanged at all, which ensures that a redistribution error in the local AS does not advertise additional prefixes to the eBGP peer. In XE, I use a route-map to identify which routes can be advertised with labels bound. XR decouples these functions by specifying an RPL for label allocation and for prefix advertisement. Using parameterization, I can re-use the RPL. Only CSR6 and XRv1 configurations are shown for brevity. Note that only PE loopbacks need to be advertised, but I build more generic RPLs so that adding PEs later doesn't require the BGP filters to change.

```

! CSR6
ip prefix-list PL_LOCAL_LOOPBACKS seq 5 permit 24.0.0.0/24 ge 32

route-map RM_IPV4_LUCAST_EBGP permit 10
  match ip address prefix-list PL_LOCAL_LOOPBACKS
  set mpls-label

router bgp 24
  no bgp default ipv4-unicast
  neighbor 10.5.6.5 remote-as 13
  neighbor 10.6.11.11 remote-as 13
  address-family ipv4
    neighbor 10.5.6.5 activate
    neighbor 10.5.6.5 route-map RM_IPV4_LUCAST_EBGP out
    neighbor 10.5.6.5 send-label
    neighbor 10.6.11.11 activate
    neighbor 10.6.11.11 route-map RM_IPV4_LUCAST_EBGP out
    neighbor 10.6.11.11 send-label

! XRv1
prefix-set PS_LOCAL_LOOPBACKS
  13.0.0.0/24 ge 32
end-set

route-policy RPL_IF_DEST_PASS($PS)
  if destination in $PS then
    pass
  endif
end-policy

```

```

router bgp 13
  address-family ipv4 unicast
    allocate-label route-policy RPL_IF_DEST_PASS (PS_LOCAL_LOOPBACKS)

  neighbor 10.6.11.6
    remote-as 24
    address-family ipv4 labeled-unicast
      route-policy RPL_PASS in
      route-policy RPL_IF_DEST_PASS (PS_LOCAL_LOOPBACKS) out

```

Once the configuration is complete, I will check the neighbor details to ensure the IPv4 MPLS label capability is negotiated. In XR, there is a specific AFI for it, which simplifies the logic in the parser. In XE, we need to specifically check for this capability exchange rather than look at the IPv4 unicast summary. Since the capabilities is exchanged bidirectionally with all peers, we can assume the configuration is correct so far.

```

R6#show bgp ipv4 unicast neighbors | include ^BGP|MPLS_Label
BGP neighbor is 10.5.6.5, remote AS 13, external link
  ipv4 MPLS Label capability: advertised and received
BGP neighbor is 10.6.11.11, remote AS 13, external link
  ipv4 MPLS Label capability: advertised and received

```

```

R5#show bgp ipv4 unicast neighbors | include ^BGP|MPLS_Label
BGP neighbor is 10.5.6.6, remote AS 24, external link
  ipv4 MPLS Label capability: advertised and received
BGP neighbor is 10.5.7.7, remote AS 24, external link
  ipv4 MPLS Label capability: advertised and received

```

Next, we need to exchange loopbacks across AS boundaries. The first option is to redistribute them into BGP, and then in the remote AS, redistribute them back into IGP. We will do this in AS 24. CSR7 will use network statements as this is a very simple way to advertise specific PE loopbacks without worrying about redistributing too many routes. The downside is that when new PEs are added in the future, the ASBR must be updated to advertise the new PE loopbacks. We can verify the network statements work by checking to see if BGP allocates local labels on CSR7. We see labels 7000 and 7002, which is appropriate.

```

! CSR7
router bgp 24
  address-family ipv4
    network 24.0.0.2 mask 255.255.255.255
    network 24.0.0.14 mask 255.255.255.255

```

```

R7#show bgp ipv4 unicast labels
  Network          Next Hop          In label/Out label
  24.0.0.2/32      24.7.14.14      7000/nolabel

```

```
24.0.0.14/32      24.7.14.14      7002/nolabel
```

Quickly checking CSR5, we can see these routes are learned from 10.5.7.7 (CSR7) and carry the proper outgoing labels.

```
R5#show bgp ipv4 unicast labels
  Network          Next Hop      In label/Out label
  24.0.0.2/32       10.5.7.7       nolabel/7000
  24.0.0.14/32      10.5.7.7       nolabel/7002
```

An alternative approach is to use redistribution. CSR6 will redistribute PE loopbacks from IS-IS into BGP using an intelligent filter. We could re-use the route-map/prefix-list from earlier, but that will redistribute the core and ASBR loopbacks as well as the prefix-list is not host-specific. Being specific with the IGP-to-BGP redistribution will minimize the security risks of leaking loopbacks by specifically targeting only the PE routers. To be fancy, I use IS-IS route-tags to make this a semi-dynamic process, which means we won't have to change the BGP configuration on CSR6 when new PEs are added, provided we tag the loopback properly. First, we need to add the route-tags to CSR2 and XRv4 loopback interfaces and verify success.

```
! CSR2
interface Loopback0
  isis tag 24

! XRv4
router isis 24
  interface Loopback0
    address-family ipv4 unicast
    tag 24
```

Checking CSR6, we can see the route-tags locally. These are carried inside the IS-IS LSPs.

```
R6#show ip route 24.0.0.2
Routing entry for 24.0.0.2/32
  Known via "isis", distance 115, metric 20
  Tag 24, type level-2
  Redistributing via isis 24
  Last update from 24.6.14.14 on GigabitEthernet2.564, 00:05:18 ago
  Routing Descriptor Blocks:
  * 24.6.14.14, from 24.0.0.2, 00:05:18 ago, via GigabitEthernet2.564
    Route metric is 20, traffic share count is 1
    Route tag 24
```

```
R6#show ip route 24.0.0.14
Routing entry for 24.0.0.14/32
  Known via "isis", distance 115, metric 10
  Tag 24, type level-2
```

```

Redistributing via isis 24
Last update from 24.6.14.14 on GigabitEthernet2.564, 00:04:57 ago
Routing Descriptor Blocks:
* 24.6.14.14, from 24.0.0.14, 00:04:57 ago, via GigabitEthernet2.564
  Route metric is 10, traffic share count is 1
  Route tag 24

```

CSR6's configuration becomes simple at this point as we create a route-map to match tag 24 for redistribution from IS-IS into BGP. The outbound BGP filter affords us some additional protection by only advertising (and allocating labels for) routes that match the host-route filter.

```

! CSR6
route-map RM_ISIS_TO_BGP permit 10
  match tag 24

router bgp 24
  address-family ipv4
    redistribute isis 24 level-2 route-map RM_ISIS_TO_BGP

```

We confirm it by checking CSR6 for local label allocation. We see labels 6004 and 6003 which are valid local labels for CSR6.

```

R6#show bgp ipv4 unicast labels

```

Network	Next Hop	In label/Out label
24.0.0.2/32	24.6.14.14	6004/nolabel
24.0.0.14/32	24.6.14.14	6003/nolabel

When we check CSR5, we can see these labels are distributed properly. CSR5 learns the same pair of loopbacks from CSR7 and CSR6 as expected.

```

R5#show bgp ipv4 unicast labels

```

Network	Next Hop	In label/Out label
24.0.0.2/32	10.5.6.6	nolabel/6004
	10.5.7.7	nolabel/7000
24.0.0.14/32	10.5.6.6	nolabel/6003
	10.5.7.7	nolabel/7002

XRv1 also learns these labels, but it also allocates local labels for them. We noticed that CSR5 made no effort to do this and there is "nolabel" assigned. The reason is because XR will always allocate a local label for a prefix if it receives a label from a peer, but XE does not. The logic of XE is that because ALL of the IPv4 labeled-unicast peers on CSR5 are only configured to allocate labels for routes matching 13.0.0.0/24 ge 32, there is no possibility of BGP being able to label switch traffic to these destinations. This is specific to BGP; just because BGP is not aware of a local/remote label doesn't mean RSVP, LDP, or other mechanisms cannot fulfill that role. We will see these LSP connections later when we evaluate the LFIB.

```
RP/0/0/CPU0:XRv1#show bgp ipv4 labeled-unicast labels | begin Network
  Network          Next Hop          Rcvd Label      Local Label
*> 24.0.0.2/32      10.6.11.6          6004            91004
*> 24.0.0.14/32    10.6.11.6          6003            91005
```

Next, we need to configure AS 13 to advertise its PE loopbacks to AS 24. The IGP-to-BGP option is one option and is certainly valid, but we can alternatively run IPv4 labeled-unicast internally within an AS to avoid the redistribution entirely. On all routers in AS 13, I enable IPv4 labeled-unicast. The local PEs can simply advertise their connected loopbacks directly into BGP without the ASBRs having to redistribute it from IGP. The benefit of this approach is protecting the P (core) routers as they will not have to learn the remote PE loopbacks via IGP. In these small networks, this benefit does not really materialize, but with many core routers and potentially many remote PE loopbacks, this can be significant. This requires more BGP configuration on the PEs and ASBRs, as well as an additional MPLS label in the data plane, which are small drawbacks. Labels for this AFI are also allocated for local loopbacks using identical configurations seen on XRv1.

```
! XRv2
prefix-set PS_LOCAL_LOOPBACKS
  13.0.0.0/24 ge 32
end-set

route-policy RPL_IF_DEST_PASS($PS)
  if destination in $PS then
    pass
  endif
end-policy

router bgp 13
  address-family ipv4 unicast
    network 13.0.0.12/32
    allocate-label route-policy RPL_IF_DEST_PASS(PS_LOCAL_LOOPBACKS)

  af-group IPV4_LUCAST address-family ipv4 labeled-unicast
    route-reflector-client

  neighbor 13.0.0.5
    use session-group IBGP
    address-family ipv4 labeled-unicast
    use af-group IPV4_LUCAST

  neighbor 13.0.0.8
    address-family ipv4 labeled-unicast
    use af-group IPV4_LUCAST

  neighbor 13.0.0.11
    use session-group IBGP
```

```

address-family ipv4 labeled-unicast
  use af-group IPV4_LUCAST

! XRv1
router bgp 13
  neighbor 13.0.0.12
    remote-as 13
    timers 10 40
    password encrypted 11203B22274358
    update-source Loopback0
  address-family ipv4 labeled-unicast

! CSR5
router bgp 13
  neighbor 13.0.0.12 remote-as 13
  neighbor 13.0.0.12 password IBGP13
  neighbor 13.0.0.12 update-source Loopback0
  neighbor 13.0.0.12 timers 10 40
  address-family ipv4
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 send-label

! CSR8
router bgp 13
  neighbor 13.0.0.12 remote-as 13
  neighbor 13.0.0.12 password IBGP13
  neighbor 13.0.0.12 update-source Loopback0
  neighbor 13.0.0.12 timers 10 40
  address-family ipv4
    network 13.0.0.8 mask 255.255.255.255
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 send-label

```

First we check the BGP sessions for this AFI on XRv2. We can see all 3 sessions come up. We can also make sense out of the route counters. CSR8 and XRv2 both advertise their PE loopbacks into BGP via the network statement so that the ASBRs don't need to. This is why there is 1 route (13.0.0.8/32) from CSR8. XRv1 and CSR5 are both advertising the 2 routes learned from AS 24.

```

RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast summary | begin ^Neighbor
Neighbor      Spk    AS  MsgRcvd  MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.5      0     13      23       18         3    0    0 00:02:38      2
13.0.0.8      0     13   33928   32975         3    0    0 00:00:59      1
13.0.0.11     0     13      22       19         3    0    0 00:02:55      2

```

When we check the route information, XRv2 cannot select a best-path for any of the routes from AS 24. This is because the ASBRs did not adjust the next-hop when sending traffic to XRv2. When we tested option B, AS 13 ASBRs used next-hop-self while AS 24 ASBRs advertised the transit links into IGP. Both were valid techniques, and remain so for option C. This time, AS 13 ASBRs will advertise the transit link

host addresses into IGP. Remember that XR routers require a /32 route to the BGP next-hop for VPN routes, so we cannot advertise the transit /24.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast | begin Network
  Network                Next Hop                Metric LocPrf Weight Path
* >i13.0.0.8/32          13.0.0.8                  0      100      0 i
* i24.0.0.2/32          10.5.7.7                  20      100      0 24 i
* i                      10.6.11.6                 20      100      0 24 ?
* i24.0.0.14/32         10.5.7.7                  10      100      0 24 i
* i                      10.6.11.6                 10      100      0 24 ?
```

The configuration on CSR5 is simple as there are auto-generated /32 connected routes added to the RIB when eBGP sessions relying on label exchange (IPv4/v6 labeled unicast, VPNv4/v6 unicast, etc) form across AS boundaries. A quick check of the MPLS interfaces proves it as these links are not LDP enabled but are BGP enabled.

```
R5#show mpls interfaces
Interface                IP                Tunnel    BGP  Static Operational
GigabitEthernet2.551     Yes (ldp)         Yes       No   No        Yes
GigabitEthernet2.556     No                Yes       Yes  No        Yes
GigabitEthernet2.557     No                Yes       Yes  No        Yes
GigabitEthernet2.558     Yes (ldp)         Yes       No   No        Yes
```

Checking the RIB, we can see the host routes for the eBGP peer. This is what must be redistributed into IGP.

```
R5#show ip route 10.5.6.6
Routing entry for 10.5.6.6/32
  Known via "connected", distance 0, metric 0 (connected, via interface)
  Routing Descriptor Blocks:
  * directly connected, via GigabitEthernet2.556
    Route metric is 0, traffic share count is 1
```

```
R5#show ip route 10.5.7.7
Routing entry for 10.5.7.7/32
  Known via "connected", distance 0, metric 0 (connected, via interface)
  Routing Descriptor Blocks:
  * directly connected, via GigabitEthernet2.557
    Route metric is 0, traffic share count is 1
```

To redistribute them, I create the most specific all-encompassing prefix-list possible (for additional practice). Quickly checking the OSPF LSDB, we can see only these two host routes were redistributed.

```
! CSR5
ip prefix-list PL_TRANSIT_HOST_ROUTES seq 5 permit 10.5.6.0/23 ge 32
route-map RM_CONN_TO_OSPF permit 10
  match ip address prefix-list PL_TRANSIT_HOST_ROUTES
```

```
router ospf 13
 redistribute connected subnets route-map RM_CONN_TO_OSPF
```

```
R5#show ip ospf database | begin -5
```

Type-5 AS External Link States

Link ID	ADV Router	Age	Seq#	Checksum	Tag
10.5.6.6	13.0.0.5	25	0x80000001	0x00175C	0
10.5.7.7	13.0.0.5	25	0x80000001	0x00026F	0

Because these are host routes, the LDP label allocation filter still allocates local labels for these. As seen in the option B design, CSR5 does not allocate null labels for these prefixes despite them being “connected”. They are not local routes, and because CSR5 has not adjusted the BGP next-hop, it must tunnel inter-AS traffic to CSR6 or CSR7 where the BGP label swap can occur. Revealing the BGP labeled-unicast label to CSR5, if allocated by CSR6 or CSR7, will result in the packet being dropped.

```
R5#show mpls ldp bindings 10.5.6.6 32 local
```

```
lib entry: 10.5.6.6/32, rev 30
```

```
local binding: label: 5048
```

```
R5#show mpls ldp bindings 10.5.7.7 32 local
```

```
lib entry: 10.5.7.7/32, rev 32
```

```
local binding: label: 5015
```

On XRv1, no such connected host route exists. XR only sees a /24 for the remote eBGP peer. While this is good enough for a BGP session to form, it will not suffice for MPLS forwarding.

```
RP/0/0/CPU0:XRv1#show route 10.6.11.6
```

Routing entry for 10.6.11.0/24

```
Known via "connected", distance 0, metric 0 (connected)
```

```
Routing Descriptor Blocks
```

```
directly connected, via GigabitEthernet0/0/0/0.561
```

```
Route metric is 0
```

```
No advertising protos.
```

The common fix for this problem is to add a static route host to the eBGP peer. This is the same configuration we used in the option B configuration, and we apply it again. Once we add this route, the requirement for the BGP next-hop to be a /32 host route is met. I add a route-tag of 13 for reasons discussed next.

```
! XRv1
```

```
router static
```

```
address-family ipv4 unicast
```

```
10.6.11.6/32 GigabitEthernet0/0/0/0.561 tag 13
```

```
RP/0/0/CPU0:XRv1#show route 10.6.11.6
Routing entry for 10.6.11.6/32
  Known via "static", distance 1, metric 0 (connected)
  Routing Descriptor Blocks
    directly connected, via GigabitEthernet0/0/0/0.561
      Route metric is 0
  No advertising protos.
```

Like CSR5, XRv1 must redistribute this host route into IGP and allocate a local label for it via LDP. Rather than redistribute from connected, XRv1 will redistribute from static. The logic is identical except the route-source changes. Because the static route can be tagged, I use this technique rather than a prefix-based matching configuration for a more generalized solution.

```
! XRv1
route-policy RPL_IF_TAG_PASS($TAG)
  if tag is $TAG then
    pass
  endif
end-policy

router ospf 13
  redistribute static route-policy RPL_IF_TAG_PASS(13)
```

Checking the OSPF LSDB on XRv1, we can see 3 total external LSAs. Two were originated from CSR5 which we verified earlier, and one new one is originated from XRv1. We can see the obvious age difference and route tag on the transit link to CSR6 as redistributed by XRv1. This is because CSR5 was configured a few minutes before XRv1.

```
RP/0/0/CPU0:XRv1#show ospf database | begin -5
Type-5 AS External Link States
```

Link ID	ADV Router	Age	Seq#	Checksum	Tag
10.5.6.6	13.0.0.5	688	0x80000001	0x00175c	0
10.5.7.7	13.0.0.5	688	0x80000001	0x00026f	0
10.6.11.6	13.0.0.11	4	0x80000001	0x009abf	13

Just like CSR5, XRv1 allocates a non-null local label in LDP for this prefix. This allows the BGP label to be tunneled to CSR6 so it can be swapped there; since XRv1 does not change the BGP next-hop, it will not swap the BGP label.

```
RP/0/0/CPU0:XRv1#show mpls ldp bindings 10.6.11.6/32 local
10.6.11.6/32, rev 51
  Local binding: label: 91008
```

When we check XRv2, we see that the remote loopbacks to CSR2 and XRv4 are reachable now. A new issue has arisen as XRv2 only sees CSR5 as an egress point with CSR7 as a next-hop. XRv1 is no longer advertising these routes to XRv2.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast | begin Network
  Network                Next Hop                Metric LocPrf Weight Path
*>i13.0.0.8/32           13.0.0.8                0      100      0 i
*>i24.0.0.2/32           10.5.7.7                20      100      0 24 i
*>i24.0.0.14/32          10.5.7.7                10      100      0 24 i
```

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.5       0     13     211     200         9    0    0 00:32:30      2
13.0.0.8       0     13    34125    33157         9    0    0 00:30:50      1
13.0.0.11      0     13     203     201         9    0    0 00:32:47      0
```

Upon further inspection, we see this is normal BGP behavior. Since CSR6 redistributed these loopbacks from IGP, the origin is set to “incomplete”. CSR7 used the network statement, which sets the origin to “IGP”. On CSR5, the routes from CSR7 are always preferred as a result. AS 24 (probably) unintentionally influenced AS 13’s path selection process using BGP attributes.

```
R5#show bgp ipv4 unicast 24.0.0.2/32
BGP routing table entry for 24.0.0.2/32, version 2
Paths: (2 available, best #2, table default)
  Advertised to update-groups:
    5
  Refresh Epoch 2
  24
    10.5.6.6 from 10.5.6.6 (24.0.0.6)
      Origin incomplete, metric 20, localpref 100, valid, external
      mpls labels in/out nlabel/6004
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 1
  24
    10.5.7.7 from 10.5.7.7 (24.0.0.7)
      Origin IGP, metric 20, localpref 100, valid, external, best
      mpls labels in/out nlabel/7000
      rx pathid: 0, tx pathid: 0x0
```

The RR reflects this path down to XRv1 who comes to a similar conclusion. Since it’s only eBGP peer is CSR6, it only learned the origin “incomplete” routes from AS 13 and now prefers the iBGP path via CSR5. This might be desirable, but in our case, it is not. I would prefer to have more explicit control over the ASBR links.

```
RP/0/0/CPU0:XRv1#show bgp ipv4 labeled-unicast 24.0.0.2/32 | begin 24$
  24
    10.6.11.6 from 10.6.11.6 (24.0.0.6)
```

```

Received Label 6004
Origin incomplete, metric 20, localpref 100, valid, external
Received Path ID 0, Local Path ID 0, version 0
Origin-AS validity: not-found
Path #2: Received by speaker 0
Not advertised to any peer
24
10.5.7.7 (metric 20) from 13.0.0.12 (13.0.0.5)
Received Label 7000
Origin IGP, metric 20, localpref 100, valid, internal, best, group-best
Received Path ID 0, Local Path ID 1, version 14
Originator: 13.0.0.5, Cluster list: 13.0.0.12

```

There are many solutions to this problem, but the simplest one is to configure CSR6 to set the origin to IGP in the route-map when ISIS to BGP redistribution occurs.

```

! CSR6
route-map RM_ISIS_TO_BGP permit 10
set origin igp

```

XRv1 now prefers the eBGP path since the origins tie. Because this is XRv1's best path, it can be advertised to the RR. Now XRv2 sees 2 routes from both CSR5 and XRv1 as intended. In real life, this would probably never happen, since AS 24 would have a common PE loopback leaking strategy on all ASBRs rather than use a combination of redistribution and BGP network statements.

```

RP/0/0/CPU0:XRv1#show bgp ipv4 labeled-unicast 24.0.0.2/32 | begin 24$
24
10.6.11.6 from 10.6.11.6 (24.0.0.6)
Received Label 6004
Origin IGP, metric 20, localpref 100, valid, external, best, group-best
Received Path ID 0, Local Path ID 1, version 16
Origin-AS validity: not-found
Path #2: Received by speaker 0
Not advertised to any peer
24
10.5.7.7 (metric 20) from 13.0.0.12 (13.0.0.5)
Received Label 7000
Origin IGP, metric 20, localpref 100, valid, internal
Received Path ID 0, Local Path ID 0, version 0
Originator: 13.0.0.5, Cluster list: 13.0.0.12

```

```

RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast summary | begin ^Neigh
Neighbor      Spk   AS  MsgRcvd  MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.5      0    13    263      249        9    0    0 00:40:43      2
13.0.0.8      0    13   34176    33206        9    0    0 00:39:03      1
13.0.0.11     0    13    254      250        9    0    0 00:41:00      2

```

XRv2 selects the routes from CSR5 as best over those from XRv1 as it has a lower BGP RID. This will be true for all prefixes by default, which means there is no path diversity for the inter-AS flows.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast 24.0.0.2/32 | begin 24,
24, (Received from a RR-client)
  10.5.7.7 (metric 20) from 13.0.0.5 (13.0.0.5)
    Received Label 7000

    Received Path ID 0, Local Path ID 1, version 8
  Path #2: Received by speaker 0
  Not advertised to any peer
24, (Received from a RR-client)
  10.6.11.6 (metric 20) from 13.0.0.11 (13.0.0.11)
    Received Label 6004
    Origin IGP, metric 20, localpref 100, valid, internal
    Received Path ID 0, Local Path ID 0, version 0
```

Rather than always rely on tie-breakers (which isn't interesting), I will configure XRv2 to prefer the path to CSR2 via XRv1. The path to XRv4 via CSR5 will remain best. I can use weight on XRv2 to accomplish this; as an RR, if the best-path is chosen locally, it is advertised to all other peers. Since XRv2 is also a PE, it will affect the EIGRP VPN traffic between CSR3 and CSR1, and it will also influence CSR8's routing. CSR8 only gets the best routes anyway, so we don't need to adjust any path attributes beyond the local weight value. I continue to use parameterized RPLs since they are very powerful.

```
! XRv2
prefix-set PS_REMOTE_CSR2
  24.0.0.2/32
end-set

route-policy RPL_SET_WEIGHT($PS, $WT)
  if destination in $PS then
    set weight $WT
  else
    pass
  endif
end-policy

router bgp 13
  neighbor 13.0.0.11
  address-family ipv4 labeled-unicast
    route-policy RPL_SET_WEIGHT(PS_REMOTE_CSR2, 2222) in
```

We can check the BGP tables on XRv2 and CSR8 to verify the routing changes. XRv2 selects the route via XRv1 as best due to the increased weight. This is the only route advertised to other iBGP peers (add-path not enabled) so CSR8 has no choice but to also select it as the best path. CSR8 is not aware of the weight modification.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
*>i13.0.0.8/32      13.0.0.8          0      100      0 i
* i24.0.0.2/32      10.5.7.7          20      100      0 24 i
*>i 10.6.11.6/32    10.6.11.6          20      100     2222 24 i
*>i24.0.0.14/32     10.5.7.7          10      100      0 24 i
* i 10.6.11.6/32    10.6.11.6          10      100      0 24 i
```

```
R8#show bgp ipv4 unicast | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
*> 13.0.0.8/32      0.0.0.0          0          32768 i
*>i 24.0.0.2/32      10.6.11.6          20      100      0 24 i
*>i 24.0.0.14/32     10.5.7.7          10      100      0 24 i
```

Checking the BGP route labels, we can see the local labels allocated by CSR6 and CSR7 are still present with these prefixes. This is important because during recursive lookups of VPN routes, when the VPN next-hop is a BGP labeled-unicast route, these out-labels will be pushed atop the label stack.

```
R8#show bgp ipv4 unicast labels
      Network      Next Hop      In label/Out label
13.0.0.8/32        0.0.0.0        imp-null/nolabel
24.0.0.2/32        10.6.11.6      nolabel/6004
24.0.0.14/32       10.5.7.7       nolabel/7002
```

Now that AS 13 has received all remote PE loopbacks with corresponding labels from AS 24, the opposite must occur. CSR8 and XRv2 are already advertising their loopbacks into BGP, so CSR6 and CSR7 should be learning these prefixes now. CSR6 learns both pairs of prefixes/labels from both AS 13 ASBRs, and CSR7 learns both prefixes/labels from CSR5 only. This is the correct result.

```
R6#show bgp ipv4 unicast labels
      Network      Next Hop      In label/Out label
13.0.0.8/32        10.6.11.11     nolabel/91001
                  10.5.6.5      nolabel/5003
13.0.0.12/32       10.6.11.11     nolabel/91002
                  10.5.6.5      nolabel/5001
24.0.0.2/32        24.6.14.14     6004/nolabel
24.0.0.14/32       24.6.14.14     6003/nolabel
```

```
R7#show bgp ipv4 unicast labels
      Network      Next Hop      In label/Out label
13.0.0.8/32        10.5.7.5        nolabel/5003
13.0.0.12/32       10.5.7.5        nolabel/5001
24.0.0.2/32        24.7.14.14      7000/nolabel
24.0.0.14/32       24.7.14.14      7002/nolabel
```

AS 24 is not going to run BGP labeled-unicast internally. Rather, it will redistribute these eBGP routes into IGP. LDP will be responsible for allocating local labels for them, and because they are host-routes, the existing LDP label allocation filter is valid. We will use two different redistribution strategies. On CSR7, the route-map will redistribute any BGP-labeled prefix into ISIS. This technique assumes the peer AS will only advertise BGP labels for remote PE loopbacks, so it is less secure but very simple/dynamic. The security could be increased using an inbound BGP filter as well, which might be a good compromise approach to achieve both security and simplicity. I set the metric to 10 only because the default is 0; a value of 10 allows other ASBRs to set higher or lower metrics, adding flexibility.

```
! CSR7
route-map RM_BGP_TO_ISIS permit 10
  match mpls-label
  set metric 10

router isis 24
  redistribute bgp 24 route-map RM_BGP_TO_ISIS
```

We can check CSR7's local ISIS LSP to see these prefixes successfully redistributed. We can see that the metric value of 10 has been applied properly.

```
R7#show isis database detail R7.00-00 | include 13\.
Metric: 10          IP 13.0.0.8/32
Metric: 10          IP 13.0.0.12/32
```

We also check the local LDP labels for these prefixes to ensure CSR7 allocated non-null labels. CSR6 and CSR7 will be responsible for connecting the LDP and BGP LSPs as we will see later.

```
R7#show mpls ldp bindings 13.0.0.8 32 local
lib entry: 13.0.0.8/32, rev 62
  local binding: label: 7007
```

```
R7#show mpls ldp bindings 13.0.0.12 32 local
lib entry: 13.0.0.12/32, rev 64
  local binding: label: 7015
```

Before we perform the redistribution on CSR6, I will prefer XRv1 as the next-hop router for all traffic leaving AS 24. Constantly relying on tie-breakers (eBGP oldest route in this case) is boring and nondeterministic. Since CSR6 has no other labeled-unicast peers, I can use the weight attribute again. To be a minimalist, I will configure it for the entire peer, not a per-prefix basis.

```
! CSR6
address-family ipv4
  neighbor 10.6.11.11 weight 6666

R6#show bgp ipv4 unicast | begin Network
```

	Network	Next Hop	Metric	LocPrf	Weight	Path
*>	13.0.0.8/32	10.6.11.11			6666	13 i
*		10.5.6.5			0	13 i
*>	13.0.0.12/32	10.6.11.11			6666	13 i
*		10.5.6.5			0	13 i
*>	24.0.0.2/32	24.6.14.14	20		32768	i
*>	24.0.0.14/32	24.6.14.14	10		32768	i

On CSR6, I will take a more secure approach by matching only labeled prefixes from specific prefix ranges. In doing this, I can achieve some traffic engineering for traffic leaving AS 24. Traffic leaving AS 24 towards CSR8 will prefer CSR6 as an egress point while traffic towards XRv2 will prefer CSR7. These preferences are achieved using IGP metric values. I use fancy ACLs to match the 3rd least significant bit in the network address. For 13.0.0.8, this bit is cleared (8 = 1000) and for 13.0.0.12, this bit is set (12 = 1100). This odd-ball filtering has little real-life utility but is a valid way to match prefixes in XE.

```
! CSR6
ip access-list standard ACL_REMOTE_LOOPBACKS_0
 permit 13.0.0.0 0.0.0.251
ip access-list standard ACL_REMOTE_LOOPBACKS_1
 permit 13.0.0.4 0.0.0.251

route-map RM_BGP_TO_ISIS permit 10
 match ip address ACL_REMOTE_LOOPBACKS_0
 match mpls-label
 set metric 5
route-map RM_BGP_TO_ISIS permit 20
 match ip address ACL_REMOTE_LOOPBACKS_1
 match mpls-label
 set metric 15

router isis 24
 redistribute bgp 24 route-map RM_BGP_TO_ISIS
```

Like CSR7, we check to ensure the routes were redistributed into ISIS and have the correct metrics. We also check the LDP LIB to ensure non-null local labels were allocated for both prefixes.

```
R6#show isis database detail R6.00-00 | include 13\.
Metric: 5          IP 13.0.0.8/32
Metric: 15         IP 13.0.0.12/32

R6#show mpls ldp bindings 13.0.0.8 32 local
lib entry: 13.0.0.8/32, rev 54
local binding: label: 6075

R6#show mpls ldp bindings 13.0.0.12 32 local
lib entry: 13.0.0.12/32, rev 55
local binding: label: 6066
```

A good test of our traffic engineering policy is to check the FIB on other AS 24 routers. CSR2 always traverses XRv4 since the IGP cost towards CSR7 is high. XRv4 allocates local labels for these prefixes as expected.

```
R2#show ip cef 13.0.0.8
13.0.0.8/32
  nexthop 24.2.14.14 GigabitEthernet2.524 label 94005
```

```
R2#show ip cef 13.0.0.12
13.0.0.12/32
  nexthop 24.2.14.14 GigabitEthernet2.524 label 94003
```

On XRv4, we see that traffic to CSR8 routes via CSR6 while traffic to XRv2 routes via CSR7. The outbound labels used by XRv4 are the matching local labels allocated by CSR6 and CSR7 we verified earlier.

```
RP/0/0/CPU0:XRv4#show cef 13.0.0.8/32

```

Now that all PEs have learned about all other PEs between ASes, we should have PE-to-PE reachability. Since we intend on transporting MPLS services over these links, we must also ensure that the path is always MPLS-encapsulated. We will manually trace the LSP from CSR2 to CSR8, and then in the reverse direction. Since the ASes use different remote loopback leaking strategies, the route recursion (and resulting label stacks) will differ. We will begin at CSR2. CSR2 has an IGP route to 13.0.0.8/32 via XRv4

along with a corresponding LDP label. The label stack becomes 94005; the lack of BGP labeled-unicast internal to AS 24 means that there are no recursive BGP lookups in the global table.

```
R2#show ip route 13.0.0.8

```

```
R2#show mpls ldp bindings 13.0.0.8 32 neighbor 24.0.0.14
  lib entry: 13.0.0.8/32, rev 57
  remote binding: lsr: 24.0.0.14:0, label: 94005
```

XRv4 is a P router along this LSP and performs a basic label swap between two LDP labels. If XRv4 wasn't a PE at all and only a P router for all LSPs, this would nicely illustrate the drawback of not using BGP within the AS. Now, all the P routers must learn all of the remote PE loopbacks as IGP routes and bind LDP labels for them, as XRv4 has done. Nonetheless, this is a valid technique and does work.

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94005
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94005	6075	13.0.0.8/32	Gi0/0/0/0.564	24.6.14.6	3498

```

    -----
    24.0.0.6:0    6075
```

CSR6 receives packets with label 6075 and performs a label swap, but not to another LDP label. Since the route to 13.0.0.8/32 is a BGP route, the BGP label of 91001 must be used. This was allocated by XRv1. The LFIB is smart enough to connect the LDP and BGP LSPs seamlessly.

```

R6#show mpls forwarding-table labels 6075
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop

    Route tag 13
    MPLS label: 91001

```

If we looked only at the BGP route, we might be concerned since it appears that no local label has been assigned. From the perspective of BGP, this is true, but BGP does not represent the only mechanism by which LSPs can be built. Always check the LFIB for the correct forwarding information.

```

R6#show bgp ipv4 unicast 13.0.0.8/32 bestpath
BGP routing table entry for 13.0.0.8/32, version 13
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 1
  13
    10.6.11.11 from 10.6.11.11 (13.0.0.11)
      Origin IGP, localpref 100, weight 6666, valid, external, best
      mpls labels in/out nolabel/91001
      rx pathid: 0, tx pathid: 0x0

```

When XRv1 receives packets with label 91001, it removes the topmost label and forwards the packet towards CSR8. The route is learned via IGP, so the LDP label of implicit-null is used.

```

RP/0/0/CPU0:XRv1#show mpls forwarding labels 91001
Local  Outgoing  Prefix      Outgoing  Next Hop      Bytes
Label  Label      or ID       Interface  Next Hop      Switched
-----
91001  Pop         13.0.0.8/32 Gi0/0/0/0.581 13.8.11.8     148542

RP/0/0/CPU0:XRv1#show route 13.0.0.8/32
Routing entry for 13.0.0.8/32
  Known via "ospf 13", distance 110, metric 2, type intra area
  Routing Descriptor Blocks
    13.8.11.8, from 13.0.0.8, via GigabitEthernet0/0/0/0.581

```

Route metric is 2
No advertising protos.

```
RP/0/0/CPU0:XRv1#show mpls ldp bindings 13.0.0.8/32 neighbor 13.0.0.8
13.0.0.8/32, rev 16
  Local binding: label: 91001
  Remote bindings: (3 peers)
    Peer          Label
    -----
    13.0.0.8:0    ImpNull
```

Be careful not to immediately assume BGP is performing this label swap. Looking at the BGP route, we can see a received label of 3 (implicit-null). This is because 13.0.0.8/32 is directly connected to CSR8, but this is not the implicit-null that is used. The route would have to be BGP-learned in order for this label to be consulted. Although harmless, this is an important detail; always be cognizant of the route source as it determines which label must be used.

```
RP/0/0/CPU0:XRv1#show bgp ipv4 labeled-unicast 13.0.0.8/32 | begin Local$
Local
  13.0.0.8 (metric 2) from 13.0.0.12 (13.0.0.8)
    Received Label 3
    Origin IGP, metric 0, localpref 100, valid, internal, best, group-best
    Received Path ID 0, Local Path ID 1, version 21
    Originator: 13.0.0.8, Cluster list: 13.0.0.12
```

If there were more MPLS labels in the stack (such as VPNv4, etc) then this VPN label would be exposed to CSR8 correctly. In this case, the IP packet would be exposed to CSR8 which is correct for global traffic, like the eBGP session to be configured soon. Using traceroute from CSR2, we can verify the label stack.

```
R2#traceroute 13.0.0.8 source 24.0.0.2
Type escape sequence to abort.
Tracing the route to 13.0.0.8
VRF info: (vrf in name/id, vrf out name/id)
 1 24.2.14.14 [MPLS: Label 94005 Exp 0] 6 msec 6 msec 6 msec
 2 24.6.14.6 [MPLS: Label 6075 Exp 0] 27 msec 30 msec 30 msec
 3 10.6.11.11 [MPLS: Label 91001 Exp 0] 22 msec 18 msec 21 msec
 4 13.8.11.8 25 msec 12 msec 11 msec
```

Next, we will trace the LSP from CSR8 to CSR2. CSR8 has a BGP route to 24.0.0.2/32, which is different than CSR2's IGP route to 13.0.0.8/32. This means CSR8 must push a BGP label onto the stack, and in this case, label 6004 is used. This means that CSR6 is the BGP next-hop as it allocated a local label for this prefix. This makes sense because XRv1 did not set the next-hop to itself, nor was it configured to allocate local labels for remote loopbacks.

```
R8#show ip route 24.0.0.2
Routing entry for 24.0.0.2/32
```

```
Known via "bgp 13", distance 200, metric 20
Tag 24, type internal
Last update from 10.6.11.6 00:56:58 ago
Routing Descriptor Blocks:
* 10.6.11.6, from 13.0.0.12, 00:56:58 ago
  Route metric is 20, traffic share count is 1
  AS Hops 1
  Route tag 24
  MPLS label: 6004
```

CSR8 now needs to lookup the route to the BGP next-hop, which is 10.6.11.6. XRv1 has a static route for this prefix which was redistributed into OSPF, so CSR8 will have an LDP label from XRv1 to describe the path to this prefix. The LDP label is 91008, making the label stack {91008 6004}.

```
R8#show ip route 10.6.11.6
Routing entry for 10.6.11.6/32
  Known via "ospf 13", distance 110, metric 20
  Tag 13, type extern 2, forward metric 1
  Last update from 13.8.11.11 on GigabitEthernet2.581, 01:30:51 ago
  Routing Descriptor Blocks:
  * 13.8.11.11, from 13.0.0.11, 01:30:51 ago, via GigabitEthernet2.581
    Route metric is 20, traffic share count is 1
    Route tag 13
```

```
R8#show mpls ldp bindings 10.6.11.6 32 neighbor 13.0.0.11
lib entry: 10.6.11.6/32, rev 21
remote binding: lsr: 13.0.0.11:0, label: 91008
```

When XRv1 receives this packet, it removes label 91008 and sends the packet towards CSR6. BGP is not involved in this operation at all. Since the route was locally configured/originated, XRv1 removes the label without having received an implicit-null. The label stack becomes 6004, which exposes the BGP label to CSR6 appropriately.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91008
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91008	Pop	10.6.11.6/32	Gi0/0/0/0.561	10.6.11.6	18738

```
RP/0/0/CPU0:XRv1#show route 10.6.11.6/32
Routing entry for 10.6.11.6/32
  Known via "static", distance 1, metric 0 (connected)
  Tag 13
  Routing Descriptor Blocks
    directly connected, via GigabitEthernet0/0/0/0.561
    Route metric is 0
  No advertising protos.
```

CSR6 swaps label 6004 for 94009 and forwards the packet to XRv4. The route is learned via IGP which means an outgoing LDP label is used. This is how CSR6 connects the BGP and LDP LSPs.

```
R6#show mpls forwarding-table labels 6004
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Outgoing interface	Next Hop
6004	94009	24.0.0.2/32	8794	Gi2.564	24.6.14.14

```
R6#show ip route 24.0.0.2

As always, be careful not to only check BGP. The output makes it appear like there is no outgoing label, which is true from a BGP standpoint. The LFIB connects the LSPs together even if BGP is unaware of it.

```

We quickly verify this with a traceroute. This LSP tracing is critical because it does not make sense to continue option C configurations until end-to-end LSPs are established between PEs. Otherwise, none of the MPLS services will operate properly.

```
R8#traceroute 24.0.0.2 source 13.0.0.8

```

One of my personal favorite characteristics of option C is the simplified BGP configuration on the ASBRs. We do not need to extend every MPLS service to them (option B) nor do we have to configure a per-VPN eBGP session across AS boundaries (option A). The ASBR configuration is complete and now we can focus on MPLS service delivery. The next step is to configure the service-specific BGP sessions between the RRs in different ASes. Technically, although RR loopbacks must be leaked across AS boundaries to achieve IP reachability, there is no requirement for those prefixes to be labeled. In our setup, the RRs are also PEs, so we do not need to implement any additional filtering. The benefit of having the RR loopbacks be labeled is it makes the configuration more consistent and allows the RR-to-RR BGP session to be protected by TE-FRR. Below is the basic configuration of VPNv4/v6 between XRv2 and CSR2. This must be a multi-hop eBGP session as the routers are in different ASes and are therefore many hops apart. This is also the first time XRv2 has an eBGP peer, so we will define a basic pass-any RPL for now. We verify the connection is functional on XRv2 for both AFIs before continuing.

```
! CSR2  
router bgp 24  
 neighbor 13.0.0.12 remote-as 13  
 neighbor 13.0.0.12 ebgp-multihop 8  
 neighbor 13.0.0.12 update-source Loopback0  
 address-family vpnv4  
   neighbor 13.0.0.12 activate  
 address-family vpnv6  
   neighbor 13.0.0.12 activate  
  
! XRv2  
route-policy RPL_PASS  
  pass  
end-policy  
  
router bgp 13  
 neighbor 24.0.0.2
```

```

remote-as 24
update-source Loopback0
ebgp-multihop 8
address-family vpnv4 unicast
  route-policy RPL_PASS in
  route-policy RPL_PASS out
address-family vpnv6 unicast
  route-policy RPL_PASS in
  route-policy RPL_PASS out

```

Since the RR's already have all of the intra-AS VPN routes, they immediately advertise their best-paths to their eBGP neighbors. By default, they set the next-hop to their update-sources which is expected for eBGP. We will see how this can become problematic later.

```

RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast summary | begin ^Neigh

*> 10.4.8.0/24  13.0.0.12     0          0 13 ?

```

Now that the RRs within each AS have routes from one another, we must adjust the VRF route target import/export policies. One of the main drawbacks of options B and C is that they generally require the providers to agree on these policies since RTs are directly exchanged. We could easily accomplish this by simply importing the RTs exported by the peer AS, but we tested that with option B already; it is known to work. There is an alternative solution known as “route target rewriting” which is valid for both options B and C. The logic is simple; match some RT value being advertised to a peer (outbound filter in BGP), remove that RT, and then add a new one that is already being imported by the peer. This will allow an AS to keep the RT's inside the AS and adjust their outbound values to be set to the imported RTs in the remote AS. Before we configure this feature, we will ensure all of the VRFs are

importing/exporting their local RTs only. Under no circumstances should a local VRF be importing any remote RTs. This restriction will make inter-AS central services very interesting as well.

```

```

You may notice that some of these RT policies don't even make sense. For example, there are no other EIGRP VPN PEs in AS 13, so there is no reason to import RT:13:3. The same is true for CSR2 importing RT:24:2 inside the OSPF VPN. However, if we assume that those other PEs did exist for each VPN within each AS, these RT policies might be logical. We will examine 10.9.9.9/32 inside VRF OSPF on XRv2 as an example. CSR2 sets the RT to be 24:2 which, according to the new policy, is not imported anywhere in AS 13. As such, OSPF will not import the route into VRF OSPF; in fact, the route isn't even retained in the RD table as there is no reason to keep it; if no VRF imports the RT locally, the VPN route is rejected.

```

RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 24:2 10.9.9.9/32 | begin 24$

```

```

R8#show bgp vpnv4 unicast vrf OSPF 10.9.9.9/32
% Network not in table

```

```

R8#show bgp vpnv4 unicast rd 24:2 10.9.9.9/32
% Network not in table

```

We will focus on CSR2 first. We must build extended community lists to match the RTs in question. The standard list gives some basic community options like RT, SoO, etc. We can also use a regex-based expanded list to make the RT look like whatever we want. I use a regex with some bogus RTs just to demonstrate; the second list would match 24:3, 24:8, or 24:9. Also notice that the standard list builds the same string as the extended one, but is easier to configure. The expanded list can match any extended community provided the administrator knows the exact textual string.

```
! CSR2
ip extcommunity-list standard EXTCOML_RT_24_2 permit rt 24:2
ip extcommunity-list expanded EXTCOML_RT_24_3 permit RT:24:[389]

R2#show ip extcommunity-list
Standard extended community-list EXTCOML_RT_24_2
  10 permit RT:24:2
Expanded extended community-list EXTCOML_RT_24_3
  10 permit RT:24:[389]
```

Next, we will wrap these in a route-map. Each permit clause will match a different list defined above. When a match occurs, we must remove the matching communities using the same list defined above, then append the new RT. The “additive” keyword is important otherwise unrelated extended communities, such as the custom EIGRP/OSPF ones, will be overwritten. We apply the route-map outbound to the eBGP VPNv4/v6 peers. Since there are no IPv4/v6 specific matches in these clauses, the filter is generic for all AFIs that use the RT extended community.

```
! CSR2
route-map RM_RT_REWRITE permit 10
  match extcommunity EXTCOML_RT_24_2
  set extcomm-list EXTCOML_RT_24_2 delete
  set extcommunity rt 13:2 additive

route-map RM_RT_REWRITE permit 20
  match extcommunity EXTCOML_RT_24_3
  set extcomm-list EXTCOML_RT_24_3 delete
  set extcommunity rt 13:3 additive

router bgp 24
  address-family vpnv4
    neighbor 13.0.0.12 route-map RM_RT_REWRITE out
  address-family vpnv6
    neighbor 13.0.0.12 route-map RM_RT_REWRITE out
```

After a soft-out on both AFIs (not shown), XRv2 will learn the VPN routes with updated RT values. On XRv2, we check the CSR9 and CSR1 loopbacks to confirm the proper RTs are carried. We also see all other extended communities still intact as a result of the “additive” keyword on CSR2. If we failed to delete the old RTs, that would have technically also worked as the route would have carried the RT for

both ASes. That would be more of a “RT augment” versus a “RT rewrite” design and I would consider that sloppy unless there was a compelling reason for it.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 24:2 10.9.9.9/32 | begin 24$
24
  24.0.0.2 (metric 20) from 24.0.0.2 (24.0.0.2)

```

We can take it a step further by checking for these VPN routes inside of the VRFs. XRv2 sees CSR1 inside VRF EIGRP and CSR8 sees CSR9 inside VRF OSPF. This is a good indication that the configuration worked.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast vrf EIGRP 10.1.1.1/32 | begin 24$

```
rx pathid: 0, tx pathid: 0x0
```

Next, we need to do the same thing in the opposite direction by focusing on XRv2. AS 13 was able to import VPN routes from AS 24 since CSR2 adjusted the RTs to comply with AS 13 policies. The configuration on XR is very similar to XE. I use in-line sets with RPL for brevity on XRv2; this is less flexible than parameterization but still works.

```
! XRv2
route-policy RPL_RT_REWRITE
  if extcommunity rt matches-every (13:2) then
    delete extcommunity rt in (13:2)
    set extcommunity rt (24:2) additive
  elseif extcommunity rt matches-every (13:3) then
    delete extcommunity rt in (13:3)
    set extcommunity rt (24:3) additive
  endif
end-policy

router bgp 13
 neighbor 24.0.0.2
  address-family vpnv4 unicast
    route-policy RPL_RT_REWRITE out
  address-family vpnv6 unicast
    route-policy RPL_RT_REWRITE out
```

We quickly check CSR2 for the presence of remote AS VPN routes in both the OSPF and EIGRP VPNs.

```

```

For the OSPF and EIGRP VPNs, the L3VPN control plane should be fully functional. However, this solution has not solved the central services problem for AS 24. CSR2 and XRv4 have no idea that these Internet routes are even available due to the RT policies.

```

R2#show bgp vpnv4 unicast vrf EIGRP 110.0.0.0/32
% Network not in table

```

```

R2#show bgp vpnv4 unicast vrf OSPF 110.0.0.0/32
% Network not in table

```

```

RP/0/0/CPU0:XRv4#show bgp vpnv4 unicast vrf EIGRP 110.0.0.0/32
% Network not in table

```

Just like with everything in networking, there are many solutions to this problem. Offhand, here are four potential solutions:

1. Export RTs 13:2 and 13:3 from CSR8's VRF BGP in addition to RT:13:1. These new RTs would get rewritten automatically by XRv2 to 24:2 and 24:3. This would require a minor RPL change on XRv2 as the "elseif" would need to be replaced with a regular "if" so both conditionals are evaluated independently from one another. This would allow both RTs to be rewritten.
2. Adjust the RPL on XRv2 so that all non-matched routes are still advertised, then import RT 13:1 on the AS 24 routers. This would violate the "policy" but is a valid solution.
3. Adjust the RPL on XRv2 so that all non-matched routes are still advertised, then export RTs 24:2 and 24:3 from CSR8's VRF BGP. Like #2, this also violates the RT "policy".
4. Adjust the RPL on XRv2 with a third match clause for RT 13:1. This RT would be removed and both RTs 24:2 and 24:3 would be added.

We will implement the fourth option. This effectively replaces one RT with a set of RTs, which is a valid operation. Of the four options, I find this to be the most effective, straightforward, and compliant with the "policy".

```

! XRv2
route-policy RPL_RT_REWRITE
  if extcommunity rt matches-every (13:2) then
    delete extcommunity rt in (13:2)
    set extcommunity rt (24:2) additive
  elseif extcommunity rt matches-every (13:3) then
    delete extcommunity rt in (13:3)

```

```

    set extcommunity rt (24:3) additive
elseif extcommunity rt matches-every (13:1) then
    delete extcommunity rt in (13:1)
    set extcommunity rt (24:2, 24:3) additive
endif
end-policy

```

After applying this policy, we check CSR2 for the central services routes inside both OSPF and EIGRP VPNs. The route has been imported to both and we can see both RTs 24:2 and 24:3 attached to the VPN route. We do not need to adjust RTs in the right-to-left direction since CSR2 is already rewriting the RTs exported by the AS 24 VRFs.

```

```

Now that the route exchange is complete, we can begin tracing LSPs. Since the RRs have adjusted the BGP next-hops, this means they will be performing MPLS service label swaps. It also puts them in the data plane which is highly undesirable. In the best case, this introduces a severe inefficiency, and in the worst case, it completely breaks connectivity. We will first examine the inefficiency case by examining the OSPF VPN from CSR9 to CSR4. The backdoor link is down as is the sham-link. We will manually trace the IPv6 LSP to see why this is a problem. Traffic entering CSR2 matches a VPNv6 route from XRv2 with label 92021. The route to 13.0.0.12, the VPN next-hop, is IGP-learned via XRv4. This means XRv4's LDP

label of 94003 is pushed also. The label stack becomes {92021 94003} and we confirm this by checking the IPv6 FIB.

XRv4 is a normal P router and performs a label swap between two LDP labels. The packet is forwarded to CSR7. Notice that when we traced the LSP from CSR2 to CSR8 earlier, CSR6 was the egress ASBR, not CSR7. This is because CSR2 is trying to send traffic towards XRv2 this time, so CSR7 is the correct egress ASBR per our IGP metric adjustments. The label stack becomes {7015 92021}.

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94003
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94003	7015	13.0.0.12/32	Gi0/0/0/0.574	24.7.14.7	42937

CSR7 also performs a label swap operation, but connects the LDP and BGP LSPs. Since the route to 13.0.0.12/32 is learned via BGP, CSR5's BGP label of 5001 is used. The label stack becomes {5001 92021}.

```
R7#show mpls forwarding-table labels 7015
```

CSR5 swaps label 5001 for 8000. CSR5 connects a BGP LSP to an LDP LSP since the route to 13.0.0.12/32 is IGP learned. The next-hop is CSR8 which means CSR8's local label for 13.0.0.12/32 is used. The label stack becomes {8000 92021}.

```
R5#show mpls forwarding-table labels 5001

```

```
remote binding: lsr: 13.0.0.8:0, label: 8000
```

Here we can see the inefficiency. CSR8 should be the end of the LSP since it is the remote PE. However, upon receipt of packets labeled with 8000, it forwards traffic towards XRv2. Because XRv2 changes the VPN next-hop, it must be in the transit path since VPNv6 is responsible for swapping the label on XRv2. CSR8 performs PHP to expose label 92021 to XRv2.

```
R8#show mpls forwarding-table labels 8000
```

Local Label	Outgoing Label	Prefix	Bytes Label	Outgoing	Next Hop

Label	Label	or Tunnel Id	Switched	interface	
8000	Pop Label	13.0.0.12/32	3033679	Gi2.582	13.8.12.12

XRv2 doesn't even this VRF configured locally yet it is the end of the VPN LSP. We can see the prefix indexed by RD in the LFIB entry as XRv2 swaps label 92021 for 8014. Label 8014 is CSR8's original lab that, ideally, CSR2 would have used in the first place. The reason only one label is imposed is because CSR8 is one hop away. The normal route recursion still occurs as XRv2 may need to push transport labels if CSR8 were farther away. In this case, CSR8 signals implicit-null, so the label stack becomes 8014 as packets are sent back towards CSR8.

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92021
```

Local	Outgoing	Prefix	Outgoing	Next Hop	Bytes

Using traceroute on CSR9, we can verify these LSPs. Technically there are two LSPs: one from CSR2 to XRv2, and one from XRv2 to CSR8. We can see CSR8 in the transit path twice, and we see the VPN label being swapped at XRv2.

```
R9#traceroute ipv6
Target IPv6 address: ::10:4:4:4
Source address: ::10:9:9:9
[snip]
Tracing the route to ::10:4:4:4
 1 FD00:10:2:9::2 4 msec 3 msec 4 msec

```

The second and far worse issue with setting next-hop-self for these eBGP advertisements is that sometimes, entire FECs are broken. For example, CSR3 is currently unable to send traffic to CSR1 at all. We would not expect this since the inter-PE connections appear to be operational.

```
R3#ping 10.1.1.1 source 10.3.3.3
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.1.1, timeout is 2 seconds:
Packet sent with a source address of 10.3.3.3
.....
Success rate is 0 percent (0/5)
```

Let's trace the LSP. XRv2 has a VPNv4 route via remote label 2124. The VPN next-hop is a BGP route with label 6004. The BGP next-hop is an IGP route via CSR8 who allocates label 8019. The entire label stack should be {8019 6004 2124}.

```

Using traceroute, we see that XRv2 is making no attempt to impose any labels at all. There is IP connectivity because the eBGP session works, but no MPLS services are supported to CSR2. Having just traced the route recursion, this output does not make sense. CSR8 adds some labels but the first hop is totally unlabeled, which is unacceptable.

```
RP/0/0/CPU0:XRv2#traceroute 24.0.0.2 source 13.0.0.12
```

```
Type escape sequence to abort.
```

```
Tracing the route to 24.0.0.2
```

```

5 24.2.14.2 0 msec 0 msec 39 msec

```

Checking the FIB, we see some interesting output. XRv2 claims that 24.0.0.2/32 is a local adjacency via CSR8. I am not sure how this is even possible, since if the adjacency was really local, it wouldn't have an IP next-hop unless that next-hop was equal to the queried prefix. CSR8 is, in fact, the "right direction", but this output has many issues.

```

RP/0/0/CPU0:XRv2#show cef 24.0.0.2

```

For comparison, we look at the route to 24.0.0.14/32. This route looks fine as the route recursion unfolds and the label stack is revealed. Notice the presence of the "recursive" flag below as it is absent above.

```

RP/0/0/CPU0:XRv2#show cef 24.0.0.14
24.0.0.14/32, version 682, internal 0x5000001 0x0 (ptr 0xa142e474) [1], 0x0

next hop 13.8.12.8/32 Gi0/0/0/0.582 labels imposed {8015 7002}

```

I personally think this is an XR limitation with respect to eBGP multi-hop peerings when used with inter-AS option C. I hypothesize that XR assumes that the eBGP peer is a local adjacency regardless of the route to that peer. As soon as we correct our design flaw by preserving the next-hop across the eBGP boundary, this problem disappears. XRv2 suddenly understands that it isn't actually connected to 24.0.0.2 and should impose labels when sending traffic towards that destination. This is a good time to correct the problem on both CSR2 and XRv2. The command below is really only useful for inter-AS option C and this is the perfect case to use it.

```

! XRv2
router bgp 13
neighbor 24.0.0.2

```

```

address-family vpnv4 unicast
  next-hop-unchanged
address-family vpnv6 unicast
  next-hop-unchanged

! CSR2
router bgp 24
  address-family vpnv4
    neighbor 13.0.0.12 next-hop-unchanged
  address-family vpnv6
    neighbor 13.0.0.12 next-hop-unchanged

```

As soon as we commit these changes, XRv2 writes the proper label stack to the FIB. This is a strange issue that I found particularly difficult to troubleshoot. Traceroute from XRv2 now shows a fully label switched path from XRv2 to CSR2.

```

RP/0/0/CPU0:XRv2#show cef 24.0.0.2
24.0.0.2/32, version 679, internal 0x1000001 0x0 (ptr 0xa142e3f4) [1], 0x0

```

Despite this fix, CSR3 still cannot reach the remote EIGRP routers. It seems like there are other unrelated issues with XRv2. With ICMP debugging enabled, we can see XRv2 is sending network unreachables back. We know it cannot possibly be a transport problem based on our verification above, so next we will check the VRF-aware routes.

```

R3#debug ip icmp
ICMP packet debugging is on

R3#traceroute 10.1.1.1 source 10.3.3.3
Type escape sequence to abort.
Tracing the route to 10.1.1.1
VRF info: (vrf in name/id, vrf out name/id)

```

```

1 10.3.12.12 !N !N !N

! CSR3
ICMP: dst (10.3.3.3) net unreachable rcv from 10.3.12.12
ICMP: dst (10.3.3.3) net unreachable rcv from 10.3.12.12
ICMP: dst (10.3.3.3) net unreachable rcv from 10.3.12.12

```

Checking the VRF-aware CEF entries on XRv2, we see these are marked as “unresolved”. Normally this would occur when there is no route, or an invalid route, to the next-hop. It also may occur if the route to the BGP next-hop is not a /32, but both of those conditions do not apply here. We can clearly see that CEF is trying to perform the route recursion and identifies both 24.0.0.14 and 24.0.0.2 as /32 host routes.

```

RP/0/0/CPU0:XRv2#show cef vrf EIGRP 10.13.13.13/32

labels imposed {2076}

```

This was a very difficult problem to solve. We will start from the beginning of the recursion process by checking the VPNv4 route. We see that this recursive lookup actually did succeed. Using the route to 10.1.1.1/32 as an example, the VPN label of 2076 is programmed into the FIB. In the output above, we saw label 2076 being imposed properly. We can therefore assume the problem is not with VPNv4.

```

```

The second label should be the BGP label from one of the remote ASBRs towards 24.0.0.12. The remote label shown below is 7002, but there is no local label assigned. Although not exactly intuitive, XR requires a local label for sending traffic to a destination when MPLS VPN is in use. Clearly we did not require the local label with traceroute in the global table; we had no issues with that test. XE has no such requirement as CSR8 is functioning fine without it. We would never see this problem on XRv4 since it is not running BGP labeled-unicast at all.

```
RP/0/0/CPU0:XRv2#show route 24.0.0.14 detail

```

This raises the question of how XRv1 is working correctly. Both XRv1 and XRv2 have the same label allocation policy which only allocates labels for local loopbacks within the "13.0.0.0/24 ge 32" range. Based on my experience and testing, XR will automatically allocate a label for BGP prefixes learned from eBGP peers regardless of the policy. Below, we can see that XRv1 allocates the local label 91004 which allows it to function as an LSR. This is not in compliance with the policy but happens anyway, probably because XR knows that it must do this in order for MPLS forwarding to work.

```
RP/0/0/CPU0:XRv1#show route 24.0.0.2 detail

Local Label: 0x1637c (91004)
[snip]

```

To support the claim that eBGP and iBGP peers are treated differently with respect to label allocation, I will completely delete CSR6 as an eBGP peer so that XRv1 must learn the AS 24 routes via CSR7 (learned ultimately through CSR5 using iBGP). After this change, XRv1 no longer allocates labels for the AS 24 prefixes. This would break L3VPN route recursion if XRv1 were a PE. Without a local label for those prefixes, XRv1 cannot impose labels 7000 or 7002 at imposition for VPN services.

```

! XRv1
router bgp 13
no neighbor 10.6.11.6

```

```

RP/0/0/CPU0:XRv1#show bgp ipv4 labeled-unicast labels | begin Network
  Network          Next Hop      Rcvd Label    Local Label
*>i13.0.0.8/32      13.0.0.8        3             91001
*>i13.0.0.12/32     13.0.0.12       3             91002
*>i24.0.0.2/32      10.5.7.7        7000          nolabel
*>i24.0.0.14/32     10.5.7.7        7002          nolabel

```

Before continuing, I restore XRv1's original neighbor configuration to CSR6. The most obvious way to fix this is to expand the label allocation policy to encompass the remote loopbacks on all XR PEs within AS 13. Those who configure option C and simply say "allocate-label all" would never have seen this problem in the first place. Instead of modifying the RPL itself, I create a new prefix-set to better reflect the prefixes that require label allocation.

```

! XRv2
prefix-set PS_PE_LOOPBACKS
  13.0.0.0/24 ge 32,
  24.0.0.0/24 ge 32
end-set

no prefix-set PS_LOCAL_LOOPBACKS

router bgp 13
address-family ipv4 unicast
allocate-label route-policy RPL_IF_DEST_PASS(PS_PE_LOOPBACKS)

```

If we check the local labels for these BGP routes, now they exist. The CEF entries within the VPN tables are also resolved. We see a 3 label stack as expected, including the LDP, BGP, and VPN labels in

sequence. In summary, ensure your XR PEs running IPv4 labeled-unicast are configured to allocate local labels for remote and local loopbacks. This is not required on XR ASBRs, XE ASBRs, or XE PEs.

```
RP/0/0/CPU0:XRv2#show route 24.0.0.2 detail

  next hop 13.8.12.8/32 Gi0/0/0/0.582 labels imposed {8019 6004 2076}
```

If additional control is needed over these local labels which would normally not be allocated, we can statically define the actual label value once the RPL permits the allocation. Although not related to option C at all, I adjust the local label values so they are more visually apparent on XRv2. I use the format 925XX where XX is equal to the last octet.

```
! XRv2
mpls static
  address-family ipv4 unicast
    local-label 92502 allocate per-prefix 24.0.0.2/32
    local-label 92514 allocate per-prefix 24.0.0.14/32
```

This creates a syslog on XRv2 saying that there is a label discrepancy. BGP allocated the original values dynamically, and since we overrode them, we must clear this discrepancy.

```
! XRv2
%ROUTING-MPLS_STATIC-4-ERR_STATIC_LABEL_DISCREPANCY : The system detected 2
label discrepancies (static label could not be allocated due to conflict with
```

other applications). Please use 'clear mpls static local-label discrepancy' to fix this issue.

After issuing the command to clear the discrepancy, the problem is resolved. Checking the LFIB against these local labels, we can see them properly installed. These labels may never be used, but they are required to exist for MPLS to support L3VPN on XR.

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92500 92599
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92502	6004	24.0.0.2/32		10.6.11.6	0
92514	7002	24.0.0.14/32		10.5.7.7	0

For brevity, I will use traceroute to verify some key VPN connections. Both CSR1 and XRv4 can access central services resources. Per our traffic egress policy, traffic towards CSR8 egresses AS 24 via CSR6.

```
R1#traceroute 110.0.0.0 source 10.1.1.1
Type escape sequence to abort.
Tracing the route to 110.0.0.0

```

Earlier, we used BGP weight on XRv2 so that CSR8 would prefer different egress points from AS 13 as well. Traffic from CSR4 to CSR9 inside the OSPF VPN egresses via CSR6. Traffic from the central services router to XRv3 egresses via CSR7. I use IPv6 VPN routes for this test, but the LSP would be the same for IPv4 VPN routes as well.

With the LSPs operational, we bring up the OSPFv3 sham-link between CSR8 and CSR2. The configuration has not changed at all from the first time it was configured with option A and reused again

with option B. We have tested this extensively already so we will be brief with this verification. As long as the sham-link endpoints are reachable (VPNv6 between PEs) then the sham-links should form. Two sham-links exist: one for IPv4 and one for IPv6 OSPFv3 AFIs. I also bring up the backdoor link between CSR4 and CSR9.

```
R8#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::2 is up
Sham Link OSPFv3_SL1 to address FD00::2 is up
```

CSR9 learns routes to CSR4's loopback via an intra-area path. This proves that the sham-link is working. Even if the backdoor link were down, we would still see these routes as intra-area as a result of the sham-links.

```
R9#show ip route 10.4.4.4
Routing entry for 10.4.4.4/32
  Known via "ospfv3 2", distance 110, metric 3, type intra area

```

```
R9#show ipv6 route ::10:4:4:4
Routing entry for ::10:4:4:4/128
  Known via "ospf 2", distance 110, metric 3, type intra area
  Route count is 1/1, share count 0
  Routing paths:
    FE80::2, GigabitEthernet2.529
    Last updated 00:00:59 ago
```

Earlier, we conducted the traceroute shown below from CSR9 to CSR4 using the IPv6 VPN routes. We saw CSR8 in the transit path twice due to XRV2 changing the VPNv6 next-hop. Now that the issue is resolved, traffic is sent directly to CSR8. I have temporarily broken CSR6's transit links (not shown) to ensure CSR7 can be a failover for traffic destined to CSR8, which it can. I did this as an additional test to show the value in having multiple inter-AS connections and using BGP attributes and IGP metrics to influence the traffic patterns.

```
R9#traceroute ipv6
Target IPv6 address: ::10:4:4:4

```

This concludes the option C L3VPN section. There are many ways to implement this design since it is very complex and involved. The biggest benefit is a simple ASBR configuration; the future labs, such as L2VPN, are very straightforward since the MPLS services are end-to-end.

8.4.3.2 L2VPN

MPLS L2VPN with option C is generally straightforward. Unlike option A, we do not need to terminate PWs on the ASBRs to remove all MPLS encapsulation. Also unlike option B, we do not need to create MSPWs via the ASBRs since the PEs have end-to-end reachability. For this test, I will use BGP auto-discovery with BGP signaling as opposed to LDP signaling shown in the past examples. I will still use disparate VPN IDs and route-targets so that we can focus on the inter-AS mechanics. The basic VFI and bridge-domain configurations are similar to options A and B and are not discussed in detail. The significant difference is that I do not apply the PW template to this VFI as BGP signaling does not appear to support the CW at all. I re-use the RT values of 24:3 and 13:3 for reasons described later; this will not interfere with the EIGRP VPN at all since it is an entirely different AFI.

```
! CSR2
l2vpn vfi context VPLS
  vpn id 200
  autodiscovery bgp signaling bgp
  ve id 2
    route-target export 24:3
    route-target import 24:3
  no auto-route-target

bridge-domain 3
  member GigabitEthernet2 service-instance 3
  member vfi VPLS

! CSR8
l2vpn vfi context VPLS
  vpn id 800
  autodiscovery bgp signaling bgp
  ve id 8
    route-target export 13:3
    route-target import 13:3
  no auto-route-target

bridge-domain 3
  member GigabitEthernet2 service-instance 3
  member vfi VPLS
```

Next, we will quickly verify that the VFIs were configured properly. Notice that the RT policies do not currently match, nor do the VPN IDs.

```
R2#show l2vpn vfi name VPLS
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: VPLS, state: up, type: multipoint, signaling: BGP
VPN ID: 200, VE-ID: 2, VE-SIZE: 10
RD: 24:200, RT: 24:3
Bridge-Domain 3 attachment circuits:
Pseudo-port interface: pseudowire100033
Interface          Peer Address      VE-ID  Local Label  Remote Label      S
```

```
R8#show l2vpn vfi name VPLS
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: VPLS, state: up, type: multipoint, signaling: BGP
VPN ID: 800, VE-ID: 8, VE-SIZE: 10
RD: 13:800, RT: 13:3
Bridge-Domain 3 attachment circuits:
Pseudo-port interface: pseudowire100006
Interface          Peer Address      VE-ID  Local Label  Remote Label      S
```

Next, we configure BGP. Unlike other AFIs that use extended-communities, the XE parser does not automatically add “send-community extended” to the BGP neighbor statements for the L2VPN VPLS AFI. For intra-AS this does not seem to matter, but XE won’t encode these communities when sending routes to external peers without the explicit command. Thus, I add the command to CSR2’s peer to XRv2, but not to CSR8 or XRv2 at all. XR is smart enough to send these communities to eBGP peers for AFIs that require it without being explicitly told to do so. I initially do not configure CSR8 as an RR client because, at a glance, the basic BGP advertisement rules would indicate it is not necessary.

```
! XRv2
router bgp 13
 address-family l2vpn vpls-vpws

 neighbor 13.0.0.8
   use session-group IBGP
   address-family l2vpn vpls-vpws

 neighbor 24.0.0.2
   address-family l2vpn vpls-vpws
   route-policy RPL_PASS in
   route-policy RPL_PASS out
   Signalling ldp disable

! CSR2
router bgp 24
 address-family l2vpn vpls
   neighbor 13.0.0.12 activate
   neighbor 13.0.0.12 send-community extended
   neighbor 13.0.0.12 suppress-signaling-protocol ldp

! CSR8
```

```

router bgp 24
  address-family l2vpn vpls
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 suppress-signaling-protocol ldp

```

Checking CSR2 and XRv2, we can see the eBGP peer comes up. XRv2 learns routes from CSR2 but not vice versa. XRv2 also does not learn any VPLS routes from CSR8, either.

```

RP/0/0/CPU0:XRv2#show bgp l2vpn vpls summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.8      0     13    6717    6361       3     0     0  00:10:15      0
24.0.0.2      0     24   1399    1127       3     0     0  00:16:11      1

R2#show bgp l2vpn vpls all summary | begin ^Neigh
Neighbor      V      AS  MsgRcvd  MsgSent   TblVer  InQ  OutQ  Up/Down  State/PfxRcd
13.0.0.12     4      13     60     62         3     0     0  00:16:29      0

```

First, we will solve the intra-AS problem inside AS 13. XR's BGP debug for L2VPN AFI does not reveal the problem, but the issue is similar to that seen with option B. Since CSR8 is not an RR-client, XRv2 has no compelling reason to accept VPLS routes from this peer if it isn't consuming the information locally. In the option C design, these iBGP peers would all be RR-clients and we would never see this problem. If we configured CSR8 as an RR-client, despite it not having any measurable impact on the iBGP topology, the problem would be solved. This is what we did for VPNv4/v6 with no issues. Alternatively, we can simply instruct XRv2 to retain all RTs much like the option B ASBRs did. This is odd for an option C RR but is valid in this specific design as there are no other iBGP peers in AS 13 that are part of any VPLS instance. In an option C design, configuring CSR8 as an RR-client makes the most sense and is most realistic, but for variety, we will use the alternative method. Once we commit this change, XRv2 learns a VPLS route from CSR8.

```

! XRv2
router bgp 13
  address-family l2vpn vpls-vpws
    retain route-target all

```

```

RP/0/0/CPU0:XRv2#show bgp l2vpn vpls summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd
13.0.0.8      0     13    6817    6457       5     0     0  00:08:36      1
24.0.0.2      0     24   1423    1151       5     0     0  00:26:21      1

```

Next, we need to figure out why CSR2 is not learning routes from XRv2. By enabling debugging on CSR2, we see this is a classic RT import/export problem. CSR2 advertises routes with RT:24:3 and imports the same RT. The route received from XRv2, originated by CSR8, has RT:13:3. No local VPLS instances are importing this RT, so the route is dropped.

```

R2#debug bgp l2vpn vpls updates in
BGP updates debugging is on (inbound) for address family: L2VPN Vpls

```

```

BGP(9): (base) 13.0.0.12 send UPDATE (format) 24:200:VEID-2:Blk-1:VBS-10:LB-
2026/136, next 24.0.0.2, metric 0, path Local, extended community RT:24:3
L2VPN L2:0x0:MTU-1500
BGP(9): 13.0.0.12 rcvd UPDATE w/ attr: nexthop 13.0.0.12, origin ?, merged
path 13, AS_PATH , extended community RT:13:3 L2VPN L2:0x0:MTU-1500
BGP(9): 13.0.0.12 rcvd 13:800:VEID-8:Blk-1:VBS-10:LB-8022/136 -- DENIED due
to: extended community not supported;

```

It follows that we would see the same issue on CSR8. We can quickly confirm with debugs for completeness.

```

R8#debug bgp l2vpn vpls updates in
BGP updates debugging is on (inbound) for address family: L2VPN Vpls

BGP(9): (base) 13.0.0.12 send UPDATE (format) 13:800:VEID-8:Blk-1:VBS-10:LB-

BGP(9): 13.0.0.12 rcvd 24:200:VEID-2:Blk-1:VBS-10:LB-2026/136 -- DENIED due
to: extended community not supported;

```

Let's assume that the RT "policy" defined earlier is still in effect. That is to say, the ASes cannot adjust their RT policies to import anything outside of the local AS. We can solve this using RT rewrite again, and because I used the same RTs from the L3VPN section, we don't need to modify any route-maps or RPLs. The local AS exported RT will match the existing conditionals and be rewritten to the remote AS imported RT. As an aside, we also notice the next-hop of 13.0.0.12 above; this is incorrect and should be 13.0.0.8, so we must use next-hop-unchanged on XRv2 at a minimum.

```

! CSR2
router bgp 24
  address-family l2vpn vpls
    neighbor 13.0.0.12 route-map RM_RT_REWRITE out

! XRv2
router bgp 13
  neighbor 24.0.0.2
  address-family l2vpn vpls-vpws
    next-hop-unchanged
    route-policy RPL_RT_REWRITE out

```

The VPLS immediately forms. Notice that we did not have to adjust the "VPLS ID" or anything of the sort. The fact that the VPN IDs differ with BGP signaling only affects the auto-RD generation. LDP signaling

used the VPLS ID as the AGI field to identify nodes in the same VPLS instance. No such concept exists with BGP signaling.

```
R8#show l2vpn atom vc
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw100007	2	800	vfi	VPLS	UP

```
R2#show l2vpn atom vc
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw100034	8	200	vfi	VPLS	UP

Looking at the details, we see a significant problem that is easy to overlook. Somehow, one of the routers selected the incorrect label. CSR2 thinks its local label is 2023 but CSR8 claims the remote label along that PW is 2033. Forwarding will certainly not work in this case.

```
R2#show l2vpn vfi name VPLS
```

Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No

VFI name: VPLS, state: up, type: multipoint, signaling: BGP

VPN ID: 200, VE-ID: 2, VE-SIZE: 10

RD: 24:200, RT: 24:3

Bridge-Domain 3 attachment circuits:

Pseudo-port interface: pseudowire100033

Interface	Peer Address	VE-ID	Local Label	Remote Label	S
pseudowire100034	13.0.0.12	8	2023	8023	Y

```
R8#show l2vpn vfi name VPLS
```

Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No

VFI name: VPLS, state: up, type: multipoint, signaling: BGP

VPN ID: 800, VE-ID: 8, VE-SIZE: 10

RD: 13:800, RT: 13:3

Bridge-Domain 3 attachment circuits:

Pseudo-port interface: pseudowire100006

Interface	Peer Address	VE-ID	Local Label	Remote Label	S
pseudowire100007	24.0.0.2	2	8023	2033	Y

I have personally never seen this happen before. After several L2VPN XC reprovisions and BGP clears, I attempted to reboot. After the routers come back online, we check the VFI details again and see a similar issue. It seems that CSR2 has allocated two label ranges.

```
R2#show l2vpn vfi name VPLS | begin Interface
```

Interface	Peer Address	VE-ID	Local Label	Remote Label	S
pseudowire100002	13.0.0.12	8	2007	8001	Y

```
R8#show l2vpn vfi name VPLS | begin Interface
Interface      Peer Address    VE-ID  Local Label  Remote Label  S
pseudowire100002  24.0.0.2        2      8001        2037         Y
```

CSR2 is the culprit. It's local VPLS route clearly shows label base 2000, yet outbound debugging on CSR2 shows it advertising a route with label base 2030. CSR2 allocates a second label base and adjusts the outbound update to carry this new value.

```
R2#show bgp l2vpn vpls all ve-id 2 block-offset 1

L2VPN L2:0x0:MTU-1500
```

Checking CSR2's LFIB, we can actually see two sets of labels have been allocated. It correctly computes that label 2007 should be forwarded to the EFP (not dropped), but because it signaled an additional label base to AS 13, CSR8 is using the incorrect label to send traffic into AS 24. When label 2037 is received, CSR2 will drop the traffic. This is the local label base (LLB) in action, shown above. I cannot find any clear documentation on what this is or why it is useful. After quickly skimming RFC 4761, this is no mention of "local label base". I would guess that the CSR2 would be smart enough to swap label 2037 for label 2007, then perform another lookup on 2007 to deliver the traffic to the correct EFP. This does not appear to happen, despite the MPLS in/out labels in the BGP prefix appearing to indicate so.

```
R2#show mpls forwarding-table labels 2000 - 2009

Unable to make sense of this behavior on CSR2, I decided to configure a workaround. XRv4 will be the L2VPN VPLS RR for AS 24. It will only serve in this role for this one AFI; I theorize that if a VPLS PE is also running eBGP, then the router assumes it isn't an option C RR and makes label adjustments to support alternative architectures. XRv2 and XRv4 must establish a new BGP session to support this, and the L2VPN VPLS AFI is removed between CSR2 and XRv2. XRv4 configures CSR2 as an RR client rather than retain the RTs as XRv2 did. CSR2 will use the RT rewrite policy towards the RR so we don't need to redefine it on XRv4. This isn't a particularly realistic use of RT rewrite since the RR should be performing the rewrite towards an eBGP peer, but since there are no other iBGP VPLS participants in AS 24, this is a valid solution.

```
! XRv2
router bgp 13
  neighbor 24.0.0.2
    no address-family l2vpn vpls-vpws

  neighbor 24.0.0.14
    remote-as 24
    ebgp-multihop 8
    update-source Loopback0
    address-family l2vpn vpls-vpws
      route-policy RPL_PASS in
      route-policy RPL_RT_REWRITE out
    Signalling ldp disable
    next-hop-unchanged
```

```

! XRv4
route-policy RPL_PASS
  pass
end-policy

router bgp 24
  neighbor 24.0.0.2

    update-source Loopback0
    address-family l2vpn vpls-vpws
    route-policy RPL_PASS in
    route-policy RPL_PASS out
    Signalling ldp disable
    next-hop-unchanged

```

Suddenly, CSR2 stops adding the LLB to its VPLS updates and the PW starts working. The in/out labels are synchronized between both PEs since CSR2 is not using multiple label bases for the same PW. In real life, one would probably never run into this issue as the RR would never also be a PE. I wanted to illustrate that the VPN IDs and RDs can be totally different for inter-AS BGP-signaled VPLS. As long as the RTs match, the PWs will form.

```

R2#show bgp l2vpn vpls rd 24:200 ve-id 2 block-offset 1
BGP routing table entry for 24:200:VEID-2:Blk-1/136, version 5

```

When we check the PW details on CSR2 and CSR8, we can see the proper label stacks are build. CSR2 only has 2 labels since there is no BGP labeled-unicast running in AS 24. CSR8 requires three labels since the P-routers in AS 13 would not have reachability to CSR2, the PW endpoint. This allows MPLS to tunnel traffic across the core to the ASBRs that do have reachability to the remote loopbacks.

```
R2#show l2vpn atom vc service-name VPLS detail | include label_stack
Output interface: Gi2.524, imposed label stack {94003 8001}
```

```
R8#show l2vpn atom vc service-name VPLS detail | include label_stack
Output interface: Gi2.581, imposed label stack {91008 6029 2047}
```

We quickly test the PW using ping and traceroute from the CSR3.

```
R3#ping vrf VPLS 10.0.0.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.0.0.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 8/9/11 ms
```

```
R3#traceroute vrf VPLS 10.0.0.1
Type escape sequence to abort.
Tracing the route to 10.0.0.1
VRF info: (vrf in name/id, vrf out name/id)
 1 10.0.0.1 46 msec 8 msec 8 msec
```

Although no CE devices will be attached, I will test static ATOM (E-LINE using EVPL) between CSR2 and CSR8 as well. This will allow us to test inter-AS CFM. The configuration is almost identical on CSR2 and CSR8 with the only difference being the MEP IDs. I used the Y.1731 ITU carrier code (ICC) based MEG-ID just for variety. It consists of a 1 – 6 character ICC and a 1 – 12 character unique MEG-ID code (UMC). It can be up to 13 characters long. In my case, I use a 4 character ICC and a 9 character UMC; in real life these ICCs would be specific to each carrier with the MEG-ID changing per CFM instance. For demonstration and variety, I use the same one for inter-AS operations.

```
! CSR2
ethernet cfm ieee
ethernet cfm global
ethernet cfm logging
ethernet cfm domain C level 5
  service icc OPTC 123456789 evc EVC_999
    mep mpid 8

	MA Name		SrvcInst	Source	
	EVC name				

```

-----
8      C                               5      001e.e64d.4dbf BD-V  I
No    C                               Up    Gi2          0
      icc OPTC123456789              999          Static
      EVC_999

```

Next, we must configure the PWs and bind them to local XC processes. The PW configuration is almost identical except with swapped IP addressing. The template was defined long ago and was discussed in the introductory section; it enables the control-word and sequencing. Both CSR2 and CSR8 have the same xconnect binding as they use the same EFP and PW interface enumerations.

```

! CSR2
interface pseudowire28
 source template type pseudowire TMP_VPLS
 encapsulation mpls
 neighbor 13.0.0.8 28

! CSR8
interface pseudowire28
 source template type pseudowire TMP_VPLS
 encapsulation mpls
 neighbor 24.0.0.2 28

! CSR2 and CSR8
l2vpn xconnect context EVPL_28
 member pseudowire28
 member GigabitEthernet2 service-instance 999

```

We confirm that the PW comes up before worrying about CFM. No issues here.

```

R2#show l2vpn atom vc service-name EVPL_28

```

Interface	Peer ID	VC ID	Type	Service Name	Status
pw28	13.0.0.8	28	p2p	EVPL_28	UP

```

R8#show l2vpn atom vc service-name EVPL_28

```

Interface	Peer ID	VC ID	Type	Service Name	Status
pw28	24.0.0.2	28	p2p	EVPL_28	UP

Next, we check for CFM RMEPs on each router. Since we statically identified the RMEPs were supposed to see, this adds a bit of security. When an expected RMEP is absent or an unexpected RMEP is preset, an alarm is raised. In our case, the network has converged properly as both CSR2 and CSR8 can see one another via CFM CCMs. The MA-ID (or MEG-ID) is identified by ICC as expected.

```
R8#show ethernet cfm maintenance-points remote domain C
```

MPID	Domain Name	MacAddress	IfSt	PtSt

As a final test, we use CFM loopback messages (LBM) to test connectivity. The inter-AS EVPL service is functioning properly and can be successfully managed with CFM.

```
R8#ping ethernet mpid 2 domain C service icc OPTC 123456789
Type escape sequence to abort.
Sending 5 Ethernet CFM loopback messages to 001e.1415.dbbf, timeout is 5
seconds:!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 6/18/48 ms
```

8.4.3.3 MVPN - GRE (Profile 0)

GRE-based MVPN complexity will vary based on how the remote PE loopbacks are leaked between ASes. Earlier, we saw two main methods: redistribute from BGP into IGP, or leave the loopbacks in BGP by running it everywhere and allocating labels for them. The first method is simpler and requires less configuration, but it exposes remote PE loopbacks to core routers. The second method requires more configuration and an additional MPLS label, but shields P router from remote PE loopbacks. AS 24 uses the IGP redistribution method while AS 13 uses BGP labeled-unicast.

We will use MVPN profile 0 to provide MVPN service to the EIGRP VPN. We begin by defining a default MDT for this VPN both IPv4 and IPv6 AFIs. This is relevant on all PEs, and like option B, the default MDT

group must match between ASes. We used SSM for simplicity for option B, so I will use ASM for option C. Each AS has its own independent RP.

```
! XRv2 and XRv4
multicast-routing
vrf EIGRP
  address-family ipv4
    mdt default ipv4 225.13.24.255
  address-family ipv6
    mdt default ipv4 225.13.24.255

! CSR2
vrf definition EIGRP
  address-family ipv4
    mdt default 225.13.24.255
  address-family ipv6
    mdt default 225.13.24.255
```

Before we configure the inter-AS MDT, we can ensure the intra-AS MDT has formed within AS 24. This means that the default MDT is functional within that AS. We can check the P(S,G) entries on each router to ensure the remote PE was discovered. Each of them have joined one another's SPT (XR has "SPT" flag and XE has 'T' flag). The XE 'Z' flag in XE indicates this is a multicast tunnel as well.

```
RP/0/0/CPU0:XRv4#show pim topology 225.13.24.255 24.0.0.2 | begin 2,2

```

10.13.14.14*      GigabitEthernet0/0/0/0.534 4d15h      00:01:36 1 (DR) B E
24.0.0.2          mdtEIGRP                      00:01:19 00:01:28 1      P
24.0.0.14*        mdtEIGRP                      00:01:38 00:01:28 1 (DR)

```

Since we are not using SSM (and have not configured BGP IPv4 MDT or IPv4 MVPN AFI), the inter-AS MDT cannot form yet. XRv2 and CSR2 are disparate RPs with no means to exchange information about sources to one another. To merge the two PIM ASM domains, we will configure a basic MSDP session between CSR2 and XRv2 so that this information can be exchanged. For security, I apply outbound filters on each router so that only P(S,G) state sourced from local loopbacks destined for the specific default MDT group will be permitted. The maximum number of SAs (in this case, remote PEs) is set to 5 for additional security. This is an odd solution for an inter-AS MPLS VPN design but it perfectly valid.

```

! CSR2
ip msdp peer 13.0.0.12 connect-source Loopback0 remote-as 13
ip msdp sa-filter out 13.0.0.12 list ACL_MSDP_FILTER
ip msdp sa-limit 13.0.0.12 5
ip access-list extended ACL_MSDP_FILTER
 permit ip 24.0.0.0 0.0.0.15 host 225.13.24.255

```

```

! XRv2
ipv4 access-list ACL_MSDP_FILTER
 10 permit ipv4 13.0.0.0 0.0.0.15 host 225.13.24.255

```

```

router msdp
 peer 24.0.0.2
   connect-source Loopback0
   remote-as 24
   sa-filter out list ACL_MSDP_FILTER
 maximum external-sa 5

```

We confirm that the MSDP session comes up on both sides. We can also see that XRv2 received 2 SAs from CSR2 while CSR2 received 1 SA from XRv2. This makes sense as the number of external SAs sent by a router should match the number of local PEs in the AS.

```

RP/0/0/CPU0:XRv2#show msdp summary
Out of Resource Handling Enabled
Maximum External SA's Global : 20000
Current External Active SAs : 2

			Downtime	Count	Count
13.0.0.12	13	Up	00:00:29	0	1 ?

We can confirm that the proper SAs were exchanged by checking the SA caches on each router. XE only shows the learned SAs, not the locally-originated ones. XR shows both; it also specifies with the “PI” flag that PIM is interested. This means there is some kind of P(*,G) or P(S,G) state that exists for this group that would make the router “care” about it.

```
R2#show ip msdp sa-cache 225.13.24.255

```

We verify the MRIB on CSR2. The existing intra-AS entries for the default MSDP now have the ‘A’ flag on them. This signifies they are candidates for MSDP advertisement as SAs when sources as discovered. The ‘M’ flag indicates that the source for this P(S,G) was installed via an MSDP SA, which is correct for the source of 13.0.0.12.

```
R2#show ip mroute 225.13.24.255 | begin \ (13
(13.0.0.12, 225.13.24.255), 00:06:44/00:02:06, flags: MTZ

```

The configuration in AS 24 is complete. Since all routers know how to reach 13.0.0.12, the remote PE, there is no need for a PIM vector. That is to say, CSR2 and XRv2 don't need to inform any core routers (if there were some) about how to perform RPF for a P(S,G) join where S is 13.0.0.12. With option B, this was always necessary, since the core routers would never know this information. By chance, the configuration in AS 13 is also complete. Given the small topology, there are no dedicated P routers in AS 13, so the PIM vector is technically not needed in this very specific network. The default MDT would not even come up if the core routers in AS 13 did not have BGP routers towards the remote PE loopbacks in AS 24. The PEs could originate the PIM vector (not with RD) to solve this problem, which XR does support. The alternative would be to extend BGP labeled-unicast to any possible core routers, ruining the BGP-free core.

Since we have not yet tested any data MDTs, I configure these on XRv2 only. Since CSR3 is our multicast source, it is possible that not all remote PEs in AS 24 are interested in every flow generated by CSR3. Since XRv3's RPF interface towards CSR3 is fixed towards CSR1, we suspect that XRv4 will not join the data MDT once the traffic starts flowing. I use SSM for these groups so there is no involvement with the RPs or MSDP session. This design can be useful for automatic PE discovery without BGP modification, while still utilizing SSM for the high-bandwidth flows via the data MDTs.

```
! XRv2
multicast-routing
vrf EIGRP
  address-family ipv4
    mdt data 232.13.24.0/26 immediate-switch
  address-family ipv6
    mdt data 232.13.24.64/26 immediate-switch
```

We will initiate an IPv4 multicast flow from CSR3 to XRv3's local group of 225.13.13.13. this is the same test flow we used for the other inter-AS MVPN options for consistency.

```
R3#ping ip
Target IP address: 225.13.13.13
Repeat count [1]: 100000
Datagram size [100]:
Timeout in seconds [2]: 1
Extended commands [n]: y
Interface [All]: loopback0
Time to live [255]:
Source address or interface: loopback0
```

I do not discuss the customer PIM registration or SPT switchover process for brevity. XRv3 does eventually join the SPT, but what triggers the data MDT is the threshold (or "immediate-switch" in this case) configured on the ingress PE, which is XRv2. XRv2 sends a PIM TLV over the default MDT to other PEs that may want to join the data MDT. This "MDT join" allows remote PEs to issue P(S,G) joins towards

the ingress PE for the new data MDT. We can see that CSR2 receives this MDT message. The P(S,G) information is shown in yellow and the C(S,G) information is shown in green.

```
RP/0/0/CPU0:XRv2#show pim vrf EIGRP mdt cache
Core Source      Cust (Source, Group)      Core Data      Expires
13.0.0.12        (10.3.3.3, 225.13.13.13)  232.13.24.0    00:02:41
```

```
R2#show ip pim mdt receive detail | begin ^Join

(10.3.3.3, 225.13.13.13), 00:09:04/00:02:53/00:02:57, OIF count: 1, flags: TY
```

CSR2 issues the P(S,G) join towards XRv4 for this new group. I won't trace the entire RPF path as it is very basic. We know RPF is working otherwise the default MDT would have never formed; whether the MDT is default or data, the P-sources are the same. XRv2 is the source PE for this new data MDT and is the root of the tree.

```
R2#show ip mroute 232.13.24.0 13.0.0.12 | begin \

```

Checking the C(S,G) entries, we see that CSR2's entry is mapped to the specific data MDT that was exchanged in the PIM TLV. The big 'Y' flag indicates reception of multicast traffic along a data MDT. On XRv2, the "MA" flag indicates a data MDT was assigned to this C(S,G) and the "MT" flag indicates the data MDT threshold was crossed. The only time (conceivably) you would have "MT" without "MA" is if the router exhausted its supply of data MDT groups.

```
R2#show ip mroute vrf EIGRP 225.13.13.13 10.3.3.3 | begin \
(10.3.3.3, 225.13.13.13), 00:12:24/00:01:27, flags: TY
Incoming interface: Tunnel5, RPF nbr 13.0.0.12,

Outgoing interface list:
GigabitEthernet2.512, Forward/Sparse, 00:12:24/00:03:27
```

```
RP/0/0/CPU0:XRv2#show pim vrf EIGRP topology 225.13.13.13 | begin 3,225
(10.3.3.3,225.13.13.13)SPT SM Up: 00:13:41
JP: Join(00:00:08) RPF: GigabitEthernet0/0/0/0.532,10.3.12.3 Flags: MT MA
mdtEIGRP 00:13:41 fwd Join(00:02:37)
```

As an additional check, we examine XRv3's MFIB counters. We can see many packets entering the router SW process which indicates success.

```
RP/0/0/CPU0:XRv3#show mfib route 225.13.13.13 10.3.3.3 | begin 225
(10.3.3.3,225.13.13.13),    Flags:
  Up: 00:16:09
  Last Used: 00:00:00
  SW Forwarding Counts: 968/968/96800
  SW Replication Counts: 968/0/0
  SW Failure Counts: 0/0/0/0/0
  Loopback0 Flags:  IC NS EG, Up:00:16:09
  GigabitEthernet0/0/0/0.513 Flags:  A, Up:00:16:09
```

To prove that CSR2 is actually in the transit path while XRv4 is not (technically XRv4 is a P router for this flow in the carrier network, but that is not the point), we can look at the egress PEs. CSR2 shows about the same number of packets as XRv3 (slightly more since I issued this command later) and XRv4 does not even have the C(S,G) entry. This is expected behavior given the customer RPF topology.

```
R2#show ip mroute vrf EIGRP 225.13.13.13 10.3.3.3 count | begin ^Group
Group: 225.13.13.13, Source count: 1, Packets forwarded: 1046, Packets
received: 1046

```

```
RP/0/0/CPU0:XRv4#show pim vrf EIGRP topology 225.13.13.13
No PIM topology table entries found.
```

8.4.3.4 MVPN – mLDP (Profile 17)

Because the remote loopbacks are leaked between ASes, building mLDP across AS boundaries should be straightforward. Before beginning, note that **XE does not support mLDP recursive FEC**. Like the PIM vector, core routers would not know how to reach remote PE loopback if BGP is used to distribute them within an AS. As such, they cannot send label mapping messages towards the mLDP roots. Just like with GRE-based MVPN, we are fortunate that AS 13 does not have any real P routers, or else this test would fail. Recursive FEC allows a router to effectively accomplish the same task the PIM vector does (update the FEC to something the core routers can reach) so that core routers are not left searching for missing remote PE routes. The XR command to enable this feature is below and is shown for demonstration purposes only. There is no XE equivalent at this time.

```
! Recursive mLDP FEC in XR
mpls ldp
  mldp
    address-family ipv4
      recursive-fec
```

Recursive FEC is less of a design/architecture and is actually an opaque type. On XR, we can see this new opaque type is an option for the mLDP database show command. The two types of recursive FEC are

basic and VPN. Just like the PIM vector, we can include the vector by itself or vector + RD. The logic is the same here, where the “recursive-rd” option includes a “root” address reachable from the core routers along with the VPN’s RD. Again, XE has no equivalent at this time, so we will not examine this in any great detail.

```
RP/0/0/CPU0:XRv1#show mpls mldp database opaquetype ?
  global-id      4 byte global LSP ID encoding
  ipv4           IPv4 opaque encoding
  ipv6           IPv6 opaque encoding
  mdt            RPF2685 VPN ID + MDT NR encoding
  recursive      Recursive opaque encoding
  recursive-rd   Recursive RD opaque encoding
  static-id      4 byte static LSP ID encoding
  vpnv4          VPNv4 opaque encoding
  vpnv6          VPNv6 opaque encoding
```

Ignoring this limitation since it doesn’t affect our particular network, we begin the basic mLDP configurations. Like the GRE-based MVPN where the default MDT group had to match between ASes, the same is true for the mLDP VPN ID. We will demonstrate this using the OSPF VPN on CSR2 and CSR8. Both of them have identical VRF configurations. As seen in the option B mLDP attempt, we should use the “inter-as” keyword to prevent BGP from automatically adding the “no-export” community to the type-1 I-PMSI routes. We could strip the community in other ways, but this is the most elegant.

```
! CSR2 and CSR8
vrf definition OSPF
  vpn id 1300:2400
  address-family ipv4
    mdt preference mldp
    mdt auto-discovery mldp inter-as
    mdt default mpls mldp p2mp
  address-family ipv6
    mdt preference mldp
    mdt auto-discovery mldp inter-as
    mdt default mpls mldp p2mp
```

Next, we must configure BGP IPv4 and IPv6 MVPN AFI. This configuration is basic on CSR2, CSR8, and XRv2. We must be careful to keep the next-hop unchanged between ASes in accordance with the option C design. Also, since this AFI uses RTs just like VPNv4/v6 and VPLS, we need to consider RT rewrite and intra-AS distribution. On XRv2, I demonstrate both retaining all RTs for one AFI and making CSR8 an RR-client for the other. This will allow XRv2 to retain all MVPN routes from CSR2 for advertisement down to CSR8. Additionally, both CSR2 and CSR8 must rewrite their RTs before advertising these routes. The RTs for the locally-originated MVPN routes match what is exported by the VRF, so the rewrites should be the same. Fortunately, we can reuse the RT rewrite policies on both CSR2 and XRv2 for this.

```
! CSR2
```

```

router bgp 24
  address-family ipv4 mvpn
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 next-hop-unchanged
    neighbor 13.0.0.12 route-map RM_RT_REWRITE out
  address-family ipv6 mvpn
    neighbor 13.0.0.12 activate
    neighbor 13.0.0.12 next-hop-unchanged
    neighbor 13.0.0.12 route-map RM_RT_REWRITE out

! XRv2
router bgp 13
  address-family ipv4 mvpn
    retain route-target all

  address-family ipv6 mvpn

  neighbor 13.0.0.8
    address-family ipv4 mvpn
    address-family ipv6 mvpn
    route-reflector-client

  neighbor 24.0.0.2
    address-family ipv4 mvpn
    route-policy RPL_PASS in
    route-policy RPL_RT_REWRITE out
    next-hop-unchanged
  address-family ipv6 mvpn
    route-policy RPL_PASS in
    route-policy RPL_RT_REWRITE out
    next-hop-unchanged

! CSR8
router bgp 13
  neighbor 13.0.0.12 activate
  address-family ipv6 mvpn
    neighbor 13.0.0.12 activate

```

We quickly check CSR2 and XRv2 to make sure the BGP session has formed and routes are being exchanged. The reason CSR2 learns 2 routes in each AFI is because CSR8 generated one for RD 13:2 (OSPF) and one for RD 13:1 (BGP central services).

```

We will examine the MVPN route details to ensure the RT rewrite was correct. CSR2 received routes from XRv2 with RT:24:2 and XRv2 receive routes from CSR2 with RT:13:2. This is the correct RT rewrite procedure as it will enable the iBGP clients in each AS to import the MVPN routes. Other potential extended-communities should not be wiped out thanks to the “additive” keyword. We can be fancy on CSR2 by referencing the extended-community list that matches RT:24:2 to filter the output. We don’t have this capability on XR, so we will check the route details for the RT.

```
R2#show bgp ipv4 mvpn rd 24:2 extcommunity-list EXTCOML_RT_24_2 | begin

CSR2 successfully imports CSR8’s route into VRF OSPF, and vice versa. Again, the reason CSR2 sees 2 remote routes (which are identical) is because CSR8 locally imports routes from the central services VPN. Below are the detailed outputs for the IPv4 MVPN routes. Tunnel type 2 is mLDP P2MP and the root addresses in hex are highlighted in yellow as well.

```
R2#show bgp ipv4 mvpn vrf OSPF route-type 1 13.0.0.8

```

Importing these BGP auto-discovery MVPN routes into the OSPF VPN means that the mLDP tree construction can begin. I will quickly trace CSR2's IPv4 P2MP tree from CSR8's perspective to see if it was successfully able to join. The MVPN section describes this in greater detail, but GIDs beginning with 0x20000 are used for IPv4 trees while 0x40000 implies IPv6 trees. LSM ID 4 is the tree we will trace as this is rooted at CSR2.

```
R8#show mpls mldp database summary
```

LSM ID	Type	Root	Decoded Opaque Value	Client Cnt.
1	P2MP	13.0.0.8	[gid 131072 (0x00020000)]	1
4	P2MP	24.0.0.2	[gid 131072 (0x00020000)]	1
2	P2MP	13.0.0.8	[gid 262144 (0x00040000)]	1
3	P2MP	24.0.0.2	[gid 262144 (0x00040000)]	1

We check the mLDP database for details about LSM ID 4. We can see the path towards 24.0.0.2 is via XRv1, which is consistent with the unicast route recursion on CSR8. CSR8 allocates downstream label 8034 to XRv1 who can use it when sending traffic down the P2MP tree from CSR2 for IPv4 multicast. When CSR8 receives it, the traffic is replicated into the OSPF VPN as expected.

```
R8#show mpls mldp database id 4
```

```
LSM ID : 4   Type: P2MP   Uptime : 00:08:55
FEC Root      : 24.0.0.2
Opaque decoded : [gid 131072 (0x00020000)]
Opaque length  : 4 bytes
Opaque value   : 01 0004 00020000
Upstream client(s) :
  13.0.0.11:0    [Active]
    Expires      : Never
    Out Label (U) : None
    Local Label (D) : 8034
    Next Hop     : 13.8.11.11
Replication client(s):
  MDT (VRF OSPF)
    Uptime       : 00:08:55
    Interface    : Lspvif0
    Path Set ID  : None
```

```
R8#show ip cef 24.0.0.2 detail
```

```
24.0.0.2/32, epoch 2, flags [rib defined all labels]
  3 RR sources [non-eos indirection, heavily shared]
    recursive via 10.6.11.6 label 6029
    nexthop 13.8.11.11 GigabitEthernet2.581 label 91008
```

When we check XRv1, we only see two trees versus the expected 4. XRv1 knows about CSR2 as a root, which implies there are clients in AS 13 that are trying to join it. Specifically, this is CSR8, and is correct. XRv1 is not aware that CSR8 is the root for any trees because it has not received any label mapping messages from CSR6. Even without looking at more detailed output, we theorize there is a problem on the transit link. LSM ID 0x2 describes the tree we are currently tracing.

```
RP/0/0/CPU0:XRv1#show mpls mldp database brief
LSM ID    Type    Root                Up Down Decoded Opaque Value
0x00002   P2MP    24.0.0.2            0  1    [global-id 131072]
0x00001   P2MP    24.0.0.2            0  1    [global-id 262144]
```

Looking at LSM ID 0x2, we can see there are no upstream neighbors. XRv1 is not the root of the tree, so we would not expect to see this output quite yet. The issue is that LDP is not enabled on the transit links, which means mLDP label mapping messages cannot be exchanged. XRv1 did correctly process the downstream label value of 8034 from CSR8.

```
RP/0/0/CPU0:XRv1#show mpls mldp database 0x2
mLDP database
LSM-ID: 0x00002    Type: P2MP    Uptime: 00:12:42
  FEC Root          : 24.0.0.2
  Opaque decoded     : [global-id 131072]
  Upstream neighbor(s) :
    None
  Downstream client(s):
    LDP 13.0.0.8:0    Uptime: 00:12:42
      Next Hop        : 13.8.11.8
      Interface       : GigabitEthernet0/0/0/0.581
      Remote label (D) : 8034
```

Before tracing anything else, I enable LDP on all of the transit interfaces. Just like with option B, it makes sense for us to adjust the LDP transport address for the TCP session to be the connected interface. There was no reason for us to advertise the ASBR loopbacks into BGP, so the LDP RIDs won't have connectivity across AS boundaries.

```
! CSR6
interface GigabitEthernet2.556
 mpls ip
 mpls ldp discovery transport-address interface

interface GigabitEthernet2.561
 mpls ip
 mpls ldp discovery transport-address interface

! CSR7
interface GigabitEthernet2.557
 mpls ip
 mpls ldp discovery transport-address interface

! CSR5
interface GigabitEthernet2.556
 mpls ip
 mpls ldp discovery transport-address interface
```

```

interface GigabitEthernet2.557
  mpls ip
  mpls ldp discovery transport-address interface

! XRv1
mpls ldp
  interface GigabitEthernet0/0/0/0.561
  address-family ipv4
  discovery transport-address interface

```

I quickly check CSR6 and CSR5 to ensure all of the LDP peers form. Notice the TCP session addressing for the inter-AS sessions below. This shows that all of the LDP sessions have formed.

```

R5#show mpls ldp neighbor | include Peer|TCP
  Peer LDP Ident: 13.0.0.11:0; Local LDP Ident 13.0.0.5:0
    TCP connection: 13.0.0.11.44214 - 13.0.0.5.646
  Peer LDP Ident: 13.0.0.8:0; Local LDP Ident 13.0.0.5:0
    TCP connection: 13.0.0.8.32139 - 13.0.0.5.646
  Peer LDP Ident: 24.0.0.7:0; Local LDP Ident 13.0.0.5:0
    TCP connection: 10.5.7.7.27954 - 10.5.7.5.646
  Peer LDP Ident: 24.0.0.6:0; Local LDP Ident 13.0.0.5:0
    TCP connection: 10.5.6.6.28926 - 10.5.6.5.646

```

```

R6#show mpls ldp neighbor | include Peer|TCP
  Peer LDP Ident: 24.0.0.7:0; Local LDP Ident 24.0.0.6:0
    TCP connection: 24.0.0.7.28768 - 24.0.0.6.646
  Peer LDP Ident: 24.0.0.14:0; Local LDP Ident 24.0.0.6:0
    TCP connection: 24.0.0.14.55519 - 24.0.0.6.646
  Peer LDP Ident: 13.0.0.11:0; Local LDP Ident 24.0.0.6:0
    TCP connection: 10.6.11.11.39776 - 10.6.11.6.646
  Peer LDP Ident: 13.0.0.5:0; Local LDP Ident 24.0.0.6:0
    TCP connection: 10.5.6.5.646 - 10.5.6.6.28926

```

As seen in option B, one issue with this approach is that labels are still being exchanged even if the peer AS does not have routes for it. Alternatively, a peer AS may have a BGP route for a prefix, making the LDP label useless. In the option B section, we developed simple label filters that only allow labels to be advertised to internal peers. On XRv1, the logic is reversed and the router allocates labels for no prefixes to a specific peer. Thus, this halts the label exchange over the inter-AS links. This only affects unicast LDP labels; it has no effect on mLDP labels.

```

! CSR6 and CSR7
ip access-list standard ACL_ANY
  permit any
ip access-list standard ACL_INTERNAL_PEERS
  permit 24.0.0.0 0.0.0.255

no mpls ldp advertise-labels

```

```

mpls ldp advertise-labels for ACL_ANY to ACL_INTERNAL_PEERS

! CSR5
ip access-list standard ACL_ANY
 permit any
ip access-list standard ACL_INTERNAL_PEERS
 permit 13.0.0.0 0.0.0.255

no mpls ldp advertise-labels
mpls ldp advertise-labels for ACL_ANY to ACL_INTERNAL_PEERS

! XRv1
ipv4 access-list ACL_DENY_ALL
 10 deny ipv4 any any

mpls ldp
 address-family ipv4
  label
  local
  advertise
    to 24.0.0.6:0 for ACL_DENY_ALL

```

For brevity, I limit my verifications to CSR6. We can see that no remote labels are learned from any AS 13 peer. The LDP session is entirely incapable of advertising IPv4 prefix to label bindings, which is the goal.

```

R6#show mpls ldp bindings neighbor 13.0.0.11
[no output]

```

```

R6#show mpls ldp bindings neighbor 13.0.0.5
[no output]

```

We will continue tracing CSR2's P2MP IPv4 tree on XRv1. Earlier, XRv1 did not have an upstream interface as LDP was disabled on the transit link towards 24.0.0.2, which is via CSR6. Checking the same LSM ID, we see CSR6 as the upstream neighbor and its LDP RIB clearly displayed. XRv1 allocates label 91011 to CSR6 for receiving multicast from CSR2. Label 91011 is swapped for label 8034 as traffic flows downstream.

```

RP/0/0/CPU0:XRv1#show mpls mldp database 0x2
mLDP database
LSM-ID: 0x00002    Type: P2MP    Uptime: 00:30:44
  FEC Root          : 24.0.0.2
  Opaque decoded     : [global-id 131072]
  Upstream neighbor(s) :
    24.0.0.6:0 [Active] Uptime: 00:13:43
    Local Label (D) : 91011
  Downstream client(s):

```

```

LDP 13.0.0.8:0      Uptime: 00:30:44
  Next Hop          : 13.8.11.8
  Interface         : GigabitEthernet0/0/0/0.581
  Remote label (D)  : 8034

```

Continuing the trace, CSR6 allocates label 6064 towards XRv4 to receive multicast traffic from CSR2. It swaps this for label 91011 received from XRv1.

```
R6#show mpls mldp database summary
```

LSM ID	Type	Root	Decoded Opaque Value	Client Cnt.
2	P2MP	13.0.0.8	[gid 131072 (0x00020000)]	1
4	P2MP	24.0.0.2	[gid 131072 (0x00020000)]	1
1	P2MP	13.0.0.8	[gid 262144 (0x00040000)]	1
3	P2MP	24.0.0.2	[gid 262144 (0x00040000)]	1

```
R6#show mpls mldp database id 4
```

```

LSM ID : 4      Type: P2MP      Uptime : 00:15:05
  FEC Root      : 24.0.0.2
  Opaque decoded : [gid 131072 (0x00020000)]
  Opaque length  : 4 bytes
  Opaque value   : 01 0004 00020000
  Upstream client(s) :
    24.0.0.14:0 [Active]

We moved too quickly through our verification process and skipped a critical step. On CSR6, we saw an outgoing label to XRv1, but no outgoing interface. The LFIB clearly shows this LSM traffic being dropped.

```
R6#show mpls forwarding-table labels 6064
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
6064	91011	[gid 131072 (0x00020000)]	\	0	drop

I enable mLDP debugging on CSR6 and clear the mLDP neighbor with XRv11. Because I have not seen this problem before, I enable all debugging. Focusing on this particular tree, we see label 91011 from XRv1 as usual, except the interface is “NULL”. It also shows the LDP RID as the next-hop, which doesn’t make sense. CSR6 does not have a route for this ASBR loopback, nor should it need one. The TCP session between CSR6 and XRv1 is established using directly connected interfaces and CSR6 has a valid downstream label to XRv1. Historically, reachability to the LDP RID has never been necessary for ordinary IPv4 prefix to label bindings.

```
R6#debug mpls mldp all
MLDP generic debugging is on
MLDP MRIB debugging is on
MLDP MFI debugging is on
MLDP Gracefull Restart debugging is on
MLDP neighbor debugging is on
MLDP HA debugging is on
MLDP filtering debugging is on
MLDP Route-watch notification debugging is on
```

```
MLDP: Route watch started for 24.0.0.2 topology: base ipv4
MLDP-DB: Added [gid 131072 (0x00020000)] DB Entry
MLDP-DB: [gid 131072 (0x00020000)] Added P2MP branch for 13.0.0.11:0 label 91011
MLDP-MFI: PSM-ID: 5, Add Path type: PKT, Label: 91011, Nexthop: 13.0.0.11, Interface: NULL
```

Adding a temporary static host route to CSR6 with debugging still enabled, mLDP reveals that it is actually trying to find a route to the peer LDP RID.

```
! CSR6
ip route 13.0.0.11 255.255.255.255 10.6.11.11
```

```
MLDP-NBR: 13.0.0.11:0 LDP update NH: 10.6.11.11, Interface:
GigabitEthernet2.561 Add
MLDP-NBR: 13.0.0.11:0 Check branches for path change
MLDP-DB: [gid 131072 (0x00020000)] Changing branch 13.0.0.11:0 from
Null/0.0.0.0 to GigabitEthernet2.561/10.6.11.11
```

When we check CSR6's mLDP database, now the outgoing interface shows up as XRv1 as expected. However, the LFIB remains dysfunctional. Traffic arriving from XRv4 with label 6067 is still dropped.

```

```

The static route helped us understand what mLDP was really trying to do but didn't solve the forwarding problem. I remove the static route and advertise the loopback into BGP on XRv1 instead.

```
! CSR6
no ip route 13.0.0.11 255.255.255.255 10.6.11.11

! XRv1
router bgp 13
```

```
address-family ipv4 unicast
network 13.0.0.11/32
```

With debugging still enabled, we see a similar set of messages from mLDP on CSR6. The interface has been updated from “NULL” to the transit link facing XRv1. So far this is identical to what we saw with our static route.

```
! CSR6
MLDP-NBR: 13.0.0.11:0 LDP update NH: 10.6.11.11, Interface:
GigabitEthernet2.561 Add
MLDP-NBR: 13.0.0.11:0 Check branchchange
MLDP-DB: [gid 131072 (0x00020000)] Changing branch 13.0.0.11:0 from
Null/0.0.0.0 to GigabitEthernet2.561/10.6.11.11
```

However, this actually did solve the problem. The LFIB is correctly populated and LSM can be forwarded from CSR2 to CSR8. This solution isn’t terrible since there are usually a small number of ASBRs, but it does modify the original option C intent.

```
R6#show mpls forwarding-table labels 6067
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Outgoing interface	Next Hop
6067	91011	[gid 131072 (0x00020000)] \	80	Gi2.561	10.6.11.11

The reason the static route did not work is because despite having a route to 13.0.0.11/32, CSR6 did not learn a unicast label for it. This suggests that mLDP requires a unicast label (from any source) for the next-hop prefixes along the tree’s downstream path. I suppose this is a mechanism to ensure LSM is not forwarded to peers that may not be distributing labels properly. Had we not applied our LDP label filtering outbound on XRv1, the static route would have solved the problem. The BGP solution is cleaner so we will continue relying on that. For completeness, I advertise all of the ASBR loopbacks into BGP (not shown) since, presumably, CSR5 and CSR7 will have the same problem during a failover event. You could potentially use static routes at the ASBR’s and keep the loopback reachability local to the ASBRs across a transit link, but this would require label bindings for those prefixes to be exchanged. Adjusting the LDP filters appropriately is a valid alternative to using BGP labeled-unicast, but since this AFI is already negotiated for option C, adding static routes makes less sense. Additionally, we could stop using the transit interface IP addresses for the LDP TCP session now that the LDP RIDs are reachable, but I do not revert this modification.

For some reason, XR was smart enough not to use the LDP RID as the next-hop in identifying replication clients. I prove that the LSM is flowing using MPLS OAM. This may indicate an issue within XE or simply a sanity check as described earlier. This will discover all other remote PEs down the P2MP tree. Beware that when using OAM on P2MP trees, pings can only be originated at the tree’s root.

```
R2#ping mpls mldp p2mp 24.0.0.2 hex 0x1 00020000
```

```

p2mp Root node addr 24.0.0.2
Opaque type hex value (0x1), num hex digits 4

! reply addr 24.2.14.2

```

Another fast test is to check both PEs for PIM neighbors for both IPv4 and IPv6. Those outputs are shown below as further confirmation that inter-AS option C mLDP is functional.

```

To test customer multicast across this MVPN instance, CSR4 has joined an IPv6 SSM group of FF33::9 from source ::10:9:9:9 (INCLUDE mode). We confirm that CSR4 is properly joined to this group and that the appropriate C(S,G) SSM join is sent towards CSR8, the egress PE. The little 's' flag in the MRIB state signifies an SSM entry.

```
R4#show ipv6 mld groups FF33::9 detail
```

```
Interface: Loopback0
Group: FF33::9
Uptime: 3d07h
Router mode: INCLUDE
Host mode: INCLUDE
Last reporter: FE80::21E:49FF:FE80:B400
Group source list:
Source Address      Uptime    Expires    Fwd  Flags
::10:9:9:9          3d07h     00:03:53   Yes  Remote Local 2D
```

```
R4#show ipv6 mroute FF33::9 ::10:9:9:9 | begin \((
```

```
(::10:9:9:9, FF33::9), 3d07h/never, flags: sLTI
Incoming interface: GigabitEthernet2.548
RPF nbr: FE80::8
Immediate Outgoing interface list:
Loopback0, Forward, 3d07h/never
```

CSR8 learns this C(S,G) state from CSR4 and installs it in the C-MRIB. The incoming interface is the PMSI. The join is transported over the default MDT, which is a collection of dynamically-built P2MP mLDLP trees, to CSR2. CSR2 receive traffic from the customer and sends it to the PMSI.

```
R8#show ipv6 mroute vrf OSPF FF33::9 ::10:9:9:9 | begin \((
```

```
(::10:9:9:9, FF33::9), 01:41:59/00:02:34, flags: sT
Incoming interface: Lspvif0
RPF nbr: ::FFFF:24.0.0.2
Immediate Outgoing interface list:
GigabitEthernet2.548, Forward, 01:41:59/00:02:34
```

```
R2#show ipv6 mroute vrf OSPF FF33::9 ::10:9:9:9 | begin \((
```

```
(::10:9:9:9, FF33::9), 00:23:39/00:02:53, flags: sT
Incoming interface: GigabitEthernet2.529
RPF nbr: FE80::9
```

```
Immediate Outgoing interface list:  
  Lspvif0, Forward, 00:23:39/00:02:53
```

CSR9 is the root of the C-SPT and expects to receive traffic from its loopback interface. Traffic is then sent towards CSR2, the ingress PE. This customer multicast signaling will never change as SSM does not rely on an RP nor SPT switchover.

```
R9#show ipv6 mroute FF33::9 ::10:9:9:9 | begin \  
(::10:9:9:9, FF33::9), 00:24:43/00:02:53, flags: sT  
  Incoming interface: Loopback0  
  RPF nbr: FE80::21E:E5FF:FEA2:5700  
  Immediate Outgoing interface list:  
    GigabitEthernet2.529, Forward, 00:24:43/00:02:53
```

CSR9 will start sending IPv6 multicast towards FF33::9 to which CSR4 is listening.

```
R9#ping ipv6  
Target IPv6 address: FF33::9  
Repeat count [5]: 10000  
Datagram size [100]:  
Timeout in seconds [2]: 1  
Extended commands? [no]: y  
Source address or interface: ::10:9:9:9  
[snip]  
Output Interface: loopback0
```

For brevity, I check the counters on CSR2 and CSR8 to ensure the traffic is being properly encapsulated and decapsulated. Packets received on CSR2 have a frame size (including layer 2) of 118 bytes, while CSR8 sees the with a single MPLS label for LSM transport. This proves that the MVPN instance is working correctly.

```
R2#show ipv6 mroute vrf OSPF FF33::9 ::10:9:9:9 count | begin ^Group  
Group: FF33::9  
  Source: ::10:9:9:9,  
    SW Forwarding: 0/0/0/0, Other: 0/0/0  
    HW Forwarding: 92/1/118/0, Other: 0/0/0  
  Totals - Source count: 1, Packet count: 92
```

```
R8#show ipv6 mroute vrf OSPF FF33::9 ::10:9:9:9 count | begin ^Group  
Group: FF33::9  
  Source: ::10:9:9:9,  
    SW Forwarding: 0/0/0/0, Other: 0/0/0  
    HW Forwarding: 96/1/126/0, Other: 0/0/0  
  Totals - Source count: 1, Packet count: 96
```

Finally, we check the packet counters on CSR4 to ensure the end-user is receiving the traffic. CSR4 sees a 118 byte packet (including layer 2 encapsulation) after the MPLS labels are removed by CSR8.

```
R4#show ipv6 mroute FF33::9 ::10:9:9:9 count | begin ^Group
Group: FF33::9
  Source: ::10:9:9:9,
    SW Forwarding: 0/0/0/0, Other: 0/0/0
    HW Forwarding: 100/1/118/0, Other: 0/0/0
  Totals - Source count: 1, Packet count: 100
```

8.4.3.5 MPLS TE

Unlike option B, inter-AS MPLS TE actually makes sense for option C. Since the peer ASes are supposed to know about the remote PE loopbacks, building a tunnel directly between PEs is a valid design choice. Before continuing, I perform the same basic TE topology checks from option B to ensure all links/nodes are configured correctly. Both ASes have exactly 4 routers, and the transit links are enabled for TE as well. IS-IS IGP IDs show these like NETs with the high-order 32 bits mapped to the peers static TE ID. OSPF shows them as simple IP addresses. CSR6's link to XRv1 doesn't actually work, but I highlight it for completeness. XR does not have a "passive-interface" equivalent.

```

```

The normal tunnel stitching methods seen in option A and the UMPLS chapter are also valid as this gives each AS full control over inter-AS policies. Those are not examined again here. Instead, I will build a pair of inter-AS TE tunnels from XRv2 to CSR2 and XRv2 to XRv4. Below is the configuration for CSR2; the loose-hop path expansion was discussed in detail in option B. This section will details the process with debugs again. In short, the loose-hops are expanded at each router where necessary and substituted with a set of strict hops. Unlike traditional TE, PCALC is invoked at each loose-hop so they can “expand” the ERO appropriately. The design assumes that not every node sees every other node, but certain border nodes have additional information; it is somewhat similar to distance-vector routing logic. CSR2 will prefer the high-cost link directly to CSR7, then continue through XRv4 and CSR6 to exit AS 13. Once the ERO reaches CSR6, CSR6 will expand the hop to CSR7 by finding the best dynamic path. The same occurs once CSR7 receives the ERO as the path inside AS 13 will be dynamic as well. **Note: CSR6 must be a loose hop because 13.0.0.5 does not appear in the TED as a router node, despite CSR6 being statically connected to it.** I also add a 75 Mbps bandwidth reservation with custom priorities to show that this is honored across AS boundaries.

```

! CSR2
ip explicit-path name EP_2_7_14_6_L5_L12 enable
  next-address 24.0.0.7
  next-address 24.0.0.14
  next-address loose 24.0.0.6
  next-address loose 13.0.0.5
  next-address loose 13.0.0.12

interface Tunnel300
  description INTER-AS LOOSE HOP
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 13.0.0.12
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng priority 5 3
  tunnel mpls traffic-eng bandwidth 75000
  tunnel mpls traffic-eng path-option 10 explicit name EP_2_7_14_6_L5_L12

! CSR2, CSR5, and CSR6
debug mpls traffic-eng path lookup

```

First, CSR2 invokes the regular PCALC operation to find the path to 13.0.0.12 within the TE constraints. The explicit-path was supplied versus dynamically computed and contains a combination of strict and

loose hops. The intra-AS strict hops give CSR2 (headend) more control over the internal path rather than computing any dynamic path to CSR6. CSR2 is not aware of node 13.0.0.12 in the TED but finds CSR6 as a loose-hop. This node is within the AS and the strict hops to CSR6 have been supplied so the AS 13 TE midpoints don't need to invoke PCALC; they just need to perform the RSVP signaling and update the ERO as needed. The debug is left intact for reference, but the important pieces have been discussed. The remaining outputs are related to path verification and explicit hop expansion for signaling.

```

We can confirm the exact ERO message that CSR2 sends to CSR7 by checking the RSVP PATH message. The intra-AS hops have been fully expanded as CSR6's loose-hop status has been removed. CSR5 becomes the first loose-hop now.

```

R2#show ip rsvp sender detail filter session-type 7 tunnel-id 300 | section
outgoing
ERO: (outgoing)
  24.2.7.7 (Strict IPv4 Prefix, 8 bytes, /32)
  24.7.14.14 (Strict IPv4 Prefix, 8 bytes, /32)
  24.6.14.6 (Strict IPv4 Prefix, 8 bytes, /32)
  24.0.0.6 (Strict IPv4 Prefix, 8 bytes, /32)
  13.0.0.5 (Loose IPv4 Prefix, 8 bytes, /32)
  13.0.0.12 (Loose IPv4 Prefix, 8 bytes, /32)

```

Just like in option B, the LSR on the edge of the source AS (where the headend is) reports a failure to expand the loose hop. CSR6 invokes the PCALC expansion which normal TE midpoints need not do, but since the incoming ERO contained a loose-hop, CSR6 must find a path to it. Because an explicit-path to CSR5 was not supplied, CSR6 assumes any dynamic path may be used, but the bandwidth reservation and TE priorities are maintained. One thing that is NOT maintained is the affinity; between ASes, it is assumed that link coloring schemes will be totally different, so affinity is completely ignored. CSR6 also takes care not to include XRv4, CSR7, or CSR2 in the loose-hop expansion as this would create a loop. These are carried in the RSVP PATH RRO which we examine later.

```

```

Ultimately, we see CSR6 fails to expand 13.0.0.5 into strict hops. However, CSR6 removes its local addresses from the incoming ERO and adds the transit link address (specified in the TE passive interface statement) to the outgoing ERO. Although CSR6 failed to expand 13.0.0.5, it can at least continue to signal the LSP. IT assumes that someone else down the path will be able to expand 13.0.0.5, which is a valid assumption in this case. The RRO is used to ensure, when loose-hop expansion is enabled, that a router computing a loose-hop does not select a dynamic path via a node already in the LSP. This is a stack that has new TE hops pushed as the LSP is signaled.

```

```

CSR5 receives the RSVP PATH message from CSR6 containing an ERO with its own TE ID as a loose-hop. This is loose-hop need not be expanded since it is a local address, but CSR5 must invoke the PCALC loose-hop expansion process to expand 13.0.0.12. Again, a colorless dynamic path is assumed, but the bandwidth reservations and TE priorities are honored. Being in a different AS than the other routers in the RRO, CSR5 cannot find the TE RIDs for CSR6, XRv4, CSR7, or CSR2. This is acceptable since it was only

doing this to prevent loops in the first place; being unable to find them in the graph at all guarantees that a loop cannot form. CSR5 computes the shortest path to XRv2 is via CSR8.

```

CSR5 is the last router that needs to expand a loose-hop. When the ERO arrived from CSR6, it contained loose-hops. CSR5 removed 13.0.0.5 without expansion (local TE-ID) and expanded 13.0.0.12 manually (final destination). The resulting ERO signaled to CSR8 via RSVP PATH messaging contains only intra-AS strict hops. No other TE LSRs in AS 13 will need to run PCALC again.

```
R5#show ip rsvp sender detail filter session-type 7 tunnel-id 300 | section
ERO
ERO: (incoming)
  10.5.6.5 (Strict IPv4 Prefix, 8 bytes, /32)
  13.0.0.5 (Loose IPv4 Prefix, 8 bytes, /32)
  13.0.0.12 (Loose IPv4 Prefix, 8 bytes, /32)
```

ERO: (outgoing)

13.5.8.8 (Strict IPv4 Prefix, 8 bytes, /32)
13.8.12.12 (Strict IPv4 Prefix, 8 bytes, /32)
13.0.0.12 (Strict IPv4 Prefix, 8 bytes, /32)

Checking XRv2, we can see that it is the tail end for a single TE LSP. The tunnel has been signaled properly with the bandwidth reservation and TE priorities maintained. The RSVP PATH RRO shows the entire LSP back to the remote AS source, which allows the tail end to see the entire path. I show all of the details for reference, but the tunnel generally looks like a normal TE tunnel.

```
RP/0/0/CPU0:XRv2#show mpls traffic-eng tunnels role tail

Another nice feature of these inter-AS tunnels is the RSVP RESV RRO is automatically enabled. Though we did not configure it, CSR2 is also shown all hops along the path. I show the entire RESV message

because this also confirms the 75 Mbps bandwidth reservation for the headend. It also carries the MPLS label, and the first hop is via CSR7 using label 7093.

```
R2#show ip rsvp reservation detail filter session-type 7 tunnel-id 300

```

We can quickly check the integrity of the TE LSP using MPLS OAM traceroute. This reveals all of the TE labels along the way. It also confirms that the tunnel formed in an acceptable manner; CSR2 as only able to influence the first few intra-AS hops. Everything after CSR6 was entirely dynamic. Notice label 7093 at the first hop.

```
R2#traceroute mpls traffic-eng tunnel 300 source 24.0.0.2 force-explicit-null
Tracing MPLS TE Label Switched Path on Tunnel300, timeout is 2 seconds

```

In the configuration, CSR2 used autoroute destination to automatically installed a static route to 13.0.0.12/32 via the TE tunnel. Autoroute announce and forwarding adjacency are not supported for inter-AS or inter-area tunnels, so static routes are the best option when using TE to support MPLS VPNs. The static routing database also notes that this was dynamically added via MPLS TE and is currently active.

```
R2#show ip route 13.0.0.12
Routing entry for 13.0.0.12/32
  Known via "static", distance 1, metric 0 (connected)
  Routing Descriptor Blocks:
    * directly connected, via Tunnel300
      Route metric is 0, traffic share count is 1
```

```
R2#show ip static route | begin RIB
Static local RIB for default
TE 13.0.0.12/32 [1/0] via Tunnel300 [A]
```

Since CSR2 is routing all traffic to 13.0.0.12 in this tunnel, we can assume the eBGP session packets from CSR2 to XRv2 are also inside the tunnel. Using traceroute on CSR1 inside the EIGRP VPN, we can verify that the tunnel is used. The label stack only ever consists of two labels since LDP and BGP labeled unicast are entirely bypassed with this design. We confirm label 7093 at the first hop, proving that the TE LSP is in use. The reverse LSP is whatever XRv2 was always using as the TE LSP is unidirectional.

```

```

We also must ensure that this TE tunnel does not break multicast. Since CSR2 is supporting an MVPN profile 0 deployment for the EIGRP VPN, we must consider that the TE tunnel will break RPF towards 13.0.0.2. PIM is not enabled on the TE tunnel.

```
R2#show ip rpf 13.0.0.12
failed, no route exists
```

This solution is discussed in other chapters involves telling IGP not to consider TE tunnels as RPF interfaces. This does not work when static routes are used to route traffic into TE tunnels, and I prove it quickly. This technique is only valid when “autoroute announce” is used.

```
! CSR2
router isis 24
  mpls traffic-eng multicast-intact
```

```
R2#show ip rpf 13.0.0.12
failed, no route exists
```

To solve this problem, we can use BGP IPv4 multicast or a simple static multicast route. I choose the latter for simplicity. This solution can be sloppy in a network with multiple links and does not scale well.

```
! CSR2
ip mroute 13.0.0.12 255.255.255.255 24.2.14.14

R2#show ip rpf 13.0.0.12
RPF information for ? (13.0.0.12)
  RPF interface: GigabitEthernet2.524
  RPF neighbor: ? (24.2.14.14)
  RPF route/mask: 13.0.0.12/32
  RPF type: multicast (static)
  Doing distance-preferred lookups across tables
  RPF topology: ipv4 multicast base
```

With CSR2's RPF fixed, we should still be able to send multicast from CSR2 to XRv2. A quick ping test on CSR3 confirms it. CSR3 sends packets and XRv3 receives them.

```
R3#ping ip
Target IP address: 225.13.13.13

```

We shut down this tunnel on CSR2 and create another [ID 301] using the “verbatim” option. This technique was discussed in detail in the TE section and is particularly useful for inter-AS TE (along with other cases such as the intermediate nodes not support TE IGP extensions). Normally, explicit paths are checked against the TED for consistency; this protects against signaling impossible paths. There is no reason to waste RSVP signaling messages trying to build a path that is nonexistent, so the local PCALC process will not even attempt to signal the LSP. The “verbatim” keyword overrides this sanity check which bypasses the TED entirely. The configured explicit-path can use TE IDs within an AS but must use

the specific link addresses in the remote AS. RSVP RESV RRO is not very valuable on explicit-path tunnels like this, but I enable it anyway to demonstrate it does work inter-AS. It is not enabled automatically on tunnels which actively use an explicit-path with the verbatim option.

```
! CSR2
ip explicit-path name EP_2_14_7_5_11_12_VERBATIM enable

  tunnel mpls traffic-eng bandwidth 10500
  tunnel mpls traffic-eng path-option 10 explicit name
  EP_2_14_7_5_11_12_VERBATIM verbatim
  tunnel mpls traffic-eng record-route
```

MPLS path debugging remains enabled on CSR2 but disabled on all other routers. Since there is no loose-hop expansion, no other router will invoke PCALC except CSR2. The PCALC logic is very simple as PCALC does essentially nothing at all for TE IDs it does not recognize. I highlight all the debug output that shows us the TED bypass in action. PCALC is aware that it may not be able to find all of the TE IDs for all nodes. It is able to find the hop addresses for the intra-AS hops, which allows us to use TE IDs versus exact link addressing, so PCALC does a small amount of work.

```

success

```

Looking at the ERO details, PCALC literally makes no changes other than removing the local addresses from the ERO before sending it onward. Even the TE IDs remain unexpanded, but the receiving router can quickly find the next-hop based on the intra-AS TE ID. The entire LSP is signaled very literally, hence the word “verbatim”.

```

13.0.0.12 (Strict IPv4 Prefix, 8 bytes, /32)

```

Of note, CSR2 is smart enough to prevent any possible loops. Like the loose-hop expansion, verbatim paths are susceptible to loops, so CSR2 includes the RSVP PATH RRO in the first PATH it sends. We can confirm this by checking XRv4. In seeing this message, XRv4 continues to push TE hops onto the RRO stack so that ultimately XRv2 will see the entire TE LSP path. Also notice that XRv4 simply removes its

local addresses from the incoming ERO and sends out the remaining ERO addresses with no additional effort.

The static multicast route for 13.0.0.12/32 is still configured on CSR2 and is required with verbatim paths just as it is for loose-hop expansion paths (when used inter-AS). A quick multicast test from CSR2 to XRv3 confirms that the MVPN for the EIGRP customer remains operational.

```

```

Before continuing, I shut down tunnel301 on CSR2 and apply an AD of 255 to the multicast route (not shown). I also verify the route to 13.0.0.12/32 is IS-IS learned again. This returns the network to its baseline operation with the TE configurations on standby (shutdown but easily enabled for future testing). I quickly confirm these configurations are correct.

```

I enable debugging for the MPLS path lookup on all routers responsible for invoking PCALC, whether it is the headend or the loose-hop expansion nodes.

```
! XRv2, CSR5, and CSR6
debug mpls traffic-eng path lookup
```

XRv2's debug output is much more verbose and less straightforward than XE. The logic begins the same: XRv2 tries to find a way to 24.0.0.2 and waits, so it finds a path to the first loose-hop instead. It resolves the link addresses for XRv1 and CSR8 and leaves CSR5 (and all other loose addresses) inside the ERO for further processing later.

```

```

CSR5 receives the RSVP PATH message with 13.0.0.5 in the ERO and immediately removes it; this is CSR5's TE ID. CSR5 is unable to expand the hop for CSR6 so instead it leaves the ERO intact and sends the RSVP PATH message to CSR6 with 24.0.0.6 as the first loose-hop. As expected, the bandwidth reservation and TE priorities are maintained. The affinity is cleared as link colors are not expected to be consistent between ASes, much like IGP or TE metrics.

```

! CSR5

TE-PCALC-API: 13.0.0.5_10->24.0.0.6_300 {7}: LSP Path Expand result: failed

```

We can check this on CSR5 by examining the RSVP PATH details. The ERO is as I described it above, with CSR5 leaving 24.0.0.6 as the first loose-hop in the ERO for CSR6 to evaluate. Of note, there is no RSVP PATH RRO seen here. XR does not automatically enable this as XE does.

```

R5#show ip rsvp sender detail filter session-type 7 tunnel-id 300 | section
[ER]RO
  ERO: (incoming)
    13.5.8.5 (Strict IPv4 Prefix, 8 bytes, /32)
    13.0.0.5 (Strict IPv4 Prefix, 8 bytes, /32)
    24.0.0.6 (Loose IPv4 Prefix, 8 bytes, /32)
    24.0.0.2 (Loose IPv4 Prefix, 8 bytes, /32)
  ERO: (outgoing)
    10.5.6.6 (Strict IPv4 Prefix, 8 bytes, /32)
    24.0.0.6 (Loose IPv4 Prefix, 8 bytes, /32)
    24.0.0.2 (Loose IPv4 Prefix, 8 bytes, /32)

```

Because I would prefer to see the RSVP PATH RRO be evaluate by loose-hop expansion nodes, I quickly add it to XRv2's tunnel. Now, CSR5 sees this in the PATH message from CSR8 and passes it on to CSR6.

```

! XRv2
interface tunnel-te300

    13.11.12.12/32, Flags:0x0 (No Local Protection)

```

We won't revisit CSR5's debug output after enabling RSVP PATH RRO since CSR6 shows it. CSR6 invokes the loose-hop expansion algorithm and checks the paths to the routers already in the RRO. This includes CSR5, CSR8, and XRv1, and XRv2. Since those are in another AS, it is impossible for a loop to form, so CSR6 continues with its calculation. CSR6 computes any dynamic path to CSR2 as XRv2 cannot control this with loose-hop expansion.

```

```

As the tail end, CSR2 sees the tunnel as up, along with the full RSVP PATH RRO. The tail end can clearly see the entire reverse path along the LSP, and since the headend request RSVP RESV RRO as well, CSR2 adds itself to that list so the headend has the same awareness. With loose-hop expansion, this is valuable for both head and tail routers.

```

Next, XRv2 needs to route traffic into the tunnel. Since autoroute announce and forwarding adjacency do not work design-wise, and autoroute destination is not supported on XRv, we resort to a static route. We already foresee that this will break MVPN for the EIGRP customer as it did on CSR2. The RPF interface shows as connected with a distance of 1 and metric of 0, which hints to a static route. The unicast route was imported into the MRIB and is currently breaking MVPN traffic entering XRv2 from CSR2.

```
! XRv2
router static
 address-family ipv4 unicast
  24.0.0.2/32 tunnel-te300
```

RP/0/0/CPU0:XRv2#show pim rpf 24.0.0.2

Table: IPv4-Multicast-default

* 24.0.0.2/32 [1/0] [Connected]

```
via Null with rpf neighbor 0.0.0.0
```

```
RP/0/0/CPU0:XRv2#show route ipv4 multicast static  
S 24.0.0.2/32 is directly connected, 00:01:00, tunnel-te300
```

Since AS 13 is using a BGP-free “core” (if core routers existed here), BGP is already running between the PEs and ASBRs. We could run BGP IPv4 multicast to exchange RPF routes, but that would also involve AS 24. Because the AS 13 ASBRs learn the remote PEs via BGP, we cannot use a network statement on them to leak the route from unicast to multicast BGP. We would have to originate the route into BGP multicast on CSR6 and CSR7, which makes the configuration rather involved. For brevity, I use a multicast static route on XRv2 as well so that the focus of this lab remains on MPLS-TE, not MVPN.

```
! XRv2  
router static  
address-family ipv4 multicast  
24.0.0.2/32 13.8.12.8
```

```
RP/0/0/CPU0:XRv2#show pim rpf 24.0.0.2  
Table: IPv4-Multicast-default  
* 24.0.0.2/32 [1/0]  
via GigabitEthernet0/0/0/0.582 with rpf neighbor 13.8.12.8
```

Next, I will test basic L3VPN from CSR2 to CSR1. With BGP labeled-unicast running in AS 13, this used to require a 3-label stack. Now, the entire LSP is 2 labels since there is a PE-PE tunnel. The first transport label is 91014 which was verified earlier using OAM. This confirms that traffic is inside the TE LSP.

```
R3#traceroute 10.1.1.1 source 10.3.3.3  
Type escape sequence to abort.

 8 10.1.2.1 19 msec 11 msec 10 msec
```

I also test multicast from CSR3 to XRv3 again. This works as well; a design consideration of inter-AS TE is that it requires RPF fixup methods when supporting multicast transport for VPN customers.

```
R3#ping ip  
Target IP address: 225.13.13.13  
Repeat count [1]: 10000  
Datagram size [100]:
```

```

Timeout in seconds [2]: 1

```

I will shut down tunnel300 on XRv2 to create a verbatim path tunnel on XR. This tunnel will be PE-P and will terminate on XRv4 rather than CSR2. This implies we need some kind of mechanism to learn XRv4's label for 24.0.0.2/32 as XRv2 will need to push this onto the label stack. If it doesn't, the MPLS service label allocated by CSR2 will be revealed to XRv4 and traffic will be dropped. We can technically use BGP labeled-unicast for this (as seen in the U MPLS section), but using LDP would be simpler. The verbatim configuration is almost identical to XE.

```

! XRv2
explicit-path name EP_12_8_5_6_7_14_VERBATIM
  index 10 next-address strict ipv4 unicast 13.0.0.8
  index 20 next-address strict ipv4 unicast 13.0.0.5
  index 30 next-address strict ipv4 unicast 10.5.6.6
  index 40 next-address strict ipv4 unicast 24.6.7.7
  index 50 next-address strict ipv4 unicast 24.7.14.14
  index 60 next-address strict ipv4 unicast 24.0.0.14

interface tunnel-te301
  description INTER-AS VERBATIM
  ipv4 unnumbered Loopback0
  priority 6 5
  signalled-bandwidth 32000
  destination 24.0.0.14
  record-route
  path-option 10 explicit name EP_12_8_5_6_7_14_VERBATIM verbatim

```

With debugging still enabled on XRv2, we can observe the PCALC process. XR sees that the path-option is "verbatim" which bypasses the TED consistency checks. The bandwidth reservation and TE priorities remain intact. Link coloring (affinity constraint) is also enforced as evidenced by the non-zero mask.

```
! XRv2

[snip]

```

Skipping to CSR5, we can see the incoming and outgoing ERO, as well as the RRO. CSR5 removes its own address (as a TE ID) and sends the PATH to CSR6 who will forward the path based on TE link addresses. The RRO contains XRv2 and CSR8 so far as it records the reverse path to help prevent loops. This is mostly useful for loose-hop expansion as intermediate routers will run PCALC expansion, but verbatim midpoints will not.

```

R5#show ip rsvp sender detail filter session-type 7 tunnel-id 301 | section

```

A quick traceroute reveals that the LSP is operational in the data plane. Traffic is sent through the proper routers in accordance with the verbatim path. Notice the first label of 8030 which is allocated by CSR8 along this TE LSP. This should be the top most label for all traffic from XRv2 going into the tunnel.

```

When we add a static route for this tunnel, VPN traffic between EIGRP customers breaks. The eBGP session remains up, which means IPv4 connectivity is maintained at least. Traceroute in the global table reveals the problem; the last hop between XRv4 and CSR2 is unlabeled. This allows IPv4 to continue working simply by virtue of XRv4 being able to receive IP packets for 24.0.0.2/32 and route them appropriately.

```

```

Checking XRv2's VRF-aware FIB, we see a dysfunctional label stack. The VPN label of 2018 is imposed but additional labels are not.

```

RP/0/0/CPU0:XRv2#show cef vrf EIGRP 10.1.1.1/32
10.1.1.1/32, version 392, internal 0x5000001 0x0 (ptr 0xa146a8f4) [1], 0x0
(0x0), 0x208 (0xa1553578)
Prefix Len 32, traffic index 0, precedence n/a, priority 3
  via 24.0.0.2, 5 dependencies, recursive, bgp-ext [flags 0x6020]
    path-idx 0 NHID 0x0 [0xa15bbd74 0x0]
    recursion-via-/32
    next hop VRF - 'default', table - 0xe0000000
    next hop 24.0.0.2 via 92502/0/21
    next hop 0.0.0.0/32 tt301 labels imposed {ImplNull 2018}

```

Because the tunnel destination is not the same as the traffic we are routing into it, traffic is dropped at XRv4. The VPN label allocated by CSR2 is being exposed to XRv4 who cannot label-switch it. Though 24.0.0.2/32 is learned via a TE tunnel, we cannot push the TE label just yet. XRv2 must learn XRv4's LDP label for CSR2 since XRv4 has an IGP route for 24.0.0.2/32. We can accomplish this with tLDP on the tunnel. XRv2 will enable LDP on the TE tunnel and XRv4 will permit XRv2 (and no others) to form dynamic tLDP sessions. This is a good security practice when using inter-AS TE tunnels and tLDP between core routes (very rare in real life).

```

! XRv4
ipv4 access-list ACL_XRV2
 10 permit ipv4 host 13.0.0.12 any

mpls ldp
  address-family ipv4
    discovery targeted-hello accept from ACL_XRV2

! XRv2
mpls ldp
  interface tunnel-te301
    address-family ipv4

```

An LDP neighbor will form between XRv2 and XRv4 as a result. This might be forbidden by company policy as LDP peers are generally not negotiated between ASes. We bent this rule earlier using mLDP at the ASBRs, but in this case, these could potentially be core routers. Like the ASBRs, these routers will also exchange all labels with one another by default. There is only reason for XRv4 to advertise a single

label to XRv2, and there is no reason for XRv2 to advertise any labels to XRv4. I will apply some filters for cleanup so that the TE tunnel has a minimal affect on XRv2 and XRv4.

```
! XRv2
ipv4 access-list ACL_DENY
 10 deny ipv4 any any

mpls ldp
 address-family ipv4
  label
  local
  advertise
    to 24.0.0.14:0 for ACL_DENY

! XRv4
ipv4 access-list ACL_CSR2_LOOPBACK
 10 permit ipv4 host 24.0.0.2 any

mpls ldp
 address-family ipv4
  label
  local
  advertise
    to 13.0.0.12:0 for ACL_CSR2_LOOPBACK
```

We quickly verify that the label filtering worked as expected. This will help contain labels within an AS and increase security in general.

```
RP/0/0/CPU0:XRv4#show mpls ldp bindings neighbor 13.0.0.12
```

[no output]

```
RP/0/0/CPU0:XRv2#show mpls ldp bindings neighbor 24.0.0.14
```

```
24.0.0.2/32, rev 32
  Local binding: label: 92502
  Remote bindings: (2 peers)
    Peer          Label
    -----
    24.0.0.14:0   94009
```

With this LDP label of 94009, XRv2 now has the correct label stack (not including the TE label) to account for the LDP label for 24.0.0.2/32 from XRv4 (remote PE) and the VPN label for 10.1.1.1/32 (final destination). The TE tunnel will deliver traffic to the tunnel endpoint, which is XRv4. Earlier we saw the topmost label allocated by CSR8 along the TE LSP was 8030.

```
RP/0/0/CPU0:XRv2#show cef vrf EIGRP 10.1.1.1/32
10.1.1.1/32, version 392, internal 0x5000001 0x0 (ptr 0xa146a8f4) [1], 0x0
(0x0), 0x208 (0xa1553578)
```

```

Prefix Len 32, traffic index 0, precedence n/a, priority 3
via 24.0.0.2, 5 dependencies, recursive, bgp-ext [flags 0x6020]
path-idx 0 NHID 0x0 [0xa15bbd74 0x0]
recursion-via-/32
next hop VRF - 'default', table - 0xe0000000
next hop 24.0.0.2 via 92502/0/21
next hop 0.0.0.0/32 tt301 labels imposed {94009 2018}

```

Using traceroute in the VPN, we can confirm this fixed the problem. Traffic is inside the TE tunnel as the first label is 8030, and the 3 label stack is needed all the way up until XRv4. XRv4 now receives label 94009 which allows it to forward traffic towards 24.0.0.2/32. This topic is discussed in greater detail in the TE section as well.

```

```

Last, we will quickly test multicast. The RPF multicast static routes are still valid from earlier (assuming it is still enabled), so I ping from CSR3 to check for packet reception at XRv3. This proves that the MVPN is still function with the inter-AS, PE-P tunnel with tLDP on top.

```

R3#ping ip
Target IP address: 225.13.13.13

```

As a final cleanup, I shut down all TE tunnels on XRv2 and remove the static multicast route. XR does not allow me to set the AD to 255. Shutting the tunnels down allows them to remain readily accessible for testing later. I confirm that the unicast route is iBGP learned and the RPF is derived from the unicast route. This returns the option C network to its intended architecture.

```

```

8.4.3.6 Confederation variation

Confederations with inter-AS option C are similar to option B in that MPLS traffic exchange is expected to happen. The same considerations with respect to XR's "mpls activate" for multi-hop peers and XE's "mpls bgp forwarding" for all eBGP/intraconfederation peers still apply. Below is the basic BGP confederation configuration that is applied to all peers. This builds a confederation between AS 13 and 24, and adjusts CSR10 to peer with AS 42518, which is the confederation ASN. This configuration is identical to options A and B since it is not specific to MPLS VPN service with one exception. Since CSR2 and XRv2 peer directly, they must also identify the confederation peers. XRv4 also peers with XRv2 within the L2VPN VPLS AFI only. In this design, only CSR8 doesn't require the confederation peer list configuration.

```
! CSR2, CSR6, CSR7, and XRv4
router bgp 24
  bgp confederation identifier 42518
  bgp confederation peers 13

! CSR8
```

```

router bgp 13
  bgp confederation identifier 42518

! CSR5, XRv1, and XRv2
router bgp 13
  bgp confederation identifier 42518
  bgp confederation peers 24

! CSR10
router bgp 100
  neighbor 10.8.10.8 remote-as 42518
  neighbor FD00:10:8:10::8 remote-as 42518

```

In a textbook option C design, only BGP labeled-unicast is exchanged between the ASBRs. In this design, the IPv4 flavor of that feature is used, and we can verify these peers on CSR5 and CSR6. This proves that the confederation configuration was successful. CSR5 has an iBGP connections as well since sub-AS 13 is using labeled-unicast for transport rather than redistributing remote loopbacks into IGP.

```

R5#show bgp ipv4 unicast summary | begin ^Neigh

```

```

R6#show bgp ipv4 unicast summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ  OutQ Up/Down  State/PfxRcd
10.5.6.5      4      13      19      18      30    0    0 00:06:25      4
10.6.11.11    4      13      16      17      30    0    0 00:06:00      4

```

One interesting observation is that when labeled-unicast is configured on an XE router, next-hop-self is assumed. Looking at CSR6, it learns two routes for 13.0.0.12/32, which is a remote PE. The route via XRv1 has the next-hop unchanged, but CSR5 changed the next-hop to self without having been configured for it.

```

R6#show bgp ipv4 unicast 13.0.0.8/32

mpls labels in/out nolabel/imp-null
rx pathid: 0, tx pathid: 0x0
```

For some prefixes, this contributes to a routing loop with churning every few seconds. The IS-IS route has a better AD, so it beats the confed-external route's distance of 200. Normally this would be stable, but since CSR6 and CSR7 have the same problem (that is, they learn one another's IGP routes, which rely on the BGP routes first), the IS-IS route is withdraw regularly. At some point, the network may stabilize, but this is a major problem.

```

I quickly update XRv1 to set the next-hop to self for the labeled-unicast AFI. I also take this opportunity to remove any unnecessary filters as the intraconfederation peers do not require it. The outbound RPL is valuable for loopback advertisement control, so I do not remove it.

```
! XRv1
router bgp 13
 neighbor 10.6.11.6
   address-family ipv4 labeled-unicast
   no route-policy RPL_PASS in
   ! route-policy RPL_IF_DEST_PASS(PS_LOCAL_LOOPBACKS) out
   next-hop-self
```

The loop has ended, but we still have a suboptimal routing problem. The root of the problem is more focused on the administrative distance differences. CSR7 prefers the BGP route with AD 200 and redistribute it into IGP before CSR6 runs its BGP bestpath process. CSR6, therefore, must prefer the IGP route via CSR7. This is another reason to not perform BGP/IGP redistribution and to use BGP labeled-unicast everywhere; AS 13 will never have this problem. Earlier, AS 24 never had this problem since the BGP distance for external routes was 20, which was always less than 115 for IS-IS.

```

    Route metric is 20, traffic share count is 1
```

This problem can be fixed in two straightforward ways: lower the AD of the confed-external BGP routes representing remote loopbacks, or raise the AD of the IS-IS routes representing the remote loopbacks. CSR6 will use the first approach and CSR7 will use the second, but the effect is the same. First, I configure CSR6. This technique identifies any peer with address in the 10.0.0.0/8 range who advertises

loopbacks from 13.0.0.0/24, and sets the AD to 30. Note that BGP appears to require a “hard reset” for this distance modification to take effect. While this works, CSR7 is now preferring the IGP route via CSR6, which is the same problem. We just reversed the suboptimal routing path.

```
! CSR6
ip access-list standard ACL_REMOTE_LOOPBACKS
 permit 13.0.0.0 0.0.0.255

router bgp 24
 address-family ipv4
   distance 30 10.0.0.0 0.255.255.255 ACL_REMOTE_LOOPBACKS

```

Configuring CSR7 with a similar approach fixes the problem entirely. The source/wildcard specification is kept generic to match any internally-generated IS-IS routes for remote loopbacks. Now, both CSR6 and CSR7 prefer confed-external BGP routes.

```
! CSR7
ip access-list standard ACL_REMOTE_LOOPBACKS
 permit 13.0.0.0 0.0.0.255

router isis 24
 distance 230 24.0.0.0 0.255.255.255 ACL_REMOTE_LOOPBACKS

```

A quick way to verify the AD adjustments on both routers, as a final sanity check, is to check the IP protocol details. The output also shows the basic confederation details, such as peer ASNs and the confederation ASN. This reveals the default admin-distances for each protocol, along with the customizations on a per-entry basis. CSR6 adjusted BGP distance while CSR7 adjusted IS-IS distance.

```

Now that the routing is stable, I will perform some extra clean-up on the PEs. They are already configured with the proper confederation information, but many filters can be removed. The RT rewrite capabilities are still needed, but next-hop-unchanged is not. This was a critical component of the option C design but the next-hops will be preserved by default within the confederation, so this is technically not necessary. Of note, applying the confederation peer configuration to CSR2 automatically removes the next-hop-unchanged since it is only valid for true eBGP. In XR, we must do it manually.

```
! XRv2
router bgp 13
  neighbor 24.0.0.2
    address-family vpnv4 unicast
      no route-policy RPL_PASS in
      no next-hop-unchanged
      ! route-policy RPL_RT_REWRITE out

  address-family vpnv6 unicast
    no route-policy RPL_PASS in
    no next-hop-unchanged
    ! route-policy RPL_RT_REWRITE out
```

```

address-family ipv4 mvpn
  no route-policy RPL_PASS in
  no next-hop-unchanged
  ! route-policy RPL_RT_REWRITE out

address-family ipv6 mvpn
  no route-policy RPL_PASS in
  no next-hop-unchanged
  ! route-policy RPL_RT_REWRITE out

```

I also clean up the BGP-based VPLS configurations between XRv2 and XRv4. XRv4 is an RR for this AFI within sub-AS 24 since CSR2 was exhibiting undesirable label-block behavior as seen earlier. XRv2 continues to perform RT rewrite, but all other filters are removed.

```

! XRv2
router bgp 13
  neighbor 24.0.0.14
  address-family l2vpn vpls-vpws
    no route-policy RPL_PASS in
    ! route-policy RPL_RT_REWRITE out
    no next-hop-unchanged

! XRv4
router bgp 24
  neighbor 13.0.0.12
  address-family l2vpn vpls-vpws
    no route-policy RPL_PASS in
    no route-policy RPL_PASS out
    no next-hop-unchanged

```

Cisco XE 3.13.2S crashes continuously when trying to run confed-external peerings to XRv2. As soon as I “no shutdown” the BGP peer from XRv2’s perspective, CSR2 crashes shortly thereafter, probably upon receipt of some BGP updates. I also attempted Cisco XE 3.15.0S to see if it would improve, knowing that this is not the version used in the lab. The result was the same.

```

Unfortunately, this means the vast majority of our L3VPN verifications cannot be conducted since the RR for AS 24 is malfunctioning. However, we can test some L2VPN features. Since the most interesting feature of option C is the ability for the ASBRs to transport any kind of services, we can confirm the existing ATOM/CFM and BGP-based VPLS are operational. On CSR2, we can see that the remote VPLS route from CSR8 has the next-hop intact despite “next-hop-unchanged” being removed from all routers. In this case, XRv4 did not change the next-hop to self towards CSR2, and XRv2 did not change the next-hop to self towards CSR8.

```

```

R8#show l2vpn vfi name VPLS
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: VPLS, state: up, type: multipoint, signaling: BGP
VPN ID: 800, VE-ID: 8, VE-SIZE: 10
RD: 13:800, RT: 13:3
Bridge-Domain 3 attachment circuits:
Pseudo-port interface: pseudowire100009
Interface      Peer Address      VE-ID  Local Label  Remote Label  S
pseudowire100011 24.0.0.2          2      8024         2007         Y

```

I will trace the LSP for this L2VPN in both directions. Above, we see that the remote label is 2007, which was evaluated using the math detailed in the L2VPN BGP signaling section. The next-hop for this VPLS prefix is 24.0.0.2, which has a corresponding BGP route and label. The next-hop for the BGP prefix is an IGP route with an LDP label.

```

R8#show mpls ldp bindings 10.6.11.6 32 neighbor 13.0.0.11

lib entry: 10.6.11.6/32, rev 21

remote binding: lsr: 13.0.0.11:0, label: 91038

The label stack includes the VPLS label, BGP label, and LDP label, from bottom to top, as shown below. XRv1 receives label 91038, pops it, and exposes label 6013 to CSR6. This was allocated by CSR6 but not changed by XRv1, which means it must tunnel label 6013 through to a BGP router who can swap it.

R8#show l2vpn atom vc service-name VPLS detail | include label_stack

Output interface: Gi2.581, imposed label stack {91038 6013 2007}

RP/0/0/CPU0:XRv1#show mpls forwarding labels 91038

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91038	Pop	10.6.11.6/32	Gi0/0/0/0.561	10.6.11.6	243561

CSR6 has an IGP route to 24.0.0.2, not a BGP route, so the incoming BGP label of 6013 is swapped to the outbound LDP label of 94009, which tunnels traffic through XRv4. The LFIB is smart enough to connect BGP and LDP LSPs in this way, as we have seen many times.

R6#show mpls ldp bindings 24.0.0.2 32 neighbor 24.0.0.14

lib entry: 24.0.0.2/32, rev 81

remote binding: lsr: 24.0.0.14:0, label: 94009

R6#show mpls forwarding-table labels 6013

Local	Outgoing	Prefix	Bytes	Label	Outgoing	Next Hop

Label	Label	or Tunnel Id	Switched	interface	
6013	94009	24.0.0.2/32	50680	Gi2.564	24.6.14.14

XRv4 removes label 94009 to expose the VPLS label to CSR2, who delivers it to the appropriate bridge-domain for forwarding. The BD looks at the MAC address and forwards the Ethernet frame towards CSR1.

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94009
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94009	Pop	24.0.0.2/32	Gi0/0/0/0.524	24.2.14.2	71449

```
R2#show mpls forwarding-table labels 2007
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
2007	No Label	lbl-blk-id(1:7)	1418		none	point2point

Although this does not verify the VPLS label, all other labels are reveal with an ordinary traceroute from CSR8 to CSR2. Since the next-hops were modified at the ASBRs just like they would have been for eBGP, the behavior is the same.

```
R8#traceroute 24.0.0.2 source 13.0.0.8
```

Type escape sequence to abort.

Tracing the route to 24.0.0.2

```
 1 10.0.0.1 13 msec 10 msec 10 msec
```

From CSR2 to CSR8, the logic is similar. Earlier we saw label 8024 in use for the remote PW. An LDP label of 94019 is pushed onto the stack to tunnel traffic towards CSR8. CSR2 has an IGP route for this prefix, not a BGP route, so only one new label is added. XRv4 swaps this for 6022 which describes CSR6's path to 13.0.0.8/32.

```
R2#show ip cef 13.0.0.8
13.0.0.8/32
  nexthop 24.2.14.14 GigabitEthernet2.524 label 94019
```

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94019
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94019	6022	13.0.0.8/32	Gi0/0/0/0.564	24.6.14.6	112490

CSR6 has a BGP route for 13.0.0.8/32, not an LDP route, so CSR6 connects the LDP to the BGP LSP. The label is 91001 which is allocated by XRv1.

```
R6#show ip route 13.0.0.8
Routing entry for 13.0.0.8/32
  Known via "bgp 24", distance 30, metric 0
  Tag 13, type internal
  Redistributing via isis 24

  Last update from 10.6.11.11 01:19:52 ago
  Routing Descriptor Blocks:
  * 10.6.11.11, from 10.6.11.11, 01:19:52 ago
    Route metric is 0, traffic share count is 1
    AS Hops 0
    Route tag 13
    MPLS label: 91001
```

```
R6#show mpls forwarding-table labels 6022
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
6022	91001	13.0.0.8/32	136064	Gi2.561	10.6.11.11

Since XRv1 is the penultimate hop, it removes this label to expose label 8024 to CSR8. CSR8 delivers it to the bridge-domain for switching towards CSR3.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91001
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91001	Pop	13.0.0.8/32	Gi0/0/0/0.581	13.8.11.8	241390

```
R8#show mpls forwarding-table labels 8024
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
8024	No Label	lbl-blk-id(1:1)	1622	none	point2point

We can confirm the label stack using traceroute on CSR2. This confirms that the label behavior is identical to ordinary inter-AS option C.

```
R2#traceroute 13.0.0.8 source 24.0.0.2
Type escape sequence to abort.
Tracing the route to 13.0.0.8
VRF info: (vrf in name/id, vrf out name/id)

seconds:!!!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 7/7/7 ms
```

With respect to multi-hop peerings, requirements for “mpls activate” on XR are similar for option C as they are for option B. I configure CSR6 and XRv1 similarly. XRv1 configuration is simplified since only IPv4 labeled-unicast needs to be modified.

```
! CSR6
interface Loopback611
description EBGp MHOP TEST
```

```

ip address 10.6.110.110 255.255.255.255

router bgp 24
 neighbor 10.6.11.11 update-source Loopback611

! XRv1
router static
 address-family ipv4 unicast
  no 10.6.11.6/32 GigabitEthernet0/0/0/0.561
  10.6.110.110/32 GigabitEthernet0/0/0/0.561 10.6.11.6 tag 13

router bgp 13
 no neighbor 10.6.11.6
 neighbor 10.6.110.110
 remote-as 24
 ignore-connected-check
 address-family ipv4 labeled-unicast
  route-policy RPL_IF_DEST_PASS(PS_LOCAL_LOOPBACKS) out
  next-hop-self

```

Once BGP converges, we can see the route exchange works without issue. The next-hops remain reachable and labels are exchanged as well. We must include the route-tag of 13 onto the static route so that it gets redistributed into OSPF.

```

RP/0/0/CPU0:XRv1#show bgp ipv4 labeled-unicast neighbors 10.6.110.110 routes
| begin Network

```

Network	Next Hop	Metric	LocPrf	Weight	Path
*> 24.0.0.2/32	10.6.110.110	20	100	0	(24) i
*> 24.0.0.6/32	10.6.110.110	0	100	0	(24) i
*> 24.0.0.14/32	10.6.110.110	10	100	0	(24) i

```

R6#show bgp ipv4 unicast neighbors 10.6.11.11 routes | begin Network

```

Network	Next Hop	Metric	LocPrf	Weight	Path
*> 13.0.0.5/32	10.6.11.11	0	100	6666	(13) i
*> 13.0.0.8/32	10.6.11.11	0	100	6666	(13) i
*> 13.0.0.11/32	10.6.11.11	0	100	6666	(13) i
*> 13.0.0.12/32	10.6.11.11	0	100	6666	(13) i

Assuming CSR8 prefers the path to 24.0.0.2 via XRv1 (towards 10.6.11.6), the VPLS should be broken. We used weight on XRv2 to prefer the path via XRv1 to influence this. CSR8 is able to see both the BGP and LDP labels for the recursive lookups that occur, which is correct. The transport label stack becomes {91005 6006}.

```

RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast 24.0.0.2/32 brief | begin
Network

```

Network	Next Hop	Metric	LocPrf	Weight	Path
* i24.0.0.2/32	10.5.6.6	20	100	0	(24) i

```
*>i 10.6.110.110 20 100 2222 (24) i
```

```
R8#show ip cef 24.0.0.2 detail

 recursive via 10.6.110.110 label 6006
  nexthop 13.8.11.11 GigabitEthernet2.581 label 91005
```

This is the same issue we encountered with option B. XRv1 performs a recursive lookup on 24.0.0.2/32 to find a host-route. The prefix length is 32, which is correct, but forwarding is broken. This route has no label assigned since BGP is expected to see an LDP label for it.

```
RP/0/0/CPU0:XRv1#show route 24.0.0.2

  next hop 10.6.11.6
  local adjacency
  local label 91005 labels imposed {None}
```

The less desirable LDP solution could work here, provided CSR6 and XRv1 formed an LDP session. CSR6 could advertise implicit-null bound to prefix 10.6.110.110/32 which would allow XRv1 to forward MPLS traffic correctly. This was demonstrated in the option B section. However, I will jump straight to the preferred solution of using “mpls activate”. As shown in option B, this allows BGP to perform an implicit-null binding for the BGP next-hop and is used for multi-hop (but still connected) situations like this. Once the command is applied, the FIB is updated with the implicit-null label binding as expected.

```
! XRv1
router bgp 13
 mpls activate
 interface GigabitEthernet0/0/0/0.561
```

```
RP/0/0/CPU0:XRv1#show cef 10.6.110.110
```

```

10.6.110.110/32, version 25, internal 0x1000001 0x0 (ptr 0xa1401ef4) [3], 0x0

next hop 10.6.11.6
local adjacency
local label 91005 labels imposed {ImplNull}

```

CSR2 and CSR8 are flooded with log messages indicating that the VPLS PWs have formed, CFM RMEPs have been discovered, etc. This is a good indication that the network is functional again. At a glance, CSR8 shows both the BGP-signaled VPLS and statically-configured AToM circuits as up.

```
R8#show l2vpn atom vc
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw100012	2	800	vfi	VPLS	UP
pw28	24.0.0.2	28	p2p	EVPL_28	UP

A quick traceroute between PEs confirms the transport path, and a traceroute inside the VPN confirms that the VPLS is operational. I use CFM loopback messages (LBM) to ping inside the AToM circuit to test it as well. Everything is operational at this point.

```
R8#traceroute 24.0.0.2 source 13.0.0.8
```

8.4.4 Option AB Inter-AS hybrid (AKA Option D)

Option AB is a hybrid option that attempts to offer the best characteristics of options A and B. Like option A, the VRFs are configured locally on each ASBR and traffic is exchanged as raw IP (in most cases). This keeps the VRFs isolated and allows for per-VRF QoS enforcement on the IP packets. Like option B, a single inter-AS BGP session is formed in the global table to exchange VPN prefixes. All VPN routes can be exchanged in a single connection with each individual VRF configured separately for flexibility. While still configuration intensive, it allows option A to scale better due to using a single inter-AS BGP session. This is somewhat similar to VRF route-leaking and next-hop adjustment; routes are learned via a global VPNv4 session with next-hop resolved inside of their specific VRF. Normally this is not how MPLS VPNs work, but it is a specific design case on ASBRs which are MPLS LERs and ASBRs concurrently.

This option has some significant drawbacks. First, it is only supported on IOS/XE based platforms, as there is no support for XR or other vendors. It is sometimes called Option D, which was a draft RFC to detail the procedure, but it does not appear popular (draft is also expired). Second, VPNv6 is not supported at all, so support for IPv6 VPN continues to use option A. Lastly, the testing below reveals some challenging inconsistencies with L3VPN and MVPN architectures, which make the feature more difficult to understand, deploy, and troubleshoot.

Additional Reading – Reference configurations “inter-as-mpls-ab”

8.4.4.1 L3VPN

This lab continues from the option A lab. Before beginning, I quickly verify that the proper VRFs are configured on the ASBRs. All 4 ASBRs should have all VRFs configured for redundancy.

```
R5#show vrf | include ipv4
  EIGRP          13:3          ipv4,ipv6    Tu2
  OSPF           13:2          ipv4,ipv6    Tu3

R6#show vrf | include ipv4
  EIGRP          24:3          ipv4,ipv6    Tu2
  OSPF           24:2          ipv4,ipv6    Tu3

R7#show vrf | include ipv4
  EIGRP          24:3          ipv4,ipv6    Tu2
  OSPF           24:2          ipv4,ipv6    Tu3

RP/0/0/CPU0:XRv1#show vrf all | include ^[ ^ ]
VRF          RD          RT          AFI    SAFI
  EIGRP       13:3
  OSPF        13:2
```

Checking CSR6 and CSR5, we can see VPNv4/v6 sessions for each neighbor within the VPN. This is the traditional option A design that we will be changing with option AB. For VPNv6, we will continue to use the classic option A approach as it is not supported with option AB.

```

Next, I will enable option AB between CSR5/CSR6 and CSR5/CSR7. The first step is to create a common transit link in the global table. This is similar to option B except we don't need MPLS forwarding as it is used for control-plane traffic only. These transit links are almost identical to options B and C except MPLS and all supporting functions (RSVP, TE, LDP, etc) are disabled. There is also no reason to run IPv6 on these links at all since only VPNv4 is supported for option AB.

```

! CSR5
interface GigabitEthernet2.556
 encapsulation dot1Q 3556
 ip address 10.5.6.5 255.255.255.0
 ip pim bsr-border
 ip pim sparse-mode

interface GigabitEthernet2.557
 encapsulation dot1Q 3557
 ip address 10.5.7.5 255.255.255.0
 ip pim bsr-border
 ip pim sparse-mode

```

```

! CSR6
interface GigabitEthernet2.556
 encapsulation dot1Q 3556
 ip address 10.5.6.6 255.255.255.0
 ip pim bsr-border
 ip pim sparse-mode

```

```

! CSR7
interface GigabitEthernet2.557
 encapsulation dot1Q 3557
 ip address 10.5.7.7 255.255.255.0
 ip pim bsr-border
 ip pim sparse-mode

```

A quick way to check if the transit links are configured correctly is to check the PIM neighbors on CSR5. Although not a 100% verification, this is a quick way to see if the basic layer 2/3 reachability exists.

```

R5#show ip pim neighbor | begin ^Neighbor
Neighbor      Interface      Uptime/Expires    Ver    DR
Address
13.5.11.11    GigabitEthernet2.551    4d23h/00:01:24    v2      1 / DR P G
13.5.8.8      GigabitEthernet2.558    2d07h/00:01:25    v2      1 / DR S P G
10.5.6.6      GigabitEthernet2.556    00:00:45/00:01:28 v2      1 / DR S P G
10.5.7.7      GigabitEthernet2.557    00:00:45/00:01:28 v2      1 / DR S P G

```

Next, we will update the BGP configuration on all devices. This involves removing the VRF-aware BGP sessions for IPv4 as there is no need for BGP to be VRF-aware for this AFI with option AB. CSR6 and XRv1 will continue to run classic option A for both IPv4/v6 as XR does not support option AB at all. CSR5 and CSR7 can safely remove the entire AFIs from their configuration, while CSR6 must selectively delete specific neighbors. The peers are identified as “inter-as-hybrid” which implies option AB is used. Note that the Cisco documentation shows the command “no bgp default route-target filter” which is the preferred way to configure option B ASBRs in the configuration for option AB. This is technically not required since the ASBRs are locally importing the RTs within each AS, as well as advertising them via eBGP VPNv4. I comment them out below but leave them in the snippet as a reference.

```

! CSR5
router bgp 13
 no address-family ipv4 vrf EIGRP
 no address-family ipv4 vrf OSPF
 neighbor 10.5.6.6 remote-as 24
 neighbor 10.5.7.7 remote-as 24
 address-family vpnv4
  ! no bgp default route-target filter
 neighbor 10.5.6.6 activate
 neighbor 10.5.7.7 activate
 neighbor 10.5.6.6 inter-as-hybrid
 neighbor 10.5.7.7 inter-as-hybrid

```

```

! CSR6
router bgp 24
 neighbor 10.5.6.5 remote-as 13
 address-family ipv4 vrf EIGRP
   no neighbor 10.5.6.5
 address-family ipv4 vrf OSPF
   no neighbor 10.5.6.5
 address-family vpnv4
   ! no bgp default route-target filter
 neighbor 10.5.6.5 activate
 neighbor 10.5.6.5 inter-as-hybrid

```

```

! CSR7
router bgp 24
 neighbor 10.5.7.5 remote-as 13
 no address-family ipv4 vrf EIGRP
 no address-family ipv4 vrf OSPF
 address-family vpnv4
   ! no bgp default route-target filter
 neighbor 10.5.7.5 activate
 neighbor 10.5.7.5 inter-as-hybrid

```

We can confirm the BGP sessions are up by checking CSR5. We can see several routes being exchanged as well.

```

R5#show bgp vpnv4 unicast all summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ OutQ Up/Down  State/PfxRcd
10.5.6.6      4      24      73      75      84    0    0 00:15:17      7
10.5.7.7      4      24      43      43      84    0    0 00:12:44      7
13.0.0.12     4      13     479     507      84    0    0 01:08:39     15

```

Despite routes being learned, they cannot be imported by the AS 24 VRFs due to RT mismatches. One of the benefits of option A is that this information is contained within an AS, but with option AB, it is exchanged between AS boundaries like option B.

```

R5#show bgp vpnv4 unicast rd 24:2 10.9.9.9/32

```

Cisco's documentation suggests adding adding "import" statements on PEs that need to import foreign RTs. This is simpler than configuring new export RTs or the RT rewrite technique.

```

! CSR5
vrf definition EIGRP
  address-family ipv4
    route-target import 24:3

vrf definition OSPF
  address-family ipv4
    route-target import 24:2

! CSR6 and CSR7
vrf definition EIGRP
  address-family ipv4
    route-target import 13:3

vrf definition OSPF
  address-family ipv4
    route-target import 13:2

```

We check a single route on CSR5 to confirm the logic of this solution. The newly imported eBGP VPNv4 route also happens to be the best path on CSR5. The iBGP-learned path was the classic option A route via XRv1, which is still functional also.

```

R5#show bgp vpnv4 unicast vrf OSPF 10.9.9.9/32

```

Despite this being a best-path, CSR5 does not advertise it to XRv2. Although this may seem counter-intuitive, the reason is because CSR5 imports the route locally. Unless the peer is an RR client, eBGP VPN routes aren't advertised to iBGP peers if those routes are imported locally.

```

R5#show bgp vpnv4 unicast all neighbors 13.0.0.12 advertised-routes
Total number of prefixes 0

```

This is the symptom of an incomplete configuration. The VRF itself is not yet aware we are trying to run option AB. The VPN routes have a next-hop of 10.5.6.6; coincidentally, this is the correct next-hop in the VPN table as well as the global eBGP peer. We need to explicitly tell the VRF that it is running in "inter-as-hybrid" mode and optionally specify the VRF-aware next-hop. Normally this next-hop would be the option A eBGP peer.

```

! CSR5
vrf definition EIGRP
  address-family ipv4
    inter-as-hybrid next-hop 10.5.6.6

```

After issuing the command, the router tells us that the VRF table is being reloaded so that the changes take effect. We immediately see the EIGRP VPN routes being advertised to XRv2 as expected; the typically VPN RT import advertisement rules are relaxed in this configuration.

```

R5(config-vrf-af)#inter-as-hybrid next-hop 10.5.6.6
% The VRFs routing table is being reloaded to enforce the new configuration

```

```

R5#show bgp vpnv4 unicast all neighbors 13.0.0.12 advertised-routes | begin
Network

```

```

      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 13:3 (default for vrf EIGRP)
*> 10.1.1.1/32      10.5.6.6                      0 24 ?
*> 10.1.2.0/24      10.5.6.6                      0 24 ?
*> 10.1.13.0/24     10.5.6.6                      0 24 ?
*> 10.13.13.13/32   10.5.6.6                      0 24 ?
*> 10.13.14.0/24    10.5.6.6                      0 24 ?

```

We repeat the process for the OSPF VPN except I do not specify a next-hop. This technique works because CSR6 has the same IP address for all VPNs and the global table. Since all the VPNs are separate, this is a simple way to provision transit links for option A. It also means a simpler option AB VRF configuration as the next-hop need not be manually specified.

```
R5#show bgp vpnv4 unicast all neighbors 13.0.0.12 advertised-routes | begin Network
```

Network	Next Hop	Metric	LocPrf	Weight	Path
Route Distinguisher: 13:2 (default for vrf OSPF)					
*> 10.2.9.0/24	10.5.6.6			0 24	?
*> 10.9.9.9/32	10.5.6.6			0 24	?
Route Distinguisher: 13:3 (default for vrf EIGRP)					
*> 10.1.1.1/32	10.5.6.6			0 24	?
*> 10.1.2.0/24	10.5.6.6			0 24	?
*> 10.1.13.0/24	10.5.6.6			0 24	?

*> 10.13.14.0/24	10.5.6.6			0 24	?

I quickly check XRv2 to ensure the routes are learned. One would think that a next-hop-self issue would have occurred, but option AB handles that automatically. Because it knows the data-plane is based on option A, the next-hop is automatically set to the ASBR without us having to manually configure it. This is a nice feature that simplifies configuration.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 13:2 | begin Network
```

Network	Next Hop	Metric	LocPrf	Weight	Path

*>i10.4.8.0/24	13.0.0.8	0	100	0 ?	
*>i10.9.9.9/32	13.0.0.5	0	100	0 24	?
* i	13.0.0.11		100	0 24	?

After we configured the VRF for inter-as-hybrid support, the ASBRs were able to advertise locally imported routes to iBGP peers. These routes are technically exports from the local VRF rather than pass-through advertisements from the eBGP peer. To prove it, I show the eBGP route to 10.9.9.9/32 on CSR5 and the iBGP route on CSR8. The RT advertised by CSR6/CSR7 was 24:2. CSR5 did not perform any kind of explicit rewrite but was configured to import 24:2. We did not change CSR8's RT import/export policies at all and it is still able to import this route into VRF OSPF. This is because CSR5 re-exported the route with RT:13:2 per the local RT export policy. This allows the ASBRs to import remote RTs but the remote PEs do not. This also increases option AB scalability over option B in some cases since the PE/RR is unaware of an RT change.

```

      mpls labels in/out nlabel/6031
      rx pathid: 0, tx pathid: 0x0

```

To simplify the initial test, the OSPF backdoor and sham-links are disabled. Both CEs have a route to one another via the MPLS network. This shows that the control-plane is correct, at least within the OSPF VPN.

```

R9#show ip cef 10.4.4.4
10.4.4.4/32
  nexthop 10.4.9.4 GigabitEthernet2.549

R4#show ip cef 10.9.9.9
10.9.9.9/32
  nexthop 10.4.8.8 GigabitEthernet2.548

```

We will manually trace the LSP from CSR9 to CSR4. On CSR2, there is a VPNv4 route from CSR6 using label 6031. The route to the VPN next-hop is learned from ISIS via XRv4, so XRv4's local LDP label is used. The label stack becomes {94008 6031} and we can quickly confirm this by checking the FIB.

```

```

XRv4 is the penultimate hop so the topmost label is removed, exposing label 6031 to CSR6.

```

RP/0/0/CPU0:XRv4#show mpls forwarding labels 94008

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94008	Pop	24.0.0.6/32	Gi0/0/0/0.564	24.6.14.6	248618

Like an ordinary option A ASBR, CSR6 removes all labels and sends the packet inside of the OSPF VPN towards CSR5. There aren't many fancy show commands to see option AB in action as most of the inner workings are done behind the scenes. It is similar to global/VRF route and traffic leaking discussed in another chapter.

```

R6#show mpls forwarding-table labels 6031 detail

No output feature configured

```

CSR5 imposes a single VPN label for prefix 10.4.4.4/32 inside VRF OSPF since it is both the ingress LSR and penultimate hop. The label value is 8020; when CSR98 receives packets with this label, it removes all MPLS encapsulation and sends the IP packet to CSR4, the CE.

```

We use traceroute to confirm this path. Just like option A, the traffic over the transit links is raw IP. Option AB is transparent to customers in this way as there is no way to tell whether option A or AB is in use based on the output below. The IPv6 traceroute, for example, is using option A and exhibit identical data-plane behavior. We did not explicitly trace the VPNv6 LSPs but this demonstrates that VPNv6 option A still functions independently from VPNv4 option AB.

```

Although there is nothing special required for option AB in particular, we bring up the backdoor link between CSR4 and CSR9, as well as the pair of sham-links from CSR2 to CSR8. Since the sham-link endpoints are ordinary VPNv6 prefixes from the perspective of BGP, they are carried via the traditional option A method between the ASBRs. I quickly verify that the sham-links and OSPFv3 backdoor neighbors are up.

```
R8#show ospfv3 vrf OSPF sham-links | include ^Sham
Sham Link OSPFv3_SL0 to address FD00::2 is up
Sham Link OSPFv3_SL1 to address FD00::2 is up
```

```
R4#show ospfv3 neighbor gig2.549
```

```
OSPFv3 2 address-family ipv4 (router-id 10.4.8.4)
```

Neighbor ID	Pri	State	Dead Time	Interface ID	Interface
10.4.9.9	0	FULL/ -	00:00:35	26	Gig2.549

```
OSPFv3 2 address-family ipv6 (router-id 10.4.8.4)
```

Neighbor ID	Pri	State	Dead Time	Interface ID	Interface
10.4.9.9	0	FULL/ -	00:00:37	26	Gig2.549

The sham-link signaling and construction was a result of the option A VPNv6 design, but IPv4 forwarding over the sham-link still follows the option AB mechanisms. The ASBRs still have eBGP VPNv4 routes in the global table for inter-as IPv4 prefixes, which are advertised to the RRs within each AS. We can check this quickly by comparing the VPNv4 and VPNv6 routes to CSR9. The VPNv4 route has a next-hop in the default table (which is overridden by the inter-as-hybrid functionality) while the VPNv6 route has a next-hop in VRF OSPF.

```

To show the seamless interworking with existing option A architectures, I bring up the VRF-aware IPv4/v6 connections between CSR6 and XRv1; these were previously shutdown on CSR6 (removal of “shutdown” not shown). Using outbound RPL on XRv1, I increase the MED for routes advertised from AS

13 to AS 24. This will “hint” to AS 24 that XRv1 is a suboptimal point of ingress, which will prefer CSR5. This is so that the option AB links are preferred over the option A links.

```
! XRv1
route-policy RPL_SET_MED($MED)
  set med $MED
end-policy

router bgp 13
  vrf OSPF
    neighbor 10.6.11.6
      remote-as 24
      address-family ipv4 unicast
        route-policy RPL_SET_MED(11) out

    neighbor fd00:10:6:11::6
      address-family ipv6 unicast
        route-policy RPL_SET_MED(11) out
```

Checking CSR6 for the VPNv4 route to 10.4.4.4/32, we can see the MED value carried from XRv1. The eBGP route from CSR5 is preferred as a result of having a lower MED. So far, this has no impact on the traffic pattern since this was CSR6’s only option before. Also, we can see the next-hops are in different tables according to BGP; this is an indication that a combination of options A and AB are in use on this particular ASBR.

```
R6#show bgp vpnv4 unicast vrf OSPF 10.4.4.4/32
BGP routing table entry for 24:2:10.4.4.4/32, version 28

      mpls labels in/out 6027/5019
      rx pathid: 0, tx pathid: 0x0
```

To test XRv1 as a backup, I shut down the VPNv4 eBGP session from CSR6 to CSR5. Now, CSR7 is preferred since the MED of the iBGP learned route is still lower than the eBGP route. CSR9 will be routing to CSR5 via CSR7 now. XRv1 is still not used, which is the correct behavior. The current configuration identifies it as a backup for CSR5 entirely.

```

We also test central services to ensure it works over option AB. Since the VPNv4 routes advertised by the ASBRs (CSR6 and CSR7) have the local export RTs, not the eBGP-learned ones, we expect these to be accepted within an AS. CSR2 learns the VPN route from both CSR6 and CSR7. CSR6 is the best path but both VPN routes carry RT:24:3, which was exported from the ASBRs, not rewritten by BGP route-maps.

```

```

Next, we will look at some minor variations of option AB. The design tested above is an “easy” one because the VPN next-hops and global next-hops are the same at the ASBRs. For example, CSR5 has a global eBGP VPNv4 session with 10.5.6.6, and this is also the VPN next-hop for all VRFs. This simplifies the configuration as manual option AB next-hops need not be specified. To better see the consequence of having different next-hops, I change the IPv4 address of CSR5’s transit link towards CSR6 inside both VRFs.

```

! CSR5
interface GigabitEthernet2.5562
 ip address 10.5.6.52 255.255.255.0

interface GigabitEthernet2.5563
 ip address 10.5.6.53 255.255.255.0

```

The VPN next-hop is still 10.5.6.5, and since the VRF did not specify a different next-hop, CSR6 still thinks 10.5.6.5 is accessible within the VPN. CSR6 continuously tries to ARP for this IPv4 next-hop as one would expect, but it does not exist.

```

R6#show ip route vrf OSPF 10.4.4.4
Routing Table: OSPF

```

To fix it, we can use the same solution we configured initially on CSR5 as a demonstration. Under the VRFs on CSR6, I manually specify the VRF next-hops.

```
! CSR6
vrf definition EIGRP
  address-family ipv4
    inter-as-hybrid next-hop 10.5.6.53

vrf definition OSPF
  address-family ipv4
    inter-as-hybrid next-hop 10.5.6.52
```

Checking VPNv4, it is totally unaware of this change, at least from a VPN next-hop perspective. It still shows 10.5.6.5 as the VPN next-hop in the global table. Option AB overrides this and adjusts the next-hop to the value specified above.

```
R6#show bgp vpnv4 unicast vrf OSPF 10.4.4.4/32 bestpath

Now, CSR6 can ARP for this IPv4 next-hop to bind a MAC address for encapsulation. CSR9's VPN connectivity to CSR4 and central services has been restored. The output is identical to earlier examples except the untagged inter-AS traffic transits through 10.5.6.52 rather than 10.5.6.5.

```

```

The same is true for EIGRP. On CSR6, the VPN routes to CSR3 has a global next-hop of 10.5.6.5 which was the eBGP VPNv4 peer address. The option AB hybrid configuration overrides this to correct the VRF-aware RIB, and ultimately the VRF-aware FIB. CSR6 is able to ARP for this MAC address once the VRF-aware route is updated with the manually-configured next-hop.

```

Last, we can test the CSC extension to option AB. This is generally useful for when the CSC core carrier is actually two carriers. For example, if AS 13 and AS 24 were the conglomerate “core carrier” while CSR4 and CSR9 represented customer carriers, the traffic would need to remain MPLS encapsulated end-to-end. The CSC feature with option AB supports this and is very easy to configure; it is supported in conjunction with an explicit or implicit next-hop as shown below. I enable CSC for VRF OSPF only, so that VRF EIGRP will remain only IP-encapsulated over the transit link.

```

! CSR6
vrf definition OSPF
  address-family ipv4
    inter-as-hybrid csc next-hop 10.5.6.52

```

```

! CSR5 and CSR7
vrf definition OSPF
  address-family ipv4
    inter-as-hybrid csc

```

The only difference in behavior is that the MPLS labels exchanged with the eBGP VPN routes are swapped at the ASBRs, much like option B. On CSR6, we can see the next-hop in the BGP route is still incorrect as the manual configuration overrides it. However, VPN label swapping occurs like option B.

```

R6#show bgp vpnv4 unicast vrf OSPF 10.4.4.4 bestpath
BGP routing table entry for 24:2:10.4.4.4/32, version 33

```

The RIB indicates an outgoing MPLS label of 5019, which is the VPN label carried in the eBGP route seen above. Despite this label always being exchanged, it was not delivered to the RIB/FIB for encapsulation when the CSC option was disabled.

```
R6#show ip route vrf OSPF 10.4.4.4

```

If we examine the VPNv4 debugging on CSR6, we can see that all of the prefixes learned from CSR5 have the same label value within each VPN. Even though we didn't even enable CSC support on VRF EIGRP, the label aggregation occurs for that VPN also. We can clearly see that CSC is not enabled for VRF EIGRP.

```
! CSR5
R5#show vrf detail | include Hybrid|^VRF
VRF EIGRP (VRF Id = 1); default RD 13:3; default VPNID <not set>
  Inter AS Hybrid mode configured, next-hop 10.5.6.6
VRF OSPF (VRF Id = 2); default RD 13:2; default VPNID <not set>
  Inter AS Hybrid mode configured, with CSC
```

This is a per-VRF label that is advertised inside of the VPNv4 update. Label aggregation is discussed in the multi-VRF CE chapter, but in summary, this is used in contract to the per-prefix label. A single label represents all VPN routes inside of a VRF, which conserves labels. The downside of this approach is that the payload of the MPLS packet must be consulted for a routing decision. CSR5's LFIB proves this; when packets arrive with label 5019, the label is removed and the OSPF RIB is consulted.

```
R6#debug bgp vpnv4 unicast updates 10.5.6.5 in
BGP updates debugging is on for neighbor 10.5.6.5 (inbound) for address
family: VPNv4 Unicast
```

The EIGRP VPN has connectivity still, as expected, since nothing really changed. We use EPC outbound on CSR6 to confirm that MPLS encapsulation is not observed. Since QinQ is used, the Ethernet payload is another dot1q frame. We do not see ethertype 0x8847 in the packet and the length of 522 suggests that the packet is not MPLS encapsulated (14 Ethernet + 4 dot1q + 4 second dot1q). The IP addresses in the hex dump are shown in green.

```

```

We can prove that the traffic is untagged another way. CSR2 uses VPN label 6026, which is allocated by CSR6. The LSRs along the path inside AS 24 will forward the packet to the penultimate hop, which performs PHP to reveal label 6026 to CSR6. CSR6's LFIB performs a pop, not a swap, and then uses the MPLS payload for a routing decision. This is the expected behavior for VRF-wide aggregate labels since there is no per-prefix or per-CE (per-next-hop) granularity. Forwarding traffic based on the incoming label alone is ambiguous to a second lookup is necessary. The traffic is routed without addition labels directly to CSR5 across the VRF-aware transit link.

```

```

Pinging in VRF OSPF does not succeed and EPC reveals nothing. Since CSR6 would essentially be swapping the VPN label 6064 with the VPN aggregate label 5019, we expect MPLS to be functional. However, packets are being dropped per the LFIB. The in/out labels are correct but the LFIB does not specify an outgoing interface.

```

R2#show ip cef vrf OSPF 10.4.4.4/32
10.4.4.4/32
  nexthop 24.2.14.14 GigabitEthernet2.524 label 94008 6046
```

```
R6#show mpls forwarding-table labels 6046
Local      Outgoing  Prefix          Bytes Label  Outgoing  Next Hop
Label      Label     or Tunnel Id    Switched     interface
6046       5019      10.4.4.4/32 [V]  0            drop
```

The solution is to enable MPLS on the VRF-aware transit links for BGP forwarding. Normally this is configured automatically with option B, but since there are no VRF-aware VPNv4 sessions, we must configure it manually on all transit links expected to support CSC. This is only needed on the VRF OSPF interfaces as VRF EIGRP is not configured for CSC support.

```
! CSR6
interface GigabitEthernet2.5562
 mpls bgp forwarding
```

```
! CSR7
interface GigabitEthernet2.5572
 mpls bgp forwarding
```

```
! CSR5
interface GigabitEthernet2.5562
 mpls bgp forwarding
```

```
interface GigabitEthernet2.5572
 mpls bgp forwarding
```

I quickly verify that BGP-based MPLS is enabled on all VRF-aware transit links. Without this command, all of the control plane functions appear functional (BGP, routing, etc) but forwarding does not work.

```
R5#show mpls interfaces vrf OSPF
Interface          IP          Tunnel  BGP Static Operational
VRF OSPF:
GigabitEthernet2.5562 No          No      Yes  No      Yes
GigabitEthernet2.5572 No          No      Yes  No      Yes
```

```
R6#show mpls interfaces vrf OSPF
```

Interface	IP	Tunnel	BGP	Static	Operational
VRF OSPF:					
GigabitEthernet2.5562	No	No	Yes	No	Yes
Lspvif1	No	No	No	No	Yes

```
R7#show mpls interfaces vrf OSPF
```

Interface	IP	Tunnel	BGP	Static	Operational
VRF OSPF:					
GigabitEthernet2.5572	No	No	Yes	No	Yes
Lspvif1	No	No	No	No	Yes

Now, when we verify the LFIB, we can see the label swap occurring properly. The LFIB is now aware that BGP is allowed to perform MPLS forwarding operations on this interface, allowing it to be added to the LFIB properly.

```
R6#show mpls forwarding-table labels 6046
```

Local	Outgoing	Prefix	Bytes	Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched		interface	
6046	5019	10.4.4.4/32 [V]	0		Gi2.5562	10.5.6.52

Using ping and EPC, we confirm that the traffic is MPLS-encapsulated with a single label value of 5019 as it is sent towards CSR5. The packet size is now 526, which is 4 bytes larger than the untagged packet in the EIGRP VPN. Label 5019 is in the stack (0x139B), which makes this a valuable tool for CSC operations. The VPN IP addresses is highlighted in green again.

```
R9#ping 10.4.4.4 source 10.9.9.9 size 500
```

```
Type escape sequence to abort.
```

```
Sending 5, 500-byte ICMP Echos to 10.4.4.4, timeout is 2 seconds:
```

```
Packet sent with a source address of 10.9.9.9
```

```
!!!!
```

```
Success rate is 100 percent (5/5), round-trip min/avg/max = 13/59/89 ms
```

```
R6#show monitor capture CAP buffer detailed
```

```
1 526 0.851998 00:50:56:A9:DE:0D -> 00:50:56:A9:DC:63 VLAN-tagged frame
```

```
0000: 005056A9 DC630050 56A9DE0D 81000DE4 .PV..c.PV.....
0010: 81000002 88470139 B1FC4500 01F4004D .....G.9..E....M
0020: 0000FE01 99A20A09 09090A04 04040800 .....
0030: 50360016 00000000 0000A525 502AABCD P6.....%P*..
```

We confirm that the LFIB counters increment when sending traffic. This is expected regardless of whether the outgoing label is an aggregate label or not. The reason it is important to verify this feature with EPC and packet counters is because VPN traceroute does not reveal this interim LSP, as shown below. I suspect the reason is because CSR5 perform its final routing lookup based on the MPLS payload (IP packet), not the MPLS aggregate label, so the reply does not include that label.

```
R6#show mpls forwarding-table labels 6046
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
6046	5019	10.4.4.4/32 [V]	7060	Gi2.5562	10.5.6.52

```
R9#traceroute 10.4.4.4 source 10.9.9.9
Type escape sequence to abort.

To perform a quick verification on CSR7, the backup CSC path, I shut down CSR6's BGP session to CSR5. CSR6's new best-path becomes a non-CSC enabled link to XRv1, which should never be used as it would blackhole traffic. The aggregate label was never generated on XRv1 and not even exchanged with CSR6. I leave this link operational for demonstration, but BGP MED ensures that CSR7 will be preferred as an alternate. We can also see label 7005, which we assume to be CSR7's local aggregate label for VRF OSPF.

```

```

We verify that label 7005 is, in fact, the local aggregate label for VRF OSPF. This should be swapped to 5019, which was CSR5's aggregate label for VRF OSPF. This hasn't changed as a result of shutting CSR6 down as CSR5 advertises it to all BGP peers for all prefixes. Since CSR2 will prefer the VPN route from CSR7 as the best path, we expect 7005 to be the VPN label for 10.4.4.4/32, as well as other VPN prefixes.

```

```

```
R2#show ip cef vrf OSPF 10.4.4.4/32
10.4.4.4/32
  nexthop 24.2.14.14 GigabitEthernet2.524 label 94010 7005
```

We notice a slight change in CSR7's local label allocation for 10.4.4.4/32 compared to CSR6. CSR6 allocated per-prefix local labels for inter-AS VPN routes, such as 6046, which could be swapped to the peer's aggregate label without invoking an IPv4 FIB lookup inside the VPN. CSR7 does not explicitly specify a VPN next-hop under the VRF configuration. Without CSC, this had no impact on performance, but in this case, CSR7 has to remove the local aggregate label, and then perform an IPv4 FIB lookup in the VPN while pushing the peer's aggregate label. The VPN-aware FIB lookup still relies on the existing 10.5.7.5 next-hop, which was unchanged, so the design is valid. This two-step operation (pop/push rather than swap) is less efficient, which is why specifying the next-hop is a good design choice when using the CSC option with option AB.

```
R7#show mpls forwarding-table labels 7005
Local      Outgoing   Prefix      Bytes Label  Outgoing   Next Hop
Label      Label      or Tunnel Id  Switched     interface
7005       Pop Label  IPv4 VRF[V]  13670        aggregate/OSPF
```

```
R7#show ip cef vrf OSPF 10.4.4.4/32
10.4.4.4/32
  nexthop 10.5.7.5 GigabitEthernet2.5572 label 5019
```

This makes the traceroute even more awkward looking inside the VPN. Since CSR7 and CSR5 are both performing FIB (not LFIB) lookups to route the VPN traffic, neither of them include the MPLS labels associated with each hop.

```
R9#traceroute 10.4.4.4 source 10.9.9.9
Type escape sequence to abort.
```

```

```

Some of these inconsistencies appeared strange, and furthermore, the documentation clearly states that “per-prefix” labels should be allocated when CSC is enabled. After reloading the ASBRs, the behavior changes significantly. I assume this is the result of a configuration order-of-operations issue despite the configuration above being functional. Below, I show CSR5 and CSR6 label allocations for VPNv4 inside VRF OSPF; there are no aggregate labels. On CSR6, notice that label swapping only occurs when CSR5 is the next-hop, which is accurate since XRv1 only supports option A in this architecture.

```

```

```

R5#show bgp vpnv4 unicast vrf OSPF labels

```

Network	Next Hop	In label/Out label
Route Distinguisher: 13:2 (OSPF)		
10.2.9.0/24	10.5.6.6	5009/6048
10.4.4.4/32	13.0.0.8	5021/8007
10.4.8.0/24	13.0.0.8	5022/8008
10.9.9.9/32	10.5.6.6	5010/6049
110.0.0.0/32	13.0.0.8	5023/8003
110.0.0.1/32	13.0.0.8	5024/8004
110.0.0.2/32	13.0.0.8	5025/8005
110.0.0.3/32	13.0.0.8	5026/8006

The implication of this is that the LSPs will operate more efficiently now. For example, if traffic arrives at CSR5 with label 5010 and destined for 10.9.9.9/32 in the remote AS, it will be swapped directly to 6049 in a single LFIB lookup. Label 6036 entering CSR6 along the reverse LSP should behave similarly by swapping directly to label 5021 and sending to CSR5. With a next-hop interface in the LFIB below, there is no need for another FIB lookup. The comments earlier about next-hop specification with CSC are no longer true since CSR6 and CSR5 both behave identically now. Again, this is probably the result of a configuration sequence error, but I leave the existing documentation in place as a troubleshooting aid.

```
R5#show mpls forwarding-table labels 5010
```

Local	Outgoing	Prefix	Bytes Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched	interface	
5010	6049	10.9.9.9/32 [V]	3402	Gi2.5562	10.5.6.6

```
R6#show mpls forwarding-table labels 6036
```

Local	Outgoing	Prefix	Bytes Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched	interface	
6036	5021	10.4.4.4/32 [V]	7512	Gi2.5562	10.5.6.52

Traceroute proves this as the path looks more like “option B” from a traceroute perspective. I recommend ensuring that, when inter-AS option AB with CSC is enabled, labels are allocated per-prefix. The only method that worked in this setup was an ASBR reload. This is true in both directions.

```

8.4.4.2 L2VPN

MPLS L2VPN using option AB works identically as it does for option A. Since only VPNv4 is supported, and the whole idea of option AB is to isolate customer traffic into separate VPN transit links, an option B-like forwarding mechanism would violate the general design. This section is largely similar to the option A L2VPN section but is verified briefly for completeness. We will limit our verifications to CSR5 and CSR6; no configuration changes were made between option A and option AB (this section). First, I verify that the ASBRs have a single “core PW” over MPLS to their respective PEs, as well as the VFI interface that links the bridge-domain. All connections are reported as being up.

```
R5#show l2vpn service vfi name VPLS | begin Interface
Interface          Group          Encapsulation          Prio   St   XC St
-----
VPLS name: VPLS, State: UP
pw100001           VPLS (VFI)           0           UP   UP
pw100002           core_pw              13.0.0.8:3 (MPLS)      0           UP   UP

R6#show l2vpn service vfi name VPLS | begin Interface
Interface          Group          Encapsulation          Prio   St   XC St
-----
VPLS name: VPLS, State: UP
pw100001           VPLS (VFI)           0           UP   UP
pw100002           core_pw              2:3 (MPLS)          0           UP   UP
```

Next, I check for the data-plane learning on the ASBRs. I first record the MAC address of CSR1 (yellow) and CSR3 (green) for easy identification.

```
R1#show interfaces gig2 | include bia
Hardware is CSR vNIC, address is 0050.56a9.1aaa (bia 0050.56a9.1aaa)

R3#show interfaces gig2 | include bia
Hardware is CSR vNIC, address is 0050.56a9.8ccf (bia 0050.56a9.8ccf)
```

Looking at the ASBR bridge-domains, we can see both MAC addresses are learned. On CSR5, CSR1’s MAC is learned via the VPLS PW to CSR2 while CSR3’s MAC is learned via the inter-AS EFP. The opposite is true on CSR6.

```
R5#show bridge-domain 3
Bridge-domain 3 (2 ports in all)
```

```

State: UP                               Mac learning: Enabled

  GigabitEthernet2 service instance 30
    vfi VPLS neighbor 13.0.0.8 3
AED MAC address    Policy Tag          Age Pseudoport
0  0050.56A9.1AAA  forward dynamic  221 GigabitEthernet2.EFP30
1  FFFF.FFFF.FFFF flood   static    0  OLIST_PTR:0xe80d0400
0  0050.56A9.8CCF forward dynamic  236 VPLS.1004011

```

```

R6#show bridge-domain 3
Bridge-domain 3 (2 ports in all)
State: UP                               Mac learning: Enabled
Aging-Timer: 300 second(s)
  GigabitEthernet2 service instance 30
    vfi VPLS neighbor 24.0.0.2 3
AED MAC address    Policy Tag          Age Pseudoport
0  0050.56A9.1AAA  forward dynamic  213 VPLS.1004011
1  FFFF.FFFF.FFFF flood   static    0  OLIST_PTR:0xe8125400
0  0050.56A9.8CCF forward dynamic  228 GigabitEthernet2.EFP30

```

A similar bridge-domain MAC address check on CSR2 and CSR8 confirms that the MAC addresses are being learned properly. The PE learns its local CE via the PE-CE EFP and the remote CE via the VPLS pseudoport towards the neighboring ASBR.

```

8.4.4.3 MVPN - GRE (Profile 0) and mLDP (Profile 1)

MVPN over option AB is similar to option A but is worth investigating because the control-plane changed for VPNv4. AS 13 uses GRE encapsulation (Profile 0) and AS 24 uses MPLS encapsulation via mLDP (Profile 1). First, I verify that the default MDT forms correctly inside AS 13. Although not recommended, I used ASM groups to demonstrate that IPv4 MDT/MVPN is not a requirement for GRE-based MVPN. For brevity, I limit the verifications to the OSPF VPN. Since the MVPN features used are deployed per-AS, not per-VPN, it is acceptable to only verify one VRF per AS for illustration. CSR8, CSR5, and XRv1 are all inside of the same default MDT. So far, this is identical to MVPN for option A. I highlighted the inter-AS PIM neighbors on CSR5 in green as well; this verification gives us the bonus information of ensuring those PIM neighbors are functional.

```

```

Inside of AS 24, we quickly trace the MP2MP tree from root to leaves. Although mLDP trees are built upstream towards the root, I verify it in the reverse direction for brevity. Without checking the MDT database in brief format, we know the opaque is MDT and the VPN ID is 24:2 as this was identified in the VRF configuration earlier. The root is XRv4 and it has no upstream neighbors as expected. All upstream labels are local labels since XRv4 allocated these to inform downstream nodes how to forward traffic up the tree (towards the root). The remote labels are downstream labels, learned by XRv4 via each peer's label-mapping messages, which describe how to forward traffic down the tree (away from the root). The tree has 3 downstream peers: CSR6 and CSR7 are ASBRs and CSR2 is the PE. All of them appear the same to XRv4 as it is a P-router from the perspective of the data-plane.

```

Though we did not verify EIGRP, we expect that all of the PIM neighbors are in place and are functional. A quick check would be to ensure the RP information (10.3.3.3) is present on all PEs and ASBRs. We can see that all routers learn this information except CSR2.

Enabling VRF-aware PIM BSR debugging on CSR2, the issue is revealed. CSR2 receives BSR messages from both CSR6 and CSR7 over the PMSI as expected, but RPF fails. CSR2 expects to receive them from 13.0.0.12, which is in another AS. The first statement of the error message can be ignored since the BSR message did arrive on the correct interface, but from the incorrect neighbor address.

```
R2#debug ip pim vrf EIGRP bsr
```

```
PIM-BSR debugging is on
```

```
PIM(1): Received v2 Bootstrap on Lspvif0 from 24.0.0.6
```

```
PIM-BSR(1): bootstrap (10.3.3.3) on non-RPF path Lspvif0 (expected Lspvif0)
or from non-RPF neighbor 24.0.0.6 (expected 13.0.0.12) discarded
```

```
PIM(1): Received v2 Bootstrap on Lspvif0 from 24.0.0.7
```

```
PIM-BSR(1): bootstrap (10.3.3.3) on non-RPF path Lspvif0 (expected Lspvif0)
or from non-RPF neighbor 24.0.0.7 (expected 13.0.0.12) discarded
```

At a glance, this seems odd because, in option A, this inter-AS information should not be exchanged. Option AB bends those rules since the control-plane information is shared, to some degree, between ASes. This initially included VPNv4 routes, their RDs, and their extended communities (RT, etc). However, we can confirm that 13.0.0.12 is, in fact, the RPF neighbor for 10.3.3.3/32 inside the EIGRP VPN. The key to this output is the “BGP originator”. This attribute was discussed in the option B section and is used for RPF checks against multicast packets coming from the remote AS. In this case, BSR messages are rejected since multicast traffic is arriving from the ASBRs as opposed to the remote PE. The unicast FIB clearly shows 24.0.0.6 as the preferred unicast path, which is the VPN next-hop for 10.3.3.3/32.

```

R2#show ip rpf vrf EIGRP 10.3.3.3
RPF information for ? (10.3.3.3)
  RPF interface: Lspvif0
  RPF neighbor: ? (13.0.0.12)
  RPF route/mask: 10.3.3.3/32
  RPF type: unicast (bgp 24)
  Doing distance-preferred lookups across tables
  BGP originator: 13.0.0.12
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base

```

```

R2#show ip cef vrf EIGRP 10.3.3.3/32 detail
10.3.3.3/32, epoch 0, flags [rib defined all labels]
  recursive via 24.0.0.6 label 6046
    nexthop 24.2.14.14 GigabitEthernet2.524 label 94008

```

This attribute cannot be overridden or modified in any obvious way. The designers of this feature likely did not consider option AB and MVPN being used together as the RPF lookup should be making decisions similar to option A. Even the multicast route, replicated from the unicast iBGP route, correctly says 24.0.0.6 is the next-hop. Only the BGP connector attribute, when present, is processed.

```

```

An odd behavior is observed when we test this on the opposite side of the network. CSR2 saw a BGP connector attribute from AS 13 claiming 13.0.0.12 was the originator of 10.3.3.3/32, which is true. CSR8's view of 10.1.1.1/32, which originates at 24.0.0.2, shows the local ASBR CSR5 as the originator. For this reason, MVPN should work fine from the perspective of AS 13.

On XRv2, we can see that both XRv1 and CSR5 adjusted the connector attributes to be their own addresses. This is the result of the VPN routes being imported locally into VRFs, then re-advertised towards the RRs.

There appears to be some inconsistency between when a routers applies the connector attribute or not. For example, CSR7 receives an EIGRP VPN route from XRv4 and CSR2. The one from XRv4 has a connector attribute but the one from CSR2 does not. The PE configurations are nearly identical yet the behavior appears to differ between XE and XR.

```

I suspect these inconsistencies are related to the MVPN methods used. AS 13 uses the GRE method which appears to always allocated the BGP connector attribute, whereas the mLDP methods appear less consistent. Since MVPN ASM clearly cannot work as the RP information cannot transit the VPN, we will quickly test SSM. We expect to have a similar problem as the VPN route 10.4.4.4/32 carries a connector attribute specifying CSR8 as the originator. The RPF check expects traffic to come from CSR8, not the local ingress ASBR CSR6.

```

R2#show ip rpf vrf OSPF 10.4.4.4
RPF information for ? (10.4.4.4)
  RPF interface: Lspvif1
  RPF neighbor: ? (13.0.0.8)
  RPF route/mask: 10.4.4.4/32
  RPF type: unicast (bgp 24)
  Doing distance-preferred lookups across tables
  BGP originator: 13.0.0.8
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base

```

We can demonstrate the problem by configuring an IGMP SSM join on CSR9 to receive traffic from CSR4. CSR2 will receive the C(S,G) join from CSR9 for (232.9.9.9, 10.4.4.4). CSR2's RPF neighbor for this C-

source is 13.0.0.8 which is accessible via the PMSI. CSR2 attempts to send the join, but cannot. The C(S,G) state looks correct on CSR2, but no other OSPF VPN routers will have this state entry. So long as the BGP connector attributes are used in an option AB network (they are supposed to be optional attributes, but modification appears impossible), MVPN will be broken at points. The attribute origination inconsistencies make it increasingly challenging to test this feature.

```

8.4.4.4 MPLS TE

MPLS TE works identically for option AB and it does for option A. The tunnels configuration in option A are quickly examined again for completeness. Re-using tunnel100 on XRv2 and CSR2, defined in the option A section, I quickly trace the LSPs to prove the correct operation. From XRv2, we can see the TE tunnel to CSR5 is operational. Tracing the LSP for the EIGRP VPN route 10.1.1.1/32, we see that CSR5 is the best-path due to having the lower BGP RID. The VPN label bound is 5016.

```

8.4.5 Confederation variation

Inter-AS option AB confederation is not currently supported in XE. Once the confederation configurations are applied, the “inter-as-hybrid” command is automatically removed. Adding it back generates the error message shown below. This chapter is a placeholder in the event this feature is supported in the future.

```

R6(config-router-af)#neighbor 10.5.6.5 inter-as-hybrid
%BGP: this command is only valid for eBGP peers

```

9. Describe multicast P2MP TE

Because this fits within the scope of MVPN profiles, it is documented there in the appropriate chapters. Specifically, it is documented under profiles 8 and 10, and both tests include configurations files.

10. Describe EVPN (EVPN and PBB-EVPN)

Ethernet VPN was developed as a next-generation L2VPN technology to overcome existing VPLS limitations. Since VPLS acts like an Ethernet switch by learning MAC addresses (data-plane learning), its scalability can be limited by the number of MAC addresses in the customers network. For this reason, many VPLS deployments have a small number of MAC addresses behind each site, which is not appropriate for data-center interconnect (DCI) service. EVPN also introduces per-flow load balancing, which is somewhat available in VPLS given the flow-aware transport PW (FAT-PW) label, but EVPN improves upon it. EVPN also supports multi-homing at layer 2 to prevent loops and duplicate packets; its lack of fully/partially meshed PWs means that it has the same scalability as MPLS L3VPN. It uses a new BGP AFI to carry new EVPN routes that essentially enables “MAC routing”. Multicast inclusion can also be signaled to indicate interest in multicast reception. Both EVPN and PBB-EVPN are discussed in this section with a limited demonstration. XRv does not support the L2VPN data-plane, and XE platforms (ASR1000, CSR1000v, etc) only support EVPN BGP features and none of the data-plane features at all. In this way, both XRv and CSR1000v make good EVPN route-reflectors. For data-plane support, ASR9000 series are the best choice. First, we must understand several key definitions.

BUM: Broadcast, multicast, or unknown unicast. Though not specific to EVPN, this is used extensively in the descriptions and is defined here for clarity. BUM traffic generally requires special handling by EVPN and is often treated like a multicast Ethernet frame.

EVI: Ethernet VPN Identifier. This is analogous to the virtual circuit ID (VCID) seen in VPLS which identifies an EVPN to BGP. An EVI may support multiple bridge-domains. Classic design options, such as

E-LINE/E-LAN/E-TREE (port-based transparent service) and EV-LINE/EV-LAN/EV-TREE (VLAN-based service) are still available, but we can also map specific C-VLANs to EVIs flexibly.

ES: Ethernet segment. This is analogous to an access circuit (AC) in VPLS which defines a link to the customer. An ES differs from an AC in that an ES actually defines a “site” which could be connected to multiple PEs. As such, multiple PEs could share the same ES if the customer is multi-homed at layer 2. Thus, the ES could be a single CE device or an entire network if the customer has multiple CE devices. A customer can follow one of these four models:

1. **Single-homed device (SHD).** This is a single device connected to a single PE which terminates the broadcast domain (like a router).
2. **Multi-homed device (MHD)** using LACP. This is a single device connected to multiple PEs. The CE devices terminate the broadcast domain.
3. **Single-homed network (SHN).** Like SHD, this is a single device connected to a single PE, but with layer 2 network behind it.
4. **Multi-homed network (MHN)** using LACP. This consists of multiple CE devices connected to multiple PE devices with a layer 2 network behind the CEs.

ESI: Ethernet Segment Identifier. Every ES is identified by a unique ESI. It is a 10 byte field that can be derived one of three ways. Of note, on singly-attached networks, the ESI is always 0; there is no compelling reason to track the ESI in these cases.

1. **LACP:** Based on the CEs information, the first 2 bytes will be the CE’s system priority, the next 6 bytes will be the CE’s LACP system-ID (like a MAC address), and the last 2 bytes will be a port key, if defined. This information is carried in the LACPDUs received from the CE.
2. **MST:** If LACP is not in use, MST can be used to create the ESI for an ES. This is based on the CIST’s root parameters: first 2 bytes is the bridge priority, next 6 bytes is the bridge MAC address, and the last 2 bytes are always 0. Essentially, the 8 byte bridge ID is used with trailing zeroes.
3. **Manual configuration:** If LACP and MST are not in use, it can be manually configured. The manual configuration only allows main interfaces to be used, not subinterfaces, and requires input that looks like LACP. One will specify the system priority, system ID, and port key for a given Ethernet interface, which represents the ES from the PE’s perspective. This would need to be the same on all PEs service the same ES.

I-SID: Instance Service identifier. An identifier telling the router where to map a customer frame. It represents a service instance like an EFP. Different I-SIDs can be mapped to the same EVI if their topologies are similar, or to different EVIs if their topologies are different. The I-SID is a 24-bit value that is used by the PBB edge domain to determine how frames should be forwarded.

There are two different redundancy models when multi-homing:

1. **Single-active:** One PE is active and all others are in standby, which means only this active PE is allowed to forward traffic towards the customer. VPLS also supports this option by way of active/backup PWs.

2. **All-active:** All PEs can forward traffic down to the customer concurrently. This does not apply to BUM traffic as it would could cause loops, but is valid for unicast frames. VPLS cannot support this functionality.

There are 4 new types of BGP routes used for the BGP EVPN AFI. Each one is referenced by its “type” number. Both EVPN and PBB-EVPN use these routes, except that type 1 routes only apply to EVPN.

1. **Ethernet active discovery (AD) route:** This route is used to signal MAC withdrawals, aliasing, and split-horizon labels. This applies to EVPN only and is not used for PBB-EVPN. These details are described in the EVPN section.
2. **MAC advertisement route:** This carries MAC addresses along with EVPN ESIs and MPLS labels.
3. **Inclusive multicast route:** This route uses provider multicast service interface (PMSI) attributes to represent ingress replication (IR); MVPN technologies are discussed at length in a dedicated section. Other multicast tunneling options can be configured as well, but IR is the default since it does not assume an LSM architecture is available. This also carries the root of the multicast deliver tree (a subcomponent of PMSI) and an MPLS label.
4. **Ethernet Segment (ES) route:** This route carries information relevant for multi-homed layer 2 connections (redundancy via ICCP) and the designated forwarder (DF) election. In networks without multi-homing, these routes are not shown.

Both EVPN and PBB-EVPN must also prevent loops via split-horizon mechanisms. Since these mechanisms differ between EVPN and PBB-EVPN, split-horizon is discussed in the individual sections.

In multi-homed deployments, the SP network must identifier designated forwarders (DF) who are allowed to send traffic towards the customer. If a BUM frame is flooded across the network between ESes, multiple remote PEs on the other end of the network may both flood the same BUM frame to the customer, which is not ideal. Instead, only one of the PEs is allowed to do this. The DF election is the same for EVPN and PBB-EVPN and operates as follows:

1. Identify each PE by its lowest IP address. The PEs connected to an ES are then assigned an index starting at 0. For example, if PE1 has address 1.11.11.11 and PE2 has address 1.12.12.12, then PE1 is assigned index 0 and PE2 is assigned index 1. This is the PE “ordered list” and has length ‘n’.
2. Evaluate $[EVI \text{ modulo } 'n']$ for each EVI. If EVIs 1000 and 1001 are used, the following occurs:
 - a. $EVI \ 1000 \text{ modulo } 2 = 0$, therefore PE1 is the DF and PE2 is the backup DF (BDF)
 - b. $EVI \ 1001 \text{ modulo } 2 = 1$, therefore PE2 is the DF and PE1 is the BDF

Aliasing is a technique used to ensure that, when operating in all-active mode, that all PEs are aware of all MACs addresses in an ES, even if they have not received traffic from that MAC address. For example, if a CE is multi-homed to PE1 and PE2 using LACP, and a unicast frame is forwarded to PE1, PE2 will not know about it. If PE2 receives a frame from the core destined to this MAC address, it won’t know how to

forward it unless PE1 tells it how. Aliasing is handled differently in EVPN and PBB-EVPN and is discussed there.

When using the active-standby (single-active) model, there needs to be a mechanism to notify the backup PE that it should become the active PE. Using BGP route withdrawal, both EVPN and PBB-EVPN signal this differently.

10.1 EVPN

After searching for some time, I was not able to find a configuration example that shows an EVPN implementation on IOS XR. It is discussed in detail on many presentations but the configuration examples all refer to PBB, probably because PBB-EVPN scales much better and there isn't much benefit to EVPN over PBB-EVPN. This section will briefly describe how EVPN works.

In VPLS, the split-horizon rule states that traffic arriving on a PW cannot be sent out of any other PW. One of the few reasons to relax this rule is to support H-VPLS, but generally it makes sense. It is also why VPLS requires a full mesh of PWs; without it, some kind of spanning-tree protocol would be needed. EVPN may suffer from similar problems in multi-homed layer 2 environments. If two PEs (PE1 and PE2) are connected to the same CE which is running multi-chassis LACP (one link to each PE), then the possibility of a loop exists when the CE sends BUM traffic. If the CE selects PE1 to send a multicast frame, the frame will be replicated to all other remote PEs, including PE2, despite PE2 serving the same ES. The solution is to use a split-horizon label; the label is included with the BUM frame and identifies the source ES of the frame. When PE2 receives it, it drops the traffic as it is already connected to the source ES via LACP.

Aliasing in EVPN, like split-horizon, is achieved using the type 1 route. When a PE learns a C-MAC from the CE, it advertises this C-MAC into BGP along with the ESI from which the MAC was learned. The PE also attached to this ES will evaluate the ESI, see a match, then know that this MAC address is reachable via the connected ES shared with the PE that originated the BGP route.

Backup path signaling is done by withdrawing the type 1 routes associated with a MAC address. Since there is a type 1 BGP route for each C-MAC, each one is withdrawn for a given ESI that signals the backup PE to become active.

10.2 PBB-EVPN

PBB-EVPN extends the scalability of EVPN by combining the 802.1ah MAC-in-MAC (or PBB) logic into EVPN. Each PE has a backbone MAC (B-MAC) which is used to identify that PE. In this way, only one type 2 (MAC advertisement) route is created per PE in each EVI, versus one per C-MAC in regular EVPN. This is why the type 1 route is not needed in PBB since MAC withdrawals and aliasing are not relevant.

Split-horizon is also possible in PBB-EVPN as in EVPN. However, a split-horizon label is not necessary to prevent loops with PBB-EVPN. PEs connected to the same ES will use the same B-MAC for that ES: that

is, there is a 1:1 mapping between B-MAC and ESI. The receiving PEs simply check the source B-MAC on incoming BUM frames and compare it against their own. If the two match, the packet is dropped.

Aliasing in PBB-EVPN is simpler than in EVPN, much like split-horizon. Since two PEs connected to the same ES will have the same B-MAC, if a PE receives a frame destined for its own B-MAC but doesn't have the explicit C-MAC installed, it can safely assume this C-MAC is reachable via the connected ES. No explicit routing is needed since the traffic would not have been sent to this PE if the remote PE (across the core) wasn't already aware that it was mapped to the proper B-MAC shared by other PEs on the ES. Since type 1 BGP routes are not used for PBB-EVPN, a router simply withdraws its type 2 router for that ESI. Because the B-MAC is bound to that ESI with PBB, other routers will know that when a PE loses connectivity to an ES, that B-MAC cannot be used for forwarding anymore. The other PEs on the ES will have the same B-MAC so there is no need for per-MAC withdrawals as with EVPN.

PBB operations are similar to EVPN with some exceptions. First, the concept of a B-MAC is mapped to an ESI on a 1:1 basis. The B-MAC can be automatically derived from the LACP system ID of the CE by flipping the U/L bit, sort of like EUI-64 for IPv6 SLAAC. In this way, all PEs connected to an ES will have the same B-MAC. The route distinguishers (RDs) are still unique per PE as they are auto-generated based on the BGP router-IDs. An EVPN type 2 route will include several key components, include the RD, ESI, B-MAC, MPLS label, and route-target (RT). The label is a downstream label advertised to other PEs to use when sending traffic towards this B-MAC within a given EVI. When multiple PEs exist on a segment, their B-MACs will be the same, but their labels will not be. Like the RD, the RT is automatically configured based on the BGP ASN and the EVI. This is like VPLS auto-route-target and can be overridden if necessary. This ensures that all endpoints within an EVI are connected in a LAN topology by default (can adjust RTs to build a tree, etc).

Since PBB control-plane is supported on XRv, we will look at some of the PBB details. The network diagram is kept simple with 3 PBB edge routers and some CE routers as well. Both XRv4 and CSR6 are EVPN route-reflectors; this is the extent of IOS XE's support for EVPN at present. The remaining CSRs are CE routers with OSPFv3 enabled for IPv4 and IPv6. If PBB-EVPN ever suddenly starts working on XRv, then they should form neighbors according to the EVPN configuration. CSR5, CSR7, and CSR8 share a LAN, while CSR9 and CSR10 do the same in a different VPN.

The basic configurations are shown below using XRv3 as the demonstration, since XRv1 and XRv2 basic PBB configurations are identical. As discussed earlier, we identify PBB “edge” and “core” bridge-domains. PBB edge domains are assigned I-SIDs which identify ESes/VLANs and map to interfaces. PBB core domains specify the EVI used which is the basis for RT generation. Every PBB edge I-SID must map to a core bridge-domain so the router can build the internal plumbing from the EFP to the MPLS core. Using terminology from the 802.1ah (MAC in MAC) section, the PBB edge domain handles the service component (I-SID) and the PBB core domain handles the backbone component (B-MAC and B-tag). This multi-stage encapsulation allows for maximal flexibility when building EVPNs. XRv3 runs BGP to XRv4 and CSR6 which are EVPN route-reflectors. Of note, XRv3 has a second CE and thus defines a second PBB edge group. It shares the same bridge group as the other PBB edges but uses a separate bridge-domain. This will become relevant when looking at BGP routes.

```

There is nothing exciting about the BGP configurations on XRv4 and CSR6. They are just RRs for the L2VPN EVPN SAFI and don't do anything fancy. This is just demonstrating the RR capability on XE and XR.

```

```

First and most simply, we can verify the B-MAC configuration worked on one of the routers. In verifying this, we can also see the “chassis” MAC which would have been used had we not configured one.

```

RP/0/0/CPU0:XRv3#show l2vpn pbb backbone-source-mac
Backbone Source MAC: 0000.0013.0013
Chassis MAC          : 0b16.212c.3742

```

We can look at XRv3 to see all routes in the topology. So far, we only see type 2 and type 3 routes. This makes sense because type 1 only applies to EVPN (which does not appear configurable on XR) and type 4 only applies to multi-homed environments (multi-chassis LACP not supported on virtual platforms). Giving this output a closer look, we notice the word “vrf” used to identify PBB_CORE. This is odd because PBB_CORE is a bridge-domain that maps to an EVI. However, the cosmetics of the output treat this like a VRF since it maps to an RD. It would make sense, then, for the administrator to name the PBB core bridge-domains based on the EVIs they support. Next, we can see that each PE generates exactly one type-2 MAC advertisement route (yellow). They carry a 48-bit MAC address which represents the manually-configured B-MAC on each router; I manually configure it for ease of understanding, but doing so is not necessary. We then see several type 3 Inclusive Multicast routes (green). We see 5 of these, so clearly PEs can advertise more than one, unlike type 2 routes. In this case, all PEs are part of I-SID 1001, which is a PBB edge domain, and thus each one advertises a route (cyan). I-SID 1002 is only present on XRv2 and XRv3, so only those two PEs generate a route for this I-SID (pink). Because these are multicast inclusion routes, this ensures that multicast traffic doesn’t leak across PBB edge domains even if they share the same PBB core domain.

```

RP/0/0/CPU0:XRv3#show bgp l2vpn evpn rd 1.13.13.13:1000 | begin Network

```

Network	Next Hop	Metric	LocPrf	Weight	Path

*> [3] [1002] [32] [1.13.13.13]/80	0.0.0.0			0	i

We can also view information by specifying the PBB core domain by name (versus using the RD), much like using a VRF name. In this way, we will examine the type 2 route from XRv2. Like MVPN, EVPN BGP show commands require you to enter the entire prefix string on XR. Below, we can see many of the key fields carried inside this route. The MAC address is shown in the prefix, but the MPLS label, RT, and ESI are carried inside of the route itself. Much like VPNv4/v6, the B-MAC address 0000.0012.0012 is bound to local label 92004 on XRv2. The ESI is always 0 unless multi-homing is configured, so we ignore that for now.

```
RP/0/0/CPU0:XRv3#show bgp l2vpn evpn bdomain PBB_CORE
[2][0][48][0000.0012.0012][0]/104
BGP routing table entry for [2][0][48][0000.0012.0012][0]/104, Route

candidate, imported, rib-install
    Received Path ID 0, Local Path ID 1, version 10
    Extended community: RT:1:1000
    Originator: 1.12.12.12, Cluster list: 1.6.6.6
    EVPN ESI: 0000.0000.0000.0000.0000
    Source VRF: default, Source Route Distinguisher: 1.12.12.12:1000
```

Now that we know the local label on XRv2 for receiving MPLS packets, we can check the LFIB to see what happens when that label is received. The bridge-domain ID is identified as 0 (more on this later) and the router is identified as a PE. The detailed output shows us that PW flow label is automatically

enabled which means load-sharing is inherent with EVPN. This label is popped before sending traffic to the customer's bridge-domain.

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92004 detail
Local   Outgoing   Prefix           Outgoing   Next Hop        Bytes
Label   Label       or ID            Interface                Switched
-----
92004   Pop          No ID            BD=0 PE             point2point          0

PW Flow Label: Enabled
MAC/Encaps: 0/0, MTU: 0
Label Stack (Top -> Bottom): { }
Packets Switched: 0
```

The “BD=0” is referring to the PBB_CORE bridge-domain on XRv2. This delivers the packet from the MPLS process to the core domain.

```
RP/0/0/CPU0:XRv2#show l2vpn bridge-domain bd-name PBB_CORE brief
Legend: pp = Partially Programmed.
Bridge Group:Bridge-Domain Name  ID      State           Num ACs/up    Num PWs/up
-----
PBB_CORE:PBB_CORE                0       up              0/0           0/0
```

To see the auto-generated RD/RTs without looking at BGP, we can query the EVPN EVI details for EVI 1000. This output also shows us some interesting label information; we see a unicast and multicast label for the EVI. The unicast label is 92004 which is what we just saw. We have not seen label 92005 yet.

```
RP/0/0/CPU0:XRv2#show evpn evi vpn-id 1000 detail
EVI      Bridge Domain      Type
-----
1000     PBB_CORE                  PBB

Unicast Label   : 92004
Multicast Label : 92005
Flow Label: N
RD Config: none
RD Auto   : (auto) 1.12.12.12:1000
RT Auto   : 1:1000
Route Targets in Use      Type
-----
1:1000                    Import
1:1000                    Export
```

Checking the LFIB for label 92005, we can see the output is very similar to the unicast label except that it identifies an “inclusive multicast” (IM) entry. The output is otherwise identical, but having a separate label is important to differentiate unicast from BUM traffic.

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92005 detail
Local   Outgoing   Prefix           Outgoing   Next Hop        Bytes
Label   Label       or ID           Interface
-----
92005   Pop          No ID           BD=0 PEIM    point2point     0
      PW Flow Label: Enabled
      MAC/Encaps: 0/0, MTU: 0
      Label Stack (Top -> Bottom): { }
      Packets Switched: 0
```

When looking at the BGP type 2 route, we did not see this label being signaled. The label is carried in the type 3 routes and is the same for all I-SIDs. This is the first time we have ever seen a non-zero MPLS label being carried within the PMSI attributes; the MVPN section did not operate this way. Looking at the type-3 routes for I-SIDs 1001 and 1002, we see the same label for both of XRv2's locally-originated BGP routes. Both of these I-SIDs (PBB edge domain) map to the same EVI (PBB core domain) so the RD/RT information is identical as well. Although not terribly significant for EVPN, the tunnel type of 6 represents ingress replication (IR) and the ID is the IP address of the LSM root, which is 1.12.12.12 (XRv2 loopback). I show this in green because it is of less importance right now.

```
RP/0/0/CPU0:XRv3#show bgp l2vpn evpn bdomain PBB_CORE

```

We can see a summary of the type 2 (unicast) labels for EVPN using basic BGP show commands. Since the type 3 multicast labels are carried inside of PMSI attributes, they are not shown in summary form using BGP. Again, we can see label 92004 being used for unicast traffic towards XRv2's B-MAC of 0000.0012.0012.

```
RP/0/0/CPU0:XRv3#show bgp l2vpn evpn bdomain PBB_CORE labels | begin Network
  Network          Next Hop          Rcvd Label          Local Label
Route Distinguisher: 1.13.13.13:1000 (default for vrf PBB_CORE)

          1.12.12.12          92004          nolabel
*> [2] [0] [48] [0000.0013.0013] [0]/104
          0.0.0.0          nolabel          93004
```

For completeness, we will examine some of the BGP show commands on XE as well. Looking at XRv2's routes, we can see the output is significantly different from XR when looking at the summary information. The type 2 route is expanded more literally on XE; the 20 zeroes in a row is the ESI, where in XR it is displayed as a single zero. The summary output also contains the MPLS label for the type 2 route. XE is clearly struggling to display information in the type 3 routes as it specifies some fields are UNKNOWN.

```
R6#show bgp l2vpn evpn rd 1.12.12.12:1000 | begin Network
  Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 1.12.12.12:1000
*>i
[2] [1.12.12.12:1000] [00000000000000000000] [0] [48] [000000120012] [0] [*] [92004] /
33
          1.12.12.12          100          0 i
*>i [3] [1.12.12.12:1000] [1001] [32] [UNKNOWN] /17
          1.12.12.12          100          0 i
*>i [3] [1.12.12.12:1000] [1002] [32] [UNKNOWN] /17
          1.12.12.12          100          0 i
```

Examining XRv2's type 2 in detail, we only see the RT. Nothing else is revealed since XR crams it into the summary information without saying much about it. Considering the feature isn't supported in XE in the data-plane at all, this is understandable, and XE is just transporting BGP information (no local processing or path-related evaluations on the payload data).

```
R6#show bgp l2vpn evpn rd 1.12.12.12:1000 route-type 2
BGP routing table entry for
[2] [1.12.12.12:1000] [00000000000000000000] [0] [48] [000000120012] [0] [*] [92004] /

```

We will detail inclusive multicast operations a bit more as well. We can clearly see a mapping between I-SIDs, IP addresses, and EVIs using a basic show command on a per EVI basis. In this example, we can see both I-SIDs 1001 and 1002, their participating routers, and the EVI common for all I-SIDs.

```

RP/0/0/CPU0:XRv3#show evpn evi vpn-id 1000 inclusive-multicast
ISID                Originating IP                vpn-id

```

1001	1.11.11.11	1000
1001	1.12.12.12	1000
1001	1.13.13.13	1000
1002	1.12.12.12	1000
1002	1.13.13.13	1000

The detailed output shows the BGP next-hops, along with the MPLS labels and whether the entry was locally generated or remotely learned. Again, this shows the same inclusive multicast MPLS label (as signaled as a subfield in the PMSI attribute) within each I-SID.

```
RP/0/0/CPU0:XRv3#show evpn evi vpn-id 1000 inclusive-multicast detail

```

Ingress replication, as a method to transport LSM, is somewhat self-explanatory. Packets arriving from the CE are replicated to each remote PE that has expressed interest. That is to say, if the remote RT was imported for a route, it is assumed that PE is interested in receiving multicast. IR is easy to deploy because core routers treat them just like ordinary MPLS frames and don't need to run anything special, unlike RSVP P2MP-TE and mLDP, which may not be supported by all routers. Core routers won't even see the inclusive multicast labels since ordinary transport labels, such as LDP, RSVP-TE, or SR will be used to transport traffic across the network.

It is important to note that because the MPLS label is the same for multicast I-SID traffic within an EVI, the PBB encapsulation (802.1ah described later) is responsible for providing the demultiplexing capability to achieve per I-SID granularity, not the MPLS label. We can prove this by creating a second EVC between XRv1 and XRv3 using bogus ESes. For additional variety, we will configure custom RD's and RT's on XRv1 and XRv3 for this EVI. The ES doesn't actually connect a host device but for verifying the

control plane, it doesn't matter. Only XRv3 is shown, but XRv1 has a near-identical configuration. The RTs are reversed so that XRv1 and XRv3 import one another's RTs, and the RDs are different as well.

```
! XRv3
interface GigabitEthernet0/0/0/0.1113 l2transport
 encapsulation dot1q 1113 exact
 rewrite ingress tag pop 1 symmetric

evpn
 evi 1313
  bgp
   rd 0.0.11.13:13
   route-target import 1113:11
   route-target export 1113:13

l2vpn
 bridge group PBB_CORE
  bridge-domain PBB_CORE_3
  pbb core
  evpn evi 1313

bridge group PBB_EDGES
 bridge-domain PBB_EDGE_3
  pbb edge i-sid 3111 core-bridge PBB_CORE_3
  interface GigabitEthernet0/0/0/0.1113
```

Checking BGP on XRv3, we can see XRv1's type 2 and type 3 routes within this new EVI. Since the PBB core domain is different, the EVI is different, which means the RDs, RTs, and MPLS labels will be different. We can see XRv3's custom RD below. Also note that there are only two type 3 IM routes because there is only one I-SID within PBB_CORE_3 (only one PBB edge domain). The I-SID value is 3111 as expected; there is no knowledge of I-SIDs 1001 or 1002 within this PBB core domain, which is a separate EVI than the one previously configured.

```
RP/0/0/CPU0:XRv3#show bgp l2vpn evpn bdomain PBB_CORE_3 | begin Network
      Network                Next Hop                Metric LocPrf Weight Path
Route Distinguisher: 0.0.11.13:13 (default for vrf PBB_CORE_3)
*>i[2][0][48][0000.0011.0011][0]/104
      1.11.11.11                                100          0 i
*> [2][0][48][0000.0013.0013][0]/104
      0.0.0.0                                    0          0 i
*>i[3][3111][32][1.11.11.11]/80
      1.11.11.11                                100          0 i
*> [3][3111][32][1.13.13.13]/80

```

Looking at XRv1's type 2 route, we can see the original RD was XRv1's customer RD, and the route also contains the custom RT. A new MPLS label 91006 was allocated for this new PBB core domain.

```
RP/0/0/CPU0:XRv3#show bgp l2vpn evpn bdomain PBB_CORE_3 [2][0][48][0000.0011.0011][0]/104

```

Before checking the LFIB on XRv1, we can verify the PBB_CORE_3 bridge-domain ID to correlate it with the LFIB next. This PBB core domain has an ID of 3. For sanity, we verify the local label by checking the EVI details as well, expecting to see value 91006 as the unicast label carried in the BGP type 2 message. The LFIB shows verifies all of this; label 91006 is popped upon reception and the packet is delivered to PBB_CORE_3, which is bridge-domain 3.

```
RP/0/0/CPU0:XRv1#show l2vpn bridge-domain bd-name PBB_CORE_3 brief
Legend: pp = Partially Programmed.
Bridge Group:Bridge-Domain Name  ID      State          Num ACs/up    Num PWs/up
-----
PBB_CORE:PBB_CORE_3             3      up              0/0            0/0
```

```
RP/0/0/CPU0:XRv1#show evpn evi vpn-id 1313 detail | include Unicast
Unicast Label   : 91006
```

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91006
Local   Outgoing   Prefix           Outgoing   Next Hop        Bytes
Label   Label      or ID           Interface
-----
91006   Pop          No ID           BD=3 PE      point2point      0
```

The same is true for multicast labels. Since XRv3 and XRv1 are connected with two separate EVIs, we expect the multicast labels assigned for their I-SIDs to vary. In this case, we see label 91008 used for the new I-SID of 3111 (EVI 1313) and 91005 still in use for the old I-SID of 1001 (EVI 1000). Note that this verification was performed remotely on XRv3 based on received BGP type 3 routes.

```
RP/0/0/CPU0:XRv3#show evpn evi inclusive-multicast service-id 3111 orig-ip
1.11.11.11 detail
ISID: 3111, Originating IP: 1.11.11.11                      1313
Nextthop: 1.11.11.11
```

```
Label : 91007
Source : Remote
```

```
RP/0/0/CPU0:XRv3#show evpn evi inclusive-multicast service-id 1001 orig-ip
1.11.11.11 detail
ISID: 1001, Originating IP: 1.11.11.11                      1000
Nexthop: 1.11.11.11
Label : 91005
Source : Remote
```

We can confirm both entries in XRv1's LFIB. We can see that label 91005 is an include multicast label for BD 0, which is PBB_CORE seen earlier. Label 9107 is an IM label for BD 3, which is PBB_CORE_3, verified above. In this way, the MPLS label is mapped to an EVI which allows MPLS to deliver untagged packets to the proper PBB core domain. The PBB encapsulation provides the specific I-SID, not the MPLS label.

```
RP/0/0/CPU0:XRv1#show mpls forwarding labels 91005 91007
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
91005	Pop	No ID	BD=0 PEIM	point2point	0
91006	Pop	No ID	BD=3 PE	point2point	0
91007	Pop	No ID	BD=3 PEIM	point2point	0

We will finish with some additional show commands. Although I have not found a command to show this in BGP, the remote PEs signal whether they are running in single-active or all-active mode. I assume that this command confirms that each remote PE is single-homed as a result of this signaling. Notice that this output does not show any local labels.

```
RP/0/0/CPU0:XRv3#show evpn internal-label detail
```

Although we will not see any MAC addresses, we can confirm some basic data-plane configurations are correct. First, we look at the bridge-domain summary. We see 3 PBB edge domains and 2 PBB core domains, which is consistent with the BGP verifications we performed earlier. The BGP verifications showed two separate EVIs (1000 and 1313) with three I-SIDs (1001 and 1002 mapped to EVI 1000, and 3111 mapped to EVI 1313).

```
RP/0/0/CPU0:XRv3#show l2vpn bridge-domain summary
Number of groups: 2, bridge-domains: 5, Up: 5, Shutdown: 0, Partially-
programmed: 0
Default: 0, pbb-edge: 3, pbb-core: 2
Number of ACs: 3 Up: 3, Down: 0, Partially-programmed: 0
Number of PWs: 0 Up: 0, Down: 0, Standby: 0, Partially-programmed: 0
Number of P2MP PWs: 0, Up: 0, Down: 0, other-state: 0
Number of VNIs: 0, Up: 0, Down: 0, Unresolved: 0
```

Looking at PBB_EDGE_1 as a bridge-domain, we confirm its configured as PBB-edge and has a valid I-SID. We can see it is mapped to a PBB and has one AC that is online.

```
RP/0/0/CPU0:XRv1#show l2vpn bridge-domain bd-name PBB_EDGE_1

Additional Reading – Reference configurations “pbb-evpn”

11. Describe IEEE 802.1ad (QinQ), IEEE 802.1ah (Mac-in-Mac), and ITU G.8032 (REP)

11.1 802.1ad QinQ

QinQ (dot1q tunneling or provider bridging) is a method of adding additional 802.1q headers to an Ethernet frame to tunnel it across different networks. 802.1ad is an amendment to 802.1q which doesn't change any aspects of dot1q headers per se, but simply allows them to be stacked in an Ethernet frame's header. This is demonstrated many times throughout this document so a dedicated lab is not built for this section. There are many benefits to tag stacking:

1. The original specification can create 2^{12} (4096) theoretical VLANs since the VLAN-ID is a 12 bit number. VLANs 0 and 4096 cannot be used, though, so the math is imprecise so far. Adding an additional tag squares this ($2^{24} = 16777216$) which allows for greater network growth. I personally use this extensively in many labs where I don't want to provision public VLANs (I am only allowed to use VLANs 3501 – 3600 for my labs), so I tunnel my private VLANs inside of these publicly switched VLANs.
2. Tags can be added (pushed), removed (popped), or changed (translated) by network devices as necessary.
3. Provides the basis for provider bridging and provider backbone bridging (PBB) which is described later. When used in conjunction with PBB, hierarchical bridging networks can be designed to achieve very high scalability.

The standard denotes Ethertype 0x88A8 for the outer tag (service tag, carrier tag, metro tag, tag 1, or S-tag) and 0x8100 for the inner tag (customer tag, tag 2, or C-tag). This new Ethertype isn't terribly significant other than identifying the Ethernet frame as tunneled or not. Below is a copy of a packet dump from another section later in the lab that shows the QinQ stack. In this case, the S-tag in yellow has value 3544 (0xDD8) and the C-tag in green has value 460. As mentioned earlier, this can be used to tunnel VLANs not allowed by my cloud provider inside VLANs that are. Immediately following the QinQ encapsulation is the ethertype of 0x0800 (cyan), which identifies an IP packet inside of the following Ethernet frame.

```
R6#show monitor capture CAP buffer detail
 6 152      1.376039  00:50:56:A9:DE:0D -> 00:50:56:A9:EA:77 MPLS unicast
0000:  005056A9 EA770050 56A9DE0D 81000DEF      .PV..w.PV.....
0010:  884701B5 D0FF00FA A1FF0000 00000050      .G.....P
0020:  56A9862A 005056A9 EA5488A8 0DD88100      V...*.PV..T.....
0030:  01CC0800 45000064 00010000 FF01A77D      ....E..d.....}
```

Although 802.1ad does not specify more than 2 tags pushed, there is no limitation in many devices to this upper bound. In that case, the inner-most tag is the C-tag where all other tags are considered S-tags. The outer-most tag is "tag 1" and the next tag is "tag 2", which would be another S-tag if more than 2 tags exist. Another interesting change in 802.1ad is that the canonical format ID (CFI) field, formerly used when bridging token ring networks, has been recycled for drop probability use. This is similar to the frame-relay discard eligibility (DE) bit and is called the drop eligibility indicator (DEI). This can be used in conjunction with or in lieu of the 3 priority bits in the dot1q header which are also examined in later sections. Those priority bits are referenced in 802.1p and are called the priority code points (PCP).

Q-tunneling has some downsides as well. The C-MAC addresses are always exposed, even when being bridged over a service provider's network. The S-tag helps keep the C-tag intact and separates some data-plane functionality, but the provider network still must program all C-MACs within the S-VLAN CAM tables on all switches in the transit path. This leads to poor scalability for data center interconnect (DCI) applications where many customers will have many C-MACs. QinQ also makes the assumption that no two networks will ever have the same MAC address, which may not be true if custom MAC addressing is configured in software for aggregation/filtering reasons.

11.2 802.1ah MAC in MAC (Provider Backbone Bridges)

This feature was written to address some of the concerns previously identified with QinQ tunneling. It is also known as provider backbone bridging (PBB) since it introduces the concept of backbone MACs (B-MACs). Like S-tags shown in QinQ tunnel, B-MACs are service provider switch MACs that serve as the outer encapsulation for customer traffic. In this way, provider switches don't need to learn all C-MACs, only B-MACs, of which there is one per PE. This greatly enhances scalability as the B-MAC is like a tunnel or aggregate MAC. PBB was defined to offer total separation between customer and provider MAC address spaces, which is somewhat similar to MPLS L3VPN (or IP-in-IP/GRE) does for IP VPNs. PBB is comprised of three main encapsulation components:

1. **Backbone component:** Contains a destination address (B-DA), source address (B-SA), the ethertype 0x88A8 as defined in 802.1ad for QinQ tunneling, and a B-tag to represent the backbone VLAN. The B-tag is similar to the S-tag but is renamed for clarity between the specifications, since PBB technically can carry QinQ frames inside of it.
2. **Service component:** Contains ethertype 0x88E7 (defined for PBB) and an I-SID (24-bit service ID). The I-SID is used as a method of defining to which customer the frames belong, since the B-tag isn't customer specific.
3. **Original frame:** This could be an IP packet inside of an Ethernet frame (0x0800), an Ethernet frame inside of dot1q with a single C-tag (0x8100), or part of a hierarchical bridging architecture with two tags already on it (0x88A8). This is why the B-tag isn't called the S-tag, as the S-tag may actually exist within the original frame that arrived at the PBB device. This component is highly variable in length and composition, but PBB doesn't care.

This PBB encapsulation can be used in an ordinary Ethernet switched network or as a pre-encapsulation before MPLS. In PBB-EVPN, this PBB encapsulation happens first, then the entire backbone frame is encapsulated inside MPLS labels to represent the remote PE within a VPN (BGP) and the transport labels to get there (LDP, RSVP-TE, SR, etc). I am unable to demonstrate this encapsulation due to lack of hardware devices that support it.

11.3 Ethernet Ring loop-prevention

11.3.1 Cisco Resilient Ethernet Protocol (REP)

REP is a Cisco-proprietary protocol that is used to rapidly converge a layer 2 Ethernet network arrayed in a ring topology. This is an alternative to STP which works in a very specific set of network designs, but offers very fast (50 – 300 ms) convergence time. The entire "circumference" of the ring, including the endpoints, are part of the REP domain. This domain is called a "segment" in REP terms, but I personally

find this term confusing. The segment is not like a LAN segment, nor is it a single link between two switches. Rather, the segment is the end-to-end circumference of the REP ring, which is terminated by exactly two edge ports. Each switch in the REP segment can have up to 2 ports in a segment (for intermediate nodes), and each link must have exactly one REP neighbor. To illustrate this, we will test two different REP topologies shown below. The left diagram is a “ring segment” in which one switch terminates the segment on both ends, since both edge ports are configured on this one switch. This is a simpler design but it is highly reliant on this one switch. The right diagram is an “open segment” in which the edge ports exist on disparate switches. The network in between can use STP (Cisco Catalyst 3560, for example), and since there are multiple switches with REP edge ports, this more complex design offers higher availability (more ingress/egress points).

First, we will configure the ring topology. REP is very easy to configure as there are not many commands. Before configuring any interfaces, we will discuss the REP admin VLAN. This VLAN is used for the flooding of REP messages to an ordinary MAC multicast address, which is the IEEE STP MAC 0180.c200.0000 also used for STP on VLAN 1 in PVST, for example. The reason this ordinary address is used is to improve REP performance; by using the hardware flood layer (HFL), REP bypasses the delay with software forwarding. Certain REP messages are therefore flooded throughout the entire REP admin VLAN, even beyond the REP segment. For this reason, the admin VLAN can be pruned to only exist in the REP segment, giving the operator additional control. We will configure VLAN 29 for this. It is important to note that the REP link-status layer (LSL) PDUs, which are like STP BPDUs, are always sent untagged in the native VLAN.

```
! All ME switches
vlan 29
  name REP_ADMIN

rep admin vlan 29
```

We can verify this configuration by checking the REP interface details, which is not intuitive. There are many other important fields in this output we look at later, but for now, we just verify the admin VLAN.

```
ME3#show interfaces port-channel 13 rep detail | include Admin-vlan
```

Admin-vlan: 29

There are two key requirements for enabling REP on an interface: it must be an NNI and it must be a trunk port. Any other combination of port-types and switch port modes is not supported. REP is also supported on port-channel interfaces as we shown between ME1 and ME3. Of the two edge ports, one is the “primary” edge port and one is the secondary. This is relevant later, but for now, we configure the LACP bond as the primary towards ME1 and the other port towards ME2 as the secondary. Ideally, you would work clockwise or counter-clockwise around the ring and not configure both edge ports at the same time. Moving in sequence is the best way to migrate to REP from STP, but since this is a “greenfield” deployment, I will configure all REP ports per device as I have console access and don’t care about temporary traffic blackholes.

```
! ME3
interface Port-channel13
  description LACP TO ME1
  port-type nni
  switchport mode trunk
  rep segment 1 edge primary

interface FastEthernet0/13
  description TO ME2
  port-type nni
  switchport mode trunk
  rep segment 1 edge
```

Notice that configuring REP generates a message warning you about the effects on STP. STP is totally disabled on any REP port, which means BPDUs are not sent nor received. We can prove this with a show command as well.

```
ME3(config-if)#rep segment 1 edge
Warning: Enabling REP automatically disables STP on this port.  It is
recommended to shutdown all interfaces which are not currently in use to
prevent potential bridging loops.
```

```
ME3#show spanning-tree interface fastEthernet 0/13
no spanning tree info available for FastEthernet0/13
```

Configuring the intermediate nodes is simple. All we do is specify the REP segment as there is no need to specify edge port status. I do not show the descriptions, NNI, or trunk configurations for brevity.

```
! ME2
interface FastEthernet0/13
  rep segment 1

interface FastEthernet0/15
  rep segment 1
```

```

! ME3
interface FastEthernet0/15
  rep segment 1

interface Port-channel13
  rep segment 1

```

At this point, we can use some simple show commands to verify the REP topology. Assuming the ring is complete, all nodes will have the same view of the topology, so we can issue this command anywhere. The command starts with the primary edge port and moves around the ring until it reaches the secondary edge port. Each bridge and port along the way are identified, along with their port roles. Notice that ME2 port 15 is blocking; this is similar to STP where one port in the ring must be blocking to prevent a loop. This means that traffic from ME2 to ME1 will transit ME3, just like in STP. These ports are called “alternate” ports because a break in the ring anywhere automatically means this blocked port will be opened. If the edge ports lose connectivity, there is a never a case where the ring should contain a blocked port.

```

ME3#show rep topology segment 1
REP Segment 1

```

BridgeName	PortName	Edge	Role
ME3	Po13	Pri	Open
ME1	Po13		Open
ME1	Fa0/15		Open
ME2	Fa0/15		Alt
ME2	Fa0/13		Open
ME3	Fa0/13	Sec	Open

Before we dig into detailed show commands, we will verify REP operation. Using a local SPAN session on ME3, I look at traffic on ME3’s primary edge port. At present, we can see several LSL PDUs captured by Wireshark.

```

! ME3
monitor session 1 source interface Po13
monitor session 1 destination interface Fa0/12 encapsulation replicate

```

No.	Time	Source	Destination	Protocol	Length
	20.007003000	CiscoInc_0b:16:93	Spanning-tree-(for-bridges)_00	LLC	
	20.671019000	CiscoInc_92:f7:13	Spanning-tree-(for-bridges)_00	LLC

+ Data (568 bytes)					

It is interesting to see that Wireshark is calling this an STP frame, primarily because it doesn't understand REP, and really only understands the STP destination MAC address. That MAC address is highlighted below in the REP packet debug (green). I also verify the MAC address of ME1's LACP bond as this is the source MAC of the frame (yellow). This debug matches the Wireshark capture, and because the Ethertype isn't specified (it's a length of 576, which is 590 – 14 bytes of Ethernet encapsulation), the DSAP and SSAP are. Both of them are 0xAA (pink), so I am confident that this is the same type of packet seen above.

```
ME1#show interfaces port-channel 13 | include bia
Hardware is EtherChannel, address is 001d.4692.f713 (bia 001d.4692.f713)
```

```
ME3#debug rep packet
REP debug packets debugging is on
```

```
! ME2
00:43:21: REP store seq#1310 for re_tx on Fa0/13 (pak ref:2) fifo size <2>

00:43:21: 0x46 0x92 0xF7 0x13 0x02 0x40 0xAA 0xAA
```

For fastest convergence, we can reduce the LSL age timer on each interface. We can only set the “age timer”, which is a dead timer, and the hello interval is one third of this value. The downside to using port-channels with REP is that the fastest age timer is 1 seconds.

```
ME3(config-if)#rep lsl-age-timer 120
Error: LSL Age Out timer value less than 1000 not supported on etherchannel
```

That being said, we will configure an LSL age-timer of 1 second on the port-channel interface and the minimum of 120 ms on all other interfaces. Notice that if you have mismatched timers, the REP ring

becomes unstable. By configuring only ME3 with this new interval, I've created a mismatch with ME1. ME3 is flapping up and down since ME1 is sending hellos too slowly.

```
! ME3
interface Port-channel13
  rep lsl-age-timer 1000

! ME1
%REP-4-LINKSTATUS: Port-channel13 (segment 1) is non-operational due to
neighbor mismatch

! ME3
%REP-4-LINKSTATUS: Port-channel13 (segment 1) is operational
%REP-4-LINKSTATUS: Port-channel13 (segment 1) is non-operational due to
neighbor not responding
%REP-4-LINKSTATUS: Port-channel13 (segment 1) is operational
%REP-4-LINKSTATUS: Port-channel13 (segment 1) is non-operational due to
neighbor not responding
```

We can confirm the issue by checking the REP interface details on both ME1 and ME3 to see the different timers. Filtering on "LSL" also shows us the PDU counters, similar to how STP interface-level show commands would reveal BPDU TX/RX counters.

```
ME3#show interfaces port-channel 13 rep detail | include LSL
LSL Ageout Timer: 1000 ms
LSL PDU rx: 4964, tx: 3907
BPA (STCN, LSL) TLV rx: 0, tx: 0
```

```
ME1#show interfaces port-channel 13 rep detail | include LSL
LSL Ageout Timer: 5000 ms
LSL PDU rx: 3921, tx: 5104
BPA (STCN, LSL) TLV rx: 0, tx: 0
```

To fix it, we simply match the timers on ME1 using the same configuration (not shown). Then, I adjust the timer to 120 ms on all ordinary ports (also not shown). The blinking lights on the switches are going crazy now, as expected, on the inter-switch links not including the LACP members. Below is a quick verification of all REP interfaces to show their LSL ageout timers.

```
ME1#show interfaces rep detail | include ^(Fast|Port-)|Ageout
FastEthernet0/15    REP enabled
LSL Ageout Timer: 120 ms
Port-channel13     REP enabled
LSL Ageout Timer: 1000 ms
```

```
ME2#show interfaces rep detail | include ^(Fast|Port-)|Ageout
FastEthernet0/13    REP enabled
LSL Ageout Timer: 120 ms
```

```
FastEthernet0/15    REP enabled
LSL Ageout Timer: 120 ms
```

```
ME3#show interfaces rep detail | include ^(Fast|Port-)|Ageout
```

```
FastEthernet0/13    REP enabled
LSL Ageout Timer: 120 ms
Port-channel13      REP enabled
LSL Ageout Timer: 1000 ms
```

Even with this fast timer, only about 12-16 kbps of bandwidth is used. It only consumes a small amount of CPU cycles as well, but more REP interfaces implies more CPU consumed for hello generation/processing. These are important things to check when using any kind of fast failover active detection mechanism.

```
ME1#show interfaces fastEthernet 0/15 | include put_rate
 5 minute input rate 16000 bits/sec, 23 packets/sec
 5 minute output rate 12000 bits/sec, 23 packets/sec
```

```
ME1#show processes cpu sorted
CPU utilization for five seconds: 5%/0%; one minute: 6%; five minutes: 6%
PID Runtime(ms)   Invoked      uSecs   5Sec   1Min   5Min  TTY Process
 198      10674        2175    4907  0.31%  0.08%  0.04%   0 Exec
 126       2642     125673      21  0.31%  0.35%  0.30%   0 REP LSL Hello PP
```

To avoid flooding these LSLs to our Wireshark capture, from now on we will only look at messages in the admin VLAN 29. We apply a quick SPAN filter to achieve this, which allows us to test REP failover. I verify the SPAN configuration because failing to do so may degrade my sniffer PC.

```
! ME3
monitor session 1 filter vlan 29
```

```
ME3#show monitor session 1
Session 1
-----
Type                : Local Session
Source Ports        :
    Both            : Po13
Destination Ports   : Fa0/12
    Encapsulation   : Replicate
    Ingress         : Disabled
Filter VLANs        : 29
```

Before we simulate a failure, we can trace the basic traffic flow for a number of VLANs. Test VLANs 100-103 have been defined on every switch with corresponding SVIs. We quickly check the REP topology again for reference, which indicates port 15 on ME2 is blocking. Traffic between ME1 and ME2 should therefore transit ME3.

```
ME3#show rep topology segment 1
REP Segment 1
BridgeName      PortName      Edge Role
-----
ME3              Po13          Pri  Open
ME1              Po13          Open
ME1              Fa0/15        Open
ME2              Fa0/15        Alt
ME2              Fa0/13        Open
ME3              Fa0/13        Sec  Open
```

To prove this, I ping the broadcast address from ME2. This will source broadcast pings from all connected interfaces, which should quickly discover all of the other SVIs on the network. Specifically, we want to ensure we see responses from ME1's test VLANs.

```
ME2#ping 255.255.255.255 repeat 1
```

Type escape sequence to abort.

Sending 1, 100-byte ICMP Echos to 255.255.255.255, timeout is 2 seconds:

103	001d.4692.f744	DYNAMIC	Fa0/13
103	001f.9d0b.16c4	DYNAMIC	Fa0/13

Now, I will simulate a failure by unplugging the cable between ME2 and ME3. First, I enable pertinent REP debugs on all switches to observe the event.

```
! All switches
debug rep failure-recovery
debug rep prsm
```

Because this breaks the ring, traffic should immediately be allowed to forward over ME2's port 15. First, ME2 and ME3 receive the link-down notification from the platform after the carrier-delay expires. Both of them show the exact same debug as they both witness the layer 1 failure. The port transitions from the OPEN to FAILED state. Both switches also flush MAC addresses learned on this port from the CAM table, which will trigger temporary unknown unicast flooding until the new port is learned. Each of them notify the other switches in the segment as well.

```
! ME2 and ME3
[Fa0/13]: Link down notification received
    rep_pr Fa0/13 - pr: during state OPEN_PORT, got event 1(link_not_op)
@@@ rep_pr Fa0/13 - pr: OPEN_PORT -> FAILED_PORT[Fa0/13]rep_pr_act_fp@101:
PRSM->failed state, 0x80

HREP: Sent hfl pak on Fa0/13, vlan_id 29, di 379
REP Flush from Fa0/13 to REP, sending msg[Fa0/13]: Local failure handling
[Fa0/13]rep_pr_act_send_hw_ind@251: PRSM->sending hw failure
```

Even with debug off, both ME2 and M3 generate syslog messages to show the REP link failure.

```
! ME2 and ME3
%REP-4-LINKSTATUS: FastEthernet0/13 (segment 1) is non-operational due to
port down
```

ME1 is connected to both switches and receives this HW failure indication from both ME2 and ME3 on its LACP bond and port 15.

```

! ME1
REP LSL-OP Rx EXT Local (Fa0/15) seg:1, tc:1, frs:0) prio:
0x80 0x00 0x0F 0x04 0xC5 0xA4 0x53 0xD8
0x00
REP Flush from Fa0/15 to REP, sending msg

0x80 0x00 0x0F 0x04 0xC5 0xA4 0x53 0xD8
0x00
REP Flush from Po13 to REP, sending msg

```

From a topology perspective, we can see that ME3 sees a failure in the topology. Failed ports terminate segments just as edge ports do, however since the segment is incomplete, all ports are open. We now see that ME2 port 15 is available for forwarding. We also check it from ME2's perspective which lists the nodes in the reverse order, but with the same port roles. The presence of a failed port on any segment causes REP to warn the user that there is a segment failure.

```

ME3#show rep topology segment 1
REP Segment 1
Warning: REP detects a segment failure, topology may be incomplete

```

BridgeName	PortName	Edge	Role
ME3	Po13	Sec	Open
ME1	Po13		Open
ME1	Fa0/15		Open
ME2	Fa0/15		Open
ME2	Fa0/13		Fail

```

ME2#show rep topology segment 1
REP Segment 1
Warning: REP detects a segment failure, topology may be incomplete

```

BridgeName	PortName	Edge	Role
ME2	Fa0/13		Fail
ME2	Fa0/15		Open
ME1	Fa0/15		Open
ME1	Po13		Open
ME3	Po13	Sec	Open

We ping the broadcast address from ME2 again (not shown) so that all MAC addresses in all VLANs are resolved. Check the CAM for all non-VLAN 1 entries, we can see that port 15 is used to reach ME1's test SVIs as expected.

```

ME2#show mac address-table dynamic | exclude _1_
Mac Address Table
-----

```

Vlan	Mac Address	Type	Ports
----	-----	-----	-----
100	001d.4692.f741	DYNAMIC	Fa0/15
100	001f.9d0b.16c1	DYNAMIC	Fa0/15
101	001d.4692.f742	DYNAMIC	Fa0/15
101	001f.9d0b.16c2	DYNAMIC	Fa0/15
102	001d.4692.f743	DYNAMIC	Fa0/15
102	001f.9d0b.16c3	DYNAMIC	Fa0/15
103	001d.4692.f744	DYNAMIC	Fa0/15
103	001f.9d0b.16c4	DYNAMIC	Fa0/15

With debugging enabled, we will plug the cable back in. Both ME2 and ME3 change their port state from “FAILED” to “FAILED with no external neighbor”. This is an indication that the electrical carrier is back up but REP is not operational yet.

```
! ME2 and ME3
@@@ rep_pr Fa0/13 - pr: FAILED_PORT ->
FAILED_PORT_NO_EXT_NEIGHBOR[Fa0/13]rep_pr_act_no_ext_neighbor@415: PRSM-
>fp_no_ext_neighbor state
[Fa0/13]rep_pr_lsl_event_handler@645: REP_MSG_EXT_PEER_GONE rcvd
```

After exchanging LSL PDUs, the two neighbors discover one another again, and move their ports to the alternate state. There is still no forwarder on the segment, which is incomplete.

```
! ME2 and ME3
    rep_pr Fa0/13 - pr: during state FAILED_PORT_NO_EXT_NEIGHBOR, got event
0(link_op)
@@@ rep_pr Fa0/13 - pr: FAILED_PORT_NO_EXT_NEIGHBOR ->
ALTERNATE_PORT[Fa0/13]rep_pr_act_ap@216: PRSM->alternate state
[Fa0/13]rep_pr_lsl_event_handler@625: REP_MSG_LINKOP_TRUE rcvd
```

Since one of the ports needs to be forwarding, an election process takes place during the formation of a REP ring which was not discussed until now as it is very detailed. Like STP, each port has a 64-bit priority associated with it, and in REP it is the concatenation of several fields. Towards the beginning the first 4 bits of the election include a failed bit (the most significant bit, only set on failed ports) followed by user configurable fields. The next 12 bits represent a port identifier, and the remaining 48 represent the bridge MAC address. The alternate port election only happens on these blocked ports when an “open” port must be chosen, so the switches exchange blocked port advertisements (BPAs) containing their priorities. If a port receives a BPA with a higher priority, it transitions to the open state as shown below. At the end of the link-up condition, REP displays a syslog message.

```
! ME3
    rep_pr Fa0/13 - pr: during state ALTERNATE_PORT, got event
2(pre_empty_ind)
@@@ rep_pr Fa0/13 - pr: ALTERNATE_PORT -> UNBLOCK_VLANS_ACT
```

```

    rep_pr Fa0/13 - pr: during state UNBLOCK_VLANS_ACT, got event
3(no_local_block_vlan)
@@@ rep_pr Fa0/13 - pr: UNBLOCK_VLANS_ACT ->
OPEN_PORT[Fa0/13]rep_pr_act_op@391: PRSM->active state

! ME2 and ME3
%REP-4-LINKSTATUS: FastEthernet0/13 (segment 1) is operational

```

To see the priorities, we can show the details of the REP topology. Since the link is not failed and the port priorities are both zero, the port numbers are compared. These also match, so then the MAC addresses are compared. Since ME3 port 13 receives a BPA with a better priority, it opens, and since ME2 received a BPA with a worse priorities, it remains an alternate port. BPAs are only sent by alternate ports during this election process as this information contains the VLAN information for blocked VLANs; VLAN load sharing is discussed later.

```

ME3#show rep topology segment 1 detail | begin ME2, Fa0/13
ME2, Fa0/13 (Intermediate)
  Alternate Port, some vlans blocked
  Bridge MAC: 04c5.a453.d800
  Port Number: 00F
  Port Priority: 000
  Neighbor Number: 5 / [-2]
ME3, Fa0/13 (Secondary Edge)
  Open Port, all vlans forwarding
  Bridge MAC: 001f.9d0b.1680
  Port Number: 00F
  Port Priority: 000
  Neighbor Number: 6 / [-1]

```

While we don't have much control over the exact port priority values, we can administratively configure a preferred alternate port. This is somewhat unintuitive since we normally adjust priorities to prefer something, but in this case, the opposite is true. Since the reception of a superior BPA causes a port to open, we can configure a higher priority on ME3 port 13 so that ME2 port 13 becomes open for this link. We now identify this port as the secondary edge port with the "preferred" flag. We can verify the configuration by checking the REP interface details.

```

! ME3
interface FastEthernet0/13
  rep segment 1 edge preferred

ME3#show interfaces fastEthernet 0/13 rep detail | include Pref
Segment-id: 1 (Preferred Edge)
Preferred flag: Yes

```

However, when we check the REP topology, nothing has changed. Despite having a higher priority, ME3 port 13 is still forwarding.

```
ME3#show rep topology segment 1 detail | begin ME2, Fa0/13
ME2, Fa0/13 (Intermediate)
  Alternate Port, some vlans blocked
  Bridge MAC: 04c5.a453.d800
  Port Number: 00F
  Port Priority: 000
  Neighbor Number: 5 / [-2]
ME3, Fa0/13 (Secondary Edge)
  Open Port, all vlans forwarding
  Bridge MAC: 001f.9d0b.1680
  Port Number: 00F
  Port Priority: 010
  Neighbor Number: 6 / [-1]
```

The alternate port elections only happen once during the initial negotiation when a segment is complete, and they are not preemptive. As such, I quickly disconnect and reconnect the cable which triggers the election again. Now, ME2 port 13 is forwarding and the secondary edge port is blocked. In this way, we can somewhat influence the REP convergence around the ring.

```
ME3#show rep topology segment 1 detail | begin ME2, Fa0/13
ME2, Fa0/13 (Intermediate)
  Open Port, all vlans forwarding
  Bridge MAC: 04c5.a453.d800
  Port Number: 00F
  Port Priority: 000
  Neighbor Number: 5 / [-2]
ME3, Fa0/13 (Secondary Edge)
  Alternate Port, some vlans blocked
  Bridge MAC: 001f.9d0b.1680
  Port Number: 00F
  Port Priority: 010
  Neighbor Number: 6 / [-1]
```

Unplugging the cable again, we can see the “failed” bit in action. Notice that the priority is a very high number, and nothing can ever be higher than it. As such, assuming the link was up but there was a REP communication issue, this port would always be the alternate port.

```
ME3#show rep topology segment 1 detail | begin ME2, Fa0/13
ME2, Fa0/13 (Intermediate)
  Failed Port, Reason: Physical link down
  Bridge MAC: 04c5.a453.d800
  Port Number: 00F
  Port Priority: 800
  Neighbor Number: Not available
```

Wireshark doesn't help us decode the HFL packets at all, but we note something interesting. First, despite the dot1q tag not showing up, we know that this was in VLAN 29 since the local SPAN filter is only capturing that VLAN. The destination MAC address looks similar to the one typically used by Cisco for VTP, CDP, and others, except the last character is an 'e'. Wireshark identifies this as ISL encapsulation. Either way, we know that since it isn't the IEEE STP MAC address, even STP-aware non-Cisco switches would forward this traffic throughout the network. That is why the administrative VLAN can scope the REP signaling traffic.

No.	Time	Source	Destination	Protocol	Length
27.	644018000	CiscoInc_53:d8:0f	ISL-Frame_cc:cc:ce	LLC	565
+ Frame 8: 565 bytes on wire (4520 bits), 565 bytes captured (4520 bi					
- IEEE 802.3 Ethernet					
+ Destination: ISL-Frame_cc:cc:ce (01:00:0c:cc:cc:ce)					
+ Source: CiscoInc_53:d8:0f (04:c5:a4:53:d8:0f)					

Edge ports also sent end point advertisements (EPAs) occasionally via LSL in the native VLAN (not HFL in the REP admin VLAN). We can enable debugs on ME3 to see the EPAs being sent, which contain much more information than normal LSLs. In fact, the large LSL packet we saw earlier in the packet dumps was probably an EPA. Both the primary and secondary edge ports originate these. The network is currently stable so the states aren't changing, but we can see the topology information summarized in the debug. The primary edge port lists itself first and then the hops to the secondary edge port. The secondary edge port does the opposite in the reverse direction; this is how the edge ports know the segment is complete.

```

Bridge:ME1  Port1:Fa0/15  Port2:Po13
```

If we unplug the cable to cause a segment failure, the EPA state machine transitions the primary edge port to the secondary edge port. The reason for this is because the primary edge port is also responsible for VLAN load balancing; when there is a break in the segment, VLAN load balancing is impossible. As such, the edge port becomes a secondary port so it can effectively ignore that configuration. The debug also shows us that the triggering state change was a “segment break”.

```
! ME3
03:15:32:      rep_epa_edge Po13 - epa-edge: during state EDGE_PRIMARY, got
event 4(seg_break)
03:15:32: @@@ rep_epa_edge Po13 - epa-edge: EDGE_PRIMARY ->
EDGE_SECONDARY[Po13]rep_epa_edge_act_edge_sec@113: EPA: edge sec
[Po13]rep_epa_egde_act_update_key@208: new key=61757
```

Each port in a REP segment is numbered with offsets as well. This isn't the same as the hexadecimal port numbers seen earlier, but rather is a way of measuring distance away from edge ports. The primary edge port is number 1 and the secondary edge port is -1. Ports increment by 1 as they move away from the primary edge port and decrement by 1 as they move away from the secondary port. From any switch, we look at the topology details and filter based on the more important information. We can see that each port is assigned both a positive and negative number. The positive number measures the distance from the primary edge port and the negative number measures the distances from the secondary edge port.

```
! ME1
ME1#show rep topology segment 1 detail | include ^ME|Port,|Neighbor
ME3, Po13 (Primary Edge)
  Open Port, all vlans forwarding
  Neighbor Number: 1 / [-6]
ME1, Po13 (Intermediate)
  Open Port, all vlans forwarding
  Neighbor Number: 2 / [-5]
ME1, Fa0/15 (Intermediate)
  Open Port, all vlans forwarding
  Neighbor Number: 3 / [-4]
ME2, Fa0/15 (Intermediate)
  Open Port, all vlans forwarding
  Neighbor Number: 4 / [-3]
ME2, Fa0/13 (Intermediate)
  Open Port, all vlans forwarding
  Neighbor Number: 5 / [-2]
ME3, Fa0/13 (Secondary Edge)
  Alternate Port, some vlans blocked
  Neighbor Number: 6 / [-1]
```

Ports also have unique IDs. We can reveal these using the interface-level REP show command. Notice that this is the 64-bit field that is used in BPA elections to determine alternate ports. The port number is the 12-bit number following the first nibble. Below, the port number for ME1 port 15 is 0x011, or 17 in decimal. This makes sense since port 15 is the 17th port on the switch as the two SFPs count as the first two. Virtual interfaces like LACP bonds use system-generated values, like 160 (0x0A0) shown below.

```
ME1#show interfaces rep detail | include REP_enabled|^PortID
FastEthernet0/15    REP enabled
PortID: 0011001D4692F700
Port-channel13     REP enabled
PortID: 00A0001D4692F700
```

Using these numbers/port IDs, we can achieve VLAN load balancing. This is configured only on the primary edge port and performs two key tasks. First, the administrator specifies a port in the segment where certain VLANs should be blocked. Any VLANs not specified by this list are blocked at the primary edge port. An interface can be specified in one of three ways:

1. Using the port ID specified manually.
2. Using the neighbor offset number, positive or negative, specified manually.
3. Using the “preferred” keyword, which will reference the preferred port previously configured in the ring.

Normally, enforcing these kind of changes on a REP ring is disruptive. Cisco decided not to break the REP ring just to enable VLAN load balancing, so after configuring any of these three methods, we must enable the feature one of two ways, but in both cases, it is a disruptive event.

1. Manually pre-empt the ring from the switch with the primary edge port. This will likely result in some traffic disruption.
2. Configure a delay on the interface which begins counting down after a link failure and recovery.

We will quickly test all methods. Our first test will be using the port ID method. We will choose ME1 port 15 as the alternate port for VLANs 100 and 101, while the primary edge port (ME3 LACP bond) will be the alternate port for all other VLANs. A quick look at the topology shows no change, as expected.

```
! ME3
interface Port-channel13
  rep block port id 0011001D4692F700 vlan 100-101
```

```
ME3#show rep topology segment 1
REP Segment 1
BridgeName      PortName      Edge Role
-----
ME3             Po13          Pri  Open
ME1             Po13          Open
ME1             Fa0/15        Open
```

ME2	Fa0/15	Open
ME2	Fa0/13	Open
ME3	Fa0/13	Sec Alt

I will manually preempt this REP ring to enable VLAN load balancing. The parser warns us about traffic interruptions as well.

```
ME3#rep preempt segment 1
```

The command will cause a momentary traffic disruption.

```
Do you still want to continue? [confirm]y
```

Proceeding with Manual Preemption

Now, we look at the topology in detail. We see two alternate ports in the topology, both of which specify that “some” VLANs are blocked. The primary edge port has an increased port-priority, which means it will become the alternate port for this link. The same is true for the port we specified above, which is also an alternate port.

```
ME3#show rep topology segment 1 detail
```

```
REP Segment 1
```

ME3, Po13 (Primary Edge)

Alternate Port, some vlans blocked

Bridge MAC: 001f.9d0b.1680

Open Port, all vlans forwarding
Bridge MAC: 001f.9d0b.1680
Port Number: 00F
Port Priority: 010
Neighbor Number: 6 / [-1]

```

We can check the individual port-level details to see which VLANs are blocked per-port. Notice that the “block VLAN” output shows the VLANs actually blocked, while the “configured” outputs show only what is configured. The configuration only exists on the primary edge port, which is why ME1 doesn’t show it.

```

ME3#show interfaces port-channel 13 rep detail | include Block
Blocked VLAN: 1-99,102-4094
Configured Load-balancing Block Port: 0011001D4692F700
Configured Load-balancing Block VLAN: 100-101

```

```

ME1#show interfaces fast 0/15 rep detail | include Block
Blocked VLAN: 100-101
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none

```

Based on this output, we quickly verify the CAM tables. Since VLAN 101 is blocked on ME1 port 15, ME1 should reach ME2’s VLAN 101 SVI via its LACP bond to ME3. That is to say, it should take the “long way” around the switched network. However, VLAN 102 traffic should go direct over port 15 to ME2. We can check the ARP cache and CAM table on ME1 to confirm this. VLAN 101 entries are in green and VLAN 102 entries are in yellow.

```

ME1#show ip arp | include 0\0\2
Internet 101.0.0.2 0 04c5.a453.d842 ARPA Vlan101
Internet 102.0.0.2 0 04c5.a453.d843 ARPA Vlan102

ME1#show mac address-table dynamic | include 04c5.a453.d84[23]
101 04c5.a453.d842 DYNAMIC Po13
102 04c5.a453.d843 DYNAMIC Fa0/15

```

Next, we will use the numbering method. We will block ME2 port 13 for VLANs 100 and 101. We can use the number 5 (distance from primary edge) or -2 (distance from secondary edge) for the same effect. The topology will not change unless we manually preempt it again, or configure a preempt delay. To trigger this, I unplug ME1 port 15, which isn’t part of this VLAN load balancing scheme. It should not matter since the BPA elections will ultimately block the port we specify below, along with the primary edge port.

```

! ME3
interface Port-channel13

```

```
rep preempt delay 15
rep block port -2 vlan 100-101
```

After plugging the cable back in, we can see that it takes 15 seconds for the VLAN load balancing to start. 15 seconds is the minimum timer, so the classic REP ring behavior will converge at first, then be changed. Ultimately, we see the primary edge port blocking, along with the port we specified. The offset of -2 specifies a port that is adjacent to the secondary edge port; we verify that by checking the topology as well.

```
ME3#show rep topology segment 1
REP Segment 1
BridgeName      PortName      Edge Role
-----
ME3             Po13          Pri  Open
ME1             Po13          Open
ME1             Fa0/15        Alt
ME2             Fa0/15        Open
ME2             Fa0/13        Open
ME3             Fa0/13        Sec  Open
```

```
ME3#show rep topology segment 1
REP Segment 1
BridgeName      PortName      Edge Role
-----
ME3             Po13          Pri  Alt
ME1             Po13          Open
ME1             Fa0/15        Open
ME2             Fa0/15        Open
ME2             Fa0/13        Alt
ME3             Fa0/13        Sec  Open
```

The primary edge port looks similar as it did before, except now it shows the configured offset of -2 instead of an explicit port ID. We see that only VLANs 100 and 101 are allowed through the primary edge port, while all other VLANs are allowed through ME2 port 13.

```
ME3#show interfaces port-channel 13 rep detail | include Block
Blocked VLAN: 1-99,102-4094
Configured Load-balancing Block Port: -2
Configured Load-balancing Block VLAN: 100-101
```

```
ME2#show interfaces fast 0/13 rep detail | include Block
Blocked VLAN: 100-101
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
```

We quickly confirm this on ME2 by looking at the MAC addresses in the CAM table for ME3 in VLAN 100 and VLAN 103. Traffic in VLAN 103 (and most other VLANs) goes directly to ME3 via port 13, but traffic for VLANs 100 and 101 goes the long way through ME1 via port 15.

```
ME2#show ip arp | include 10[03]\.0\.0\.3
Internet 100.0.0.3          6  001f.9d0b.16c1  ARPA  Vlan100
Internet 103.0.0.3          0  001f.9d0b.16c4  ARPA  Vlan103

ME2#show mac address-table dynamic | include 001f.9d0b.16c[14]
100  001f.9d0b.16c1  DYNAMIC  Fa0/15
103  001f.9d0b.16c4  DYNAMIC  Fa0/13
```

The last VLAN load balancing configuration option is to rely on the previously-configured “preferred” port. We configured this on the secondary edge port earlier. We quickly verify this again.

```
ME3#show interfaces fast 0/13 rep detail | include Prefer
Segment-id: 1 (Preferred Edge)
Preferred flag: Yes
```

On the primary edge port, we remove the offset option and use the preferred option instead. This is more dynamic since now the user can just move the “preferred” option around the ring to make adjustments, rather than use port IDs or neighbor offsets.

```
! ME3
interface Port-channel13
 rep block port preferred vlan 100-101
```

The result of this configuration is that both edge ports are alternate ports for complementary VLAN sets. I quickly unplug a cable and plug it back in on ME2; either link is fine. Looking at the REP topology summary after waiting 15 seconds for VLAN load balancing to start, this looks incorrect since both edges are blocking. One may think that the network is dysfunctional since no traffic can ever leave the REP ring, but this is normal for VLAN load balancing.

```
ME3#show rep topology segment 1
REP Segment 1
BridgeName      PortName      Edge Role
-----
ME3             Po13          Pri  Alt
ME1             Po13          Open
ME1             Fa0/15        Open
ME2             Fa0/15        Open
ME2             Fa0/13        Open
ME3             Fa0/13        Sec  Alt
```

The interface details are predictable as the configuration is based on the “prefer” flag, and the VLANs allowed are complementary.

```
ME3#show interfaces port-channel 13 rep detail | include Block
Blocked VLAN: 1-99,102-4094
Configured Load-balancing Block Port: prefer
Configured Load-balancing Block VLAN: 100-101
```

```
ME3#show interfaces fast 0/13 rep detail | include Block
Blocked VLAN: 100-101
Configured Load-balancing Block Port: none
Configured Load-balancing Block VLAN: none
```

We quickly verify that forwarding occurs according to this REP topology. ME1 in VLAN 100 is reachable via the LACP bond while ME1 in VLAN 102 is reachable via the indirect path through ME2. Personally, this kind of load balancing scheme is easiest to understand. If you make the secondary edge port the preferred port, then use the “prefer” option on the primary edge port, the forwarding paths are simple. Traffic will either flow through one edge port of the other and it’s very easy to determine which way the traffic is going. This is especially useful in “open segments” which are described next. The configurations for the REP ring segment are presented below separately.

```
ME3#show ip arp | include 10[02]\.0\.0\.1
Internet 100.0.0.1      0 001d.4692.f741  ARPA  Vlan100
Internet 102.0.0.1      0 001d.4692.f743  ARPA  Vlan102

ME3#show mac address-table dynamic | include 001d.4692.f74[13]
100 001d.4692.f741  DYNAMIC Po13
102 001d.4692.f743  DYNAMIC Fa0/13
```

Next, we modify the architecture slightly to introduce the REP open segment. A fourth switch (Cisco Catalyst 3560G) has been introduced to the ring, with produces a square. This switch is not REP-capable but will run RPVST+ and serve as the gateway into the rest of the notional layer 2 domain. Although REP is not compatible with STP, it can interwork seamlessly with it at the boundaries. ME2 and ME3 are connected to this C3560. The diagram is shown below again for reference.

We will make an edge port adjustment on ME2 by introducing a new option. We can specify the “uplink” port towards the C3560 as an edge port, but clarify that there will be no REP neighbor on it. This is loosely analogous to an IGP passive-interface, but in this case, the port is part of the REP ring. The benefit of this approach is that ME2 does not need to run STP for any VLANs now. On ME3, we will leave the primary edge port on the LACP bond to ME1, which means its uplink port will run STP. These uplink ports only carry VLANs 1 and 100-103, not the REP admin VLAN 29. This confines the BPAs to the REP ring. C3560 is the root for all VLANs and the basic configurations are shown below. Not shown are 4 test SVIs on C3560 for VLANs 100-103 which are used to test connectivity to the ME SVIs.

```
! ME2
interface FastEthernet0/15
  rep segment 1

interface FastEthernet0/23
  description TO C3560
  port-type nni
  switchport trunk allowed vlan 1,100-103
  switchport mode trunk
  rep segment 1 edge no-neighbor preferred
  rep stcn stp

! ME3
interface FastEthernet0/21
  description TO C3560
  port-type nni
  switchport trunk allowed vlan 1,100-103
  switchport mode trunk
  spanning-tree guard loop

! C3560
spanning-tree vlan 1-4094 priority 0

interface GigabitEthernet0/21
  description TO ME3
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 1,100-103
  switchport mode trunk
  switchport nonegotiate
  spanning-tree guard root

interface GigabitEthernet0/23
  description TO ME2
  switchport trunk encapsulation dot1q
  switchport trunk allowed vlan 1,100-103
  switchport mode trunk
  switchport nonegotiate
  spanning-tree guard root
```

We first begin by verifying the REP topology. VLAN load balancing should still be in effect based on the “prefer” flag, which is still set on the secondary edge port. However, ME3 displays a syslog message that says the configuration is now invalid. In order for VLAN load balancing to work, the port specified must have a REP neighbor (I assume). The topology shows only one alternate port, which implies VLAN load balancing is disabled. The asterisk next to the edge port role means that there is no neighbor.

```
! ME3
%REP-5-PREEMPTIONFAIL: can not perform preemption on segment 1 due to invalid
Load-balancing block port
```

```
ME3#show rep topology segment 1
REP Segment 1
BridgeName      PortName      Edge Role
-----
ME3             Po13          Pri  Open
ME1             Po13          Open
ME1             Fa0/15        Open
ME2             Fa0/15        Alt
ME2             Fa0/23        Sec* Open
```

To fix this, we could move the preferred port to somewhere else, or use the port ID / neighbor offset method. I will use the neighbor offset of 4, which selects ME2 port 15. A value of -2 would have also worked.

```
ME3#show rep topology segment 1 detail | section ME2, Fa0/15
ME2, Fa0/15 (Intermediate)
  Alternate Port, some vlans blocked
  Bridge MAC: 04c5.a453.d800
  Port Number: 011
  Port Priority: 000
  Neighbor Number: 4 / [-2]
```

```
! ME3
interface Port-channel13
 rep block port 4 vlan 100-101
```

Next, we preempt the topology to enable VLAN load balancing. ME2 port 15 is now blocking VLANs 100 and 101 while the primary edge port blocks all other VLANs.

```
ME3#rep preempt segment 1
The command will cause a momentary traffic disruption.
Do you still want to continue? [confirm]y
Proceeding with Manual Preemption
```

```
ME3#show rep topology segment 1
```

REP Segment 1

BridgeName	PortName	Edge	Role
ME3	Po13	Pri	Alt
ME1	Po13		Open
ME1	Fa0/15		Open
ME2	Fa0/15		Alt
ME2	Fa0/23	Sec*	Open

Another important aspect of REP/STP interworking is topology change notification (TCN). REP has its own TCN mechanism for convergence, but STP has a TCN BPDU as well. Upon receipt of the TCN, a switch will reduce its MAC address aging timers from the default of 300 seconds to 35 seconds (max age plus forward delay time using default timers). This doesn't clear the current CAM table in regular STP, but it does in RSTP. It would be ideal if REP could inform the STP network about changes in the REP segment so that STP switches can age-out stale MAC addresses after a topology change. Because the segment has two ends, traffic that may have been flowing through one edge port was quickly transition to the other edge port, which is why the STP TCN propagation is useful. We will configure the REP segment TCN (STCN) to be reflected as an STP TCN on ME2 and ME3; notice that ME2 configures this on the port facing C3560 while ME3 does not. The command must go on the REP edge port regardless of whether the port is REP-facing (ME3) or STP-facing with no neighbor (ME2).

```
! ME2
interface FastEthernet0/23
 rep stcn stp
```

```
! ME3
interface Port-channel13
 rep stcn stp
```

We can see the details of the TCN propagation within the REP segment using the interface show commands. At present, the network is stable, so no TCNs have been sent. We can see that the STCN to STP TCN propagation has been enabled on this interfaces.

```
ME3#show interfaces port-channel 13 rep detail | include TCN
STCN Propagate to: STP
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
```

```
ME2#show interfaces fast 0/23 rep detail | include STCN
STCN Propagate to: STP
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 0
```

Based on the VLAN load-balancing scheme, traffic from C3560 to ME1 on VLAN 100 should flow through ME3 (primary edge port) and traffic to ME1 on VLAN 102 should flow through ME2 (secondary edge port). VLAN 100 is shown in yellow and VLAN 102 is shown in green.

```
C3560#show ip arp | include 10[02]\.0\.0\.1_
Internet 100.0.0.1          0 001d.4692.f741 ARPA Vlan100
Internet 102.0.0.1          0 001d.4692.f743 ARPA Vlan102

C3560#show mac address-table dynamic | include 001d.4692.f74[13]
100 001d.4692.f741 DYNAMIC Gi0/21
102 001d.4692.f743 DYNAMIC Gi0/23
```

On ME1, I shutdown port 15 which triggers a TCN. We can see the counter increment on both ME2 and M3 to represent this BPA activity.

```
ME3#show interfaces port-channel 13 rep detail | include TCN
STCN Propagate to: STP
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 1
```

```
ME2#show interfaces fast 0/23 rep detail | include STCN
STCN Propagate to: STP
BPA (STCN, LSL) TLV rx: 0, tx: 0
BPA (STCN, HFL) TLV rx: 0, tx: 1
```

With debugging enabled on C3560, we can see the TCNs being received on every VLAN allowed on the trunk. Because the network is so small, the TC event (with respect to signaling) ends immediately.

```
C3560#debug spanning-tree switch general
Spanning Tree Switch Shim general debugging is on

STP SW: VLAN1: topology change over - this bridge is root
STP SW: VLAN100: topology change over - this bridge is root
STP SW: VLAN101: topology change over - this bridge is root
STP SW: VLAN102: topology change over - this bridge is root
STP SW: VLAN103: topology change over - this bridge is root
```

Checking the STP details for VLAN 100 as an example, we can see the TC flag is still set. This flag remains set for 35 seconds (max age plus forward delay) and effectively flushes the CAM table for this VLAN when the TCN is received. If we check the command after 35 seconds, we see the flag is cleared.

```
C3560#show spanning-tree vlan 100 detail
VLAN0100 is executing the rstp compatible Spanning Tree protocol
Bridge Identifier has priority 0, sysid 100, address 0023.5dc9.5a80
Configured hello time 2, max age 20, forward delay 15, transmit holdcount 6
We are the root of the spanning tree
```

```

    hello 2, max age 20, forward delay 15
Timers: hello 0, topology change 8, notification 0, aging 300
```

```
C3560#show spanning-tree vlan 100 detail
VLAN0100 is executing the rstp compatible Spanning Tree protocol
Bridge Identifier has priority 0, sysid 100, address 0023.5dc9.5a80
Configured hello time 2, max age 20, forward delay 15, transmit holdcount 6
We are the root of the spanning tree
Topology change flag not set, detected flag not set
Number of topology changes 12 last change occurred 00:00:37 ago
    from GigabitEthernet0/21
Times: hold 1, topology change 35, notification 2
    hello 2, max age 20, forward delay 15
Timers: hello 0, topology change 0, notification 0, aging 300
```

I've also configured a basic SPAN session on C3560 to capture these TCNs as they are flooded from the REP segment onto the C3560 designated ports. I don't need to apply a VLAN filter since I know the REP LSLs aren't being sent to the STP switches on VLAN 1.

```
! C3560
monitor session 1 source interface Gi0/21 , Gi0/23 rx
monitor session 1 destination interface Gi0/22 encapsulation replicate
```

Notice that a single TCN BPDU is sent from the REP primary and secondary edge ports (MAC addresses shown below) towards the STP switch. Even though the TCN propagation was configured on ME3 LACP bond to ME1, the actual TCN BPDU is sourced from the proper uplink interface which is STP-enabled. The exception is VLAN 1; both a PVST and IEEE TCN is sent for this VLAN, which is where the "plus" comes from in PVST+. This means that the STP-aware switch in the network could be running Cisco PVST variations (Cisco multicast MAC destination) or any other vendor that supports the IEEE STP variations without PVST. Even though the REP counters only showed 1 TCN being flooded, that really indicates one REP STCN, which may translate into several STP TCNs if running PVST variants beyond the REP ring. I use a red circle as a marker in the capture below to show the column where the VLAN IDs are shown inside of the TCN BPDUs. In total, we see 12 TCNs, 6 from each REP edge-port.

With the link still broken, C3560 now prefers ME3 for all traffic to ME1 as it is the only available path. Since there is a failure in the REP segment, all ports are opened, including the primary edge port which was recently blocking all VLANs except 100 and 101.

```
C3560#show mac address-table dynamic | include 001d.4692.f74[13]
```

```
100    001d.4692.f741    DYNAMIC    Gi0/21

```

```
ME3#show rep topology segment 1
```

```
REP Segment 1
```

```
Warning: REP detects a segment failure, topology may be incomplete
```

BridgeName	PortName	Edge	Role
ME3	Pol3	Sec	Open
ME1	Pol3		Open
ME1	Fa0/15		Fail

Before continuing, we fix the REP segment by bringing ME1 port 15 back up. There are two other kinds of TCN propagation options to discuss, but not test. We looked at the STP option in detail and saw how it worked. The remaining options are shown below.

1. **Segment:** When there are different REP segments on a single switch, this is used to propagate REP STCNs from one segment to a list of other segments. This would support their CAM table flushes for faster layer 2 data-plane convergence. The command example is below, and assuming this was applied to an interface in REP segment 1, would propagate segment 1 STCNs into the segments specified by this command.

```
rep stcn segment 2-5,6,7
```

2. **Interface:** When REP segments are not terminate on the same switch and might be only “one link” away, this command is useful. Rather than use full-blown STP on a P2P link between two switches where that link is not part of any REP segment, this interface can specify the outgoing interface for the REP STCNs to send. Assuming port 7 was a back to back link between two REP-aware switches, this command could be used to exchanged REP STCNs.

```
rep stcn interface fastEthernet 0/7
```

11.3.2 ITU G.8032

Also known as Ethernet Ring Protection Switching (ERPS), this feature works similar to Cisco's REP but is a standards-based variant. The terminology changes from REP but the general concepts remain the same. A segment is called a "ring" and an independent link between two ring nodes is called a "ring link". The ports that run this protocol on ring links are called "ring ports". The alternate (blocked) port is known as the ring protection link, or RPL. The node that is actually blocking a port is known as the "RPL owner node". Just like REP, a single port in the ring will be blocked (the RPL) to prevent loops in the ring topology. In REP, the port adjacent to the alternate port just looks like an ordinary open port, but in G.8032/ERPS, this port is called the RPL neighbor node. The loose equivalent of REP BPA/EPA messages would be the ring automatic protection switching (R-APS) series of messages. These are passed along the ring to communicate RPL information and other significant events. A failure along the ring triggers an R-APG signal failure (R-APS SF) failure, and when the RPL owner receives this message, the port is immediately unblocked. Just like when a failed port exists in a REP topology, the existing alternate port is immediately opened.

Unlike REP, G.8032 relies on existing Ethernet OAM technologies like connectivity fault management (CFM). Switches participating in ERPS must be part of the same CFM domain as a prerequisite to ERPS working; REP does not have this requirement. It is also recommended to configure CFM MEPs; although this is not required, it allows for additional CFM monitoring. ERPS registers to CFM as a client much like protocols register to BFD. In this way, the CFM process ERPS of failures. ERPS uses CFM continuity check messages (CCM) at the fast rate of one packet of 3.3 ms. This helps ERPS achieve SONET-level performance in terms of HA. Because G.8032 is not supported on the ME3400 series, it is not tested in detail here.

12. Describe broadband forum TR-101 VLAN paradigms (N:1 and 1:1)

The entire purpose of the TR-101 document is to detail how to aggregate DSL connections from the access layer into Ethernet versus ATM. The document provides several options, both for general architecture and encapsulations. This section only shows the VLAN paradigms but other notes from the document are rolled into the SP Architecture section.

TR-101 states that the access nodes (AN) must support both of the following VLAN allocation paradigms:

N:1 - Many-to-one mapping between ports and VLAN. This would mean several downstream (customer) facing ports in the same VLAN, likely because they have subscribed to the same service. For example, they all have the same destination service provider gateway device. The VLAN still has its own independent MAC address-table so that its traffic does not mix with other VLANs. The AN also must have a mechanism to prevent communication between user ports (user isolation). In Cisco ME switches, this is automatically enforced between UNI and ENI ports. In Catalyst switches, the Private VLAN (PVLAN) feature can be used to map secondary VLANs to a primary VLAN; in this case, a collection of

secondary community VLANs or a single secondary isolated VLAN would face towards the customers, while the primary VLAN promiscuous port (or the ME switch's NNI port) faces towards the provider.

Additional restrictions are as follows:

- * Traffic may be received 802.1Q tagged on the user port
- * Traffic must be S-Tagged for C-Tag transparency within the aggregation network (QinQ)
- * The 802.1Q tag value must be preserved as the C-Tag (QinQ)
- * Access Node must apply an S-Tag. Must have a way to multiplex multiple services whether the received traffic was tagged or not.
- * The S-Tag will be common to a TLS instance if switching is performed within the aggregation network.

1:1 - One-to-one binding between a user port and a VLAN. This basically means one VLAN per customer, where a single access port facing a customer is the only UNI in that VLAN. This paradigm is required to support both single and dual 802.1Q tagged frames and also must have the capability to disable MAC address learning. The document references the Independent VLAN Learning (IVL) model described in 802.1Q. Additional restrictions are as follows:

- * Access Node must apply at least an S-Tag (outer tag)
- * Access Node may apply a C-Tag for scalability reasons (QinQ)
- * S-Tag must not be shared across Access Nodes
- * S-Tag/C-Tag pair must be unique within Access Node

The demonstration uses three hardware Cisco ME-3400-24TS-A switches. There are 3 customers which are simulated by ME1. Each of them has a dot1q trunk to the AN, which is ME2, and because I am using a single customer switch to represent 3 customers, each one uses different C-VLANs. I can still demonstrate QinQ tunneling with this approach, but I cannot demonstrate using the same C-VLANs on a physical switch. Customers 1, 2, and 3 use VLANs 10, 20, and 30 respectively. C1 and C2 are both connected to UNI ports on ME2 and use the same S-TAG of 101 for transport across the aggregation switched network. ME3 serves as a backbone switch which also simulates the customer endpoints inside VRFs using jumper cables; the setup is very sloppy at layer 1 but demonstrates the technology. Below is the logical flow, since the physical cabling is less relevant.

C3 connects to an ENI port so that LACP can run, and this uses S-VLAN 102. Since all the ports are UNI ports of some kind, they cannot talk to one another. The sharing of S-tag 101 by multiple customers C1 and C2 represents the N:1 paradigm while the dedicated S-tag of 102 for C3 represents the 1:1 paradigm. This might make sense if C1 and C2 are subscribing to a similar service and have similar SLA requirements, etc, while C3 may later have a requirement to disable MAC learning (RSPAN VLANs perhaps). The relevant configuration for ME1 is shown below. The configuration is monotonous as we must define VRFs, VLANs, and ports to the AN. Notice that C1 and C2 are regular trunk ports with a single C-VLAN allowed, while C3 uses an LACP bond to accomplish the same thing.

```

  ip address 10.255.30.1 255.255.255.0

```

ME2 is really the focus of this test. It defines a set of S-VLANs for QinQ tunneling, but I don't name them for brevity. The port-types are actually realistic and there aren't any crazy workarounds. Facing the customer, the ports are UNI for C1 and C2 and ENI for C3. These are all user-to-network interfaces of sorts, so they cannot communicate with one another, which makes sense for customer-facing links. C1 and C2 are tunneled inside S-VLAN 101 while C3 is tunneled inside S-VLAN 102.

```

! ME2
vlan 101-109

interface FastEthernet0/13
  description C1
  switchport access vlan 101
  switchport mode dot1q-tunnel

interface FastEthernet0/14
  description C2
  switchport access vlan 101
  switchport mode dot1q-tunnel

interface FastEthernet0/15
  description C3
  port-type eni
  switchport access vlan 102
  switchport mode dot1q-tunnel
  channel-protocol lacp
  channel-group 2 mode passive

interface FastEthernet0/16
  description C3
  port-type eni
  switchport access vlan 102
  switchport mode dot1q-tunnel
  channel-protocol lacp
  channel-group 2 mode passive

interface Port-channel2
  description LACP BOND TO CUSTOMER C3
  port-type eni
  switchport access vlan 102

```

```
switchport mode dot1q-tunnel
```

For upstream connectivity to ME3, the backbone switch, we can bond the high-speed 1 Gbps interfaces together. These should be NNI ports which participate in STP, and we will enable loop-guard on the LACP bond to prevent against sudden loss of BPDUs from the upstream switch towards the root. Only S-VLANs are allowed over this link and ME2 does not need to account for any of the C-VLANs as they are tunneled inside dot1q.

```
! ME2
interface GigabitEthernet0/1
  description LACP TO GATEWAY
  port-type nni
  switchport trunk allowed vlan 101-109
  switchport mode trunk
  channel-protocol lacp
  channel-group 1 mode active

interface GigabitEthernet0/2
  description LACP TO GATEWAY
  port-type nni
  switchport trunk allowed vlan 101-109
  switchport mode trunk

interface Port-channel1
  description LACP TO GATEWAY
  port-type nni
  switchport trunk allowed vlan 101-109
  switchport mode trunk
  spanning-tree guard loop
```

ME3 is the other end of the LACP gateway bond and allows the S-VLANs in. It is the root for all S-VLANs, uses root-guard on the port-channel to ensure the downstream designated port never becomes an upstream root port.

```
! ME3
spanning-tree vlan 1-4094 priority 8192

interface GigabitEthernet0/1
  description LACP TO ACCESS NODE
  port-type nni
  switchport trunk allowed vlan 101-109
  switchport mode trunk
  channel-protocol lacp
  channel-group 1 mode passive
```

```

interface GigabitEthernet0/2
  description LACP TO ACCESS NODE
  port-type nni
  switchport trunk allowed vlan 101-109
  switchport mode trunk
  channel-protocol lacp
  channel-group 1 mode passive

interface Port-channel1
  description LACP TO ACCESS NODE
  port-type nni
  switchport trunk allowed vlan 101-109
  switchport mode trunk
  spanning-tree guard root

```

In real life, this traffic would be MPLS-encapsulated and transported to the other end of the network once it hits the network core. In this case, I configure another dot1q-tunnel port to remove the outermost encapsulation from the frames. This is because ME3 is going to respond to the traffic locally for testing purposes. ME3 defines the same VRFs and C-VLANs as ME1 so that the two can communicate. Ports 21/22 and 23/24 are jumped together; ports 22 and 24 are the correctly-configured dot1q-tunnel ports at the remote end of the customer circuit, which removes the S-tag. Ports 21 and 23 simulate the customer switch by processing the customer VLANs. I used two ports because I had two separate S-tags in this test, so S-tag 101 carries VLANs 10 and 20 while S-tag 102 only carried VLAN 30. This is for testing purposes only given a lack of hardware.

```

! ME3

```

First, we ping from ME1 to ME3 within VRF C1. This represents end-to-end customer connectivity inside C-VLAN 10, which was encapsulated inside S-VLAN 101 for transport between ME2 and ME3. Since the ping succeeds, we assume everything is working, and begin verification.

```
ME1#ping vrf C1 10.255.10.3
```

Type escape sequence to abort.

Sending 5, 100-byte ICMP Echos to 10.255.10.3, timeout is 2 seconds:

!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 1/5/9 ms

When ME1 sends traffic to ME2, it does so on port 13 which is forwarding per STP. There is no BPDU exchange between customer and AN as I've filtered BPDUs on the customer side, and the UNI ports never run STP. ENI ports support STP but it is disabled by default; I do not enable it anywhere in this test. ME1 has a CAM entry for ME3's MAC address inside the C-VLAN out of this port.

```
ME1#show spanning-tree vlan 10 interface fa0/13
```

Vlan	Role	Sts	Cost	Prio.Nbr	Type

VLAN0010	Desg	FWD	19	128.15	P2p Edge

```
ME1#show mac address-table dynamic vlan 10
```

Mac Address Table

Vlan	Mac Address	Type	Ports
10	001f.9d0b.16c1	DYNAMIC	Fa0/13

Looking at ME2's CAM for the S-VLAN, we can see this MAC address being identified as learned in VLAN 101. Even though port 13 is not really in VLAN 101, that is the S-tag for that port, so the CAM entry counts for that VLAN. This makes sense since when frames are received for this MAC, ME2 should forward them out port 13, but also remove the topmost dot1q tag. Traffic towards ME3 is forwarding out of the LACP bond towards the gateway switch, which is correct.

```
ME2#show mac address-table dynamic vlan 101
```

Mac Address Table

Vlan	Mac Address	Type	Ports
101	001d.4692.f70f	DYNAMIC	Fa0/13
101	001d.4692.f710	DYNAMIC	Fa0/14
101	001d.4692.f741	DYNAMIC	Fa0/13
101	001f.9d0b.1681	DYNAMIC	Po1
101	001f.9d0b.16c1	DYNAMIC	Po1

When ME3 receives these frames, they arrive on the high-speed Gigabit Etherchannel (GEC) from ME2. The VLAN is 101 since the frames are still double-tagged. The destination MAC address of the frames from ME1 matches the second CAM entry, which is forward out port 24.

```
ME3#show mac address-table dynamic vlan 101
```

Mac Address Table			
Vlan	Mac Address	Type	Ports
101	001d.4692.f741	DYNAMIC	Po1
101	001f.9d0b.16c1	DYNAMIC	Fa0/24

Since ME3 is also the test endpoint, it will see the C-VLAN on its jumped interface. Since ports 23 and 24 are connected, it sees the C-VLAN tag of 10 on port 23.

```
ME3#show mac address-table dynamic vlan 10
Mac Address Table
-----
Vlan    Mac Address      Type      Ports
----    -
10      001d.4692.f741   DYNAMIC   Fa0/23
Total Mac Addresses for this criterion: 1
```

We won't trace the process in the reverse direction or for the other C-VLANs since it is exactly the same. We quickly test that ME3 has reachability to ME1 for the other C-VLANs to ensure they work.

```
ME3#ping vrf C2 10.255.20.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.255.20.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/4/9 ms
```

```
ME3#ping vrf C3 10.255.30.1
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.255.30.1, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/5/9 ms
```

The downside to QinQ in this way is that the switches unaware of the C-VLAN tags, such as ME2, will continue to increase the size of their CAM tables since the C-MACs are still exposed. VLAN 101 shows 2 C-MACs per site and VLAN 102 shows 1 C-MAC per site. This can be resolved with provider backbone bridges (PBB), which are discussed in another chapter.

```
ME2#show mac address-table dynamic vlan 101
Mac Address Table
-----
Vlan    Mac Address      Type      Ports
----    -

```

Additional Reading – Reference configurations “tr101”

13. Describe QoS link fragmentation (LFI), cRTP, and RTP

QoS link fragmentation and interleaving (LFI) is a common technique for slow WAN links to reduce latency for priority traffic. Large data packets, such as seen in an FTP download, take longer to serialize over slow WAN links than small voice packets do. The small voice packets are latency-sensitive while the FTP packets are not. PPP specifically has a mechanism to deal with this that is built into multi-link PPP (MLP or MLPPP). Because multi-link bundles aren’t supported with PPPoE, we will test this using a small GNS3 topology with Cisco 3725 images running 12.4(15)T. R1 is the customer site router with the 512 kbps WAN connection, while R2 is the “Internet” simulator and R3 is a LAN client.

The basic MLP configurations are shown below. R3 is also an NTP server and IP SLA responder which will help when approximating VOIP performance. R1 and R2 share many common configuration parameters mostly related to basic PPP/MLP configuration. The differences are shown below as well, since R2 issues

IP addresses to R1 via IPCP from a local pool. R1 installs a default route back to those addresses, and CSR2 uses a simple static route for customer reachability. R3 has an IP address and default route, which is so basic that it is not shown.

```
! R1 and R2 (common)
interface Serial0/0
  encapsulation ppp
  ppp multilink
  ppp multilink group 2

interface Serial0/1
  encapsulation ppp
  ppp multilink
  ppp multilink group 2

interface Multilink2
  bandwidth 512
  fair-queue 64 256 0
  ppp multilink
  ppp multilink group 2
  max-reserved-bandwidth 100

! R1
interface Multilink2
  ip address negotiated
  no peer default ip address
  ppp ipcp route default

! R2
ip local pool PPPOE_IPV4 10.1.2.100 10.1.2.200

interface Loopback0
  ip address 10.1.2.2 255.255.255.0

interface Multilink2
  ip unnumbered Loopback0
  peer default ip address pool PPPOE_IPV4

ip route 10.0.0.0 255.0.0.0 Multilink2
```

We will conduct basic MLP checks and ensure we have reachability from R2 to R3. R1 shows the multilink bundle as operational with Serial0/0 and Serial0/1 as member interfaces. We can clearly see the local/remote endpoints (hostnames for clarity). We also confirm reachability between the Internet and the LAN client.

Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.1.3.3, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 28/45/104 ms

```

Since this is a simulation, it will be hard to measure real latency on this slow link, but we will work out all the math anyway. First, we must define what a “slow” WAN link is. The formula for determining serialization delay is:

$$\text{Delay (sec)} = \text{size (bits)} / \text{rate (bits/sec)}$$

As an example, a 1500 byte packet (12000 bits) going over a T1 link (1544000 bps) will take about ~8ms (0.008 seconds) to serialize. In our case, since we are using a 512 kbps link, that same sized packet will take about 3 times longer to serialize since the link is about one third as fast. Specifically, $12000 / 512000 \approx 23.4\text{ms}$. While this might not seem like a long time, imagine a tiny VOIP packet stuck behind this giant 1500 packet in the TX ring. It has to wait a relatively long time before it can be serialized.

An effective VOIP SLA will meet the following requirements as recommended by Cisco (and others):

1. Packet loss should be no more than 1 percent.
2. One-way latency (mouth to ear) should be no more than 150 ms.
3. Average one-way jitter should be less than 30 ms.

With stringent requirements like this, VOIP latency must be minimized. A general recommendation for per-link VOIP latency is 10 ms of serialization delay. This is forgivable up to 20 ms per link but is not desirable, especially for long-distance calls where there are many transit links in the path. Incurring more than that will make the cumulative 150 ms target difficult to achieve. That begin said, we can use the combination of the 10 ms per-link target and the serialization delay formula to determine what a “slow” link is. In essence, we want to answer the question “What is the slowest speed that can serialize a 1500 byte packet in 10ms or less”? If a link is faster than this number, many of the techniques discussed in this section are moot, since that “huge” 1500 byte packet serializes very quickly on fast links. To evaluate it, we use a variant of the formula above: **rate = speed * delay = 1.2 Mbps. Despite**

this value, it is commonly understood that 768 kbps (half T1) is the cutoff for a slow link.

Mathematically, a 768 kbps link would take ~15.6 ms to serialize a 1500 packet, this is considered acceptable when combined with LLQ and header compression. Since our link is 512 kbps, we assume this is a slow link.

The first tool to deal with this is an intelligent QoS policy. QoS is covered in detail in another section, but the basic idea is to treat VOIP traffic as low latency by guaranteeing bandwidth for it. In addition, low latency queuing (LLQ) also ensures that this traffic is serviced before any other queue, regardless of their class weights. This makes it a fitting solution for VOIP and other latency-sensitive flows. A sample policy is configured on R1 and attached to the MLPPP interface. For simplicity, we match the first 2 bits of the TOS byte to look for a binary value of 101; this will match IPP5, DSCP CS5, DSCP EF, and any value beginning with 101, which is generally low-latency traffic. Next, a shaper wraps this queue to limit it to 512 kbps as an average rate. The mathematics behind the priority value and shaper are described next.

```
! R1
class-map match-all CMAP_VOICE
  match precedence 5

policy-map PMAP_QUEUE
  class CMAP_VOICE
    priority 45
  class class-default
    fair-queue
    random-detect dscp-based

policy-map PMAP_SHAPE
  class class-default
    shape average 512000 5120 2560
    service-policy PMAP_QUEUE

interface Multilink2
  service-policy output PMAP_SHAPE
```

First, we analyze the value of 45 kbps for the voice reservation. This policy was built on the assumption that exactly two concurrent G.729 VOIP phone calls needed to be supported on this link. We will assume (and test via IP SLA) that the G.729 calls will be 20 byte payloads at a rate of 50 packets/second. The full packet size is much larger when we add all of the overhead: 20 payload + 12 RTP + 8 UDP + 20 IP + 8 PPP = 68 bytes total. 50 packets/second is the rate, and multiplying this by 68 yields 3400 Bytes/second. Converting to bits, this is about 27.2 kbps per phone call. 27.2 kbps multiplied by 2 is 44.4 kbps, so reserving 45 kbps for the LLQ will cover both calls. Recall that Cisco queuing strategies always account for layer 2 overhead, as well as all overhead from upper layer protocols, which is why we must include the 8 bytes of PPP encapsulation.

Next, we examine the shaper configuration. We will assume that the SP will let us burst up to 768 kbps within a single time interval if we have accumulated credit (achieved by not sending at CIR rate in

previous intervals). Since we want to achieve a 10 ms time interval to ensure the shaper “runs” and sends data every 10 ms, we must select a burst committed (Bc) value that works. The relationships between Tc, Bc, Be, CIR, and PIR are shown below.

$$Tc = Bc / CIR$$

$$Tc = (Bc + Be) / PIR$$

First, we solve for Bc using the first formula. Tc is set to 0.01 seconds (10 ms) and CIR is set to 512000 bits/second. Evaluation: $0.01 = Bc / 768000 \rightarrow 0.01 * 512000 = Bc = 5120 \text{ bits}$. Next, we solve for Be using the second formula. This will be used to determine how many bits can we accumulate and send during periods of burst; this involves the PIR which is 768 kbps. Evaluation: $0.01 = (5120 + Be) / 768000 \rightarrow 0.01 * 768000 = 5120 + Be \rightarrow 7860 = 5120 + Be = 2560 \text{ bits}$. We can show the result of our math using the show command below. We can see Tc was evaluated to be 10 ms based on the Bc we computed. The burst excess (Be) is 2560 bits but the PIR of 768 kbps is not explicitly shown.

```

Adapt	Queue	Packets	Bytes	Packets	Bytes	Shaping
Active	Depth			Delayed	Delayed	Active
-	0	139	25548	0	0	no

Although testing the shaper will be difficult, we can ensure G.729 VOIP traffic is matching the voice queue we configured. We can achieve this using IP SLA on R3. We specify a 20 byte packet payload using G.729A (the ‘A’ doesn’t affect the bandwidth and relates only to payload processing) with a TOS of 160, which is IPP5. The codec-interval is 20 ms (1000ms / 50 pps = 20 ms) but that is the default and not shown in the configuration, but I show it below for completeness. Note that the codec-size of 32 is also the default, but since this isn’t a real RTP stream, we must manually account for the 12 RTP bytes. The payload of a real call would be 20 bytes with 12 RTP bytes, but in this case, the payload is 32 bytes with only an additional 8-byte UDP header.

```
! R3
ip sla 3
```

```

udp-jitter 10.1.2.2 16384 source-port 16386 codec g729a codec-size 32 codec-
interval 20
tos 160
timeout 10000
ip sla schedule 3 life forever start-time now

```

Checking R3, we can see the IP SLA operation is successful and we resolve both latency and jitter measurements. As seen later in the IP SLA section, this means that NTP is operational, as is the dynamic IP SLA responder on R2.

```

To further optimize the WAN for our slow 512 kbps link, we can enable LFI. Because large 1500 byte packets will take about 24 ms to serialize, we won't want our VOIP traffic to get stuck behind it. LFI has two main components: fragmentation and interleaving. Fragmentation is often times viewed negatively because it is usually discussed in the context of layer 3 protocols, like IP. IP fragmentation occurs end to end (unless virtual reassembly occurs in the network, which is CPU intensive) but layer 2 fragmentation is local to a link or potentially an entire layer-2 domain. MLPPP can use this to break up large packets into smaller fragments. For example, a 1500 byte packet broken into three 500-byte packets still requires 24 ms to serialize everything, but individually, they take about 8 ms. That is well within the latency range for VOIP traffic on a link, and assuming we can break up large packets, we can squeeze VOIP packets in between them. This is interleaving and is often enabled in conjunction with fragmentation with MLP. **In summary, we can fragment large data packets and interleave small VOIP packets in between them to achieve VOIP SLAs.** The downside of this approach is additional CPU resources to perform the fragmentation/reassembly and a small amount of additional overhead added to each fragment.

Before enabling fragmentation, we need to determine the fragment size. This goes back to the shaper math and the serialization delay, and should be coordinated with other QoS features appropriately. We want to maintain a 10 ms serialization delay on this link for VOIP, so we can extend that logic to ALL packets on the link. Thus, we must find out what is the largest packet we can serialize on a 512 kbps link in 10ms. Evaluation: $0.01 = \text{size} / 512000 \rightarrow 0x01 * 512000 = \text{size} = 5120 \text{ bits}$. **Converting this to bytes, we get 640 bytes.** This sounds about right, since this is a little over one third the size of a 1500 byte packet which took ~24 ms to serialize. PPP can break packets up into fragments of 640 regardless of how large they are, which guarantees that every single packet will take no more than 10 ms to serialize. VOIP packets are only 68 bytes, so those will serialize about 10 times faster at 1 ms. The goal was to ensure that a VOIP packet never gets stuck waiting for more than 10 seconds, so we have to fragment the big packets to meet this goal. Combined with the fragmentation, the shaper running every 10 ms ensures that VOIP packets do not wait long before being serialized. Configuring this on R1 and R2 is simple.

```

! R1 and R2
interface Multilink2
  ppp multilink fragment size 640

```

We can verify this took affect for all member interfaces by checking the MLP details.

```
R1#show ppp multilink active
```

```

Multilink2
  Bundle name: R2
  Remote Endpoint Discriminator: [1] R2
  Local Endpoint Discriminator: [1] R1
  Bundle up for 01:12:44, total bandwidth 3088, load 1/255
  Receive buffer limit 24000 bytes, frag timeout 1000 ms
    0/0 fragments/bytes in reassembly list
    0 lost fragments, 227 reordered
    0/0 discarded fragments/bytes, 0 lost received

    Se0/0, since 01:12:44, 5790 weight, 640 frag size
    Se0/1, since 01:12:44, 5790 weight, 640 frag size

```

MLP is very smart in that it can use multiple physical links in the bundle to serialize the fragments, further reducing latency. We can see this in the debug on R1. R3 sends a single 1000-byte packet, and R1 breaks it up. The fragment of size 648 is the largest packet that can be sent (640 + 8 PPP overhead) which takes a tiny bit longer than 10 ms to serialize. We could account for these 8 bytes by reducing the fragment size to 632, but it's not significant. We can see the fragment sequence numbers increase as well to show fragments as part of the same packet on a per-interface basis.

```

R3#ping 10.1.2.2 size 1000 repeat 1
Type escape sequence to abort.
Sending 1, 1000-byte ICMP Echos to 10.1.2.2, timeout is 2 seconds:
!
Success rate is 100 percent (1/1), round-trip min/avg/max = 64/64/64 ms

```

```

R1#debug ppp multilink fragments
Multilink fragments debugging is on
Se0/0 MLP: O frag 80005212 size 648 encsize 4
Se0/1 MLP: O frag 40005213 size 370 encsize 4
Se0/1 MLP: I frag 400051D7 size 370 encsize 4
Se0/0 MLP: I frag 800051D6 size 648 encsize 4

```

We have not yet enabled interleaving. This is a simple command that enables VOIP packets to be inserted in between other packets. The way PPP knows about packet priorities is using fair-queuing, which MUST be enabled on the multilink bundle for interleaving to work. We configured it earlier since it is off by default on multilink interfaces. Despite having a custom queuing policy on the multilink, we still need the “fair-queue” command, at least in older versions.

```

! R1 and R2
interface Multilink2
  ppp multilink interleave

```

We can verify the configuration was successful by checking the MLP details again. We can see that interleaving is now enabled, which allows the VOIP packets to be woven in between the other packets, assuming they have TOS set appropriately.

```
R1#show ppp multilink active
Multilink2
  Bundle name: R2
  Remote Endpoint Discriminator: [1] R2
  Local Endpoint Discriminator: [1] R1
  Bundle up for 01:24:18, total bandwidth 3088, load 1/255
  Receive buffer limit 24000 bytes, frag timeout 1000 ms
  Interleaving enabled
    0/0 fragments/bytes in reassembly list
    0 lost fragments, 285 reordered
    0/0 discarded fragments/bytes, 0 lost received
    0x562D received sequence, 0x566D sent sequence
  Member links: 2 active, 0 inactive (max not set, min not set)
    Se0/0, since 01:24:18, 5790 weight, 640 frag size
    Se0/1, since 01:24:18, 5790 weight, 640 frag size
```

The final technique is using header compression for RTP. Although this technique throws off some of the math we did earlier, specifically with respect to the LLQ, it isn't a big deal in most cases. First, we will discuss the basics of the RTP header. The three main components of the header, ignoring minor fields like version/flags, are the timestamp, sequence number, and synchronization source (SSRC). The SSRC is a way to identify a source, like an IP address would, but is seldom used in any meaningful way. It could be used to find a looped audio source, potentially. Of greater importance are the timestamps and sequence numbers. This is a way to determine if packets are dropped and to compute delay/latency so that software can attempt to make corrections as necessary.

Before configuring this feature, we will capture the original size of the packets on the MLPPP link. If we debug PPP fragments before header compression, we can see a ton of output for each of the VOIP packets generated by the IP SLA probe on CSR3. I recommend sending this to the buffer. Each fragment is shown as 58 bytes, but this is after the packet is split in half and sent down each MLPPP link. Don't fret on the number 58, just remember it for now.

```
! R1
Se0/0 MLP: I frag C0005018 size 58 encsize 4
Se0/0 MLP: I frag C000501A size 58 encsize 4
Se0/1 MLP: O frag C0005053 size 58 encsize 4
Se0/0 MLP: O frag C0005054 size 58 encsize 4
```

There are two formats available: IETF and IHPC, the latter of which is the default. Since we only expect two phone calls, we can also limit the header compression to conserve resources.

```
! R1 and R2
```

```
interface Multilink2
 ip rtp header-compression iphc-format
 ip rtp compression-connections 2
```

We can confirm the feature is enabled by checking the compression details. We can see most of the packets being compressed with a high hit ratio. Since the packets are small to begin with, they don't compress terribly well, but it does save several overhead bytes. Real G.729 calls would compress very poorly as the codec has already heavily compressed the voice to minimize the bandwidth requirements. It also includes the IP and UDP headers as well, which is shown in the header of the output for clarity. Generally the 40 bytes of overhead (20 IP + 8 UDP + 12 RTP) is compressed to approximately 5 bytes.

```
R1#show ip rtp header-compression multilink 2
RTP/UDP/IP header compression statistics:
Interface Multilink2 (compression on, IPHC, RTP)
  Rcvd: 2009 total, 1977 compressed, 0 errors, 0 status msgs
        0 dropped, 0 buffer copies, 0 buffer failures
  Sent: 2009 total, 1979 compressed, 0 status msgs, 1979 not predicted
        41559 bytes saved, 79157 bytes sent
        1.52 efficiency improvement factor
Connect: 2 rx slots, 2 tx slots,
          9 misses, 0 collisions, 0 negative cache hits, 2 free contexts
          99% hit ratio, five minute miss rate 0 misses/sec, 0 max
```

If we debug PPP fragments again, we can see the fragment size is now 49, which is 9 bytes smaller than before. This is a good indication that RTP header compression did a little bit for us.

```
! R2
Se0/1 MLP: I frag C0002B80 size 49 encsize 4
Se0/1 MLP: O frag C0002B84 size 49 encsize 4
Se0/0 MLP: O frag C0002B85 size 49 encsize 4
Se0/1 MLP: I frag C0002B82 size 49 encsize 4
```

Additional Reading - Reference configurations "lfi-crtip"

14. Describe Multichassis/Clustering High Availability (HA)

The ASR9000 supports many HA mechanisms. Many of these mechanisms work together during RSP/RP failure events, control-plane failure events, and other faults that could cause network outages.

SSO: Stateful switchover. The RSP/RP cards are deployed in an active/standby fashion and SSO allows the state from the active RSP/RP to be written to the backup one so that it can immediately take over if the primary one fails. SSO is complementary (and a prerequisite) for NSF/GR and NSR technologies discussed next. It synchronizes the device configuration and other critical non-routing, non-forwarding related information.

NSF: Non-stop forwarding. During an SSO event, NSF ensures that despite a brief loss of the control plane due to an RSP/RP failure, traffic can still be forwarded. The line-cards still have FIBs and can forward traffic; functions like ARP, BFD, ACL, and QoS can be handled by line-cards as well, so the impact on forwarding transit (non-exception) traffic is minimal. NSF also takes affect when soft reboots of certain software modules occurs, provided the line-cards are not affected. NSF relies on active communication with peers who “help” a failed router recover using a set of special messages that vary per protocol. NSF is also called “Graceful Restart” (GR) for some protocols, and the terms NSF and GR are interchangeable. NSF is available with almost all routing or routing-related technologies, except for RIP.

NSR: Non-stop routing. Like NSF, this maintains the routing protocol information during an SSO event. BGP sessions can remain intact to continue supporting MPLS L3VPN services on a PE router, for example. Unlike NSF/GR, NSR occurs locally on a router using a checkpoint mechanism to synchronize information between RSPs/RPs. It can be used when NSF is not supported on all devices in the network. The peer devices won’t know that anything happened on the device sustaining a failure at all. Neighbor sessions and all pertinent information are migrated between RSP/RP cards when an SSO event occurs without notifying the peer, which is different than NSF. NSR is available with OSPFv2/v3, IS-IS, BGP, LDP routing technologies currently. RVSP-TE, EIGRP, and RIP are not included.

“Process restartability” isn’t so much of a feature as it is a capability. If a process has failed, it will not affect any other process, and can freely be stopped, started, or restarted at any time within IOS XR. Each process runs in a protected address space, and often times a failed process will restart itself (can be controlled manually as well).

The ASR9000 can be clustered together to create a single logical router. This negates the need for complex protocol-based HA schemes since there is only a single router with increased capabilities. The RSPs can be connected directly together using Ethernet Out-of-Band Channel (EOBC) interfaces on the RSP; each RSP has two of these. The idea is that between two routers with two RSPs each, each port will connect to a remote RSP on the other router, creating a full mesh of links between RSPs across the two platforms. This uses the same nV technology used for satellite operations on the ASR9000 and is known as “nV Edge”. These links are used for control information and not for data traffic, which is why high speed interfaces on the line cards must also be identified and connected. These are known as Inter Rack Links (IRLs) which must be at least 10 GbE and be direct layer 1 connections to the remote routers line cards. A minimum of 2 IRLs is required and preferably are connected between different pairs of line cards on each router for extra resiliency. Below are some common failover scenarios:

1. Active RSP failures on the primary node. The backup RSP on the same node detects the failure through the backplane, and becomes the active RSP for the system as a whole. The primary node then informs the backup node of the change via inter-chassis control link messaging.
2. Both the active and backup RSPs on the primary node fail (entire router lost power, for example). The failed router is detected by the UDLD running on the IRLs from the backup node. The backup node then becomes the primary node.

14.1 High Availability (HA) Demonstration (NSF/NSR/GR)

Although many of these features don't make much sense on virtual platforms, the configurations are supported in the parser and some of the feature behaviors are supported. These labs quickly examine the HA configurations for all supported protocols. Recall that GR and NSF are interchangeable terms, and the chapter headers below will use whichever feature name is supported by the parser. For example, in OSPFv2, the command "nsf" is used, while OSPFv3 uses the command "graceful-restart". All of these features share a large unified MPLS topology so that they can be tested concurrently. The network diagram is shown below.

First, I quickly skim the ISIS LSPDB and OSPF LSDB within the IGP. Not all configurations are examined since there are dedicated sections for these features. The goal is to ensure the topology shows all of the proper routers and links at a quick glance. Looking at the ABRs, we can see the entire topology quickly. CSR7 shows the output for the aggregation and core IGPs, while XRV2 shows just its aggregation IGP.

I repeat the same test as above using the MPLS TED show commands. This shows that all routers are TE-enabled with the proper links in the topology. Assuming all IGP links are TE-capable, the TE topology should mirror the IGP topology.

```

R7#show mpls traffic-eng topology level-2 brief | include IGP_Id

```

To ensure MPLS transport will function when TE is not configured, I also spot-check some LDP sessions. Ideally, one would verify all sessions, but for brevity I demonstrate that most of them are functional. Selecting routers with many links is a good way to verify this. Out of 15 links in the network, we can verify 10 quickly using 3 show commands.

```

R9#show mpls ldp neighbor | include Peer

```

```

Peer LDP Ident: 222.0.0.8:0; Local LDP Ident 222.0.0.9:0
Peer LDP Ident: 222.0.0.1:0; Local LDP Ident 222.0.0.9:0
Peer LDP Ident: 222.0.0.14:0; Local LDP Ident 222.0.0.9:0

```

```

R1#show mpls ldp neighbor | include Peer
Peer LDP Ident: 222.0.0.9:0; Local LDP Ident 222.0.0.1:0
Peer LDP Ident: 222.0.0.13:0; Local LDP Ident 222.0.0.1:0
Peer LDP Ident: 222.0.0.12:0; Local LDP Ident 222.0.0.1:0
Peer LDP Ident: 222.0.0.10:0; Local LDP Ident 222.0.0.1:0

```

```

R7#show mpls ldp neighbor | include Peer
Peer LDP Ident: 222.0.0.6:0; Local LDP Ident 222.0.0.7:0
Peer LDP Ident: 222.0.0.11:0; Local LDP Ident 222.0.0.7:0
Peer LDP Ident: 222.0.0.14:0; Local LDP Ident 222.0.0.7:0

```

Next, we will validate the interconnected UMPLS topology. The core IGP is IS-IS level-2 with aggregation IGPs of OSPFv2/v3 and IS-IS level-1. To override the default IS-IS behavior, I apply a pair of filters on CSR7. The attached-bit is never allowed to be set into L1 (which would create a default routing entry), while L1 routes are never allowed to be distributed into L2. Though this would normally break IPv4/v6 reachability, it is suitable for UMPLS since BGP carries those prefixes. MPLS is used to tunnel traffic through routers that don't have the IGP routes, but do have reachability to the ABRs.

```

! CSR7
clns filter-set CLNS_FILTER_CLEAR_ATT permit 49.beef

route-map RM_ATT_BIT permit 10
match clns address CLNS_FILTER_CLEAR_ATT

route-map RM_DENY_ALL deny 10

router isis 222
set-attached-bit route-map RM_ATT_BIT
redistribute isis ip level-1 into level-2 route-map RM_DENY_ALL

```

CSR8 is a traditional RR that transports prefixes between aggregation islands. CSR1, CSR7, and XRv2 are modified RRs that adjust BGP next-hops between AS boundaries. This forces BGP to swap labels (labeled-unicast AFI) between aggregation islands, allowing UMPLS to scale as IGP routes are never redistributed. The only BGP AFI that the ABRs need to support is IPv4 labeled-unicast. We quickly verify that this capability is negotiation between CSR8 and the ABRs.

```

R8#show bgp ipv4 unicast summary | begin ^Neigh
Neighbor      V      AS MsgRcvd MsgSent  TblVer  InQ  OutQ Up/Down  State/PfxRcd
222.0.0.1      4      222   520    520     19    0    0 01:20:43      2
222.0.0.7      4      222   376    374     19    0    0 00:56:37      2
222.0.0.12     4      222   291    308     19    0    0 00:46:44      1

```

```

```

```
R8#show bgp ipv4 unicast neighbors 222.0.0.12 | include ^BGP|MPLS_Label
BGP neighbor is 222.0.0.12, remote AS 222, internal link
  ipv4 MPLS Label capability: advertised and received
```

For L3VPN service, XRv1 and CSR10 are RRs within their aggregation IGP. Other PEs peer with those RRs, and the RRs peer with one another. The cluster-IDs must be different since these aggregation RRs do not service the same set of clients. These RRs will only have reachability to one another once the aggregation/core infrastructures are functional. This is somewhat similar to CSC where the “customer carriers”, or aggregation IGP in this example, must use MPLS encapsulation for their control plane traffic to communicate over the “core carrier”, or core IGP. Both XRv1 and CSR10 have all of their VPNv4/v6 sessions online.

```
RP/0/0/CPU0:XRv1#show bgp vpnv4 unicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent   TblVer  InQ  OutQ  Up/Down  St/PfxRcd

222.0.0.11    4      222    44    44       22    0    0  00:05:00      8
222.0.0.13    4      222    39    48       22    0    0  00:05:23      5
```

Next, I quickly verify that CSR6 and XRv3, which are PEs, have BGP routes towards one another. The next-hops have been adjusted to the local ABRs so that label swapping occurs there. CSR6 only has one ABR servicing its aggregation IGP while XRv3 has two ABRs. Traceroute indicates that the proper number of labels are being imposed: BGP labels on the bottom with LDP labels on top, as necessary. Seeing only a single label during these tests may indicate that the BGP route recursion is not occurring, and remote loopbacks are IGP learned instead. This negatively affects the scalability of BGP.

Several different PE-CE routing protocols are demonstrate in this lab. CSR5 (BGP) and CSR4 (IS-IS) share a VPN, and CSR3 (OSPFv3) and CSR2 (EIGRP) share a VPN. A quick traceroute for IPv4 and IPv6 within each VPN confirms that the general design is functional. Note that IS-IS is not supported for IPv6 inside of a VRF, so only IPv4 is verified there. Since this lab is focused on GR/NSR, we will not trace all LSPs.

```

Now that the basic network has been validated, we can progress to the GR/NSR tests. Note that the CSR1000v does not support SSO, which is a requirement for NSF/GR. Some applications of NSF/GR have value outside of the traditional use-case of having redundancy route processors (RP), but generally, these labs cannot be tested in detail.

Additional Reading – Reference configurations “ha”

14.1.1 IS-IS NSF and NSR

IS-IS supports both NSF and NSR. The NSF capability of IS-IS is signaled using the Restart TLV, which is carried in the hello PDUs used by IS-IS. When an IS-IS router supports NSF, this TLV is included for hellos out of all interfaces to signal support for the feature. Both XE and XR support it by default and it is true regardless of the adjacency’s IS-IS level. We confirm this on CSR7 which participates in multiple IS-IS levels and peers with XE and XR routers.

```

```

Enabling NSF is very simple and the command is the same for XE and XR. We enable this on all IS-IS level-2 and level-1-2 routers. The “ietf” option must be used with the command to enable NSF; this is discussed more later.

```

! CSR1, CSR7, CSR8, CSR9, XRv2, and XRv4
router isis 222
nsf ietf

```

While not very exciting, NSF is not entirely enabled on these routers. Without SSO to synchronize all of the non-routing information between RPs, such as device configurations, NSF cannot realistically work. The routers will already operate in “helper” mode, which can acknowledge that a peer is performing a switchover and continue forwarding traffic (or any control-plane information required) towards it. Using basic show commands, we can verify it is enabled. XR’s only show command appears to be a simple yes/no field inside the general IS-IS protocol details.

```

R7#show isis nsf
Tag 222:
NSF is ENABLED, mode 'ietf'

RP/0/0/CPU0:XRv4#show isis protocol | include Non-stop
Non-stop forwarding: IETF NSF Restart enabled

```

Since the feature is not enabled on CSR6 and XRv1, I use the same show commands to demonstrate the output when NSF is disabled. On XE, this also shows us that SSO is not configured or operational.

```

R6#show isis nsf
Tag 222:
NSF is DISABLED
RP is ACTIVE, standby not ready, RTR chkpt peer not ready, UPD chkpt peer not
ready, bulk sync pending
NSF interval timer expired (NSF OK, checkpoint pending)
Checkpointing disabled, no errors
Local state: ACTIVE, Peer state: DISABLED, Config Mode: non-SSO, Operating
Mode: non-SSO

RP/0/0/CPU0:XRv1#show isis protocol | include Non-stop
Non-stop forwarding: Disabled

```

Debugging NSF, in a stable network, shows the adjacency timer refreshes occurring every 10 seconds, which is the P2P hello timer for IS-IS by default. I color-code the timers to show the difference of 10 seconds across 3 different interfaces.

```

R8#debug isis nsf
IS-IS NSF events debugging is on for router process 222

17:13:35.392: ISIS-NSF (222): Adjacency timer refreshed: GigabitEthernet2.584
17:13:36.781: ISIS-NSF (222): Adjacency timer refreshed: GigabitEthernet2.589
17:13:39.840: ISIS-NSF (222): Adjacency timer refreshed: GigabitEthernet2.582
17:13:44.841: ISIS-NSF (222): Adjacency timer refreshed: GigabitEthernet2.584
17:13:44.973: ISIS-NSF (222): Adjacency timer refreshed: GigabitEthernet2.589
17:13:49.049: ISIS-NSF (222): Adjacency timer refreshed: GigabitEthernet2.582

```

I enable debugging on CSR7 and also clear its ISIS process. As an L1/L2 router, we can see CSR7 trying to establish both types of adjacencies. It iterates through them, bringing up the L1 adjacencies first. The true/false markers indicate what kinds of adjacencies IS-IS needs to establish with each peer. L1

adjacencies are shown in yellow while L2 adjacencies are shown in green. XR does not appear to have an equivalent debug.

```
R7#debug isis nsf
IS-IS NSF events debugging is on for router process 222

R7#clear isis *

%CLNS-5-ADJCLEAR: ISIS (222): All adjacencies cleared
ISIS-NSF (222): Pick ADJ - XRv1 (Gi2.571):

%CLNS-5-ADJCHANGE: ISIS (222): Adjacency to XRv4 (GigabitEthernet2.574) Up,
new adjacency
```

Next, we will configure several minor options. There are several timers associated with NSF. The “T3” timer is used to determine how long to wait before setting the overload bit (similar to OSPF max-metric) when a switchover occurs. “T3” is equivalent to the “restart-time” in other protocols or the “lifetime” in XR. This would force traffic to avoid a particular node by causing IGP to converge around it. The “interface” timer determines how long to wait for interfaces to come up before completing the restart/switchover. The “interval” timer is a throttle to ensure NSF restarts to do not happen too quickly, and serves as a hold-down time between them. XR allows you to define the interface timer (T1) which defines how long to wait before resending an unacknowledged restart attempt. This should be a few seconds, and I adjust it to 5. The expiration counter tells IS-IS to stop trying after 3 attempts. These timers do not appear in any obvious show commands. They are demonstrated here to show NSF’s granularity.

```

! CSR7
router isis 222
  nsf interval 7
  nsf interface wait 15
  nsf t3 manual 60

router isis 222
  nsf lifetime 60
  nsf interface-timer 5
  nsf interface-expires 3

```

Enabling NSR is less straightforward than NSF. The primary difference between IS-IS NSR and NSF is that NSF is an IETF standard that involves interactions between routers. The capability is signaled via the Restart TLV and routers are expected to know when peers switchover. NSR is local-only and does not signal anything to remote peers. The configuration for XE and XR is below. This uses the “cisco” keyword as it was developed before IETF NSF.

```

! CSR6 and XRv1
router isis 222
  nsf cisco

```

When this is configured on the CSR1000v, several errors are printed as shown below. This is followed by syslog messages every 60 seconds as well. I assume this is because the virtual platform does not support it, or possibly because SSO is not configured (also unsupported). Despite these errors, the configuration command can remain in the configuration for reference.

```

R6(config-router)#nsf cisco
Adjacency and LSP information learned from interface GigabitEthernet2.561
cannot be checkpointed due to an interface encoding error.
Adjacency and LSP information learned from interface GigabitEthernet2.567
cannot be checkpointed due to an interface encoding error.

```

Please verify that these interface types are supported for NSF in this release. If so, report the problem to the TAC.

```

%CLNS-3-NSF_CP_IDB_ENCODE_FAIL: ISIS (222): Interface Gi2.561 cannot be
encoded for nsf cisco
%CLNS-3-NSF_CP_IDB_ENCODE_FAIL: ISIS (222): Interface Gi2.567 cannot be
encoded for nsf cisco

```

CSR6 still reports NSF as being enabled, but this is effectively NSR when the mode is “cisco”.

```

R6#show isis nsf
Tag 222:
NSF is ENABLED, mode 'cisco'

```

```
RP is ACTIVE, standby not ready, RTR chkpt peer not ready, UPD chkpt peer not ready, bulk sync pending
NSF interval timer expired (NSF restart enabled)
Checkpointing disabled, no errors
Local state: ACTIVE, Peer state: DISABLED, Config Mode: non-SSO, Operating Mode: non-SSO
```

XRv1 appears to accept the command without complaint, but the feature is still inoperable.

```
RP/0/0/CPU0:XRv1#show isis protocol | include Non-stop
Non-stop forwarding: Cisco Proprietary NSF Restart enabled
```

14.1.2 OSPFv2 NSF and NSR

OSPFv2 NSF and NSR are similar to IS-IS in concept. NSF requires some extensions to OSPF (IS-IS used a Restart TLV, which isn't really an extension) so that the peer routers remain aware of the restarting router. When the router performs a switchover, the neighbors will continue to sustain the existing LSA1 information that describes the network topology. This allows traffic to continue forwarding through the router until the grace period expires. OSPF uses new "grace LSAs", which are link-local opaque LSAs containing the grace period time in their payloads. This is how NSF information is exchanged between routers, and being link-local in scope, they are not flooded throughout the area/domain. The configuration is identical to IS-IS, and is also the same on XE and XR.

```
! CSR1 and XRv2
router ospf 222
nsf ietf
```

XE has a number of verification methods while XR does not. Of note, NSF "helper" support is enabled by default in both platforms, which is valuable on virtual routers. If they were peered with hardware routers that actually supported SSO/NSF, they could honor the received grace LSAs and react accordingly. XE clearly tells us that NSF is not operating due to SSO not being configured.

```
R1#show ip ospf | include NSF|IETF
IETF Non-Stop Forwarding enabled
IETF NSF helper support enabled
Cisco NSF helper support enabled
```

```
R1#show ip ospf nsf
Routing Process "ospf 222"
IETF Non-Stop Forwarding enabled
  restart-interval limit: 120 sec
  Router is not operating in SSO mode
  Global RIB has not converged yet
IETF NSF helper support enabled
Cisco NSF helper support enabled
  OSPF restart state is NO_RESTART
Handle 140512595585760, Router ID 222.0.0.1, checkpoint Router ID 0.0.0.0
```

```
Config wait timer interval 10, timer not running
Dbase wait timer interval 120, timer not running
```

```
RP/0/0/CPU0:XRv2#show ospf | include Non-Stop
Non-Stop Forwarding enabled
```

```
RP/0/0/CPU0:XRv2#show protocols ospf | include Non-Stop
Non-Stop Forwarding: Enabled
```

We also see that the default restart interval is 2 minutes. If the neighbor does not complete switchover during that time, the helper routers will update the LSA1s to cause a reconvergence event. Setting this timer too short may not give the switching router enough time to complete the SSO process. Setting it too long may create a longer black hole if the router legitimately fails and cannot fail over, yet somehow fails to signal it. For demonstration, I increase the timer to 10 minutes on both CSR1 and XRv2. Note that this “restart-interval” is equivalent in purpose to the “T3” timer in IS-IS.

```
! CSR1
router ospf 222
 nsf ietf restart-interval 600

! XRv2
router ospf 222
 nsf lifetime 600

R1#show ip ospf nsf
Routing Process "ospf 222"
IETF Non-Stop Forwarding enabled
 restart-interval limit: 600 sec
Router is not operating in SSO mode
Global RIB has not converged yet
[snip]
```

We can also adjust a router’s willingness to be a helper for NSF. The pre-standard NSF version described by Cisco is not discussed in detail here, but unlike IS-IS, “nsf cisco” does not enable NSR. It was a proprietary Cisco implementation that extended OSPF; it was not internal-only as NSR is. XRv2 disables the helper capability for IETF NSF while CSR1 disables it for the Cisco version. You cannot disable helper support for Cisco NSF on XR.

```
! XRv2
router ospf 222
 nsf ietf helper disable

! CSR1
router ospf 222
 nsf cisco helper disable

R1#show ip ospf nsf | include helper
```

```
IETF NSF helper support enabled
Cisco NSF helper support disabled
```

Next, we configure OSPF NSR on XRv3 and CSR10. This actually uses the “nsr” command which simplifies the logic as compared to IS-IS NSR (using the command “nsf cisco”). This is good for routers in a heterogeneous environment where it is not guaranteed that the peers are NSF-capable. For example, XRv2 is not willing to be an IETF NSF helper, so CSR10 should consider using NSR versus NSF. The configuration is a single command with no arguments, and there are no other options to tune.

```
! CSR10 and XRv3
router ospf 222
nsr
```

XE has a rich set of show commands to verify NSR. I’ve highlighted several fields that suggest NSR is enabled but inoperable. NSR works by checkpointing the routing state and synchronizing that to the standby RP internally. Such checkpoints cannot be synchronized when there is only one RP.

```
R10#show ip ospf nsr
Active RP
Operating in simplex mode
Redundancy state: ACTIVE
Peer redundancy state: DISABLED
Checkpoint peer not ready
Checkpoint messages enabled
ISSU negotiation not complete
ISSU versions not compatible

Routing Process "ospf 222" with ID 222.0.0.10
NSR configured
Checkpoint message sequence number: 0
Standby synchronization state: unsynchronized
Bulk sync operations: 0
Next sync check time: -
LSA Count: 18, Checksum Sum 0x000A1D2B
```

Assuming checkpoints were being generated, the statistics below would have non-zero values. This can be used to verify the synchronization within a router is functional.

```
R10#show ip ospf nsr statistics
Pending checkpoint requests (current/max): 0/0
Pending checkpoint messages (current/max): 0/0

Routing Process "ospf 222" with ID 222.0.0.10
Pending checkpoint requests (current/max): 0/0
Pending checkpoint messages (current/max): 0/0
Time spent scheduling bulk syncs (max): 0 ms
```

```
Time spent in checkpoint loop (average/max): 0/0 ms
Checkpoint loop interruptions: 0
```

XR validation is limited to a single line of output, but this confirms the feature is enabled.

```
RP/0/0/CPU0:XRv3#show ospf | include NSR
NSR (Non-stop routing) is Enabled
```

14.1.3 OSPFv3 GR and NSR

OSPFv3 is very similar to OSPFv2 in terms of HA. One notable difference is that OSPFv3 calls NSF “graceful-restart”, but the terms NSF and GR are interchangeable. To configure NSF/GR, we generally substitute the word “nsf” for “graceful-restart” and the command syntax is similar to OSPFv2. There is no Cisco proprietary feature in OSPFv3, so differentiating Cisco from IETF is not necessary. I enable GR on all routers in the right-most aggregation IGP. I also adjust the restart-interval to 5 minutes, allowing any switching routers some extra time to complete the switchover.

```
! CSR1 and CSR10
router ospfv3 222
 graceful-restart restart-interval 300
```

```
! XRv2 and XRv3
router ospfv3 222
 graceful-restart
 graceful-restart lifetime 300
```

We can verify OSPFv3 GR using some simple show commands on XE and XR. Just like OSPFv2, XE provides more detail about the feature than XR. Both platforms also support GR helper mode by default, which could be valuable on virtual routers that peer with physical routers. There aren’t many timers to adjust with this feature, either.

```
R10#show ospfv3 graceful-restart

      OSPFv3 222 address-family ipv6 (router-id 222.0.0.10)

Graceful Restart enabled
restart-interval limit: 300 sec
Router is NOT running in SSO mode
Graceful Restart helper support enabled
Number of neighbors performing Graceful Restart is 0
```

```
RP/0/0/CPU0:XRv2#show ospfv3 | include Grace
Graceful Restart enabled
```

To test OSPFv3 NSR, I will use the PE-CE connection between CSR3 and CSR6. CSR6 disables GR helper mode, which means CSR3 should support NSR (heterogeneous environment). CSR6 could technically run GR since CSR3 did not disable helper mode, but for consistency, both PE and CE use NSR over GR.

```
! CSR6
router ospfv3 3
  nsr
  graceful-restart helper disable

! CSR3
router ospfv3 3
  nsr
```

Before verifying NSR, we verify that GR helper mode is enabled on CSR3 (default) and disabled on CSR6. This is the main motivation for wanting to use NSR on CSR3 specifically. Since NSR can be VRF-aware, we must issue the proper show command to verify this on CSR6.

```
R3#show ospfv3 graceful-restart
      OSPFv3 3 address-family ipv4 (router-id 3.3.0.1)
Graceful Restart helper support enabled
      Number of neighbors performing Graceful Restart is 0

      OSPFv3 3 address-family ipv6 (router-id 3.3.0.1)
Graceful Restart helper support enabled
      Number of neighbors performing Graceful Restart is 0

R6#show ospfv3 vrf OSPF graceful-restart
      OSPFv3 3 address-family ipv4 vrf OSPF (router-id 10.3.6.6)
Graceful Restart helper support disabled

      OSPFv3 3 address-family ipv6 vrf OSPF (router-id 10.3.6.6)
Graceful Restart helper support disabled
```

Like OSPFv2, XE provides great detail regarding NSR state and behavior. I highlight the important lines, just as in OSPFv2, which indicate that NSR is configured but not operational. NSR is configured for both IPv4 and IPv6 AFIs automatically.

```
R6#show ospfv3 vrf OSPF nsr
Active RP
Operating in simplex mode
Redundancy state: ACTIVE
Peer redundancy state: DISABLED
Checkpoint peer not ready
Checkpoint messages enabled
ISSU negotiation not complete
ISSU versions not compatible
```

```
OSPFv3 3 address-family ipv4 vrf OSPF (router-id 10.3.6.6)
NSR configured
Checkpoint message sequence number: 0
Standby synchronization state: unsynchronized
Bulk sync operations: 0
Next sync check time: -
LSA Count: 10, Checksum Sum 0x00078C5F
```

```
OSPFv3 3 address-family ipv6 vrf OSPF (router-id 10.3.6.6)
NSR configured
Checkpoint message sequence number: 0
Standby synchronization state: unsynchronized
Bulk sync operations: 0
Next sync check time: -
LSA Count: 10, Checksum Sum 0x00055A60
```

NSR statistics regarding the checkpoints are available, but unpopulated as the feature is not properly enabled.

```
R6#show ospfv3 vrf OSPF nsr statistics
Pending checkpoint requests (current/max): 0/0
Pending checkpoint messages (current/max): 0/0
```

```
OSPFv3 3 address-family ipv4 vrf OSPF (router-id 10.3.6.6)
Pending checkpoint requests (current/max): 0/0
Pending checkpoint messages (current/max): 0/0
Time spent scheduling bulk syncs (max): 0 ms
Time spent in checkpoint loop (average/max): 0/0 ms
Checkpoint loop interruptions: 0
```

```
OSPFv3 3 address-family ipv6 vrf OSPF (router-id 10.3.6.6)
Pending checkpoint requests (current/max): 0/0
Pending checkpoint messages (current/max): 0/0
Time spent scheduling bulk syncs (max): 0 ms
Time spent in checkpoint loop (average/max): 0/0 ms
Checkpoint loop interruptions: 0
```

14.1.4 BGP GR and NSR

Unlike many other forms of GR/NSF/NSR on virtual platforms, BGP GR actually has value. BGP GR's primary purpose is the same as the other protocols: don't introduce churn into the protocol while a router switches over, specify a grace period, and continue forwarding as normal. BGP accomplishes this by introducing the End-of-RIB (EoR) marker, as well as a new "Graceful Restart" capability.

RFC 4724 makes specific mention that this EoR marker can be valuable to speed up convergence as well.

Because it marks the end of RIB, it is effectively an explicit signal to the peer that the BGP UPDATE messages have ceased. Rather than wait for more updates, a BGP speaker is able to immediately begin

running best-path selections once all peers indicate EoR. Normally this period is controlled by the “update-delay” timer which specifies how long BGP can stay in read-only mode. The EoR marker is a more event-driven mechanism for starting the best-path selection process. Specifically, the EoR marker for IPv4 is an UPDATE message with no prefixes. For all other AFIs, it uses the MP_UNREACH_NLRI, a multi-protocol extension used for identifying unreachable prefixes (withdrawals). No prefixes are contained inside this message, either.

XR advertises the BGP GR capability to all peers by default. We can check CSR8 to prove this. CSR8 has GR disabled for all peers by default, yet the capability is advertised from XRv2. This is not an AFI-specific feature and applies to the BGP session in general. Checking XRv1 for VPNv4, we can see it advertises the GR capability to CSR10 and CSR6 by default even though only VPNv4/v6 is negotiated, not IPv4.

```
R8#show bgp ipv4 unicast neighbors | include ^BGP|race
BGP neighbor is 222.0.0.1, remote AS 222, internal link
  Graceful-Restart is disabled
BGP neighbor is 222.0.0.7, remote AS 222, internal link
  Graceful-Restart is disabled
BGP neighbor is 222.0.0.12, remote AS 222, internal link
  Graceful Restart Capability: received
  Graceful-Restart is disabled
```

```
RP/0/0/CPU0:XRv1#show bgp vpnv4 unicast neighbors | utility egrep '^BGP|race'
BGP neighbor is 222.0.0.6
  Graceful Restart (GR Awareness): advertised
BGP neighbor is 222.0.0.10
  Graceful Restart (GR Awareness): advertised
```

To be clear, XR advertises that it is “GR-aware” but the actual feature is not enabled by default in XR. Below, I show the output on XRv2 within the IPv4 labeled-unicast AFI. GR awareness is advertised to the XE peers, and bidirectionally exchanged with the XR peers.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast neighbors | utility egrep
'^BGP|race'
BGP neighbor is 222.0.0.8
  Graceful Restart (GR Awareness): advertised
BGP neighbor is 222.0.0.10
  Graceful Restart (GR Awareness): advertised
BGP neighbor is 222.0.0.13
  Graceful Restart (GR Awareness): advertised and received
```

Next, I enable the feature on XRv2 and re-issue the show command. GR is now “enabled” for each neighbor by default.

```
! XRv2
router bgp 222
```

```
bgp graceful-restart
```

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast neighbors | utility egrep  
'^BGP|race'
```

```
BGP neighbor is 222.0.0.8
```

```
Graceful restart is enabled
```

```
Graceful Restart (GR Awareness): advertised
```

```
Graceful Restart capability advertised
```

```
BGP neighbor is 222.0.0.10
```

```
Graceful restart is enabled
```

```
Graceful Restart (GR Awareness): advertised
```

```
Graceful Restart capability advertised
```

```
BGP neighbor is 222.0.0.13
```

```
Graceful restart is enabled
```

```
Graceful Restart (GR Awareness): advertised and received
```

```
Graceful Restart capability advertised
```

XRv2 will assume that CSR10 is incapable of GR. Whether this is true or not does not matter; below I illustrate explicitly disabling BGP GR for a specific peer. XRv2 continues to notify CSR10 that it is GR-aware, but is not running the feature with CSR10 anymore. GR is still enabled for the other peers as shown below.

```
! XRv2
```

```
router bgp 222
```

```
neighbor 222.0.0.10
```

```
graceful-restart disable
```

```
RP/0/0/CPU0:XRv2#show bgp ipv4 labeled-unicast neighbors | utility egrep  
'^BGP|race'
```

```
BGP neighbor is 222.0.0.8

```

```
Graceful Restart (GR Awareness): advertised
```

```
BGP neighbor is 222.0.0.13
```

```
Graceful restart is enabled
```

```
Graceful Restart (GR Awareness): advertised and received
```

```
Graceful Restart capability advertised
```

Enabling BGP GR on XE is identical, except that BGP sessions must be hard-reset before the changes take effect. I begin with CSR8.

```
! CSR8
```

```
router bgp 222
```

```
bgp graceful-restart
```

```
R8(config-router)#bgp graceful-restart
```

All BGP sessions must be reset to take the new GR config

```
R8#clear bgp ipv4 unicast *
```

Now, CSR8 advertises this capability to all routers. CSR1 and CSR7 are not advertising it yet, but XRv2 always was; CSR8 and XRv2 are now capable of using BGP GR fully with one another. Again, the NSF capabilities of GR still require SSO and redundant RPs, so this would be specific to the routing optimization aspect (via the EoR marker). CSR8 claims GR is enabled for all peers, but the capability should be exchanged bidirectionally first.

```
R8#show bgp ipv4 unicast neighbors | include ^BGP|race
BGP neighbor is 222.0.0.1, remote AS 222, internal link
    Graceful Restart Capability: advertised
    Graceful-Restart is enabled, restart-time 120 seconds, stalepath-time 360
seconds
BGP neighbor is 222.0.0.7, remote AS 222, internal link
    Graceful Restart Capability: advertised
    Graceful-Restart is enabled, restart-time 120 seconds, stalepath-time 360
seconds
BGP neighbor is 222.0.0.12, remote AS 222, internal link
    Graceful Restart Capability: advertised and received
    Graceful-Restart is enabled, restart-time 120 seconds, stalepath-time 360
seconds
```

I quickly enable GR on all other BGP speakers except CSR10 and XRv3. To avoid any inconsistent behavior, I hard-clear all BGP sessions on all BGP routers. CSR8 now shows that the capability is exchanged with all peers. XRv1 exchanges it correct with CSR6, but not CSR10, which is correct. We are assuming CSR10 and XRv13 are not GR capable.

```
! CSR1, CSR6, CSR7, and XRv1
router bgp 222
    bgp graceful-restart
```

```
R8#show bgp ipv4 unicast neighbors | include ^BGP|tart_Cap
BGP neighbor is 222.0.0.1, remote AS 222, internal link
    Graceful Restart Capability: advertised and received
BGP neighbor is 222.0.0.7, remote AS 222, internal link
    Graceful Restart Capability: advertised and received
BGP neighbor is 222.0.0.12, remote AS 222, internal link
    Graceful Restart Capability: advertised and received
```

```
RP/0/0/CPU0:XRv1#show bgp vpnv4 unicast neighbors | utility egrep '^BGP|race'

    Graceful restart is enabled
    Graceful Restart (GR Awareness): advertised
    Graceful Restart capability advertised
    Graceful Restart capability advertised

```

For cleanup, any routers that peer with CSR10 or XRv3 will disable GR towards that peer. This was demonstrated once in XRv2, but I apply it everywhere necessary. It is hard to see the value of BGP GR on Cisco routers with respect to using EoR for routing optimization. This is because they send BGP keepalives as soon as the updates are finished sending, which allows BGP best-path to start sooner. Routers that do not behave this way (such as other vendor products) may benefit. This keepalive technique is not a BGP requirement and is specific to Cisco platforms. When used only for routing convergence optimizations, BGP GR makes more sense in multi-vendor environments. The remainder of this test will focus on the traditional use-case of GR/NSF and not the convergence optimizations.

```

! XRv1
router bgp 222
    neighbor 222.0.0.10
        graceful-restart disable

! XRv2
router bgp 222
    neighbor 222.0.0.13
        graceful-restart disable

! CSR1
router bgp 222
    neighbor 222.0.0.10 ha-mode graceful-restart disable
    neighbor 222.0.0.13 ha-mode graceful-restart disable

```

BGP GR specifies two significant timers: restart-time and stalepath-time. The restart-time begins counting down once a TCP session fails between a pair of peers during an RP switchover. The peer router (not the restarting router) must provide routing information to the new standby RP, and this timer controls how long to wait for a BGP OPEN message from the router that is switching over. It is equivalent to the IGP NSF restart-timers that limit the switchover time. When a router begins an RP switchover, all routes learned from that peer are marked as stale, yet traffic is still allowed to forward through that peer. The stalepath-time controls how long these routes can be used before they are flushed. Normally, it is longer than the restart-time because receiving an OPEN message will happen before total BGP convergence, especially in large networks. When BGP GR is enabled on XR, these timers are explicitly added to the configuration using their default values as shown below. The restart and stale timers are 2 and 6 minutes respectively.

```

! XE default values for BGP GR

```

```
router bgp 222
  bgp graceful-restart restart-time 120
  bgp graceful-restart stalepath-time 360
  bgp graceful-restart
```

This does not occur in XR, so for consistency, I configure these timers on the BGP XR routers manually. XRv3 is excluded since it notionally does not support GR.

```
! XRv1 and XRv2
router bgp 222
  bgp graceful-restart restart-time 120
  bgp graceful-restart stalepath-time 360
```

NSR is less straightforward. On XE, we adjust the HA-mode to SSO in order to enable NSR. On XR, the command is simply “nsr”. Although the goal of NSR is identical to the IGP NSR features, the BGP use-case is focused heavily on PE-CE routing. A common case would be that the CE router does not support BGP GR, which means it cannot “help” the PE. Rather than just configure NSR on the PE, which is supported, it makes sense to leave GR configured and add NSR as well. This will allow the router to be “helped” by iBGP peers within the provider’s network, while also allowing it to not rely on GR if it is unavailable. XRv1 is configured with BGP NSR below, and it’s supported CE, CSR5, was never configured with BGP GR.

```
! XRv1
router bgp 222
  nsr
```

The “show bgp nsr” command prints about 5 pages of output. For brevity, I show the first few stanzas. Most of this output isn’t NSR specific, but lists the critical BGP behaviors that are expected to be consistent when the RP changes. This includes basic fields such as the BGP ASN, BGP router ID, GR capability, and various timers. In this configuration, XRv1 can be protected by iBGP peers via GR and can protect itself using NSR.

```
RP/0/0/CPU0:XRv1#show bgp nsr
BGP Process Information:
BGP is operating in STANDALONE mode

```

I enable NSR on all provider BGP speakers running XE, as well as XRv2 for completeness. Just like BGP GR, this requires a hard reset on all peers for which NSR is configured on XE routers.

```
! CSR1, CSR6, CSR7, and CSR8
router bgp 222
  bgp ha-mode sso

! XRv2
router bgp 222
  nsr
```

Just like before, we should not enable this feature towards CSR4 or XRv3. There is no way to control this on XR, but XE allows it to be disabled on a per-neighbor basis, just like GR.

```
! CSR1
router bgp 222
  neighbor 222.0.0.10 ha-mode sso disable
  neighbor 222.0.0.13 ha-mode sso disable
```

To verify the feature, I begin with CSR8. NSR is being used interchangeably with SSO here, and it is enabled for all peers. The XE peers show a communication failure while the XR peer shows that the feature is not enabled. This is probably a result of different implementations, and since the feature doesn't work on virtual machines anyway, I do not examine the output further.

```
R8#show bgp ipv4 unicast neighbors | include ^BGP|SSO
BGP neighbor is 222.0.0.1, remote AS 222, internal link
SSO is enabled
SSO last disable reason: Application disable (Active)
BGP neighbor is 222.0.0.7, remote AS 222, internal link
SSO is enabled
SSO last disable reason: Communication failure (Active)
BGP neighbor is 222.0.0.12, remote AS 222, internal link
SSO is enabled
SSO last disable reason: Application disable (Active)
```

Like XR, there are custom commands for NSR as well, except they are executed per AFI. The XR commands can also be issued per-AFI, but the global command shown above returns output for all AFIs. The output is very verbose, and most of it is invalid as a result of the feature not being fully supported on the CSR1000v. There are 3 sessions established with NSR enabled, but none of them support SSO.

```
R8#show bgp ipv4 unicast sso summary
Total sessions with stateful switchover support enabled: 0
Total sessions configured with NSR mode and in established state: 3
Total number of times throttle ON by TCP: 0
Total number of times throttle OFF by TCP: 0

```

```
tcp_syncQ: 0, enable_syncQ: 0, update_syncQ: 0
Bulk Sync Done: NO
```

For completeness, we can see CSR6 trying to use NSR towards XRv1 inside the VPNv4/v6 AFI. Although it still fails, this shows that NSR is supported in many AFIs.

```
R6#show bgp vpnv4 unicast all neighbors | include ^BGP|SSO
BGP neighbor is 222.0.0.11, remote AS 222, internal link
SSO is enabled
SSO last disable reason: Application disable (Active)
```

```
R6#show bgp vpnv6 unicast all neighbors | include ^BGP|SSO
BGP neighbor is 222.0.0.11, remote AS 222, internal link
SSO is enabled
SSO last disable reason: Application disable (Active)
```

14.1.5 LDP GR and NSR

Although not a routing protocol, LDP is critical for most MPLS applications. It also has the concept of GR/NSF and NSR for this reason. Because LDP is an overlay protocol of sorts, it is recommended that the underlying protocols in the network that interact with LDP are also GR/NSF-enabled. This includes OSPF, IS-IS, and/or BGP. Similar to the IGP, when LDP GR is enabled without SSO being supported, the router can only operate in “helper” mode to synchronize state with a device that is actively switching over. Enabling SSO is a requirement to achieve literal “nonstop forwarding” with LDP, which we cannot test in a virtual environment. I begin by enabling the feature on all P and PE routers.

```
! CSR1, CSR6, CSR7, CSR8, CSR9, CSR10
mpls ldp graceful-restart

! XRv1, XRv2, and XRv3
mpls ldp
 graceful-restart
```

When applying these changes, XE warns us that GR will not apply for existing LDP sessions, but only new ones. I manually clear all LDP peers on all LDP GR routers to avoid any confusion. XR automatically flaps all LDP peers when the feature is configured, so a manual clearing is not required.

```
R8(config)#mpls ldp graceful-restart
% Previously established LDP sessions may not have graceful restart
protection.
```

When LDP GR is negotiated, we can see the details on both platforms. This reveals several new timers that will be discussed later. For now, we can verify that all peers on CSR9 and XRv2 are GR-enabled, as expected. There are no obvious incompatibilities between XE and XR with this feature. The “connect count” on XRv2 simply counts the number of times the session forms; if a session is cleared, or a peer fails, this number will increment.

```
R9#show mpls ldp graceful-restart
LDP Graceful Restart is enabled
Neighbor Liveness Timer: 120 seconds
Max Recovery Time: 120 seconds
Forwarding State Holding Time: 600 seconds
Down Neighbor Database (0 records):
Graceful Restart-enabled Sessions:
  VRF default:
    Peer LDP Ident: 222.0.0.1:0, State: estab
    Peer LDP Ident: 222.0.0.8:0, State: estab
    Peer LDP Ident: 222.0.0.14:0, State: estab
```

```
RP/0/0/CPU0:XRv2#show mpls ldp graceful-restart
Forwarding State Hold timer : Not Running
```

```
GR Neighbors : 3
```

Neighbor ID	Up	Connect Count	Liveness Timer	Recovery Timer
222.0.0.1	Y	1	-	-
222.0.0.8	Y	2	-	-
222.0.0.10	Y	2	-	-

Alternatively, XE has a command to see some extra detail per-neighbor regarding GR. This lists all GR-enabled peers along with their reconnection timers of 2 minutes.

```
R8#show mpls ldp neighbor graceful-restart
Peer LDP Ident: 222.0.0.9:0; Local LDP Ident 222.0.0.8:0
  TCP connection: 222.0.0.9.12152 - 222.0.0.8.646
  State: Oper; Msgs sent/rcvd: 12/12; Downstream
  Up time: 00:03:10
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
Peer LDP Ident: 222.0.0.12:0; Local LDP Ident 222.0.0.8:0
  TCP connection: 222.0.0.12.14292 - 222.0.0.8.646
  State: Oper; Msgs sent/rcvd: 12/19; Downstream
  Up time: 00:03:10
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
Peer LDP Ident: 222.0.0.14:0; Local LDP Ident 222.0.0.8:0
  TCP connection: 222.0.0.14.43579 - 222.0.0.8.646
  State: Oper; Msgs sent/rcvd: 12/16; Downstream
  Up time: 00:03:06
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
```

To test what this reconnection timer does, we can cause an LDP failure in the network. Clearing all peers on CSR10 triggers a GR event (not shown). If we quickly check XRv3 and CSR1, we can see that their recovery timers start counting down from 2 minutes. Although the peer session forms before 2 minutes, this timer effectively represents the grace period seen in other GR/NSF implementations. If the active RP failed, the session must be restored within those 2 minutes.

```
RP/0/0/CPU0:XRv3#show mpls ldp graceful-restart
Forwarding State Hold timer : Not Running
GR Neighbors : 2
```

Neighbor ID	Up	Connect Count	Liveness Timer	Recovery Timer
222.0.0.1	Y	1	-	-
222.0.0.10	Y	2	Not running	106 sec remaining

```
R1#show mpls ldp graceful-restart
LDP Graceful Restart is enabled
Neighbor Liveness Timer: 120 seconds
Max Recovery Time: 120 seconds
Forwarding State Holding Time: 600 seconds
Down Neighbor Database (1 records):
VRF default:
  Peer LDP Ident: 222.0.0.10:0 [inst 2], Local LDP Ident: 222.0.0.1:0
  Status: recovering (25 seconds left)
  Address list contains 0 addresses:
Graceful Restart-enabled Sessions:
VRF default:
  Peer LDP Ident: 222.0.0.13:0, State: estab
  Peer LDP Ident: 222.0.0.9:0, State: estab
  Peer LDP Ident: 222.0.0.12:0, State: estab
  Peer LDP Ident: 222.0.0.10:0, State: estab
```

XE also generates log messages to show that the session failed and that GR begins its 2 minute countdown. After 2 minutes, the process completes.

```
! CSR1
21:07:49.534: %LDP-5-GR: GR session 222.0.0.10:0 (inst 2): interrupted--
recovery pending
21:07:52.995: %LDP-5-GR: GR session 222.0.0.10:0 (inst 5): starting graceful
recovery
21:09:52.995: %LDP-5-GR: GR session 222.0.0.10:0 (inst 5): completed graceful
recovery
```

The LDP GR timers are not intuitively named. The “neighbor-liveness” timer is the equivalent of the grace period, while the “max-recovery” timer determines how long to continue using stale label bindings after an LDP session is established. A third timer, the “forwarding-holding” timer, determines how long label bindings should be stored after a control plane resets. This sounds very similar to the “max-recovery” timer but begins counting down at the time of failure, not restoration. The defaults for the first two timers is 2 minutes, and the default for “forwarding-holding” is 10 minutes. To test these timers, I adjust them on CSR7 first.

```
! CSR7
mpls ldp graceful-restart timers neighbor-liveness 30
```

```
mpls ldp graceful-restart timers max-recovery 60
mpls ldp graceful-restart timers forwarding-holding 120
```

Before testing anything, we verify that the timers were accepted by the router. CSR7 still has 3 LDP neighbors and adjusting the timers did not cause them to flap.

```
R7#show mpls ldp graceful-restart
LDP Graceful Restart is enabled
Neighbor Liveness Timer: 30 seconds
Max Recovery Time: 60 seconds
Forwarding State Holding Time: 120 seconds
Down Neighbor Database (0 records):
Graceful Restart-enabled Sessions:
  VRF default:
    Peer LDP Ident: 222.0.0.6:0, State: estab
    Peer LDP Ident: 222.0.0.14:0, State: estab
    Peer LDP Ident: 222.0.0.11:0, State: estab
```

Next, I clear all of CSR7's neighbors, then check their status a few seconds later. We cannot adjust the reconnection timer of 2 minutes, but we see that the max-recovery timer begins counting down as soon as the session is established. I color-code the peers for consistency with other tests.

```
R7#show mpls ldp neighbor graceful-restart
Peer LDP Ident: 222.0.0.6:0; Local LDP Ident 222.0.0.7:0
  TCP connection: 222.0.0.6.646 - 222.0.0.7.21879
  State: Oper; Msgs sent/rcvd: 11/6; Downstream
  Up time: 00:00:17
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
  Down Neighbor Information:
    Status: recovering (42 seconds left)
    Address list contains 0 addresses
Peer LDP Ident: 222.0.0.14:0; Local LDP Ident 222.0.0.7:0
  TCP connection: 222.0.0.14.49261 - 222.0.0.7.646
  State: Oper; Msgs sent/rcvd: 11/13; Downstream
  Up time: 00:00:14
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
  Down Neighbor Information:
    Status: recovering (45 seconds left)
    Address list contains 0 addresses
Peer LDP Ident: 222.0.0.11:0; Local LDP Ident 222.0.0.7:0
  TCP connection: 222.0.0.11.20174 - 222.0.0.7.646
  State: Oper; Msgs sent/rcvd: 11/8; Downstream
  Up time: 00:00:14
  Graceful Restart enabled; Peer reconnect time (msecs): 120000
  Down Neighbor Information:
    Status: recovering (45 seconds left)
    Address list contains 0 addresses
```

Looking at the specific timestamps, we can see exactly 60 seconds pass between the time a peer is established to the time the graceful recovery completes. This removes the stale label bindings from the peer since it is expected that new bindings can be exchanged.

```
! CSR7
21:27:48.559: %LDP-5-GR: GR session 222.0.0.6:0 (inst 4): starting graceful
recovery
21:27:48.559: %LDP-5-NBRCHG: LDP Neighbor 222.0.0.6:0 (4) is UP

21:27:50.958: %LDP-5-GR: GR session 222.0.0.14:0 (inst 5): starting graceful
recovery
21:27:50.958: %LDP-5-NBRCHG: LDP Neighbor 222.0.0.14:0 (5) is UP

21:27:51.699: %LDP-5-GR: GR session 222.0.0.11:0 (inst 6): starting graceful
recovery
21:27:51.699: %LDP-5-NBRCHG: LDP Neighbor 222.0.0.11:0 (6) is UP

21:28:48.559: %LDP-5-GR: GR session 222.0.0.6:0 (inst 4): completed graceful
recovery
21:28:50.959: %LDP-5-GR: GR session 222.0.0.14:0 (inst 5): completed graceful
recovery
21:28:51.698: %LDP-5-GR: GR session 222.0.0.11:0 (inst 6): completed graceful
recovery
```

To see the “neighbor-liveness” timer in action, I clear all LDP peers on CSR7 again. I immediately (within 5 seconds) check the GR status to see that 2 of the neighbors are still down, and one has already recovered. The recovering router has already started its “max-recovery” time, which begins after the session establishes. The liveness timer begins counting down when the peer fails, which is still counting down for XRv1 and XRv4. When the peer is still waiting for a connection, all addresses bound to that LDP are shown in this list until the session reforms.

```
R7#show mpls ldp graceful-restart
LDP Graceful Restart is enabled
Neighbor Liveness Timer: 30 seconds
Max Recovery Time: 60 seconds
Forwarding State Holding Time: 120 seconds
Down Neighbor Database (3 records):
  VRF default:
    Peer LDP Ident: 222.0.0.6:0 [inst 4], Local LDP Ident: 222.0.0.7:0
      Status: recovering (57 seconds left)
      Address list contains 0 addresses:
    Peer LDP Ident: 222.0.0.11:0 [inst 6], Local LDP Ident: 222.0.0.7:0
      Status: waiting for reconnection (25 seconds left)
      Address list contains 3 addresses:
        222.6.11.11      222.7.11.11      222.0.0.11
    Peer LDP Ident: 222.0.0.14:0 [inst 5], Local LDP Ident: 222.0.0.7:0
      Status: waiting for reconnection (25 seconds left)
```

```
Address list contains 5 addresses:
    222.14.9.14      222.7.14.14      222.8.14.14      222.9.14.14
    222.0.0.14
```

Graceful Restart-enabled Sessions:

VRF default:

Peer LDP Ident: 222.0.0.6:0, State: estab

Seconds later, the remaining LDP sessions to XRv1 and XRv4 come up. The output is not shown again as we know the max-recovery timers begin counting down from 60 seconds after the session forms. Next, we will examine the available timers on XR. XR allows us to configure the reconnection-timeout, which is equivalent to the XE neighbor-liveness timer. This specifies how long to wait for the peer to return after a failure. The recovery timer is fixed at 2 minutes where as XE allowed us to adjust this (max-recovery). The forwarding-state-holdtime behaves identically to the forwarding-holding timer.

```
! XRv2
mpls ldp
 graceful-restart reconnect-timeout 60
 graceful-restart forwarding-state-holdtime 150
```

Clearing the LDP peers on XRv2 and immediately looking at the LDP GR status, we can see a similar output as we did on XE. CSR8 comes up quickly and begins counting down from 60, which mimics the max-recovery timer, except it is fixed at 2 minutes. The other peers that are still down, CSR1 and CSR10, count down from the reconnection-timeout of 60 seconds.

```

-----
222.0.0.1                     N    1              52 sec remaining  Not running
222.0.0.8                     Y    3              Not running      118 sec remaining
222.0.0.10                    N    2              52 sec remaining  Not running
```

Last, we examine LDP NSR. Like the other NSR variants, this is used to mask RP failures on a router by handling all of the switchover locally. This can be used in environments where LDP GR is not supported by all platforms. The LDP sessions will not flap during switchover and the entire operation will appear transparent to all LDP peers.

```
! CSR10
mpls ldp nsr
```

```
! XRv3
mpls ldp
 nsr
```

We can verify the NSR configuration by checking the summary information on both routers. Interestingly, CSR10 shows XRv3 as not ready, but XRv3 shows CSR10 as ready. I assume this is an artificiality of the virtual environment.

```
R10#show mpls ldp nsr
LDP Non-Stop Routing is enabled
LDP Non-Stop Routing Sessions:
  VRF default:
    Peer LDP Ident: 222.0.0.1:0      State: Not Ready
    Peer LDP Ident: 222.0.0.12:0     State: Not Ready
    Peer LDP Ident: 222.0.0.13:0     State: Not Ready
```

```
RP/0/0/CPU0:XRv3#show mpls ldp nsr summary
Sessions:
  Total: 2, NSR-eligible: 2, Sync-ed: 0
  (2 Ready)
```

Like the other NSR implementations, we can query the routers for their NSR exchanges with their peers. Although NSR is not a negotiated capability like the GR/NSF family of features, statistics are still tracked per peer.

```
R10#show mpls ldp nsr statistics neighbor 222.0.0.13

    Stdbdy Adj: 0 join, 0 leave
```

14.1.6 RSVP-TE GR

RSVP-TE supports GR but not NSR. RSVP GR applies only to TE applications, not ordinary IP, and is used to maintain state information when a node in the LSP performs an RP switchover. Below, I configure RSVP GR on XRv3 and CSR10. I also enable it on CSR1 and XRv2 so that all interfaces within the OSPFv2

aggregation IGP are using this feature, but those configurations are not shown for brevity. I make minor adjustments to the hello and “miss” interval; this specifies how frequently RSVP hello messages are sent. Additionally, I enable RSVP GR under all interfaces also enabled for OSPF2.

```
! XRv3
rsvp
 interface GigabitEthernet0/0/0/0.503
   signalling hello graceful-restart interface-based

 interface GigabitEthernet0/0/0/0.513
   signalling hello graceful-restart interface-based

 signalling graceful-restart
 signalling hello graceful-restart refresh misses 5
 signalling hello graceful-restart refresh interval 6000

! CSR10
interface GigabitEthernet2.502
 ip rsvp signalling hello graceful-restart

interface GigabitEthernet2.503
 ip rsvp signalling hello graceful-restart

interface GigabitEthernet2.510
 ip rsvp signalling hello graceful-restart

ip rsvp signalling hello graceful-restart mode full
ip rsvp signalling hello graceful-restart refresh interval 6000
ip rsvp signalling hello graceful-restart refresh misses 5
```

Just like TE-FRR, nothing happens until a TE tunnel is configured. RSVP is like BFD in a way where it does not have a discovery mechanism; RSVP does have hellos, but they are used for specific applications.

```
RP/0/0/CPU0:XRv2#show rsvp graceful-restart neighbors
[no output]
```

At a minimum, we can at least ensure the feature was configured properly before configuring any TE tunnels. XRv2 and CSR1 both indicate that RSVP GR is enabled with the correct timers.

```
RP/0/0/CPU0:XRv2#show rsvp graceful-restart
Graceful restart: enabled   Number of global neighbors: 0
Restart time: 120 seconds  Recovery time: 120 seconds
Recovery timer: Not running
Hello interval: 6000 milliseconds  Maximum Hello miss-count: 5
Pending states: 0

R1#show ip rsvp hello
```

Hello:

```
RSVP Hello for Fast-Reroute/Reroute: Disabled
Statistics: Disabled
BFD for Fast-Reroute/Reroute: Disabled
RSVP Hello for Graceful Restart: Enabled (full mode)
```

R1#show ip rsvp hello graceful-restart

```
Graceful Restart: Enabled (full mode)
Refresh interval: 6000 msecs
Refresh misses: 5
DSCP: 0x30
Advertised restart time: 5 msecs
Advertised recovery time: 0 msecs
Maximum wait for recovery: 3600000 msecs
```

Next, I configure a TE tunnel on XRv3 to route traffic to CSR1 over any link except the one directly connected to CSR1. This means that CSR10 will always be in the transit path. After configuring the tunnel, we verify that it forms correctly. The tunnel comes up and routes via CSR10 to CSR1 as expected. There is no need to route any traffic into the tunnel for this test.

```
! XRv3
explicit-path name EP_AVOID_DIRECT
index 10 exclude-address ipv4 unicast 222.1.13.1
index 20 exclude-address ipv4 unicast 222.1.13.13

```

[snip]

We know that the RSVP RESV message travels from tail to head which binds RSVP labels at each hop for the TE tunnel being signaled. RSVP GR hello requests are originated at each upstream router to establish GR connectivity and a hello acknowledgement is expected in return from the downstream router. That is

to say, the hello initiation and acknowledge travels in the same direction as the RSVP PATH message. Below, we see that CSR1 received two sets of hello request messages. These are traveling down the LSP (head to tail) and originate from CSR10. One set of hellos uses TTL=255 so that the failure of an intermediate node will not prevent the RSVP hello from arriving. This session is between node IDs, much like an LDP session would be. The normal, link-based RSVP session still has TTL=1 as expected. These hellos are different than normal RSVP hellos as they contain the RESTART capability, which is supported in XR (unlike regular RSVP hellos). We will examine these two different “neighbors” later. Also, note that the recovery time is 0 (green) and restart time is 5 msec (cyan).

```
R1#debug ip rsvp dump-messages
RSVP message dump debugging is on
```

```

XRv3 generates a syslog message when the RSVP neighbor session is formed to CSR10. Notice that CSR10's node ID is specified, not the link ID. This is because RSVP GR only supports node failures, so it tracks the node address.

```
! XRv3
rsvp[1049]: %ROUTING-RSVP-6-RSVP_HELLO_STATE_UP : A graceful restart hello
session to 222.0.0.10 has been established
```

Starting from the headend, we will verify the RSVP GR neighbors. I show a summary and detailed view at each router along the way. Of note, XRv3 always identifies CSR10 by its node address. Hellos are successfully being sent and received, which indicates a functional configuration.

```

Lsp GR DN Node nbr: 222.0.0.1 Intf nbr: 222.1.10.1
```

CSR1 is the tail end of this TE tunnel. Notice that it has two neighbors. The first is the TTL=225 “multi-hop” session between the routers while the other uses the directly connected interfaces at TTL=1. This is

consistent with the debug evaluated earlier. Although GR cannot protect against link failures, the multi-hop adjacency allows the router to continue communicating, which is the reason why a second session is made. The details reveal that the single-hop session is bound to a specific interface, while the multi-hop session is not.

```

```

To simulate a failure of CSR10, I shut down its physical interface, effectively removing it from the network entirely. Though this is not an appropriate way to simulate an RP switchover, it allows us to see how XRv3 will react. After 5 missed hellos, the neighbor is torn down and a syslog is generated. XRv3 will track the number of times the neighbor fails, along with other timestamp-related statistics.

```
! XRv3
rsvp[1049]: %ROUTING-RSVP-6-RSVP_HELLO_STATE_DOWN : Graceful restart hello

```

Before continuing, I restore CSR10 and ensure that it forms its RSVP neighbors again. A total of 4 neighbors are shown: 2 single-hop sessions (yellow) and 2 multi-hop sessions (green), one of each for CSR1 and XRv3. Despite GR being configured, all routers immediately purged all TE LSP information when CSR10 failed.

```
R10#show ip rsvp hello client nbr
```

Local	Remote	Type	NBR_STATE	HI_STATE	LSPs
222.0.0.10	222.0.0.1	GR	Normal	Up	1
222.0.0.10	222.0.0.13	GR	Normal	Up	1
222.10.13.10	222.10.13.13	GR	Normal	Up	1
222.1.10.10	222.1.10.1	GR	Normal	Up	1

The restart time and recovery time observed earlier should change this behavior. A recovery time of 0 indicates that a router has no ability to preserve its forwarding information. This causes RSVP peers adjacent to a failed node to immediately delete all LSP information through that peer. A number greater than zero causes routers on either side of the failure to continue sending RSVP PATH messages (if downstream from the failed node) or RSVP RESV messages (if upstream from the failed node) so that the failure is masked. These soft-state refreshes are imperative to normal RSVP operation. The restart timer specifies how long a peer should wait for the session to establish, and the recovery time specifies how long it should take to synchronize the label forwarding constructs. XE only lets you adjust the recovery time, but XR allows you to adjust both. I use 90 seconds for both timers. XE has a hidden command for the restart time, but it doesn't even stick in the configuration. It is included below for reference.

```

! CSR1 and CSR10
ip rsvp signalling hello graceful-restart send recovery-time 90000
ip rsvp signalling hello graceful-restart send restart-time 90000 ! HIDDEN

! XRv2 and XRv3
rsvp
 signalling graceful-restart restart-time 90
 signalling graceful-restart recovery-time 90

```

Using debug on CSR1, we can verify that the timers have changed. 0x15F90 in decimal is 90,000 which represents the time in msec.

```

R1#debug ip rsvp dump-messages hello
RSVP message dump debugging is on

```

Incoming Hello:

```
version:1 flags:0000 cksum:0137 ttl:255 reserved:0 length:32
HELLO type HELLO REQUEST length 12:

RESTART_CAP type 1 length 12:
Restart_Time: 0x00015F90, Recovery_Time: 0x00015F90
```

We can also use show commands. CSR10 and XRv3 both indicate the proper values. Ideally, this should give CSR10 plenty of time to recover from another failure.

```
R10#show ip rsvp hello graceful-restart
```

```
Graceful Restart: Enabled (full mode)
Refresh interval: 6000 msec
Refresh misses: 5
DSCP: 0x30
Advertised restart time: 90000 msec
Advertised recovery time: 90000 msec
Maximum wait for recovery: 3600000 msec
```

```
RP/0/0/CPU0:XRv3#show rsvp graceful-restart
```

```
Graceful restart: enabled Number of global neighbors: 1
Local MPLS router id: 222.0.0.13
Restart time: 90 seconds Recovery time: 90 seconds
Recovery timer: Not running
Hello interval: 6000 milliseconds Maximum Hello miss-count: 5
Pending states: 0
```

Since shutting down interfaces is not a valid test of an RP switchover, this lab cannot be tested further. The test results on CSR10 appear to be the same even with these new timer configurations. I was not able to see any noticeably different, however I was able to capture some new output on CSR1. We can see that when CSR10 fails, CSR1 does change the state to “Restarting” which implies, for a short time, CSR1 believed CSR10 was performing SSO. This did not last the entire 90 seconds because when IGP reachability was lost, the peer failed entirely (even though IGP converged faster than 90 seconds). I theorize that a real RP failure would have caused this behavior to reflect the timer adjustments configured earlier.

```
R1#show ip rsvp hello client nbr
```

Local	Remote	Type	NBR_STATE	HI_STATE	LSPs
222.0.0.1	222.0.0.10	GR	Restarting	Lost	1
222.1.10.1	222.1.10.10	GR	Restarting	Lost	1

14.1.7 EIGRP NSF

Like RSVP, EIGRP supports GR/NSF but not NSR. The concept is identical to all other GR/NSF features discussed so far. A router undergoing a switchover requires peers to “help” it synchronize its standby RP during an SSO event. In the case of EIGRP, it also assists with stuck-in-active (SIA) events where an “active” route has unanswered queries from at least one peer regarding its reachability status. When a restart operation begins on an EIGRP router, the restart bit (RS-bit) is set in the hello packets towards all peers. Those who receive and understand this message immediately send their EIGRP topology tables to the restarting router. When complete, an end-of-table (EoT) message is sent to signal the end of the topology transfer. Once the switching router is finished converging, it uses the EoT message towards the “helpers” to signify that convergence is complete. Interestingly, NSF is enabled by default on XR. No other NSF features are enabled by default for any other protocol on XR or XE. We can confirm this with some show commands.

```
RP/0/0/CPU0:XRv3#show protocols ipv4 eigrp vrf EIGRP | include NSF
```

```
EIGRP NSF: enabled
```

```
NSF-aware route hold timer is 480s
```

```
NSF signal timer is 20s
```

```
NSF converge timer is 300s
```

```
RP/0/0/CPU0:XRv3#show protocols ipv6 eigrp vrf EIGRP | include NSF
```

```
EIGRP NSF: enabled
```

```
NSF-aware route hold timer is 480s
```

```
NSF signal timer is 20s
```

```
NSF converge timer is 300s
```

Because we cannot “enable” NSF on XRv3, I will disable it from the IPv6 AFI. The word “disable” is the only option in the parser. After issuing this command, XRv3 issues a log message about degraded ISSU capabilities. We also verify the NSF has been fully disabled for IPv6 as a demonstration.

```

! XRv3
router eigrp VPN
  vrf EIGRP
    address-family ipv6
      nsf disable

! XRv3
eigrp[1003]: %ROUTING-EIGRP-4-ISSU_SUPPORT : EIGRP-VPN: EIGRP-v6 213: NSF
disabled. ISSU requires NSF to be enabled.

```

```

RP/0/0/CPU0:XRv3#show protocols ipv6 eigrp vrf EIGRP | include NSF
  EIGRP NSF: disabled
    NSF-aware route hold timer is 480s
    NSF signal timer is 20s
    NSF converge timer is 300s

```

To mirror XRv3's capabilities, CSR2 enables NSF for IPv4 only. We can verify this by checking the IPv4/v6 protocol details.

```

! CSR2
router eigrp VPN
  address-family ipv4 unicast autonomous-system 213
    nsf

```

```

R2#show ip protocols | include eigrp|NSF
*** IP Routing is NSF aware ***
Routing Protocol is "eigrp 213"
  NSF-aware route hold timer is 240
  EIGRP NSF enabled
    NSF signal timer is 20s
    NSF converge timer is 120s

```

```

R2#show ipv6 protocols | include eigrp|NSF
IPv6 Routing Protocol is "eigrp 213"
  NSF-aware route hold timer is 240
  EIGRP NSF disabled
    NSF signal timer is 20s
    NSF converge timer is 120s

```

As a quick test, I enabled NSF debugging on CSR2 and clear the EIGRP neighbor table on XRv3 (not shown). CSR2 cannot execute NSF because the neighbor was "hard cleared", which means that administrator was intentionally trying to reset the control-plane. At a minimum, this shows that EIGRP NSF is operational as the feature "tried to" work. We can see that EoT was received from XRv3 which indicates convergence is complete; this is carried as a special flag inside of EIGRP packets.

```

R2#debug eigrp nsf
EIGRP NSF debugging is on

```

```

EIGRP: NSF: AS213: Checking if Graceful Restart is possible with neighbor
10.2.13.13, peer_down reason 'Interface PEER-TERMINATION received'
EIGRP: NSF: Not possible: 'peer_down was called with a HARD resync flag'
EIGRP: NSF: Enqueuing NULL update to 10.2.13.13, flags 0x1:(INIT)
EIGRP: NSF: AS213, Receive EOT from 10.2.13.13, Flags 0x8:(EOT)

```

Performing the same test in the opposite direction, XRv3 indicates similar results. NSF cannot be used, but the software tries to apply the feature. This is likely the result of having a single RP with SSO unsupported. The last line of this debug probably means that an EoT was received from CSR2 as this indicates convergence from an EIGRP neighbor.

```

eigrp[1003]: IPv4-EIGRP(VPN-213): NSF: Self NOT in NSF restart mode. Received
a non-RS non-INIT Update from peer 10.2.13.2
eigrp[1003]: IP-EIGRP(VPN-213): NSF: RIB Converged notification received for
VRF EIGRP-v4

```

Last, we will examine the EIGRP NSF timers briefly. On XE, you actually use both GR and NSF syntax, which is confusing. They are effectively describing the same feature. In the outputs above, we saw the route hold timer, signal timer, and converge timer. The route hold-timer is configured as the GR purge-time and determines how long EIGRP will keep routes for an inactive peer if EoT is not received. The signal timer indicates how long to wait after sending packets with the RS-bit set, which was described earlier. The converge timer indicates how long to wait before receiving the EoT message from all neighbors, which is similar to the BGP EoR marker. These minor details should not be adjusted unless there is a compelling reason. I adjust these to new values for variety, then confirm them with show commands on both CSR2 and XRv3.

```

! CSR2
router eigrp VPN
 address-family ipv4 unicast autonomous-system 213
   timers nsf signal 25
   timers nsf converge 100
   timers graceful-restart purge-time 150

! XRv3
router eigrp VPN
 vrf EIGRP
   address-family ipv4
     timers nsf route-hold 150

```

```
timers nsf signal 25
timers nsf converge 100
```

```
R2#show ip protocols | include eigrp|NSF
```

```
*** IP Routing is NSF aware ***
```

```
Routing Protocol is "eigrp 213"
```

```
NSF-aware route hold timer is 150
```

```
EIGRP NSF enabled
```

```
NSF signal timer is 25s
```

```
NSF converge timer is 100s
```

```
RP/0/0/CPU0:XRv3#show protocols eigrp vrf EIGRP | include NSF
```

```
EIGRP NSF: enabled
```

```
NSF-aware route hold timer is 150s
```

```
NSF signal timer is 25s
```

```
NSF converge timer is 100s
```

15. Describe Layer 1 failure detection

This section will be brief and covers only two features: carrier delay and link debounce. The network diagram is shown below, which uses two Cisco ME-3400-24TS-A switches with 3 links between them. Two are 100 Mbps copper NNIs and one is a 100BaseFX 100 Mbps fiber NNI. There is no link bundling.

Carrier delay is a timer that runs in software to identify when a link goes down at layer 1. This is normally set to 2 seconds to prevent against very short flaps, which may introduce churn. This slows convergence significantly, so we can adjust it to a smaller value. We can specify a value in seconds or ms, and we reduce this to 0 on ME1. The interface will go down as soon as the cable is unplugged on ME1, but on ME2, this will occur 2 seconds later. On most IOS platforms, 2 seconds is the default carrier delay (not revealed in the show command).

```
! ME1
interface FastEthernet0/15
carrier-delay msec 0
```

```
ME1#show interfaces fastEthernet 0/15 | include Carrier
```

```
Carrier delay is 0 msec
```

Before continuing, we configure basic NTP so we can use the logging timestamps to approximate the carrier delay changes. We verify the clocks are synchronized; see the NTP section for more details.

```
! ME1
ntp master
```

```
! ME2
ntp server 10.0.10.91
```

```
ME1#show ntp status | include sync
Clock is synchronized, stratum 8, reference is 127.127.1.1
```

```
ME2#show ntp status | include sync
Clock is synchronized, stratum 9, reference is 10.0.10.91
```

When the cable is unplugged, the link-light immediately turns off on both switches. However, there is a ~2 second delay between the log messages being issued. Since this is a software timer, the LEDs may turn off, but IOS doesn't notify any other process of the outage until the carrier delay expires. The timing of the syslog generation is imperfect which is why we only see a ~1.3 second delay in this case.

```
! ME1
03:45:32.510: %LINK-3-UPDOWN: Interface FastEthernet0/15, changed state to
down
03:45:33.500: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/15, changed state to down
```

```
! ME2
03:45:33.894: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/15, changed state to down
03:45:34.892: %LINK-3-UPDOWN: Interface FastEthernet0/15, changed state to
down
```

The carrier delay is synchronous by default and also controls how long to wait before declaring a link up event. Plugging the cable back in proves this, and this time is much closer to 2 seconds than the link-down time, which is somewhat coincidental.

```
! ME1
03:47:37.542: %LINK-3-UPDOWN: Interface FastEthernet0/15, changed state to up
03:47:38.549: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/15, changed state to up
```

```
! ME2
03:47:39.524: %LINK-3-UPDOWN: Interface FastEthernet0/15, changed state to up
03:47:40.531: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/15, changed state to up
```

We quickly compare this to port 16, which has the default carrier-delay on both switches. The down event happens at the same time.

```
! ME1
04:25:28.414: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/16, changed state to down
04:25:29.420: %LINK-3-UPDOWN: Interface FastEthernet0/16, changed state to
down
```

```
! ME2
04:25:28.389: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/16, changed state to down
04:25:29.395: %LINK-3-UPDOWN: Interface FastEthernet0/16, changed state to
down
```

Plugging port 16 back in, the up event happens at the same time also. This proves that the carrier delay is actually evaluated on the ME3400 platform, and since its running in software, should be platform-agnostic.

```
! ME1
04:25:50.929: %LINK-3-UPDOWN: Interface FastEthernet0/16, changed state to up
04:25:51.935: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/16, changed state to up

! ME2
04:25:50.946: %LINK-3-UPDOWN: Interface FastEthernet0/16, changed state to up
04:25:51.952: %LINEPROTO-5-UPDOWN: Line protocol on Interface
FastEthernet0/16, changed state to up
```

Rushing into a link-up event can be dangerous, so on some platforms we can also configure asynchronous carrier delays. The ME3400 is not one of them, which means adjusting carrier delay applies in both up and down directions at all times. For that reason, I would recommend a non-zero value, even for faster convergence, since it may lead to short-term blackholes on link-up events. An example of an “up” delay is shown below.

```
! Example (not configured on ME3400)
interface FastEthernet0/15
  carrier-delay up msec 500
```

Link debounce is not supported in the ME3400, but is used for link-down events only. It runs in firmware, not software, so it is a function of the interface driver. The default is 300 ms on copper and 10 ms on fiber interfaces, and Cisco recommends keeping it as the default. The timer is measured in ms.

```
! Example (not configured on ME3400)
interface FastEthernet0/15
  link debounce time 500
```

Additional Reading – Reference configurations “layer1-fail”

16. Describe BGPsec

This feature is discussed/tested in detail in the security section. In summary, the feature encompasses AS origin validation by way of Resource Public Key Infrastructure (RPKI). The word “resource” relates to IP resources, like prefixes, where PKI relates to existing X.509 PKI certificate infrastructure. AS origin validation seeks to ensure that only prefixes registered in a certain AS can be originated from that AS, and is most useful to prevent accidental advertisements. Attackers can easily craft BGP prefixes with AS-paths to overcome this, and BGPsec aims to stop it by having a router in each AS (only makes sense with eBGP) sign the prefix to increase its authenticity. A Resource Origination Authorization (ROA) is what binds an address space with an AS number, granting permission to that ASN to advertise prefixes in accordance with the ROA. Multiple ROAs can exist, and they may overlap; routers will consider the union of all valid ROAs when determining prefix validity. Both certificates and ROAs are published in publicly accessible repositories for general use. The time-range validity of these constructs is always relevant; if the current time does not fit within the lifetime of an ROA’s or certificate, that object cannot be used, much like a time-based key chain.

17. Describe backscatter traceback

This feature is discussed/tested in detail in the security section. In summary, the feature combines ACLs, remotely triggered blackholes (sometimes), sinkholes, and ICMP unreachables to determine the ASBR ingress routers from which an attack has entered the network. The backscatter is the forwarding of ICMP unreachables back into the core network and ultimately into a sinkhole for analysis. This is primarily employed to detect/defeat IP spoofing attacks against the SP network.

18. Describe lawful-intercept

This feature is discussed/tested in detail in the security section. In summary, this allows a mediation device to communicate to a router over SNMPv3 to setup/teardown wiretap sessions on a network device. This would be done in accordance with Government regulations and the mediation device would forward copies of “interesting” traffic back to law enforcement agencies (LEAs) that require it. Mediation devices are provided by third-party vendors and do most of the processing, but routers need to be enabled for SNMPv3 and must have the LI feature supported as required by law.

19. Describe BGP Flowspec

This feature is discussed/tested in detail in the security section. In summary, the feature is meant to add additional granularity to the remotely triggered black-hole (RTBH) feature. RTBH is a “big hammer” where it completely blackholes traffic to/from certain prefixes during a DDoS attack. BGP flowspec is like a combination of RTBH and QPPB; it can signal specific QoS actions, redirect traffic into a VRF for analysis, or drop the traffic. XE only supports it as a route-reflector (full support is introduced in version 3.15S), and XRv can only create flowspec rules; it cannot be tested in the data plane due to lacking hardware linecards.

20. Describe DDoS mitigation techniques

This feature is discussed/tested in detail in the security section. In summary, common tools include ACLs, remotely triggered black holes, unicast RPF, backscatter traceback, and BGP Flowspec.

21. Describe network event and fault management

This chapter encompasses a set of functions that detect, isolate, and correct malfunctions in the network. This includes accounting for environmental changes, examining logs and notifications, tracing/correcting faults, and running diagnostic tests. When network devices fail or suffer errors, an event-driven mechanism should be configured. For example, the device could send a syslog message to a remote syslog server or issue SNMP traps/informs to an SNMP server. This notifies the network staff of the fault and generally provides details regarding the fault. Once the condition that triggers the fault is resolved, the alarm state is cleared. Fault management systems may have internal mechanisms to map in-band severities (such as syslog priority 0, or emergencies) to another prioritization scheme based on network administrator weights. With respect to ITIL Incident Management, a fault would qualify as an incident, and is subject to the ITIL processes described in that section.

22. Describe performance management and capacity procedures

Capacity management: process of determining the network resources required to prevent a performance or availability impact on business-critical applications.

Performance management: practice of managing network service response time, consistency, and quality for individual and overall services.

Note: Performance problems are usually related to capacity; applications are slower due to congestion management and traffic conditioning (queuing and shaping).

Trending is the process of reviewing performance/capacity issues and reviewing the baselines for trends. This helps to understand future upgrade requirements.

Common areas for concern:

- a. **CPU.** Used by both control and data planes on any network device. For performance and capacity management, all devices must have sufficient CPU to service these needs. Insufficient CPU on one device can impact the entire network (BGP slow-peer, slow SPF computation blackholes, etc).
- b. **Backplane of I/O.** Refers to the total amount of traffic a device can handle. Insufficient backplane bandwidth results in dropped packets, leading to retransmissions and even more traffic on the network.
- c. **Memory and buffers.** Used by both control and data planes on any network device. Memory can often be low during periods of routing convergence.
- d. **Interface and pipe sizes.** Refers to the amount of data than be sent on any one connection. Often incorrectly referred to as speed. Congestion on these links usually results in queuing of sorts, which can increase latency.

e. **Queuing, latency, and jitter.** The larger the queue, the longer data has to wait. Tail drop occurs when the queue is full and admittance is prohibited. Acceptable for TCP, but not much else. When input queues fill, this can have a negative effect on CPU and memory as the device cannot process the incoming traffic fast enough.

f. **Speed and distance.** Data can only be forwarded up to the speed of light, which is approximately 100 miles per ms. Even with high bandwidth, low latency international links, the distance for energy to travel can be significant. Can be a large factor for certain applications if they are not tuned for specific network characteristics.

g. **Application characteristics.** Small window sizes, application keepalives, and amount of data sent over the network versus what is required is often the reason for poor application performance.

Best practices

a. **Service level management.** A deliverable that seeks to identify what service can be delivered within budgetary and staffing constraints. It can be done via an SLA between users and network organizations for a service. The service would include reports and recommendations to maintain acceptable service quality. Users must be prepared to fund the upgrades. Alternatively, the network organization can define their capacity/performance management upgrades and attempt to fund upgrades on a case-by-case basis.

b. **Network and application what-if analysis.** Used to determine the outcome of a planned change. Significantly reduces risk and helps increase network availability. Identify risk levels for individual changes and perform more detailed analyses on those that are highest risk. Cisco recommends 5 risk levels:

1. High potential impact to many users and/or business critical applications with expected downtime. Mitigation: Validation (lab) of new solution. Extensive testing and what-if analysis showing impact. New solutions require completion of an operations support document. Perform design review, create back-out plan/change process.

2. High potential impact to many users and/or business critical applications with possible downtime. Mitigation: Perform what-if analysis and review functionality. Perform design review, create back-out plan/change process.

3. Medium potential impact to less users and/or business service with possible downtime. Mitigation: Perform engineering analysis, and create implementation plan/change process.

4. Lower potential service impact, such as adding new template network modules, new WAN sites, etc. Mitigation: Create implementation plan/change process.

5. No user/service impact, such as adding individual users, changing passwords/banners/SNMP configurations, etc. Mitigation: None, all processes are optional.

General comments:

- Modeling of network topologies are recommend for all significant changes, such as routing, etc.
- Perform an application what-if analysis before deploying any business application. If you don't the application group will blame the network group for poor performance.

c. **Baselining and trending.** Allows network administrators to plan/complete network upgrades before a capacity problem arises. Can be resolved in several ways: build enough capacity so there is never an issue, divide the trend information into groups and focus on the critical network areas, or rely on reporting mechanisms to detect issues and respond to them first. All methods still require periodic review to ensure capacity demands are met over time. Graphical/chart tools are valuable for visualizing this kind of information.

d. **Exception management.** This is a reactive methodology; the network team receives notification of capacity/performance threshold violations and responds immediately. Tools like RMON and SNMP traps/informs (described in detail later) can be used for the initial reporting. Reporting must be near real-time so that the problem does not vanish before it is seen. Netflow can also be used to measure traffic, though it is passive and would require a tool to interpret the data to raise alarms.

e. **QoS management.** After baselining the network, traffic can be classified for preferential treatment. A basic design could include LLQ for voice, along with bandwidth guarantees for business critical applications. Large file transfers that are not time sensitive can be given lower priority.

Collecting and reporting capacity information: This is linked to three areas of capacity management. Each of these should have an information collection plan.

a. **What-if analyses.** Need tools to mimic the network environment and understand the effects of changes.

b. **Baselining and trending.** Need "snapshots" of current devices to shown current resource utilizations.

c. **Exception management.** Need this to alert network administrators about problems so resolution can occur.

5 steps for this process:

a. **Determine your needs.** Discover resources available and what is needed. Consider the people/expertise needed to use tools rather than just the tool/technology itself.

b. **Define a process.** Describe what happens when violations occur or what the baselining process looks like. Can be outsourced this functionality to a network services organization.

c. **Define capacity areas.** Certain areas of the network share common capacity planning strategies: LAN, WAN, field offices, critical sites, etc. LAN bandwidth is always cheaper than WAN bandwidth, so utilization should be lower. Different sites may require different SNMP MIB monitoring. Upgrades may be more difficult or time consuming in some places rather than others within the network.

d. **Define the capacity variables.** Depends on the devices/media in the network. General parameters such as CPU, memory, and link utilization are generally measured. Other things like queue depths and media-specific congestion can be valuable.

e. **Interpret the data.** Difference between peak and average is important, as peaks may be invisible based on the polling interval. Select a value that is a compromise; aggressive values cause excessive overhead while lethargic ones return less accurate information.

23. Describe maintenance and operational procedures

Maintenance procedures should be conducted in accordance with the hardware platform manual; there isn't much more to say other than that. Sustaining operations for a service provider is critical, which is why many platforms have an in-service software upgrade (ISSU) feature. This allows the administrator to upgrade/downgrade software versions of network devices while packet forwarding continues. This relies on Cisco non-stop forwarding (NSF) and stateful switchover (SSO) which implies the platform has redundant RSPs/RPs. The standby RSP/RP can be loaded with the next version, which can be manually started by the administrator while the old one is halted. Once the new version is explicitly accepted, it is written to both RSP/RPs going forward. If the new version introduces a new command or new syntax for something not recognized in the previous version, "Config Sync" is a process designed to recognize these new commands and maintain compatibility. ISSU has some limitations regarding the software versions it can support. ISSU may not be supported across major version releases if the underlying architecture changes sufficiently such that the underlying line-card FIBs must be changed, even if both versions supported ISSU. It is definitely not supported across code trains (T to S to M, for example) either. Cisco identifies code with one of three letters to denote its compatibility:

- a. **C: Compatible.** All base-level system infrastructure is supported as well as optional HW-aware subsystem components. There will be minimal service impact when performing ISSU to a version labeled compatible.
- b. **B: Base-level compatible.** ISSU will succeed but some sub-systems will not be able to maintain state during the transition. There may be some service interruption.
- c. **I: Incompatible.** The core architecture is different to the point that ISSU is not supported since SSO cannot work.

Incompatible updates are still desirable, so rather than use ISSU, one can use Fast software upgrade (FSU) which is a suboption of ISSU. By using the keyword "forced" in some platforms, you can force ISSU to perform the upgrade but it will be service impacting, so plan for that.

From a purely operational standpoint, service providers often use “runbooks” to describe their operations. This details procedures to begin, stop, supervise, and debug the system. Effective runbooks allow operations to effectively manage and troubleshoot a system, which may include automation. They are often exhaustive and include procedures for common scenarios with decision trees/flow charts to aid operators. It begins with an index of processes that are often broken down in outline form to associate processes to the operations/technologies they support. Runbook automation (RBA) is the ability to define, build, orchestrate, manage, and report on workflows that support processes that support the network.

24. Describe the network inventory management process

Network inventory management is the process of keeping records of all network assets owned by an organization, to include assets not currently in service (on the shelf, in maintenance, etc). It enables network administrators to have a record of all network equipment within the organization. Network inventory management is generally performed through asset tracking software that scans, compiles, and records data about each device/node over a network. This obviously cannot touch network devices not currently on line, but the software can be supplemented by manual inventorying done by humans.

Network inventory management would include basic information about each platform. This would include their make/model, location, serial number, network addressing (for management), software version, and license keys (along with expiration dates). Capturing this data is important for businesses. The most obvious benefit is to maintain accountability of all equipment and prevent theft. It also helps with estimating the size of a network and supports planning for growth. Knowing the network diameter also helps realize costs to maintain and grow the network.

25. Describe network change, implementation, and rollback

25.1 Processes and best practices

Configuration management best practices:

1. **Create standards.** Helps reduce network complexity, unplanned downtime, and exposure to network impacting events.

a. Software version. Deploy consistent SW versions on similar network devices. Increase interoperability, reduce SW defects and likelihood of complex issues.

b. IP addressing. Subnet allocation scheme ensures address blocks do not overlap and promotes contiguous address summarization. Identify certain hosts in the subnet for certain applications (i.e., always make the routers the first addresses, followed by switches, followed by hosts).

c. Naming conventions, DNS, and DHCP assignments. Simplifies the identification for devices and reduces the possibility of duplicate IP addresses. Adding DHCP ranges to DNS helps with identifying where hosts are also.

d. Baseline configurations and descriptors. Common configuration parameters, such as VTY settings, banners, NTP, SNMP, and AAA can be uniform on most network devices. Descriptors are used on interfaces to show the purpose and location of an interface.

e. Configuration upgrade procedures. Documenting these procedures ensures HW/SW upgrades go smoothly. The document should list all steps for the upgrade, reference vendor documentation, and provide post-upgrade validation steps for testing.

f. Solution templates. Define common solutions to common problems in modular form. Each template must be defined, tested, and documented to ensure uniformity when the templates are deployed. Templates may include HW modules, port/VLAN assignments, ACL/QoS configurations, out of band management (OOBM), and cable installations. These templates should not contain specifics like IP addresses or DNS/DHCP assignments.

2. Implement standards

3. **Maintain documentation.** Should be updated in near-real time. Cisco defines the following "critical success" factors:

a. Current device, link, and end-user inventory. Track devices, problem impact, and network change impacts. Should contain tables for similar devices, links, and user data.

b. Configuration version control system. Maintain set of current configurations and some number of previous versions for rollback, troubleshooting, or change audits. Maintain 3-5 previous versions of configuration per device.

c. TACACS configuration log. Any AAA server will do, but Cisco specifies TACACS. When used with NTP, it is easy to see who logged into a device, when it happened, and what was changed.

d. Network topology documentation. Should include both logical and physical topologies at different OSI layers for the entire network. Detail will range from routing diagrams to cabling/line-card/electrical level of detail. These are typically maintained in graphical form.

4. **Validate and audit standards.** Form a cross-functional team to measure configuration management quality. First objective is to implement change management (CM) to identify the issues.

a. Conduct integrity checks. Evaluate overall network configuration to include potential issues. This should catch inconsistent naming conventions, duplicate IP addresses, protocol mismatches, and other errors.

b. Device, protocol, and media audits. This would identify inconsistent HW/SW versions, incompatible modules, etc.

c. Standards and documentation reviews. Executed on a quarterly basis, all components of the standards (naming convention, IP subnetting plan, solution templates, etc) should be reviewed for inconsistencies and errors. New templates should be developed in accordance with new HW/SW upgrades as needed.

5. Review standards. The process restarts at "Create Standards".

25.2 NETCONF and YANG

NETCONF is an IETF standard which is short for Network Configuration Protocol (not to be confused with PPP's Network Control Protocol (NCP) mechanism). It is a standard for configuring, deleting, and modifying configurations on network devices. YANG is used to model the network configurations and state into tree structures; it is the data model for NETCONF. Put another way, YANG is to NETCONF what MIBs are to SNMP, as YANG core models contain similar definitions for how data is structured. Like SNMP, NETCONF supports similar basic operations such as "GET", "GET-NEXT", "SET", etc, which makes it appear very similar to SNMP at a glance. The NETCONF / YANG model was intended to be vendor neutral to avoid dealing with specific CLI scripts or existing tools that were inflexible.

However, NETCONF has extra features, such as being able to test configurations before committing them, being able to configure multiple network devices concurrently, and bulk-get operations that are much faster than SNMP. Performing network-wide transactions (GET, SET, etc) is made easier since NETCONF handles the error recovery and sequencing. That is to say, the operator doesn't need to worry about the order of executing configuration commands within a given transaction. NETCONF uses SSH, which is secure, and also means that the operator doesn't need to resend requests that fail as is necessary using SNMP over UDP. NETCONF messages are encoded in XML, and individual YANG data models are included as "capabilities" in NETCONF hello packets. The device notifies the manager which capabilities it supports so the system knows the appropriate mechanisms to configure the device.

YANG data structures loosely resemble "classes" in object oriented programming or "structs" in non-OOP languages. The structure contains several "types", which include integers, Booleans, enumerations, pointers, and other information types to be processed. There are some commonly used YANG types defined in RFC 6021 which are specific to networking (or at least, well suited for it). Some of these include pre-made objects for IPv4 and IPv6 addresses and prefixes, flow-labels, port-number, MAC-address, URI, domain-name, and others. This is very convenient for managing/storing configuration data within YANG. NETCONF simply manipulates this data accordingly; provided the data from the network devices fits the YANG standard, NETCONF can modify it. If a vendor simply took their CLI configuration and wrapped it in a YANG structure somehow, this would not be effective.

NETCONF / YANG is supported in both XE and XR. The diagram for this test is shown below. CSR2 will be the NETCONF server for these examples, and it shares a LAN with CSR1 and XRv4 (NETCONF clients).

Below is an XE configuration example with basic verification. Since NETCONF requires SSH, and specifically SSHv2, we must configure a domain name as well as generate crypto keys (not shown). We can optionally add a standard ACL to identify the NETCONF managers for extra security. The NETCONF maximum sessions can be between 4 and 16 and there must be one VTY line per session, so configuring a number greater than the number of available VTY sessions does not make sense (default is 4). The lock-time identifies the maximum amount of time the NETCONF configuration is locked (cannot be changed while locked); the default is 10 seconds. The max-message option limits the size of the NETCONF messages, where by default there is no limit.

```

! CSR1
ip ssh logging events
ip ssh version 2
access-list 10 permit 10.1.14.2
netconf max-sessions 5
netconf lock-time 30
netconf max-message 65535
netconf ssh acl 10
  
```

Although the documentation suggests that entering the exec command “netconf” enters the NETCONF conversation, it doesn’t appear to work on XE version 3.13S with the CSR1000v.

```

R2#ssh -l test 10.1.14.1 netconf
Password: test
Line has invalid autocommand "netconf"
[Connection to 10.1.14.1 closed by foreign host]
  
```

Even if we test it on CSR1 natively, the command doesn’t exist. However, if it did work, we can check the sessions using the command below.

```

R1#netconf
% Bad IP address or host name address

R1#net?
% Unrecognized command

R1#show netconf session
  
```

Netconf Sessions: 0 open, maximum is 5

The XR configuration is similar except we specify the SSH port 830 (the IANA recommended port) and enable NETCONF for SSH. I add several other minor options for demonstration only to adjust the NETCONF session limits and data transfer policies. XR actually does work with NETCONF in this setup. Again, the assumption is that basic SSHv2 (domain name, keys, username, etc) has been configured.

```
! XRv4
ssh server netconf port 830

netconf agent tty
  session timeout 15
  throttle memory 400
  throttle process-rate 1500

netconf-yang agent
  ssh
  session limit 5
  session idle-timeout 10
  session absolute-timeout 15
  rate-limit 65535
```

From our NETCONF server, we will log into XRv4 using SSHv2 over TCP port 830. The “netconf” option is an auto-command that gets run immediately upon log in, which drops us into the NETCONF conversation. The NETCONF client (XRv4) sends a “hello” message to CSR2 which contains its capabilities. We could respond with a hand-crafted “hello” message, but that is way beyond the scope of this test. We can see that if CSR2 were really a NETCONF manager, this would have worked.

```
R2#ssh -l cisco -p 830 10.1.14.14 netconf
```

```
IMPORTANT:  READ CAREFULLY
[snip]
Password: cisco
```

```
<?xml version="1.0" encoding="UTF-8"?>
<hello
xmlns="urn:ietf:params:xml:ns:netconf:base:1.0"><capabilities><capability>urn:ietf:params:netconf:base:1.0</capability><capability>urn:ietf:params:netconf:capability:candidate:1.0</capability><capability>urn:ietf:params:netconf:capability:notification:1.0</capability></capabilities><session-id>285212672</session-id></hello>
]]>]]>
```

Before terminating the NETCONF session, we can perform some basic verifications on XRv4. We can see the session from CSR2 in summary and detailed form. The session is idle since CSR2 didn’t send any NETCONF messages to XRv4, but we see the session is up.

```
RP/0/0/CPU0:XRv4#show netconf sessions

26. Describe the incident management process based on the ITILv3 framework

ITIL defines an incident as any event that is not part of the standard operation of the service. The event causes, or may cause, an interruption of the service or a reduction in its quality. Failures that affect an item, even if they don't affect a service, also qualify as an incident. This could be an LACP member port failing with no significant network impacts. An incident is different than a problem in that the latter consists of recurring, related incidents. Problem Management is a different process than Incident Management. The objective of Incident Management (IM) is to restore a service to normal operations with minimal impact on the business or user, and at minimal cost.

IM inputs mostly come from users, but machines (management or detection systems) can provide information as well. The output of IM are requests for changes (RFCs) which can mitigate future incidents.

Incidents can be prioritized generally by considering (summing) the impact and the urgency. Impact refers to the business criticality of the incident and the extent that it degrades the quality of the SLA (large number of users out of service, etc). Urgency reflects the required speed of resolving an incident. The chart below summarizes the prioritization scheme. Urgency is on the y-axis with impact on the x-axis.

Priority 2 Limited damage Recover within 2 hours	Priority 1 Significant damage Recover within 1 hour
Priority 4 Limited damage Recover within 8 hours	Priority 3 Significant damage Recover within 4 hours

Incidents can be escalated functionally or hierarchically. Functional escalation moves incidents from level 1 (front line service desk support) up through levels 2 and 3. Hierarchical escalation advances the incidents upward to the Incident Manager and ultimately to the Service Manager.

IM consists of several sub processes:

- Incident detection and recording
- Classification and initial support
- Investigation and analysis
- Resolution and recovery
- Incident closure
- Incident ownership, monitoring, tracking and communication
- Establish incident framework management
- Evaluation of incident framework management

27. Describe, implement, and troubleshoot advanced BGP features

27.1 Additional Paths (add-path) and Prefix Independent Convergence (PIC)

It is a well-known behavior that using BGP route-reflection within an iBGP domain can hide topological redundancies between clients in many cases. BGP only advertises it's best path, which is true for RRs also. Often times this is desirable since a route-reflector's best path might be the best path for everyone else, also. Sometimes this is a limitation since clients with multiple paths could potentially load-share, or use additional baths for fast-reroute. BGP additional-paths, or add-path, is meant to overcome the limitations with hiding the BGP topology when using RRs.

The topology below shows a square-shaped provider network which uses IS-IS Level 2 for IP routing and LDP for MPLS transport label binding. RSVP-TE is also enabled for ad-hoc testing as needed. Initially, all

interfaces use the default IS-IS metric of 10, but we will make modifications to this as we test different features. The SP network is BGP AS 100. The Internet injects several routes into the global BGP table of the SP (AS 6). The SP transports these to another SP (AS 12) and MPLS transport isn't really the goal because we are testing BGP add-path. The SP has one L3VPN customer (AS 410) so we can test BGP add-path with VPNv4 in addition to IPv4.

Let's examine the state of the network before enabling any advanced features. CSR8, CSR9, and XRV11 are route-reflectors for both VPNv4 and IPv4 (the middle column). The routers in the left and right columns are PEs which peer with all three of the RRs; some PEs only run IPv4 while some only run VPNv4 depending on who their customers are. CSR5, XRV12, and XRV13 all receive several Internet routes from CSR6 and advertise them to the RRs. All of the RR's will have the exact same routes, but may have different best-paths due to the IGP metric. For example, looking at an Internet route, CSR9 prefers the path via CSR5 due to IGP metric and lowest RID while CSR8 prefers the path through XRV12.

CSR3, for example, is going to learn the best-path from each of the three RR's. XRv11 has selected CSR5 as the best path (lowest RID), which means CSR3 has no idea there is a third path through XRv13. CSR3 now has two copies of one path and one of another, but is missing the third.

BGP add-path has many solutions for problems like this (and others). One quick solution is to direct CSR9 to only advertise its second best path, which would be via XRv13. This way, each of the three RR's coincidentally advertise a diverse path to CSR3, XRv14, and CSR7. This is sometimes called the "shadow RR" method. Of note, the Shadow RR itself has a few steps of configuration. Specifically, it has to select the backup path as the repair path, install it in the FIB, and then advertise it to its neighbor.

! CSR9

router bgp 100

template peer-policy IPV4

advertise diverse-path backup

address-family ipv4

bgp additional-paths select backup

bgp additional-paths install

Verifications are shown below. We check the BGP RIB, FIB, and advertised routes. The "bia" codes on the BGP advertised route indicate a backup-path, iBGP learned, and additional-path respectively. Notice that the ">" symbol is not shown on this route since it is a backup path, not a best path, which seems to violate the fundamental rule of BGP route advertisement at first glance.

```

When we check CSR3, we can see it has three different next-hops for this prefix, which is ideal. Notice that the route from CSR9 isn't really CSR3's best path, since we specifically directed it to advertise its second best path. This still hasn't helped us too much, since CSR3 still only picked one best path.

Of greater benefit to CSR3 would be the ability to use these paths for ECMP, since they all have equal IGP metrics. Let's enable iBGP multipath on CSR3 for the IPv4 AF. CSR3 still identifies a best-path because BGP always selects a single best-path, but marks the ECMP paths as "multipath". The reason for always needing exactly one best-path is because this what BGP would normally advertise on (with add-path we can change it, but this describes classic BGP behavior). The actual load sharing is interesting because the RIB installs three entries as expected, but based on the IGP routes to the BGP next-hops, we

see the FIB uses paths through XRv11 and CSR9 to service the three different routes. There is more diversity following these paths in the “core” of the network.

```

Looking at the labels, we come up with the following conclusions. This is significant because the FIB ultimately determines the level of HA you achieve in a network.

1. Traffic to CSR5 can be load-shared between CSR9 and XRv11.
2. Traffic to XRv12 always flows through XRv11.
3. Traffic to XRv13 always flows through CSR9.

```

```

Next, we will remove the shadow RR configuration from CSR9 and multipath configuration from CSR3 to return the network to its baseline status. A common feature to use on RR's that are spread throughout a network is disabling the IGP-metric evaluation in the BGP bestpath process. For example, CSR9 never considered XRv12 as a viable candidate because the IGP metric was 30, where the IGP metric to CSR5 and XRv13 was 10. If we disable IGP metric consideration on all RRs, then the next tie-breaker is lowest RID, and every RR will select the exact same bestpath. If we configure this feature by itself only CSR8 and CSR9 we actually cause more damage because now CSR3 only knows about the path via CSR5. We have to disable XRv11 BGP for this test since it does not appear to support ignoring the IGP metric. The

easiest way to do this is shutting down the IBGP session-group. At this point, CSR3 prefers the path via CSR5 (through CSR9) because the neighbor ID is lower. Regardless of which path CSR3 selects, it can only use CSR5 for forwarding, ignoring the other two candidate PEs.

```
! CSR8 and CSR9
router bgp 100
  address-family ipv4
    bgp bestpath igp-metric ignore

```

Earlier we used the “Shadow RR” in a highly coincidental and cherry-picked situation to solve our problem. The current network is more representative of a real setup where all of the RRs pick the exact same path. In this case, we can re-enable the Shadow RR feature on CSR9 so that it picks the next best path, ignoring the IGP metric, which is XRv12. Now, CSR3 has the backup paths. This design is more resilient because changes in IGP will not affect the BGP topology; if the RR's IGP metrics to a PE change, it doesn't matter. Since the two RRs always pick the same best paths, the shadow (CSR9) knows that it's safe to advertise the second best. Without ignoring IGP metric, RRs might pick opposing paths, and without shadow RR enabled, this is fine (we just tested that). But with shadow enabled, this might result in the remote PEs receiving the same route twice due to lack of synchronization between the RRs. Although I don't show it here, iBGP multipath would be a good option on the remote PE (CSR3) or using backup paths (discussed later) to achieve fast convergence.

```

We will remove the shadow RR configuration from CSR9 again to test other features. We will leave the IGP-metric ignore in place and leave XRv11 BGP shutdown for now. The RR's are configured to send additional paths while the PEs are configured to receive them for IPv4. The general snippet is below for reference. Before checking the BGP tables, we can verify this negotiated capability was successful by checking the BGP neighbor details. Beware the logic on the PEs; both CSR3 and XRv14 say the "send" capability was received and the "receive" capability was sent. This is actually correct. The RR's logic is easier to digest but it's effectively the opposite of the clients.

```

! XE and XR PE
router bgp 100
  address-family ipv4
    bgp additional-paths receive

```

```

! XE and XR RR
router bgp 100
  address-family ipv4
    bgp additional-paths send

```

```

CSR3#show bgp ipv4 unicast neighbors 9.9.9.9 | include Additional
  Additional Paths send capability: received
  Additional Paths receive capability: advertised

```

```

RP/0/0/CPU0:XRv14#show bgp ipv4 unicast neighbors 9.9.9.9 | include
Additional
  Additional-paths Send: received
  Additional-paths Receive: advertised

```

```

CSR9#show bgp ipv4 unicast neighbors 3.3.3.3 | include Additional
  Additional Paths send capability: advertised
  Additional Paths receive capability: received

```

First we will test selecting the best 2 paths from the BGP RIB and advertising them to all iBGP peers on CSR9. CSR9 shows best2 path as XRv12 due to lower RID than XRv13 (remember, we ignore the IGP metric). We clearly see them being advertised to CSR3 and XRv14 as examples. Notice that with this more powerful feature, the routers are actually advertising multiple paths. The shadow RR advertised a single back up, not multiple paths.

```

! CSR9
router bgp 100
  template peer-policy IPV4
    advertise additional-paths best 2
  address-family ipv4
    bgp additional-paths select best 2

```

```

CSR9#show bgp ipv4 unicast 28.10.45.0/25

```

Now, CSR3 and XRv14 will have three paths to choose from (CSR8 bestpath, CSR9 bestpath, and CSR9 best2 path). In order to make this effective, we should either use iBGP multipath or backup paths on the PEs. We will configure backup paths on CSR3 and XRv14 for variety. Notice that CSR3 is smart enough to pick a backup path that has a different next-hop than the best-path, although technically the "bestpath" from CSR9 (nexthop 5.5.5.5) is better than the backup due to lower originator-ID. We confirm this in the FIB. The bestpath using 5.5.5.5 as a next-hop has ECMP paths through CSR9 and XRv11 according to IGP, while the backup path has a single path via XRv11.

```

```

XRv14 has the exact same choices as CSR3 did. XR requires extra work, because we need to apply an RPL as an additional-path selection filter to determine not only what we want to backup, but how. Below is a sample RPL that only backs up the route in question. The configuration is shown below. I didn't have to match the specific prefix but did so for illustrative purposes. XR is also smart enough to pick a diverse BGP next-hop for its backup path. We perform a verification of both the BGP RIB and FIB.

```

! XRv14
route-policy RPL_BACKUP_45_0
  if destination in (28.10.45.0/25) then
    set path-selection backup 1 install
  endif
end-policy

We can also select the best 3 paths, which would effectively be the same as selecting all paths (both are options) in this case since we only have 3 paths. On CSR9, we will globally direct BGP to select the best 3 paths, then advertise the best 2 to all peers (default) but send the best 3 to XRv14. This is basic inheritance using the templates and overriding the settings by making changes directly on a BGP peer. Since best2 is already in the policy template for IPv4, we will override it specifically for XRv14. XRv14 now has 4 paths; one from CSR8 (it's best path) and three from CSR9. It still picks CSR8 as the best path due to lowest neighbor ID, then picks XRv12 as the backup given the lower originator ID. I highlighted the best two paths along with all three paths from CSR9.

```

This is a good opportunity to enable multipath on XRv14 to take advantage of all paths. Notice that even when enabling iBGP multipath for 4 paths, only 3 are used, since the BGP next-hop for two of them is the same. As always, we verify the BGP table, RIB, and FIB. Because I still have add-path configured, one of the paths is still considered as a backup also. Multipath and add-path are not mutually exclusive in many cases. However, notice that the FIB does not flag anything as “backup” or “repair”, because all of the paths are already in the FIB as primary, ECMP options.

Now we will shift focus to CSR5 and XRv13. CSR5 learns two paths to 28.10.45.0/25; one via eBGP and one via CSR9. Interestingly, the only reason CSR5 learns the CSR9 route is due to CSR9 sending its best 2 paths, since the path via CSR5 is the best path for both RRs (coincidental). A quick check on CSR9 confirms this.

```

CSR9#show bgp ipv4 unicast neighbors 5.5.5.5 advertised-routes | include
28.10.45.0/25
*>i 28.10.45.0/25      5.5.5.5              0      100      0 6 78 454 ?

```

XRv13, on the other hand, will show 4 routes. First comes the expected eBGP route, its best path. Both RR's select the path via CSR5 and reflect that to XRv13. Additionally, CSR9 sends its second best path to XRv13 also. Thus, two routes have a next hop of CSR5, one has a next hop of XRv12, and one is the eBGP route. The eBGP route is preferred over the iBGP ones since no BGP attributes have been modified.

```

This implies that CSR9 must not have any secondary paths or else we would have seen them reflected back to XRv13. We confirm this below. The reason is because now all of the other PEs to AS 6, such as CSR5 and XRv2, all prefer this iBGP path and do not advertise their eBGP path. Even though they have multiple iBGP paths, they are just reflections of the same local-preference 200 path. The RR's never learn anything unique, and by extension the remote PEs never learn anything unique, making the network somewhat stovepiped.

We can do some local damage-repair by configuring the PE's to install the eBGP route as a backup path. It doesn't really help the remote PEs on the other side of the network, like CSR3 and XRv14, but it's a small improvement. The XE command is simple for CSR5 but again, XRv12 requires a little more work. We will use a simple RPL for this one. As always, verify the FIB too (RIB verification doesn't matter because we are not load-sharing).

```

```

A good option for introducing more path diversity into the iBGP domain is allowing the "loser" PE's to advertise their best external route. You can enable it on all the PE's in case path selections change, but in this case, I just enable it on CSR5 and XRv12. Beware that in order for best-external to work, you must remove the negotiated add-path capability, since features like this and the shadow RR are independent (and sometimes mutually exclusive) from full-blown add-path. Now CSR5 marks this as its best eBGP path and still treats it as a fast-reroute backup.

```

CSR5(config-router-ptmp)#advertise best-external
% BGP: Addpath capability present. When negotiated, it will cause advertise
best-external to be silently disabled. Inheritance accepted anyway for
8.8.8.8

```

```

! CSR5

```

Similarly, we configure the feature on XRv12 so the RRs can learn its eBGP route also. XR seems content to advertise the best-external even when add-path capability is negotiated, unlike XE. It marks its best (and only) eBGP path as best external, and it's still a valid backup path.

```

A quick check of CSR8 and CSR9 show the paths. We did not configure any add-path options on CSR8, other than the basic negotiation, so it is still a classic RR in that it only sends its best path. CSR9, however, has now selected its three best paths. Without advertising the best-external paths from the “loser” PEs in the first place, the RRs would have never seen these additional paths in the first place. We can tell these are the “loser” paths because of the relatively low local-preference value.

```

```

Now, CSR3 and XRv14 can see the additional paths in the network from the RRs. They still select the proper "best" path because the whole reason one uses local-preference in the first place is for traffic engineering, and add-path honors that. The backup paths they select are the next-best paths with varying next-hops as we expected. However, even with this feature enabled, you should also have either add-path or shadow RR configured, otherwise all the RRs will simply pick the higher local-preference and ignore all the other best-externals. If add-path is not supported, you can use the shadow method by itself, which we examine in VPNv4 tests. Here, we can clearly see XRv13 as the primary path with CSR5 as the backup.

Another useful feature is group-best. This feature groups incoming routes together by AS, selects a best path, then picks the next best path from the group NOT from the same AS. CSR1, CSR2, and CSR4 all advertise 124.0.0.1/32 to CSR3. I've created three basic route-maps that set the local-preference to 101, 102, and 104 on this route inbound from CSR1, CSR2, and CSR4 respectively. CSR4 is the best path, with CSR2 as the "group-best" for AS 12. Another key point with group-best is that it is technically an additional-path and requires the negotiated capability. On CSR3 only, we enabled send/receive, along with CSR9. The other PE's are receive only and the other RRs are send only. CSR3's changes are below.

```

!CSR3
router bgp 100
template peer-policy IPV4

```

As expected, CSR3 will advertise this group-best path to CSR9 as a backup, additional path (b and a flags). Notice that CSR3 does not advertise it to CSR8 because CSR8 is not configured to receive additional paths. CSR9 advertises the ability to send/receive, while CSR8 only advertises the ability to send. Since each capability is distinctly different, I recommend enabling both everywhere to avoid the confusion if possible.

To demonstrate the behavior of group-best specifically, we will reduce the local-preference of CSR4 to 90. The best path becomes CSR2, but BGP cannot consider CSR1 as the next best path despite its local-preference being higher than CSR4. This is because CSR1 and CSR2 share an AS, so the group-best should have a different next-hop AS; this is a fault-tolerance mechanism. What is also interesting is that CSR3 uses the path through CSR1 as its local backup path because it's the second best, but advertises the group-best, which is CSR4. We can prove both points by checking the BGP RIB, FIB (for backup path), and neighbor advertised routes (for group-best). The advertised group-best route is no longer flagged with 'b' for backup, because it isn't one. I also include the "brief" view of the BGP table to demonstrate the differences between the three routes in summary form. All three routes are different: one best, one backup, and one additional group-best.

```

```

So far XRv11 has not been participating much in this test, mostly because of its inability to disable the IGP metric from its best path selection. This has a more significant effect on non-add-path features like shadow RR and best-external. To test XR as a RR with add-path, we will allow CSR8 and CSR9 to consider

IGP metric in their calculations again just so all RRs behave the same. We also disable ""best-external" from CSR5 so we are allowed to enable add-path negotiations. We then disable the add-path advertisements on CSR9. Essentially, we are doing some basic clean-up so that we can focus on XR.

```
! CSR5
router bgp 100
  template peer-policy IPV4
    no advertise best-external
  address-family ipv4
    no bgp additional-paths select best-external
    bgp additional-paths receive

! CSR8
router bgp 100

  template peer-policy IPV4
  advertise additional-paths best 2
  address-family ipv4
    no bgp bestpath igp-metric ignore
    no bgp additional-paths select best 3
    no neighbor 14.14.14.14 advertise additional-paths best 3

! XRv11
router bgp 100
  session-group IBGP
  no shutdown

! XRv12
router bgp 100
  address-family ipv4 unicast
  no advertise best-external
```

Let's quickly verify that XRv11 has properly negotiated the add-path capability, only because we haven't used it in awhile. Remember that we added the "send" capability on CSR3, the only PE with it configured. The remaining PEs are receive-capable while XRv11 advertises send capability.

```
RP/0/0/CPU0:XRv11#show bgp ipv4 unicast neighbors | utility egrep '^BGP
neigh|Additional'
BGP neighbor is 3.3.3.3

    Additional-paths operation: Send
    Additional-paths operation: None

```

We solved the local-preference 200 problem earlier using advertise-best-external, which allowed CSR5 and XRv12 to send their eBGP routes to the RRs. This time, we will enable BGP add-path receive capability on XRv11 and add-path send capability on CSR5 / XRv12. Then, we verify the negotiations were successful. We see that with CSR5 and XRv12, both send and receive capabilities are negotiated bidirectionally. The configuration is not shown as we have seen it many times so far.

Additional-paths operation: None

Recall that XRv13 is setting local-preference 200 inbound for the prefix 28.10.45.0/25, making it the preferred exit point from AS 100. All of the PE's on the other side of the SP network are going to have three copies of that route, one from each RR, since each RR only learns this one path, it is the only thing it can advertise. The PE's also have their less-preferred eBGP routes which can be considered additional paths. We check the detailed output on CSR3 and the brief output on XRv14 to prove it.

```
CSR5#show bgp ipv4 un 28.10.45.0/25

```

Next, we configure both CSR5 and XRv12 to select all paths as additional paths. XRv12 automatically advertises them to neighbors without a neighbor-level command, while CSR5 requires it. BGP is smart enough to know that the three copies of the exact same route on CSR5 and XRv12 do not qualify as additional paths, and additionally, the PE's are not RRs (so basic iBGP says we cannot advertise them further). We have effectively allowed the PE's to advertise their best external routes using add-path capabilities as an alternative method to achieve the same result. A quick look at XRv11 confirms this; notice the variance in next-hops and local-preference values. BGP still selects the proper best-path, though. There is still a problem; XRv11 is not advertising any of its additional-paths to clients on the other side of the network, such as CSR3 and XRv14. BGP add-path is less effective if only the RR's have visibility of the additional paths.

```
RP/0/0/CPU0:XRv11#show bgp ipv4 unicast 28.10.45.0/25 brief | begin Network
```

Network	Next Hop	Metric	LocPrf	Weight	Path
* i28.10.45.0/25	5.5.5.5	0	100	0	6 78 454 ?

28.10.45.128/25	5.5.5.5	5.5.5.5	6	78	454?

```
[snip]
```

We can correct this by specifically telling XRv11 to advertise backup paths. For some reason, XRv only lets me use the number 1, even with parameterization, but the documentation claims it can be between 0 and 7 (3 bits). After applying this configuration snippet, XRv11 selects a single back-up path via CSR5 (lower RID than XRv12) and advertises this to its neighbors. We verify the advertisement and also that the route is marked as "backup" and "add-path" in the BGP table. This is equivalent to "best2" in XE.

```
! XRv11
route-policy RPL_ADV_ADD_PATHS
  if destination in (28.10.45.0/25) then
    set path-selection backup 1 advertise
  endif
end-policy

* i	13.13.13.13	0	200	0 6 78 454 ?

It would be even better if we could get the path from XRv12 advertised to our left-side PEs also via XRv11. A simple RPL modification to select all available paths (there doesn't appear to be a best3 equivalent ... its 0, 1, or all) solves this. CSR3 still has 3 copies of the best-path, but has two additional paths received from XRv11. I show the RPL configuration, XRv11 advertisement to CSR3, CSR3 BGP table displaying all 5 paths, and the route reception on CSR3 from XRv11. The path via XRv12 may not be a hot-standby but having it locally can still be valuable for future design changes, such as ECMP, without needing to reconverge BGP.

```
! XRv11

```

So far, we have focused on IPv4 unicast. IPv6 unicast works identically, and one would expect all AFs to work this way. Unfortunately, current XE code only supports the send/receive negotiated capability for IPV4/IPv6 unicast/multicast. All other AFs, such as VPNv4, VPNv6, L2VPN variations, RT-filter, NSAP, etc do not currently support this capability. The CSR does support backup path selection and best-external-advertisement for VPNv4 and VPNv6 though, but supports no BGP add-path features for the remaining AFs. XR appears to fully support the feature for all AFs, even new AFs such as BGP-LS and BGP flowspec. That being said, we will quickly test IPv6 unicast in our setup using 6PE as the provider core is not IPv6 enabled. XRv11 BGP process is shutdown for this test as it does not support ignoring the IGP metric in the bestpath calculation.

```
! CSR8 and CSR9
router bgp 100
```

```
address-family ipv6 unicast
  bgp bestpath igp-metric ignore
```

At this point, both CSR8 and CSR9 select CSR5 as their best path due to having the lowest BGP RID. The result on CSR3 and other remote PEs is that they receive multiple copies of the same path with the same BGP next-hop. A failure of CSR5 would break 6PE despite the existence of alternative paths.

```

```

We will configure CSR9 to select its backup path for advertisement using the minimum number of commands. CSR9 is instructed to select its backup path as the additional path, then advertise it to all IPv6 labeled-unicast neighbors. CSR3 still picks CSR5 as the exit point due to lower originator ID, but the backup path is XRv12. Ideally, we should configure CSR9 to install this as a backup path also, but that technically isn't a function of the shadow RR method, just an additional optimization. We verify that this backup path exists in the BGP table and the FIB. CSR3 will ECMP to the primary destination of CSR5 via CSR9 and XRv11 while the backup path routes via XRv11 exclusively.

```

```

Next, we will demonstrate the PE's each advertising their best-external routes as this does not require add-path negotiation. XRv13 will set the local preference on the prefix 2001:28:14:170::/64 to 200 so that it is the preferred exit point from AS 100. We demonstrate the power of RPL again by using our highly generic existing configuration. Both CSR5 and XRv12 consider this their best path, and because it is iBGP learned (and these PE's are not RRs), it cannot be advertised to the RRs.

```

The result is that the RR's only have a single route to exit the AS, and this is all they distribute to their peers. The remote PEs, such as CSR3, are going to see the same copy of that single route. Our existing solution of using shadow RR in isolation won't solve the problem because the RR's only see one path in the first place.

As seen earlier, we can use best-external to solve this. CSR5, XRv12, and XRv13 are configured to advertise their best external routes to the RRs, giving them a better view of the network. Then, our existing shadow RR configuration ensures that a diverse path is advertised to the remote PEs. Note that these PE's must also install this path as a backup before they are able to advertise it to the RR. Unfortunately, this "selection" keyword on XR seems to only apply to the negotiated add-path

capability. XRv12 claims the path was selected as a backup but was not advertised to the RRs, probably because it expects the full negotiated capability to be exchanged.

```
! CSR5
router bgp 100
  template peer-policy IPV6_INTERNAL
    advertise best-external
  address-family ipv6 unicast
    bgp additional-paths select best-external
    bgp additional-paths install

! XRv12 (should be on XRv13 also to account for failovers also)
route-policy RPL_BACKUP_1
  set path-selection backup 1 advertise install
end-policy

router bgp 100
  address-family ipv6 unicast
    additional-paths selection route-policy RPL_BACKUP_1
```

At a minimum, the RR's receive the best-external from CSR5, which can be advertised to the remote PEs using the diverse-path (shadow RR) method. Another very odd issue can be observed on CSR9. Notice that the IPv6 next-hop is reachable, but is inaccessible. This is because there is no MPLS label associated with the 6PE prefix. I don't have a great reason for this, but the debug on CSR9 reveals that the MPLS label for this backup path was not advertised with the prefix from CSR5. Notice that all the other routes have labels.

On CSR5, when debugging outbound updates, we see that the label was never sent. Digging deeper, we see that local label was not even allocated. This is true on both CSR5 and XRv12, and I am concluding that the older, non-negotiated add-path features were not designed to work with labeled-unicast. MPLS wasn't supposed to reinvent the wheel, but rely on existing IGP and BGP routing, and since the shadow

RR method is breaking rules without any active communication, MPLS may not understand. BGP may see no reason to allocate labels (the local labels are highlighted) for paths that are not best. So, using additional-path best-external with labeled-unicast AFI does not appear to be a valid design.

```

Let's try to salvage this design by removing the best-external configuration from CSR5 and enabling the BGP add-path negotiation. We will enable send/receive capabilities on the PEs and RRs so we can do all our testing bidirectionally as needed. For completeness we will apply these changes on all relevant devices. This also means we can bring XRv11 back into the network. The snippets are shown below, along with the basic neighbor negotiation verifications. I am only showing outputs from the RR's to save time; if they see the proper negotiations sent/received them it's a fair assumption to assume the PE's are configured properly for add-path. It can be time consuming to do these basic verifications but trying to troubleshoot why additional-paths aren't being advertised is much more difficult.

```

CSR9 has the backup routes from CSR5 and XRv12 now. Technically, the existing selection and advertisement of the diverse-path could work, but with add-path negotiation enabled, it makes more sense to use that. The parser also tells you that the non-negotiated add-paths features are silently ignored when negotiated add-path is configured. I will configure CSR9 to select its best 3 paths for backup, and advertise 2 towards remote PEs by default. XRv14 will be an exception and receive all 3 paths. We can see the "best2" path from CSR5 and XRv12 on the RR (CSR9). We see that CSR3 has 3 copies of the best-path, and selects the CSR5 path as the backup. XRv14 also has 3 copies of the best path plus backups via CSR5 and XRv12 (on XRv14 sees the path via XRv12, though).

Next, we will examine VPNv4 and VPNv6 tests briefly. This will be short because the CSR does not support the negotiated capabilities, but just the diverse-path, best-external, and backup install mechanisms. CSR4 and CSR10 are the VPNv4/v6 customers. An interesting design note with VPN service is that we can achieve additional-paths simply by having unique RD's. For example, CSR5 uses RD 100:5, while XRv13 and XRv12 use RD 100:13. CSR9 doesn't have any VRFs locally configured, but by breaking the routes apart by RD, we see one route in table 100:5 and two in table 100:13. The RR runs best-path on these routes within an RD, never across, so there are two best-paths advertised to remote PEs. One is 100:13:10.10.10.10/32 via XRv13 and one is 100:5:10.10.10.10/32 via CSR5. We could have had three different paths if XRv12 had a unique RD, such as 100:12, but I wanted to combine it with XRv13 to demonstrate the point.

```

CSR7 has received both RD 100:13 routes with next-hops of XRv12 and XRv13. Best-path runs on these routes first, before import into the VRF, so that only one VPN route is imported per RD. Because both XRv11 and CSR8 selected XRv12 as the best path, CSR3 has a copy of each route. Ultimately, the route through CSR8 wins due to lower BGP peer ID (the last tie breaker) and progresses to the "next round".

```

Best-path within RD 100:5 is much less interesting because all three RR's selected the same best path (the only path) which is via CSR5. The path selected was based on the lowest neighbor ID (the last tie breaker), indicating the routes are equivalent in every way. This best path advances to the "next round".

```

CSR7 imports these "best within the RD" VPN routes into the VRF for further processing, which allows it to directly compare all three routes since they are competing for a spot in the VRF RIB; they already exist in the VRF BGP table though. CSR5 wins due to lower originator ID. Enabling additional-path install and backup selection gives us fast-reroute without having to do anything fancy with the route-reflectors. This is a good design case for using different RD's at each PE, even for a single customer VRF. It is simple and does not require much additional complexity in the SP network.

We will quickly demonstrate the shadow RR feature. This involves using the same RD on CSR5, XRv12, and XRv13, which forces the RR to only advertise one path. We change CSR5's RD to 100:13 to accomplish this. Beware that deleting the RD from the VRF automatically removes VRF-related BGP configuration and RT import/export policies, so backup the configuration before attempting the change. We already know that the route-reflectors are going to get three copies of the same route, pick a best path, then advertise that single path to CSR7. This creates the inherent problem add-path was meant to solve.

As usual, we ignore the IGP metric in the RR for VPNv4/v6 so that RR's have the exact same topology regardless of IGP changes. Then, we configure CSR to be the shadow RR so it can advertise a diverse, second best path. CSR8, as usual, advertises its single best path, while CSR9 advertises a backup, diverse path (which is not marked as best).

! CSR8

As expected, CSR7 runs best-path within the RD and identifies the best and backup paths. The issue is that only one of these paths is actually imported into the VRF table, which means FRR is not achieved. Even if I configured add-path install under the VRF, it did not work. I have seen online blogs and my colleagues configured it successfully, but I have personally never seen it work, and so I do not document it here.

Only one route is imported into the VRF table, which means the FIB will only have one entry. While the VRF import process is probably very fast given the backup path, the FIB not being pre-programmed is a fundamental principle of FRR. The multiple RD method is simpler, more effective, and seems to be recommended by Cisco.

Given the density of XRv, I will attempt to use the negotiated capability between XRv11, XRv12, and XRv14 to demonstrate the equivalent of "best-external". XRv3 sets the local-preference of its exported VPN routes to 200 and advertises this to its iBGP peers. It is now the preferred exit point from AS 100 for VPN customer traffic. XRv12 selects this as its best path, giving the RR's no indicating of an alternative. The eBGP path is considered an "import suspect" as it was not a candidate for import into BGP (export from VRF).

```

To fix it, we need quite a bit of configuration. We need to enable the dynamic add-path capability on XRv11, XRv12, and XRv14. Each router needs to select its backup paths using RPL, and they need to be advertised to the RRs (XRv12 to XRv11), then advertised and installed on the remote PE (XRv14).

```
! XRv11
route-policy RPL_VPN_ADD_PATH
  set path-selection all advertise
end-policy

router bgp 100
  address-family vpnv4 unicast
    additional-paths send
    additional-paths receive
    additional-paths selection route-policy RPL_VPN_ADD_PATH

! XRv12
router bgp 100
  address-family vpnv4 unicast
    additional-paths receive
    additional-paths send
    additional-paths selection route-policy RPL_BACKUP_ALL

! XRv14
route-policy RPL_ADD_BACKUP
  set path-selection backup 1 install
end-policy

router bgp 100
  address-family vpnv4 unicast
    additional-paths receive
    additional-paths send
    additional-paths selection route-policy RPL_ADD_BACKUP
```

XRv12 now considers this a valid add-path and advertises it to XRv11. The RR sees the additional path from XRv12 and can advertise it to XRv14.

```

```

Finally, the remote PE gets both routes and marks the less preferred route (lower local-preference) as a backup path. We still have the same issue as earlier, which is that only a single route gets installed in the VRF RIB and thus in the FIB. This is why unique RD is still the best solution in my eyes. The reason the FIB shows two paths is due to IGP ECMP towards 13.13.13.13; don't be fooled.

Last, we will examine VPNv6 with add-path. CSR5, XRv12, and XRv13 all still use the same RD, so we will test add-path first before testing diverse RDs. Looking quickly at CSR9, we see that the bestpath to ::10:10:10:10/128 is via CSR5 due to lowest metric, and then due to neighbor RID. CSR8 picks XRv12 for the same reason. Fortunately, we can achieve a little bit of redundancy based on NOT ignoring the IGP metric in this specific situation. The problem is that changes in the IGP topology may negatively influence our BGP topology with designs like this. Without even looking at XRv11, we know that it will select CSR5 over XRv12 due to lower RID, and rejects XRv13 due to higher IGP cost.

On CSR7, we will receive two copies of CSR5's route (via CSR9 and XRv11) and one copy of XRv12's route (via CSR8). Activating add-path install allows the route to XRv12 to be considered a backup, but not installed in the VRF FIB, because RD-level bestpath happens before VRF import from BGP. This is the same issue we saw before.

```

We can achieve a similar, and somewhat better result, by ignoring the IGP metric on CSR8 and CSR9 (we will disable XRv11 for this since it doesn't support that command), and directing CSR9 to advertise diverse paths. This is the shadow RR feature we have tested many times. CSR8 and CSR9 both select CSR5 as the bestpath given the lowest RID. In terms of advertisements, CSR8 advertises the bestpath (classic RR behavior), while CSR9 advertises its backup path (shadow RR behavior). Notice that the route advertised by CSR9 is marked as an additional and backup path, but is not the bestpath.

```

Last, we will change CSR5's RD back to 100:5 to achieve "optimal" path diversity without using BGP add-path on the RRs. Remember that it will wipe out all of the RT import/export policies and related BGP configurations. We will combine it with changing the local-preference on XRv13 to 200 for ::10:10:10:10/128 so that the remote PE's have a common exit point from the AS, but the VRF table should have the backup path installed in the FIB also.

```

BGP add-path is a very involved feature and there are many minor options worth testing. PIC, on the other hand, is a simple concept with almost no configuration involved. The idea of PIC is to create a hierarchical FIB to speed up convergence. Legacy FIBs were two-tiered, in which a prefix was mapped to an outgoing interface and next-hop value. Because the number of routes in a large router was orders of magnitude greater than the number of connected routes (possible next-hops), a reconvergence event would require a tremendous amount of updates to the FIB which took minutes to accomplish. For example, an Internet router with 400,000 routes may have 10 connected interfaces or so. This means an average of 40,000 routes all have the same next-hop, yet we still have to make 400,000 updates to each individual FIB entry. It would be much more efficient to update the next-hop references (using a pointer of sorts) while the FIB just references the pointer itself. This is called a three-tier or hierarchical FIB which greatly speeds convergence. A change in next-hop status due to IGP failure would result in the FIB updating a next-hop pointer, which is referenced by 40,000 routes. This is theoretically 40,000 times faster to converge since there is one change for 40,000 prefixes, rather than 40,000 next-hop updates for 40,000 prefixes. Enabling PIC is often done simply by designing a BGP add-path architecture.

To change the way the FIB is built, you can adjust the CEF table construction for fast convergence or efficient memory use. The two are mutually exclusive, but on modern routers the general preference (and the default) is to favor speed. We can adjust this in global configuration, and also verify the behavior as well. The default is shown below (convergence speed) while memory utilization is another option.

```

CSR1#show cef table | section favor
Output chain build favors:
platform:      not configured
CLI:           not configured
operational:    convergence-speed

```

```

CSR1(config)#cef table output-chain build favor ?
convergence-speed    Favor faster convergence
memory-utilization   Favor smaller memory utilization

```

Additional Reading – Reference configurations “bgp-add-path”

27.2 BGP RT-filter unicast / IPv4 RT-filter feature

Most designs have a BGP hierarchy using VPN RRs. If a PE is only imported a subset of RTs, the RR will reflect all VPN routes to a PE where the majority of them are rejected due to the RT-import not being locally configured for any VRF. This is generally desirable, but would be better if it could have been filtered outbound on the sender versus inbound on the receiver. The feature is also called "RT constrained route distribution". Features like aggregation (notwithstanding the default route), redistribution, and iBGP synchronization are not supported for this feature. They don't really make sense anyway since this is meant to reduce routing advertisement based on RTs. When the feature is not negotiated, the default filter states that all RTs should be sent to a peer, regardless of RT value. The local router will just reject the ones it doesn't actually need. Ensure your routers have enough memory to store all these RT-filter "routes" (also called RTC prefixes) as it could create a sizable footprint in the BGP LocRIB on the RRs. This feature is loosely analogous to Outbound Route Filtering (ORF).

Without enabling the feature yet, we configure a basic VPNv4 route exchange with proper RT import/export policies. Both routers show the prefix attributes and the VPNv4 allocated label. This was successfully imported into at least one VRF, or at a minimum, not filtered from the VPNv4 LocRIB.

```

CSR1#debug bgp vpnv4 unicast updates in
BGP(4): 11.0.0.11 rcvd UPDATE w/ attr: nexthop 11.0.0.11, origin ?, localpref
100, metric 0, extended community RT:1:111
BGP(4): 11.0.0.11 rcvd 1:1:100.11.11.11/32, label 91000
BGP(4): Revise route installing 1 of 1 routes for 100.11.11.11/32 ->
11.0.0.11(A) to A IP table

```

We see similar output in XR, except that it is a little harder to read.

```

RP/0/0/CPU0:XRv11#debug bgp update vpnv4 unicast
bgp[1046]: [default-rtr] (vpn4u): nexthop 11.0.0.1/32, origin ?, localpref
100, metric 0, extended community RT:1:101
bgp[1046]: [default-rtr] (vpn4u): Received prefix 2ASN:1:1:100.1.1.1/32 (path
ID: none) with MPLS label 1002 from neighbor 11.0.0.1

```

```
bgp[1046]: [default-upd] VRF A: table-attr walk for table TBL:A (1/1), resume
version 0, subgrp version 8, target version 10
```

On CSR1, we remove the RT import for 1:111, so CSR1 should reject it. The debug doesn't explicitly say the RT was rejected, but the generic "extended community not supported" normally indicates an RT import issue.

```
! CSR1
BGP(4): 11.0.0.11 rcvd UPDATE w/ attr: nexthop 11.0.0.11, origin ?, localpref
100, metric 0, extended community RT:1:111
BGP(4): 11.0.0.11 rcvd 1:1:100.11.11.11/32, label 91000 -- DENIED due to:
extended community not supported;
BGP(4): no valid path for 1:1:100.11.11.11/32
BGP: topo A:VPNv4 Unicast:base Remove_fwdroute for 1:1:100.11.11.11/32
```

Likewise on XRv11, we remove the RT import for 1:101. The XR debug is more explicit and tells you there is an issue with the RT import policy.

```
! XRv11
bgp[1046]: [default-rtr] (vpn4u): nexthop 11.0.0.1/32, origin ?, localpref
100, metric 0, extended community RT:1:101
bgp[1046]: [default-rtr] (vpn4u): Received prefix 2ASN:1:1:100.1.1.1/32 (path
ID: none) with MPLS label 1002 from neighbor 11.0.0.1
[default-rtr] (vpn4u): Prefix 2ASN:1:1:100.1.1.1/32 (path ID: none) received
from 11.0.0.1 DENIED RT extended community is not imported locally
bgp[1046]: [default-upd] (vpn4u): No unreachable (no path is available) sent
to sub-group 0.1 (Regular) with 2ASN:1:1:100.1.1.1/32 - already withdrawn
```

Assuming that these routers don't want one another's routes, not importing the RTs ensures the VPN topology is functional but still requires the receiving PE to process each route individually. This can consume router resources and waste network bandwidth. We will enable the rt-filter feature on both routers. It is called different things between XE and XR, though. Specifically, the XE AF is "rt-filter unicast" and the XR AF is "ipv4 rt-filter". Assuming a semi-worthless configuration where neither router imports any RTs, the LocRIB for the RT-filter AF is empty, which implicitly says "my neighbor requested no RTs, so I send him nothing". The debug on CSR1 indicates that the prefix was denied, but doesn't give much detail. We know it's due to the dynamic RT filter.

```
! CSR1
BGP(4): (base) 11.0.0.11 send UPDATE (format) 1:1:100.1.1.1/32, next
11.0.0.1, label 1002, metric 0, path Local, extended community RT:1:101
BGP(4): (base) 11.0.0.11 Peer based policy member(format) 1:1:100.1.1.1/32,
next 11.0.0.1 result(denied)
```

The debug on XRv11 indicates that the update was not sent to CSR1 and is more detailed than the CSR debug.

```
!XRv11
bgp[1046]: [default-upd] (vpn4u): Deny UPDATE to filter-group 0.2 (Regular,
pelem Regular) for 2ASN:1:1:100.11.11.11/32 (changedfl=0x1000000/0x0), path
reason Dropped by RT Filter
bgp[1046]: [default-upd] (vpn4u): No unreachable (Dropped by RT Filter) sent
to sub-group 0.1 (Regular) with 2ASN:1:1:100.11.11.11/32 - already withdrawn
```

Next, we will add the baseline RT import policy to CSR1 but not to XRv11 yet. The dynamic RT filter should be updated so that the RTs can be advertised between the neighbors. We will activate debug for both VPNv4 and rt-filter AFIs. BGP(11) in this case is rt-filter and BGP(4) is VPNv4.

```
CSR1#debug bgp vpnv4 unicast updates in
CSR1#debug bgp rt-filter unicast updates in
BGP: 111:2:1:111 bestpath, is sourced, is not multipath
BGP(11): 11.0.0.11 NEXT_HOP self is set for sourced RT Filter for net
111:2:1:111
BGP(11): (base) 11.0.0.11 send UPDATE (format) 111:2:1:111, next 11.0.0.1,
metric 0, path Local
BGP(4): 11.0.0.11 rcvd UPDATE w/ attr: nexthop 11.0.0.11, origin ?, localpref
100, metric 0, extended community RT:1:111
BGP(4): 11.0.0.11 rcvd 1:1:100.11.11.11/32, label 91000
BGP(4): Revise route installing 1 of 1 routes for 100.11.11.11/32 ->
11.0.0.11(A) to A IP table
```

First, CSR1 creates an rt-filter RTC prefix that contains A:B:C:D ...

A = BGP AS number

B = Usually 2 for the extended-community type code

C:D = The route target we are importing

```
CSR1#show bgp rtfiler unicast all detail
BGP routing table entry for 111:2:1:111, version 2
  Paths: (1 available, best #1)
  Advertised to update-groups:
    3
  Refresh Epoch 1
  Local
    0.0.0.0 from 0.0.0.0 (1.1.1.1)
      Origin IGP, localpref 100, weight 32768, valid, sourced, local, best
      RT generation: import
      rx pathid: 0, tx pathid: 0x0
```

We can also see this on XRv12 as being received from CSR1, both in debug and show commands. XR will consult this table before advertising VPN routes to a peer to ensure those RT's are requested. This is a similar operation to the outbound route filtering (ORF) capability used to communicate an inbound prefix filter to the remote peer.

```

! XRv11
bgp[1046]: [default-upd] (vpn4u): Permit UPDATE to filter-group 0.2 (Regular,
pelem Regular) for 2ASN:1:1:100.11.11.11/32 (changedfl=0x1000000/0x0), path

```

XRv11 isn't going to do anything with those as no one is exporting VPN routes with those RTs, but we can see a 1:1 correlation between imported RT's and what is advertised between the neighbors.

```
RP/0/0/CPU0:XRv11#show bgp ipv4 rt-filter

Verify that CSR1 has received them. We will look at one of them as an example. No surprises. This effectively says "11.0.0.11 wants RT:1:801".

```
CSR1#show bgp rtfilter unicast rt 1:801
BGP routing table entry for 111:2:1:801, version 8
Paths: (1 available, best #1)
  Not advertised to any peer
  Refresh Epoch 1
  Local
    11.0.0.11 from 11.0.0.11 (11.11.11.11)
      Origin IGP, localpref 100, valid, internal, best
      rx pathid: 0, tx pathid: 0x0
```

As a final test, let's pretend XRv11 is a route-reflector for VPNv4 and the RT-filter AFIs. Ideally, CSR1 should be sending all RTs it exports to XRv11 without XRv11 having to explicitly request it via individual RTC prefixes. The "default-originate" command violates many of the formatting rules defined earlier, such as encoding the BGP AS number, community code, and RT. The zeroes in the RTC instruct the RR client to send all VPN routes with any RTs to the BGP peer, which is a RR. **Notwithstanding the default route, aggregation is not supported with the RT filter feature.**

```
! XRv11
router bgp 111
 neighbor 11.0.0.1
   address-family vpnv4 unicast
     route-reflector-client
   address-family ipv4 rt-filter
     route-reflector-client
   default-originate
```

CSR1 shows this "default" RTC and uses this to send all RT's to the peer 11.0.0.11, which is the RR.

```
CSR1#show bgp rtfilter unicast all
[snip]
```

27.3 BGP RR-group and Selective RT Retention

This lab investigates how to enable efficient route retention on BGP RRs when using VPNv4 and/or VPNv6. Traditionally, BGP RRs for VPN routes must always maintain all routes from RR-clients, regardless

of their RT values. This is because the RR expects the PE to filter RTs that are unwanted. The feature in the previous chapter is one solution to the problem which actively enables a communication method between devices. This lab uses a passive feature that is local only, requires no additional AFI negotiation, and can save memory on RRs/PEs in a highly distributed RR architecture. The diagram is shown below. Several unrelated advanced technologies have been enabled for further testing in other sections, such as TE auto-primary tunnels and MVPN, but those are not the focus of this lab. CSR1, CSR2, XRv1, and XRv2 are BGP RRs for VPNv4 and VPNv6. CSRs 5 through 10 are LSRs within BGP AS 56. The IS-IS areas are built in such a way to shield the RRs from the “large” IS-IS level-2 domain. This design attempts to move BGP RRs entirely out of the control plane, both from a forwarding and feature perspective (not running MPLS, PIM, etc). All PEs peer with all RRs for VPNv4 and VPNv6. There are 2 VPNs, RED and BLUE. Each CE runs VRF-lite to support both VPNs and each PE provides service for both VPNs. VPN RED uses BGP for IPv4/v6 routing while VPN BLUE uses RIPv2 and OSPFv3 for IPv4 and IPv6 routing, respectively.

The basic configurations, such as interfaces, IS-IS routing, and BGP peers are not discussed in detail. Each router runs IS-IS on all interfaces as shown in the diagram with the loopback interfaces advertised. Instead, we quickly verify the network using cursory show commands. On CSR6, we verify the IS-IS level-2 database. In a single show command, I reveal all of the IS-IS level-2 routers and their links while hiding the IP prefixes. Quickly skimming this output, we confirm that it corresponds with the diagram above.

Since CSR6 is an L1L2 router, it also has a level-1 LSPDB. This is much smaller, but we expect to see CSR1 along with a transit link. CSR6 sets the attached-bit so that CSR1 installs a default route via CSR6. The other three L1L2 routers do this as well (not shown below).

```
R6#show isis database level-1 detail | include ^[RX]|Extended
R1.00-00      0x0000000B  0xCDE7      603      0/0/0
Metric: 10    IS-Extended R6.00

Metric: 10    IS-Extended R1.00
```

MPLS TE is enabled for IS-IS L2 only. This output should mirror the IS-IS level-2 LSPDB exactly as TE is enabled on all nodes and all links. This is a critical part of the MPLS transport infrastructure as LDP is not enabled on IS-IS interfaces.

```

```

MPLS LDP is not enabled directly on the transit links. Instead, TE auto-primary tunnels are configured. These tunnels are automatically created to every one-hop peer as determined by the TED. The tunnels have autoroute announce and FRR automatically configured as well. I enable tLDP on them so that routers more than one hop away (CSR6 to CSR9, for example) can still communicate. This feature is discussed in detail in the TE section, but in summary, the idea is to “protect every link” in the topology. This offers protection to LDP and mLDP LSPs, not just TE LSPs, and it scales quite well. CSR6, for example, is the headend for tunnels to CSR5 and CSR8. It is also the tail end for the complementary tunnels from those routers along the reverse path. I do not use this technique often which is why I configure it for variety here. Normally this feature is paired with auto-backup tunnels for TE-FRR, but I omit that configuration for clarity.

```

! All LSRs
mpls traffic-eng auto-tunnel primary onehop

```

The one-hop tunnels always bind implicit-null as the headend is always the penultimate hop. For this reason, many tunnels are PE-P or P-P, requiring an additional label in the stack. Thanks to tLDP, CSR6 is able to send MPLS-encapsulated traffic to CSR10, which is multiple hops away. This is not specific to the features addressed in this lab, but is the basis for all MPLS forwarding and must be verified.

```
R6#show ip route 56.0.0.10

```

Next, we configure BGP towards the RRs and the configuration on all four PEs is identical. The configuration is simple as all PEs peer to all four RRs using all supported AFIs. The VRFs will be configured after the core infrastructure is built. IPv4 MDT is also negotiated to support PIM/GRE MVPN, which is beyond the scope of this test as well. Since that AFI has no concept of RT, there is no ability to “filter” prefixes from IPv4 MDT based on RT extended communities.

```
! CSR5, CSR6, CSR9, CSR10
router bgp 56
  template peer-session IBGP
    remote-as 56
    update-source Loopback0
    timers 10 40

  address-family ipv4 mdt
    use af-group AF_IPV4_MDT

```

At this point, all BGP sessions should form. **Note that BGP (XE and XR) will never initiate a session when the longest-match route to a peer is the default route.** This means all of the RRs, at this point, will be passively listening for BGP OPEN messages from their peers. They can reply along the default route, but not initiate. Once the sessions form, we quickly verify them. Rather than document all sessions on all RRs for all AFIs, I show CSR1 and XRv1 only. All sessions are verified as up but are not documented. No routes are currently received by the RRs as the VRFs have not yet been configured.

```

To prove that BGP cannot initiate sessions via a default route, we can check the TCP brief on CSR1 and XRv1. Note that each RR will have one /32 route to the connected L1L2 router, so it is possible that one session may be initiated by the RR. For example, CSR1 has a route to 56.0.0.5/32 and XRv1 has a route to 56.0.0.6/32 as a result of being connected to CSR5 and CSR6, respectively. XRv1 initiated the connection to CSR6 coincidentally, while CSR1 did not. The other 3 sessions that are reachable via the default route are highlighted; the RRs are servers (not initiators) for all of them.

```

R1#show tcp brief

The PE-CE setup is configuration intensive but very simple. As described earlier, each CE (CSR3, CSR4, XRv3, and XRv4) runs VRF-lite so it can represent multiple CE routers. VPN RED uses BGP while VPN BLUE uses RIPv2/OSPFv3. The CE configurations are not shown here, and only snippets from the PEs are shown. There are 2 RDs and 8 RTs in use. VPN RED uses RD 56:100 and VPN BLUE uses RD 56:200 on all PEs. Individual PEs use different import/export RTs shown below in the configuration. CSR5, for example, exports RT:56:213 and imports 3 others. The other 3 represent the remote PEs. The same is true inside both VPNs and both AFls, totaling 8 RTs. Having RT diversity is important to test the RR-group and RT retention features. The MVPN configuration is shown for reference only. It is important to note that RED RTs contain the BGP ASN and a number within the 100-199 range. VPN BLUE is similar except the number is in the 200-299 range, which is important for matching.

```
! CSR5
vrf definition BLUE
  rd 56:200
  vpn id 56:200
  route-target export 56:213
  route-target import 56:214
  route-target import 56:203
  route-target import 56:204

  address-family ipv4
    mdt preference mldp
    mdt default mpls mldp 56.0.0.7
  address-family ipv6
    mdt preference mldp
    mdt default mpls mldp 56.0.0.7

vrf definition RED
  rd 56:100
  route-target export 56:113
  route-target import 56:114
  route-target import 56:103
  route-target import 56:104

  address-family ipv4
    mdt default 232.0.0.100
  address-family ipv6
    mdt default 232.0.0.100
```

All of the PEs use a very similar configuration except the RT import/export policies are adjusted slightly. The full-mesh L3VPN is the end-state. The basic PE-CE routing is shown below, along with the VRF-aware

RIPv2 and OSPFv3 process inside VPN BLUE. This is basic L3VPN and is not discussed in detail. The CE configurations are not shown, but they are configured similarly to exchange routes with the PE.

```
! CSR5
route-map RM_CONN_BGP deny 10

   network 10.0.0.0
   no auto-summary
   version 2
```

Assuming the CEs are configured, the PE should be learning IPv4 and IPv6 routes inside of both RED and BLUE VRFs. All of these routes would be advertised to all four RRs. Checking CSR1 and XRv1, we can see all of the routes are present from all PEs (each PE injects 4 routes per VPN, per AFI). For completeness, I show the entire VPNv4 routing table on CSR1, where it clearly depicts 4 routes from each PE within each RD. These are the routes within the two VPNs (recall that RED uses RD 56:100 and BLUE uses RD 56:200). This makes for 8 total VPN routes from each PE. Using the VPNV6 summary command, we can see this as well, which serves as a cursory check.

```

Checking XRv1, we see an interesting problem. None of the VPN routes are marked as best path. Upon closer inspection, XRv1 claims the VPN next-hop is unreachable. This is because XR expects a non-default route to the BGP next-hop, in addition to the peering restriction discussed earlier. XE did not seem to care (CSR1 and CSR2) that the only route to the VPN next-hop was a default route. XRv1 and XRv2 are ineffective as VPN RRs in the design at present.

```

Since this issue is not the focus of this lab, we can quickly resolve it by leaking PE loopbacks (not core loopbacks) into IS-IS level-1 areas on CSR5 and CSR9. To do this semi-dynamically, I apply a route tag of 56 to the PE loopbacks. The route-map on CSR5 and CSR9 matches this tag and allows those loopbacks to leak into level-1. This has the added benefit of allowing XRv1 and XRv2 initiate BGP sessions to the PEs as there is a non-default route to reach them.

```
! All PEs
interface Loopback0
isis tag 56

! CSR5 and CSR9
route-map RM_LEAK_LOOP_L1 permit 10
match tag 56

router isis 56
redistribute isis ip level-2 into level-1 route-map RM_LEAK_LOOP_L1
```

This immediately fixes the problem on XRv1 as shown below. We also check to ensure that XRv1 is receiving VPNv6 routes. Like CSR1, it receives exactly 8, as expected.

```
RP/0/0/CPU0:XRv1#show bgp vpnv4 unicast | begin Network

56.0.0.10	0	56	988	962	113	0	0	02:14:50	8

With the BGP configuration complete, I quickly test VPN connectivity on a few routers. Although MPLS forwarding is not the focus of this lab, this will ensure BGP was configured properly. We will perform more detailed BGP verification later. Using nested TCL, I can execute 16 pings between each pair of addresses within a given VPN. One example is shown below, and it succeeds.

```
! CSR3
tclsh
foreach x {
100.13.0.1
100.13.64.1
100.13.128.1
100.13.224.1
} { foreach y {
100.3.0.1
100.3.64.1
100.3.128.1
100.3.224.1
} { ping vrf RED $x source $y repeat 3 timeout 1 } }
```

The issue with this design is that the PEs have many copies of the exact same route. CSR10, for example, receives a copy from all four RRs. Upon deeper inspection, we see that the route from CSR1 is always preferred as it has the lowest BGP peer ID (the final tie-breaker). This is irrelevant since all routes are identical, but it is a waste of memory on both the RRs and PEs.

```

With such a distributed RR infrastructure, it would make sense if different RRs could service different VPNs. This is accomplished by selecting which RTs an RR can retain as discussed earlier. On XE, the feature is known as BGP “RR-groups” which are not to be confused with RR clusters. This is a simple configuration which uses an extended-community list of RTs as a pass/fail filter. A certain RR can be configured to retain only specific RTs that match the filter and reject all others. RRs assume that, by default, all RTs must be retained since any PE may need them. Using this method when there are multiple/redundant RRs in the network is a good way to increase scale and conserve memory on RRs and PEs. On CSR1 and CSR2, I configure opposing policies. CSR1 is allowed to retain only RED RTs while CSR2 is allowed to retain anything except RED RTs. In this design, there is only one non-RED VPN, but if there were more, CSR2 would retain those other RTs as well. This illustrates that both positive and negative logic are supported for the RR-group filter. On XE, the feature is supported for VPNv4, VPNv6, MVPNV4, and MVPNV6. It is not supported for L2VPN VPLS. CSR1 is examined first.

```
! CSR1
ip extcommunity-list expanded EXTCOML_RR_RED permit RT:56:1..$

router bgp 56
 address-family vpnv4
   bgp rr-group EXTCOML_RR_RED
 address-family vpnv6
   bgp rr-group EXTCOML_RR_RED
```

Applying this configuration immediately purges any VPN routes with rejected RTs. CSR1 now has no routes for RD 56:200.

```
R1#show bgp vpnv4 unicast rd 56:200
[no output]
```

If more routes are advertised to the RRs later containing rejected RTs, they are never installed. The debug output shown below looks familiar as the rejection looks identical to any RT rejection. The same output would be present if, for example, a PE failed to explicitly import a RT. I highly the RD 56:200 as well as this identifies the routes as BLUE. Make no mistake; the filter is not matching the RD, but the RTs carried by the routes. These are highlighted in green.

```
R1#debug bgp vpnv4 unicast updates in
BGP updates debugging is on (inbound) for address family: VPNv4 Unicast

BGP(4): 56.0.0.9 rcvd UPDATE w/ attr: nexthop 56.0.0.9, origin ?, localpref

BGP(4): 56.0.0.9 rcvd 56:200:200.3.192.0/18, label 9037 -- DENIED due to:
extended community not supported;
```

Examining VPN BLUE on CSR10, there are only 3 copies learned. CSR1 no longer advertises one as it cannot even retain the routes in the first place. This indicates that the feature is working correctly. CSR2 is the new best-path given the next lower BGP peer ID.

```
R10#show bgp vpnv4 unicast vrf BLUE 200.3.0.0/18 | include from|valid
56.0.0.9 (metric 10) (via default) from 56.0.0.11 (56.0.0.11)
Origin incomplete, metric 1, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.12 (56.0.0.12)
Origin incomplete, metric 1, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.2 (56.0.0.2)
Origin incomplete, metric 1, localpref 100, valid, internal, best
```

Next, we will configure CSR2 to reject RED RTs while permitting anything else. The IOS-regex logic is straightforward and applying the filter is identical as it was on CSR1. After applying the configuration, we quickly verify that CSR2 is not retaining any RED routes.

```
! CSR2
ip extcommunity-list expanded EXTCOML_RR_NOT_RED deny RT:56:1..$
ip extcommunity-list expanded EXTCOML_RR_NOT_RED permit RT:[0-9]+:[0-9]+

router bgp 56
 address-family vpnv4
   bgp rr-group EXTCOML_RR_NOT_RED
 address-family vpnv6
   bgp rr-group EXTCOML_RR_NOT_RED
```

```
R2#show bgp vpnv4 unicast rd 56:100
[no output]
```

On CSR10 within the RED VPN, CSR2 is no longer advertising reachability for RED prefixes. CSR1 remains the best path, but of greater significance is that CSR2 is not advertising any routes.

```
R10#show bgp vpnv4 unicast vrf RED 100.3.0.0/18 | include from|valid
56.0.0.9 (metric 10) (via default) from 56.0.0.11 (56.0.0.11)
Origin incomplete, metric 0, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.12 (56.0.0.12)
Origin incomplete, metric 0, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.1 (56.0.0.1)
Origin incomplete, metric 0, localpref 100, valid, internal, best
```

To further clean up the network, we will configure similar policies on XRv1 and XRv2. XRv1 will team up with CSR1 to service the RED VPN, while XRv2 will team up with CSR2 to service anything not in the RED VPN. Rather than create a custom command for this, XR uses the “retain route-target” syntax. This is often used for inter-AS MPLS option B ASBRs so that they can retain all RTs without having to configure the VRF locally or identify iBGP peers as RR-clients. When a peer is identified as an RR-client, all RTs are retained from those peers by default. XR allows the user to restrict this using RPL, so the feature has value on RRs as well as option B ASBRs. Looking at XRv1 first, we create an RT-set using an IOS-regex to match RED RTs. This is passed into a parameterized RPL for flexibility. Last, the RPL is invoked by VPNv4 and VPNv6 AFIs under BGP.

```
! XRv1
extcommunity-set rt RT_RED
  ios-regex '56:1[01][34]${'
end-set

route-policy RPL_RETAIN_IF_MATCH($RT)
  if extcommunity rt matches-any $RT then
    pass
  endif
end-policy

router bgp 56
  address-family vpnv4 unicast
    retain route-target route-policy RPL_RETAIN_IF_MATCH(RT_RED)
  address-family vpnv6 unicast
    retain route-target route-policy RPL_RETAIN_IF_MATCH(RT_RED)
```

Like XE, any existing routes with unmatched RTs are immediately purged. XRv1 has no need to maintain a separate table for RD 56:200, which saves memory. Checking the BLUE VRF on CSR10 reveals only 2 routes as both CSR1 and XRv1 have stopped servicing the BLUE VPN. CSR10 still learns RED routes from XRv1, also shown below.

```
RP/0/0/CPU0:XRv1#show bgp vpnv4 unicast rd 56:200
[no output]
```

```
R10#show bgp vpnv4 unicast vrf BLUE 200.3.0.0/18 | include from|valid
56.0.0.9 (metric 10) (via default) from 56.0.0.12 (56.0.0.12)
  Origin incomplete, metric 1, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.2 (56.0.0.2)
  Origin incomplete, metric 1, localpref 100, valid, internal, best

R10#show bgp vpnv4 unicast vrf RED 100.3.0.0/18 | include from|valid
56.0.0.9 (metric 10) (via default) from 56.0.0.11 (56.0.0.11)
  Origin incomplete, metric 0, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.12 (56.0.0.12)
  Origin incomplete, metric 0, localpref 100, valid, internal
```

```
56.0.0.9 (metric 10) (via default) from 56.0.0.1 (56.0.0.1)
  Origin incomplete, metric 0, localpref 100, valid, internal, best
```

Last, we configure XRv2 to reject RED routes. RPL helps simplify positive/negative logic by embedding the logic in the conditional construct rather than the list construct. In XE, the permit/deny action was defined in the extended-community list. XRv2 uses the same RT-set as XRv1, but inverts the RPL logic. The RPL rejects the route if it contains any RT matched within the RED list.

```
! XRv2
extcommunity-set rt RT_RED
  ios-regex '56:1[01][34]${'
end-set

route-policy RPL_REJECT_IF_MATCH($RT)
  if extcommunity rt matches-any $RT then
    drop
  else
    pass
  end
end-policy

router bgp 56
  address-family vpnv4 unicast
    retain route-target route-policy RPL_REJECT_IF_MATCH(RT_RED)
  address-family vpnv6 unicast
    retain route-target route-policy RPL_REJECT_IF_MATCH(RT_RED)
```

XRv2 no longer retains any RED routes and has no need to create a table for RD 56:100. CSR10 now only sees 2 RED routes (CSR1 and XRv1) which means CSR2 and XRv2 are no longer servicing RED VPN clients. In this design, we still have HA since there are 2 RRs servicing each VPN. If the PEs were multi-homed BGP PIC could be used for additional fault tolerance. This design reduced the memory requirements on all 4 RRs and all 4 PEs by 50% by load-splitting the VPN routes between available RRs.

```
RP/0/0/CPU0:XRv2#show bgp vpnv4 unicast rd 56:100
[no output]
```

```
R10#show bgp vpnv4 unicast vrf RED 100.3.0.0/18 | include from|valid
56.0.0.9 (metric 10) (via default) from 56.0.0.11 (56.0.0.11)
  Origin incomplete, metric 0, localpref 100, valid, internal
56.0.0.9 (metric 10) (via default) from 56.0.0.1 (56.0.0.1)
  Origin incomplete, metric 0, localpref 100, valid, internal, best
```

To confirm the claim above with respect to RR memory requirements, we check CSR1 and XRv1 for their VPN route counts per client. These numbers were 8 earlier, but now are 4, since each RR is only accepting one VPN route “color”.

```
R1#show bgp vpnv4 unicast all summary | begin ^Neigh

Additional Reading – Reference configurations “bgp-rr-group”

27.4 Accumulated IGP attribute

If you have multiple sub-ASes within a confederation (or you control the IGP metrics for both ASes), you can essentially compare the end to end cost using accumulated IGP (AIGP). The remote AS will write the AIGP value, normally by copying the IGP metric (similar to how MED is populated), then advertise it to the BGP neighbor as a new attribute. This new attribute can be added to the IGP metric to the BGP next-hop to determine the total path cost; this cannot be done with MED or cost-communities, although AIGP can be transported via those methods for legacy devices. AIGP is evaluated immediately following local-preference in the best path selection process (so, it's evaluated very early). Beware that grossly incompatible IGP metrics between the two ASes, confed-external or true eBGP, will break the usefulness of this feature. EIGRP in one AS versus RIP in another will always be bound by the EIGRP metric, since the RIP metrics will contribute comparatively little to the AIGP. As an odd workaround, you could encode AIGP inside cost-community, use the pre-bestpath POI, and apply the transitive option. This would allow one AS to override the policies of another, even for true eBGP.

27.4.1 Basic AIGP

This lab explores the basics of AIGP and how it is exchanged/processed in a BGP network. The network diagram is shown below. There are two ASes pictured with iBGP internally and eBGP between one another. We are only evaluating prefixes from the perspective of CSR1 and CSR4 in these labs. Most of

the community manipulation happens on the ASBRs. The numbers associated with the links are the IGP costs, which are symmetric.

Below I show the configurations for CSR2 and XRV3, but the equivalent AIGP configuration exists on all 4 ASBRs. We need to activate AIGP on all neighbors to pass the attribute. We also have to set the AIGP metric manually, which can be done dynamically based on the IGP cost. This can be applied to prefixes being redistributed into BGP or as an attribute modification within the “network” statement. The RPL construct in XR is very similar. Of note, the IGP costs are constantly adjusted in this lab as well.

```

! CSR2
route-map AIGP_METRIC permit 10
  set aigp-metric igp-metric

router bgp 10
  no bgp default ipv4-unicast
  address-family ipv4
    network 100.1.1.1 mask 255.255.255.255 route-map AIGP_METRIC
  neighbor 1.1.1.1 aigp
  neighbor 22.0.0.12 aigp

! XRV12
route-policy SET_AIGP
  set aigp-metric igp-cost

router bgp 20
  address-family ipv4 unicast
    network 100.4.4.4/32 route-policy SET_AIGP

  neighbor 33.0.0.3
    address-family ipv4 unicast
    aigp
  neighbor 4.4.4.4
    address-family ipv4 unicast
    aigp

```

Before looking at any routing information, we will verify the configuration between XRv13 and CSR4 as a demonstration. AIGP is a neighbor-specific feature but is not a negotiated capability nor a community value. Rather, it is like an additional BGP path-attribute, much like local-preference or MED. These commands confirm that AIGP was configured correctly.

```
CSR4#show bgp ipv4 unicast neighbors 12.12.12.12 | begin For address family
For address family: IPv4 Unicast
  Session: 12.12.12.12
  BGP table version 1, neighbor version 1/0
  Output queue size : 0
  Index 1, Advertise bit 0
  AIGP is enabled
  1 update-group member
```

```
RP/0/0/CPU0:XRv2#show bgp ipv4 unicast neighbors 4.4.4.4 | begin For Address

  AIGP is enabled
  An EoR was received during read-only mode
  [snip]
```

A quick debug on CSR2 reveals that CSR4's loopback received from XRv12 now carries a new AIGP-metric field, which is currently set to XRv12 IGP metric to 100.4.4.4/32.

```
CSR2#debug bgp ipv4 unicast update
BGP updates debugging is on for address family: IPv4 Unicast
BGP(0): 22.0.0.12 rcvd UPDATE w/ attr: nexthop 22.0.0.12, origin i, metric
10, aigp-metric 10, merged path 20, AS_PATH
BGP(0): 22.0.0.12 rcvd 100.4.4.4/32
```

We will look at CSR4's route to CSR1's loopback to start. The AIGP metric is better via XRv13 (11), but AIGP + local IGP metric (42) is worse than the sum of the same values carried by the XRv12 route (41). This is what makes AIGP special; unlike MED, it is combined with the IGP cost to form a pseudo end-to-end metric across AS boundaries.

```
CSR4#show bgp ipv4 unicast 100.1.1.1/32
BGP routing table entry for 100.1.1.1/32, version 12
Paths: (2 available, best #2, table default)
  Not advertised to any peer
```

```

Refresh Epoch 1
10
  13.13.13.13 (metric 31) from 13.13.13.13 (13.13.13.13)
    Origin IGP, aigp-metric 11, metric 11, localpref 100, valid, internal
    rx pathid: 0, tx pathid: 0
Refresh Epoch 1
10
  12.12.12.12 (metric 10) from 12.12.12.12 (12.12.12.12)
    Origin IGP, aigp-metric 31, metric 31, localpref 100, valid, internal,
best
    rx pathid: 0, tx pathid: 0x0

```

Next, we reduce CSR4's cost to XRv13 to 28. The AIGP metric is better via XRv13 (11), even though the IGP metric (29) is worse. The sum is still less for the best route (40 vs. 41). Notice that even though AIGP is compared early in the path selection process, this comparison is the sum of the AIGP and IGP costs, not just comparing the AIGP cost, as proven below.

```

CSR4#show bgp ipv4 unicast 100.1.1.1/32
BGP routing table entry for 100.1.1.1/32, version 11
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 1
  10
    13.13.13.13 (metric 29) from 13.13.13.13 (13.13.13.13)
      Origin IGP, aigp-metric 11, metric 11, localpref 100, valid, internal,
best
      rx pathid: 0, tx pathid: 0x0
  Refresh Epoch 1
  10
    12.12.12.12 (metric 10) from 12.12.12.12 (12.12.12.12)
      Origin IGP, aigp-metric 31, metric 31, localpref 100, valid, internal
      rx pathid: 0, tx pathid: 0

```

Below is an example where AIGP + local IGP is the same in both cases (41). Best-path declares a tie and continues with the selection process. In most cases, the AIGP metric was copied from the IGP metric, just like MED. Therefore, MED determines that XRv13 is the better route, and generally speaking, the lower remote IGP cost will break the tie.

```

CSR4#show bgp ipv4 unicast 100.1.1.1/32
BGP routing table entry for 100.1.1.1/32, version 13
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 1
  10
    13.13.13.13 (metric 30) from 13.13.13.13 (13.13.13.13)
      Origin IGP, aigp-metric 11, metric 11, localpref 100, valid, internal,
best

```

```

    rx pathid: 0, tx pathid: 0x0
Refresh Epoch 1
10
12.12.12.12 (metric 10) from 12.12.12.12 (12.12.12.12)
    Origin IGP, aigp-metric 31, metric 31, localpref 100, valid, internal
    rx pathid: 0, tx pathid: 0

```

If AIGP is not present, AIGP automatically wins (assuming weight and local preference are equal), even at maximum value. This is a little odd as I personally like the behavior of the cost-community where the lack of a value assumes the midpoint between minimum and maximum.

```

CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 31
Paths: (2 available, best #1, table default)
    Not advertised to any peer
    Refresh Epoch 6
    20
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
        Origin IGP, aigp-metric 4294967295, metric 10, localpref 100, valid,
internal, best
        rx pathid: 0, tx pathid: 0x0
    Refresh Epoch 6
    20
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)
        Origin IGP, metric 20, localpref 100, valid, internal
        rx pathid: 0, tx pathid: 0

```

Just to prove where AIGP sits in the best path, local preference has been increased for the route via CSR3, and now it is preferred since AIGP is not evaluated. By extension, modifying weight would also work (no example shown).

```

CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 10
Paths: (2 available, best #1, table default)
    Not advertised to any peer
    Refresh Epoch 2
    20
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)

    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
        Origin IGP, aigp-metric 4294967295, metric 10, localpref 100, valid,
internal
        rx pathid: 0, tx pathid: 0

```

Also, let's increase the AS path length of the CSR2 route. The CSR2 route stills wins because AIGP is processed first.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 12
Paths: (2 available, best #2, table default)
  Not advertised to any peer
  Refresh Epoch 3
  20
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, valid, internal
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 1
  20 20 20 20
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, aigp-metric 4294967295, metric 10, localpref 100, valid,
internal, best
      rx pathid: 0, tx pathid: 0x0
```

Below is another example where a lower AIGP does not necessary imply best-path. AIGP is just a component of the metric as the local IGP metric still counts, assuming AIGP attribute is present on all contending routes. The best path has a total metric of 31 while the path with lower AIGP has a total metric of 41.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32

27.4.2 AIGP with cost-communities and BGP confederations

AIGP can also be transported inside the cost-community. Note: As seen in the cost-community section, this does not work for true eBGP peers, only confederations and iBGP. The network has been modified to place AS 10 and AS 20 in a confederation together. The exception is using the "transitive" option which is discussed next, but oddly, there is no way to pass classic cost-communities across eBGP boundaries. It appears to be an AIGP-only extension. The network diagram is below; it is the same design with minor BGP modifications to construct a confederation between AS 10 and AS 20.

Although much less effective than real AIGP, you can encode the AIGP metric in a cost-community. If used with the pre-bestpath POI, it effectively trumps all local policies set by the receiving router and is even more powerful than ordinary AIGP. Below are the outputs from CSR1 and CSR4, respectively. Using it with igp-cost POI is probably most realistic as it comes after the IGP metric to BGP next-hop, but the two are not added together. In XR, a special command is needed to exchange standard/extended communities with eBGP peers; within iBGP, communities are automatically exchanged. In IOS, community exchange must be specified per neighbor, per type, regardless of the remote AS number.

The configuration snippet from XRv13 (the other three ASBRs have similar configurations to correspond with the show commands following this) is below.

```
! XRv13
router bgp 20
  af-group AF_IPV4 address-family ipv4 unicast
    aigp send cost-community 44 poi pre-bestpath
    next-hop-self
  neighbor 33.0.0.3
    address-family ipv4 unicast
      use af-group AF_IPV4
      send-extended-community-ebgp
```

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32

  Refresh Epoch 1
  (10)
    13.13.13.13 (metric 20) from 13.13.13.13 (13.13.13.13)
      Origin IGP, metric 11, localpref 100, valid, internal, best
      Extended Community: Cost:pre-bestpath:99:11
      rx pathid: 0, tx pathid: 0x0
  Refresh Epoch 1
  (10)
    12.12.12.12 (metric 10) from 12.12.12.12 (12.12.12.12)
      Origin IGP, metric 31, localpref 100, valid, internal
      Extended Community: Cost:pre-bestpath:99:31
      rx pathid: 0, tx pathid: 0
```

If you tell CSR2 and CSR3 to send AIGP inside cost-community towards CSR1, it will add a second cost-community with metric 0. CSR1 sees both communities. The communities are compared in sequence which is discussed in detail in the cost-community section. Essentially, the lowest community IDs are compared together first. Since there is no tie, the higher community IDs are never evaluated.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 6
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal, best
      Extended Community: Cost:pre-bestpath:44:10 Cost:pre-bestpath:99:0
      rx pathid: 0, tx pathid: 0x0
      Refresh Epoch 5
  (20)
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, valid, confed-internal
      Extended Community: Cost:pre-bestpath:44:20 Cost:pre-bestpath:99:0
      rx pathid: 0, tx pathid: 0
```

I am assuming this is because the first non-BGP route that the recursive lookup finds is a connected route. The IGP cost to the BGP next-hop, for eBGP peers in this network, is zero. CSR2's perspective is shown below.

```
CSR2#show ip route 100.4.4.4
Routing entry for 100.4.4.4/32
  Known via "bgp 10", distance 200, metric 10
  Tag 20, type internal
  Last update from 22.0.0.12 00:09:43 ago
  Routing Descriptor Blocks:
  * 22.0.0.12, from 22.0.0.12, 00:09:43 ago
    Route metric is 10, traffic share count is 1
    AS Hops 0
    Route tag 20
    MPLS label: none
```

```
CSR2#show ip route 22.0.0.12
Routing entry for 22.0.0.0/8
  Known via "connected", distance 0, metric 0 (connected, via interface)
  Routing Descriptor Blocks:
  * directly connected, via GigabitEthernet2.522
    Route metric is 0, traffic share count is 1
```

AIGP is also available inside the cost-community with the transitive option. Using the transitive keyword, we can transport the cost-community across true eBGP boundaries (configuration not shown). The

confederation has been removed and AS 10 and AS 20 are separate ASes now. All the same cost-community rules apply. I have not found a way to do this with regular cost-communities.

```
! XRv12
router bgp 20
  af-group AF_IPV4 address-family ipv4 unicast
    aigp send cost-community 44 poi pre-bestpath transitive
    next-hop-self

      rx pathid: 0, tx pathid: 0x0
```

Additional Reading – Reference configurations "aigp-costcom"

27.5 Cost-Community / Point Of Insertion (POI)

Somewhat similar to AIGP, the cost-community was developed as a mechanism to carry cost information around BGP networks. It has many different purposes which are described in this chapter, along with different points of insertion (POI) that determine when this community is evaluated. This feature is quite old, so newer features like accumulated IGP (AIGP) can use it to transport AIGP metrics for older routers. AIGP is more advanced and requires newer code versions (15.4(2)S for IOS, 3.12 for XE, 4.0.0 for XR).

Pre-bestpath POI was designed for EIGRP MPLS L3VPN architectures where backdoor links exist. Normally BGP would prefer the locally sourced routes over the BGP learned ones due to the automatic 32,768 weight value applied. This would lead to a looping condition or suboptimal routing. Using the cost-community fixes it because if a prefix loops in the control-plane back to a PE, the cost-community would have increased across the customer network and will be less than whatever the original VPNv4 prefix cost-community carried from the source PE. This is why cost-community is valuable for overriding the weight attribute.

Another use for pre-bestpath is for extreme "hot potato" routing, where getting the traffic out of the AS as quickly as possible is desired. Because it pre-empts even the weight attribute, it can be used to change path selection within an AS or between confederations (not possible with true eBGP peers). There is one exception where the cost-community is fully transitive, and that is when the AIGP metric is transported in the cost-community with the "transitive" keyword. I have not found a way to establish transitivity without the AIGP application. The ordinary IOS route-map and XR RPL does not have an option and the attribute is simply not exchanged.

IGP-cost is the default POI for cost-community with the exception of EIGRP MPLS L3VPN, which uses pre-bestpath (and is fully automatic; requires no configuration). The rules for the cost-community processing are the same (many are illustrated below) but the IGP-cost POI is evaluated after the IGP metric to the BGP next-hop criteria. It is effectively a new tie-breaker to occur before the router-ID comparison which applies to iBGP, confed-internal, and confed-external.

Hierarchical cost-community selection is achievable by affixing multiple cost-communities to a specific BGP prefix. It should be supported for all AFI/SAFI on all platforms that understand the cost-community in general. To protect your network from an accidental hijack, you can use "bgp bestpath cost-community ignore". BGP simply ignores the values and proceeds as if they never existed.

This feature is tested using a similar topology as AIGP with two BGP sub-ASes wrapped into a confederation. Because the cost-community is not transitive, we cannot test it with true eBGP.

These examples will not show the configuration changes each time. For all of them, the cost-community application on XRv12 and/or XRv13 was changed as the text describes. Here are the snippets from XRv12, but the actual community values vary during the experiments. Similar configurations are applied to XRv13. Additional communities and component routes are added to the configurations over time, but the general construct is shown below. The "COST_COMM_SET" is changed constantly in these

experiments, but the other constructs generally remain the same. The basic network configurations are also not shown.

```
! XRv12
extcommunity-set cost COST_COMM_SET
  IGP:21:100
end-set

route-policy COST_COMM
  set extcommunity cost COST_COMM_SET
end-policy

router bgp 20
  address-family ipv4 unicast
    network 100.4.4.4/32 route-policy COST_COMM
```

Before completing the confederation configuration, I quickly prove that the cost-community is not transitive. Below I attempt true eBGP between AS 10 and AS 20. Notice how CSR2 sets the cost-community locally and "debug bgp updates" verifies it was sent to XRv12.

```
CSR2#show bgp ipv4 unicast 100.1.1.1/32
BGP routing table entry for 100.1.1.1/32, version 2
Paths: (1 available, best #1, table default)
  Advertised to update-groups:
    10          11
  Refresh Epoch 1
  Local
    12.0.0.1 from 0.0.0.0 (2.2.2.2)
      Origin IGP, metric 31, localpref 100, weight 32768, valid, sourced,
local, best
      Extended Community: Cost:pre-bestpath:22:30
      rx pathid: 0, tx pathid: 0x0

CSR2#debug bgp ipv4 unicast update
BGP(0): (base) 22.0.0.12 send UPDATE (format) 100.1.1.1/32, next 22.0.0.2,
metric 31, path Local, extended community Cost:pre-bestpath:22:30
```

Despite receiving the update successfully, XRv12 never honors that value it. The same was true in the other direction, despite extended communities being enabled between the neighbors.

```
XRv12#show bgp ipv4 unicast 100.1.1.1/32 | begin Paths
Paths: (1 available, best #1)
  Advertised to peers (in unique update groups):
    4.4.4.4
  Path #1: Received by speaker 0
  Advertised to peers (in unique update groups):
    4.4.4.4
```

10

```
22.0.0.2 from 22.0.0.2 (2.2.2.2)
  Origin IGP, metric 31, localpref 100, valid, external, best, group-best
  Received Path ID 0, Local Path ID 1, version 23
  Origin-AS validity: not-found
```

When AS 10 and AS 20 are placed in a confederation together (with appropriate next-hop changes), the cost-community immediately appears. Cisco clearly states eBGP is not supported as the cost-community is not transitive. Notice that XR makes no attempt to decode the “pre-bestpath” code of 128. This number is specific to the pre-bestpath POI.

```
XRv12#show bgp ipv4 unicast 100.1.1.1/32 | begin Paths
Paths: (1 available, best #1)
  Advertised to peers (in unique update groups):
    4.4.4.4
  Path #1: Received by speaker 0
  Advertised to peers (in unique update groups):
    4.4.4.4
  (10)
    22.0.0.2 from 22.0.0.2 (2.2.2.2)
      Origin IGP, metric 31, localpref 100, valid, confed-external, best,
group-best
      Received Path ID 0, Local Path ID 1, version 27
      Extended community: COST:128:22:30
```

With respect to the community ID, the lower ID wins, even if cost is worse. This assumes that each prefix only has one cost-community with the same POI. Below, I demonstrate that 22:10 is better than 33:5 due to having a lower community ID.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 46
Paths: (2 available, best #2, table default)
  Not advertised to any peer
  Refresh Epoch 3
  (20)
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, valid, confed-internal
      Extended Community: Cost:pre-bestpath:33:5
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 5
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal, best
      Extended Community: Cost:pre-bestpath:22:10
      rx pathid: 0, tx pathid: 0x0
```

When the IDs match, a tie is declared, and the cost value is compared. The lower cost always wins in this case, as expected. In short, it is an ordered comparison of ID first, cost value second.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 47
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 3
  (20)
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, valid, confed-internal, best
      Extended Community: Cost:pre-bestpath:22:5
      rx pathid: 0, tx pathid: 0x0
  Refresh Epoch 5
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal
      Extended Community: Cost:pre-bestpath:22:10
      rx pathid: 0, tx pathid: 0
```

When there are multiple cost communities, the lowest IDs are compared first, then incrementally so. In this example, the loser route has an additional cost-community with very low cost, but it was never considered since the ID 22 cost-community was already defeated. So, even though the winner route doesn't have a second cost-community for comparison, it doesn't matter.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 47
Paths: (2 available, best #1, table default)

    Extended Community: Cost:pre-bestpath:22:10 Cost:pre-bestpath:33:1
    rx pathid: 0, tx pathid: 0x0

```

Paths without the cost-community have value set to $2^{32} / 2$ or 21^{31} (2147483647). This is considered the "default" value. The feature makes the assumption that if you don't specify anything, the middle value is used for comparison. This is in contrast to AIGP which automatically wins if it is present, even at its maximum value. Path through CSR2 wins with the value set to default – 1, but just barely so.

```

CSR1#show bgp ipv4 unicast 100.4.4.4/32

    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal
      Extended Community: Cost:pre-bestpath:22:2147483648 (default+1)
      rx pathid: 0, tx pathid: 0

```

When one prefix has a default cost-community (explicit default) and the other has no community at all (implicit default0, the BGP best-path selection process simply continues as this evaluation criterion ties. Below is an example; CSR3 wins in a tie due to lower IGP metric to BGP next hop. You may have expected CSR2 to win based on lower MED, but due to the BGP confederation, the MED is ignored in this case. You can use "bgp bestpath med confed" to select CSR2 over CSR3 in this case, but this is not the default behavior. We can tell the peers are in a confederation based on the parenthetical AS path.

```

CSR1#show bgp ipv4 unicast 100.4.4.4/32

    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal

```

```
Extended Community: Cost:pre-bestpath:22:2147483647 (default)
rx pathid: 0, tx pathid: 0
```

So far we have only looked at pre-bestpath, which is a very extreme way to change the path selection before any other attributes are considered, even weight. Below shows an attempt to override pre-bestpath behavior using weight; it fails. CSR2 is still the bestpath.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 6
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 2
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal, best
      Extended Community: Cost:pre-bestpath:22:214
      rx pathid: 0, tx pathid: 0x0
  Refresh Epoch 2
  (20)
    3.3.3.3 (metric 11) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, weight 99, valid, confed-internal
      rx pathid: 0, tx pathid: 0
```

When we change the cost-community back to the default value to create a tie, weight takes effect and wins. I also changed the IGP metric to BGP next-hop for the CSR3 route to 1000 in order to demonstrate that the CSR3 route did not win due to that value, as it did earlier. When the cost-community is compared against a route with no cost-community at the same POI, the community ID means nothing.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 7
Paths: (2 available, best #2, table default)

      Extended Community: Cost:pre-bestpath:22:2147483647 (default)
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 2
  (20)
    3.3.3.3 (metric 1000) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, weight 99, valid, confed-internal, best
      rx pathid: 0, tx pathid: 0x0
```

Next, we evaluate the IGP POI. This considers the IGP cost-community just after the IGP metric to BGP next-hop comparison. It's essentially a tie-breaker for routes before comparing the oldest route

(external) or router ID (confed-internal, confed-external, or internal). The only way eBGP routes would carry this attribute is by way of the AIGP inside cost-community with transitive option, so realistically, it is preempting the lowest RID (or originator ID with route-reflector) comparisons. As a quick comparison, when the type of cost-community varies, they are not compared directly. CSR3 wins despite having a larger "cost value" but it was considered pre-bestpath against CSR2's pre-bestpath implicit-default value of 2,147,483,647.

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 11
Paths: (2 available, best #2, table default)
  Not advertised to any peer
  Refresh Epoch 5
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal
      Extended Community: Cost:igp:22:12
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 5
  (20)
    3.3.3.3 (metric 31) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, valid, confed-internal, best
      Extended Community: Cost:pre-bestpath:22:13
      rx pathid: 0, tx pathid: 0x0
```

When the two are the same, they are considered only when the IGP metric to BGP next-hop ties. CSR2 wins in a tie due to lower RID (again, because MED is not compared within the confederation).

```
CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 12
Paths: (2 available, best #1, table default)
  Not advertised to any peer
  Refresh Epoch 5
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal, best
      Extended Community: Cost:igp:22:12
      rx pathid: 0, tx pathid: 0x0
  Refresh Epoch 5
  (20)
    3.3.3.3 (metric 31) from 3.3.3.3 (3.3.3.3)
      Origin IGP, metric 20, localpref 100, valid, confed-internal
      Extended Community: Cost:igp:22:12
      rx pathid: 0, tx pathid: 0
```

If we adjust the cost to a higher number for CSR2's prefix, CSR3 wins due to a lower cost-community value. The community ID remains 22 so that the costs can be compared directly.

```

CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 13
Paths: (2 available, best #2, table default)
  Not advertised to any peer
  Refresh Epoch 5
  (20)
    2.2.2.2 (metric 31) from 2.2.2.2 (2.2.2.2)
      Origin IGP, metric 10, localpref 100, valid, confed-internal
      Extended Community: Cost:igp:22:999
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 5
  (20)

(20)
3.3.3.3 (metric 31) from 3.3.3.3 (3.3.3.3)
    Origin IGP, metric 20, localpref 100, valid, confed-internal
    Extended Community: Cost:igp:22:2147483647 (default)
    rx pathid: 0, tx pathid: 0

```

The next example proves that the IGP cost comparison happens after the ordinary IGP metric to BGP next-hop. The cost to CSR2 has been reduced but CSR3 has a better cost-community. CSR2 is the best path, though; the IGP cost cost-community is only compared when the IGP metric to BGP next-hop is a tie. It can be viewed as the “first tie breaker” ahead of the BGP RID. This application of this POI was designed to make a less arbitrary best-path decision by assigning administrator-defined values that take effect when the tie-breakers begin.

```

CSR1#show bgp ipv4 unicast 100.4.4.4/32
BGP routing table entry for 100.4.4.4/32, version 16
Paths: (2 available, best #1, table default)
    Not advertised to any peer

    rx pathid: 0, tx pathid: 0

```

The cost-community also interacts with BGP route aggregation. The aggregate route selects the highest cost-community value, but only if the IDs match AND the "as-set" flag is used on the aggregate. If "as-set" is not applied, no communities are carried over. The first two outputs show two component /32 routes with varying cost-communities. The aggregate /24 route uses the larger one.

```

If one or more component routes have mismatched cost-community IDs, individual cost-communities are added to the aggregate for each unique ID with a default cost value. CSR2 and CSR3 have mismatched IDs and the aggregate has two IGP cost-communities, both with default cost values, per unique ID. This isn't very useful for the aggregate, since the presence of the default cost-community effectively does nothing for BGP best-path comparisons. At this point, the cost-community values just become "tags" that would be used to identify the community IDs carried by the component routes.

If one or more component routes have varying POI types (pre-bestpath versus IGP cost), the same rules apply as demonstrated above. If the IDs do not match, the metric is set to the default, and each custom ID is added to the aggregate. The only difference is that the POI is maintained. The above example has been extended with a third component route to illustrate this. The aggregate has two IGP and one pre-bestpath communities, each with varying IDs, and all with default metric.

Additional Reading – Reference configurations “costcom”

27.6 DMZ Link Bandwidth

The DMZ link bandwidth feature is used to enable unequal cost load sharing in BGP. DMZ links are the eBGP links that interconnect BGP ASes, which this document also identifies as “transit links”. This feature encodes the bandwidth of those links into an extended community (also carries the BGP ASN for administrative purposes) which is non-transitive. Routers that learn the remote BGP routes via iBGP can perform load sharing when sending traffic to those remote destinations based on the bandwidth of the DMZ links. On XE, the feature is fully supported for IPv4 and IPv6, but only supported at the edge routers (eBGP) for VPNv4. The XE routers on the AS boundary can encode the link bandwidth (LB) community but cannot use it for load sharing for VPN-iBGP paths at this time. There is currently no VPNv6 support. XR appears to fully support all four of these AFIs. This feature is implemented very differently between XE and XR which makes interworking very difficult. Between the two, the units of measurement are vastly different and are not often converted when crossing between the two. Coupled with a limited set of show/debug commands, this makes troubleshooting very challenging. The network below has two ASes using Inter AS MPLS option B for VPNv4/v6, along with ordinary IPv4/v6. CSR9 and XRv3 are VPN customers while CSR10 and CSR2 are remote Internet ASes. CSR1 and XRv4 have iBGP neighbors to each of their ASBRs, and each ASBR has a direct eBGP peering to the other ASBR at the end of the link. AS 137 uses IS-IS and MPLS-TE for transport (no LDP) while AS 173 uses OSPFv2 and LDP. This is unrelated to DMZ link bandwidth and is introduced for variety.

First, we will quickly check the BGP peers on CSR1 and XRV4 to verify the peers are up and the proper capabilities were exchanged. IPv6 uses labeled unicast (6PE) to provide IPv6 transit across an IPv4 core. Normally, we would verify each neighbor individually as we do between CSR1 and CSR6, but in this case, I will just look at the summary for each AFI for brevity. The asterisk indicates that these are dynamic neighbors using the BGP listen command.

We quickly do the same on XRv4 for the routers in AS 173. Notice that the IPv4 unicast AFI only includes the eBGP peer to CSR2; the iBGP peers are technically running IPv6 labeled-unicast which XR treats as a different AFI. This is technically more correct than the XE implementation.

```

We would continue this process for all of the eBGP peers as well, but skip it for the sake of brevity. The number of prefixes exchanged in CSR1 and XRv4 indicates that there is at least some connectivity. We will begin in AS 137 first. The goal is to load-share traffic as follows: traffic to 2.128.0.0/16 prefixes should be shared in ratio 5:3:8 using CSR6, CSR7, and XRv12 respectively. Traffic to 2.129.0.0/16 prefixes should be shared in ratio 5:3:16 using CSR6, CSR7, and XRv12 respectively. We will assign some bandwidth values to the XE routers to represent 5 Mbps and 3 Mbps on CSR6 and CSR7, respectively. There is nothing fancy about this configuration. We also need to instruct these routers to “look” at the transit links and encode this value into an extended community. Last, we need to ensure extended communities can be exchanged with CSR1, which is automatic for VPNv4/6 but not IPv4/6. I also use BGP RID comparison on CSR7 so that CSR4 always wins the tie-breaker, ignoring the oldest eBGP route.

```
! CSR6
interface GigabitEthernet2.546
  bandwidth 5000

router bgp 137
  address-family ipv4
    neighbor 10.4.6.4 dmzlink-bw
    neighbor 137.0.0.1 send-community both

```

```
address-family vpnv6
neighbor 10.4.7.4 dmzlink-bw
neighbor 10.7.11.11 dmzlink-bw
```

We can locally check CSR6 and CSR7 to ensure this community was encoded using any test prefix from AS 2. As we know, the bandwidth applied to the link-level was in kbps. In XE, this is converted to kbps (bytes) when it is received from an XE router. The CSR7-XRv1 link has bandwidth 16 Mbps but this is not a best path, and is not advertised to CSR1.

```

We verify that CSR1 receives this information. If CSR1 did not receive it, that would imply that the ASBRs were not properly sending extended communities to CSR1. CSR1 is not yet configured for load-sharing; we will come back to this after configuring XRv2. I want to point out that the bandwidth values are the same as they were on the XE ASBRs, as expected.

```

```

XR allows the LB community to be tuned based on an RPL, providing additional flexibility not present in XE. To meet the requirement stated earlier, we configure a simple RPL that changes the bandwidth based on the prefix on XRv2. Notice that the values being set are in kbps; when XE receives the LB community from XR, it does not do any conversation, so these are raw kbps values.

```
! XRv2
prefix-set PL_2_128
  2.128.0.0/16 le 24
end-set

prefix-set PL_2_129
  2.129.0.0/16 le 24
end-set

route-policy RPL_DMZ
```

```

if destination in PL_2_128 then
    set extcommunity bandwidth (137:1000)
elseif destination in PL_2_129 then
    set extcommunity bandwidth (137:2000)
else
    pass
endif
end-policy

router bgp 137
neighbor 10.11.12.11
address-family ipv4 unicast
route-policy RPL_DMZ in

```

We verify that this configuration was successful on XRv2. XR shows the extended community in the form of LB:ASN:value. The 137 was automatically added, where XE leaves this as zero. **The value 8 is confusing; this actually represents Mbps. The link was configured at 1000 kbps = 8000 kbps = 8 Mbps.** The same is true for the second prefix, where 2000 kbps was configured, yet we see 16 Mbps. This at least proves that the RPL is working properly.

```

RP/0/0/CPU0:XRv2#show bgp ipv4 unicast 2.128.192.0/20
[snip]
173 2
10.11.12.11 from 10.11.12.11 (173.0.0.11)
Origin incomplete, localpref 100, valid, external, best, group-best
Received Path ID 0, Local Path ID 1, version 3
Extended community: LB:137:8
Origin-AS validity: not-found

```

```

RP/0/0/CPU0:XRv2#show bgp ipv4 unicast 2.129.0.0/17
[snip]
173 2
10.11.12.11 from 10.11.12.11 (173.0.0.11)
Origin incomplete, localpref 100, valid, external, best, group-best
Received Path ID 0, Local Path ID 1, version 7
Extended community: LB:137:16
Origin-AS validity: not-found

```

Checking CSR1 again and only focusing on the prefix from XRv2, we see the update now carries the LB community. XE leaves this value as configured, which leads me to believe XR wants the value to be configured in kbps.

```

R1#show bgp ipv4 unicast 2.129.0.0

    Origin incomplete, localpref 100, valid, internal
    DMZ-Link Bw 2000 kbytes
    rx pathid: 0, tx pathid: 0

```

Next, we will enable CSR1 to use these three paths proportionally. On a per-AF basis, we can enable this feature. We instruct BGP to account for the LB community (default is to ignore it) and use up to 4 iBGP paths for load sharing. Now, we can see the paths are all marked as multipath. BGP still needs to select a best-path for advertisement onward.

```

We can verify proper operation by checking the RIB and FIB for share counts. Considering the bandwidth values were in the ratio of 5:3:16, the traffic share counts are not terribly important. CEF can split traffic 16 different ways, so there isn't tremendous granularity. The 16 buckets show an approximate

proportion of 5:3:16. We can see most of the traffic going towards XRv2 via its TE tunnel (11/16), significantly less going to CSR6 (3/16), and the least going to CSR7 (2/16). Given the configured bandwidth values, this appears correct.

We quickly check a 2.128.0.0/16 prefix to verify a 5:3:8 ratio. Essentially, we should see less buckets assigned to XRv2 and more assigned to CSR6 and CSR7. Notice the traffic share counts are twice as high for CSR6 and CSR7, mostly because the shares for XRv2 were halved as the bandwidth is halved.

This time, only 8/16 buckets are allocated for XRv2, while there are 5/16 for CSR6 and 3/16 for CSR7. When the ratio numbers add up to 16 as they do here, you end up with a very clean distribution scheme. This CEF load sharing scheme matches the target ratio perfectly.

```

The process is identical for IPv6. We will use the legacy method on XRv2, which is a neighbor-level command to enable DMZ LB. This applies to all AFs for which there is not a more specific RPL attachment. Unfortunately, no matter what you set the actual bandwidth on the link, XR always uses value 500,000. This means that CSR1 will interpret this as 500,000 kbps, which is worthless in the context of the current low-speed bandwidths. Since XE does not have the per-AF granularity to make adjustments, I use this as a demonstration of a bad LB design. You also cannot verify it locally on XR due to what I consider an order-of-operations issue. CSR1 clearly shows this bogus value.

As expected, the load balancing weights are heavily tilted and all traffic should be forwarded out of XRv2. I am not sure if this is an XE issue or a function of 6PE, but the CEF table shows equal distribution between all of the buckets. The IPv6 CEF has a nice distribution output that IPv4 CEF used to have. Even without knowing what the paths are, we can see they are processed in round-robin fashion (each path gets a number). This is obviously incorrect despite having the correct configuration.

```

R1#show ipv6 cef 2001:2:128:190::/62 internal | include Path index
  Path index      [ 0 1 2 0 1 2 0 1 2 0 1 2 0 1 2 ]

```

VPNv4 link bandwidth load-sharing is limited to eBGP in current XE code. On CSR7, we can demonstrate this balance between the 3 Mbps link to CSR4 and 16 Mbps link to XRv1. Take note of the inbound label.

Since there is no VRF locally configured on CSR7 (Option B), there won't be a RIB or FIB entry. Traffic will be label-switched, with BGP performing a VPN label swap, at the ASBRs. Like IPv6, the feature does not appear to work very well, and could be MPLS related. The distribution appears 1:1 despite enabling DMZ LB feature for this AFI.

```

Next, we will configure AS 173. The goal is to balance traffic in a 2:1 ratio preferring CSR4 twice as often as XRv1. When XRv4 receives the LB community from an XE ASBR, it divides it by 1000. Since the bandwidth was specified in kbps on CSR4, XR wants to view it in Mbps, so dividing by 1000 is logical. XR also cannot process LB values less than 1000, and since XR interprets the value as Mbps, this means that only 1 Gbps links (1000 Mbps) or faster will even register as having an LB value. As such, I set the

bandwidth to 8 Gbps on CSR4 to achieve a value of 4000 on XRv4. Notice how the value is wildly different on CSR4 from XRv4. In AS 137, values set by XR were untouched by XE, but values set by XE are divided by 1000 when received by XR. XE reads the value as kbps and displays it in kbps. XR reads the value as kbps and displays it in Mbps with a lower bound of 1000 Mbps. There is also an unidentifiable extended community sent by CSR4 that XR cannot read. A quick search did not reveal obvious documentation for extended community 0x0006. Also notice that CSR4 did not set the ASN inside the LB community and it remains 0, whereas XR as an ASBR set the value to the local ASN.

```
! CSR4
interface GigabitEthernet2.546
  bandwidth 8000000

Just like XE-to-XE, XR-to-XR is a little easier. While it still doesn't read the interface bandwidth properly, the value on XRv4 corresponds to what we saw earlier. CSR1 showed an LB value of 500,000 kbps when it received LB from XRv2 using the legacy configuration (no RPL). XRv4 shows a value of 4,000 Mbps; these two values are equivalent to 4 Gbps. I am not sure where XR is getting this number, but at least it is consistent. Notice that there is no unknown extended community and the ASN is encoded, unlike XE.

To enable XRv4 to use this information, we need to enable maximum-paths. I use unequal-cost since, unlike AS 137, there are different IGP costs to the BGP next-hops, and I need to multipath across the two. AS 137 used static routes with RSVP-TE so this was a non-issue. We can clearly see the weights of 8000 and 4000 being applied to the candidate routes. The XR show commands for CEF distribution are very clean. XRv4 builds 3 buckets for more accurate load sharing, rather than forcing a 2:1 ratio to be split evenly over 16 buckets, which is impossible. The load distribution shows path 0 (CSR4) being used twice as often as path 1 (XRv1).

```
! XRv4
router bgp 173
  address-family ipv4 unicast
    maximum-paths ibgp 2 unequal-cost

2	Y	GigabitEthernet0/0/0/0.514	173.11.14.11

We will turn the tables and use XRv1 twice as often when CSR4 picks CSR7 as the best path. By setting the link to 2 Gbps, we will achieve a value of 2000 on XR, which is half of XRv1's value of 4000. XR needs to specify the maximum-paths under the VRF IPv4/v6 AFI, not the VPNv4 AFI.

```

27.7 BGP Multicast VPN (MVPN) Theory

MVPN is a generalized name meant to encompass all of the solutions meant to transport multicast traffic from place to place in a VPN environment. In most cases, the “VPN environment” specifically means MPLS 3VPN. The main business driver for this is the explosion of Internet video over the past

years, and these video services are expected to increase further still. A very long set of solutions has been developed and adopted as industry standards to transport multicast across MPLS L3VPN.

The original solution, known commonly as Draft-Rosen, used GRE tunnels to connect all of the PE devices in a given MVPN instance (generally within a given L3VPN, though extranets are supported). The destination of these tunnels was multicast also, so the SP core needed to run PIM to transport it. It has worked well for many years and one of its greatest benefits is that it doesn't introduce any particularly new or difficult concepts. Both the provider and customer use PIM, except the provider tunnels (P-tunnels) just carry customer multicast inside. It can be protected with multicast-only FRR (MoFRR) and also works with PIM-ASM, PIM-SSM, or PIM-Bidir in the core. It can also transport any of these three traffic types used by the customer, along with customer BSR messaging for RP discovery. It carries IPv6 multicast inside these IPv4 P-tunnels as well. Overall, it is a good solution, and despite it being "legacy" it is still considered an MVPN solution (profile 0).

The main issue with this solution is that it does not take advantage of MPLS transport. It would be ideal if both unicast and multicast traffic used a common data plane in the SP core, ultimately removing the need to run PIM there. Label switched multicast (LSM) can be candidate for FRR using the methods already used for unicast LSPs. Two main technologies were extended to support this: RSVP-TE and LDP.

RSVP was already extended to support TE (RSVP-TE), so extending it again to transport multicast was logical. Using P2MP RSVP-TE, a multipoint tunnel can be built from headend to multiple tail ends, which is perfect for transporting one-way multicast. Like a normal TE tunnel, each sub-tunnel (also called sub-LSP) can request FRR treatment, make bandwidth reservations, and do any other kind of TE CSPF parameter tuning. This is Juniper's preferred model and it is the only model that supports bandwidth reservations and simplified FRR. XE never supported this feature (the IOS S-train did), but XR does.

LDP was extended to support this also; it is called multicast LDP (mLDP). This works like LDP where labels are exchanged on a hop-by-hop basis. mLDP can support P2MP trees, which are unidirectional kind of like RSVP-TE P2MP trees. It can also support MP2MP trees, which are similar to PIM-Bidir where traffic can flow in either direction towards the root, which is the main junction point. In P2MP trees, only downstream labels are allocated, whereas in MP2MP trees, upstream and downstream labels are exchanged. P2MP trees are more efficient (like PIM-SSM) but MP2MP trees use less state (like PIM-Bidir). Unlike RSVP LSPs, mLDP LSPs are built from tail to head as label-mapping messages are sent towards the root of the delivery tree. This is Cisco's preferred model as it has less "core state", even for P2MP trees, and generally scales better. It supports FRR but it's less straightforward than RSVP-TE P2MP, and there is no support for making bandwidth reservations.

Some solutions permit dynamic discovery of PE endpoints. Rather than statically configure RSVP-TE P2MP endpoints or mLDP MP2MP roots, BGP can automatically discover endpoints. This is often called BGP auto-discovery (AD). BGP introduces 5 new route-types under the IPv4/v6 MVPN SAFI to accomplish this. The concept of Provider Multicast Service Interface (PMSI) is an abstraction for the router. As long as the C-MRIB is smart enough to know "I need to deliver this packet to the PMSI", the MVPN process

knows what to do next. The PMSI actions will typically include some kind of encapsulation, be it IP/GRE or MPLS, for transport across the core. Traffic exiting the core traverses the PMSI as well where the encapsulation is removed. Different types of BGP routes mean different things as described below.

Type 1: Intra-AS Inclusive PMSI (I-PMSI) AD: Originated by each PE inside an AS; used to learn MVPN membership. It is called “inclusive” because it includes everyone in the MVPN, whether they want traffic or not. I-PMSI can be thought of as similar to a default MDT.

Type 2: Inter-AS I-PMSI AD: Originated by each ASBR; used to learn MVPN membership. This is examined in detail when testing inter-AS MVPN.

Type 3: Selective (S-PMSI) AD: Originated by the source (ingress) PE and used for signaling a specific P2MP tree or data MDT. This is meant to selectively target receivers that want multicast for a given C(S,G).

Type 4: Leaf AD: If the Type-3 requests it, the receiver (Egress) PEs will explicitly show interest in a specific C(S,G). Normally this is not needed for the vast majority of profiles, but has relevance for RSVP P2MP-TE auto-discovered tunnels.

Type 5: Source Active AD: Originated by the source (ingress) PE when it learns about an active source and assist with SPT switchover. This is only relevant when the customer is using PIM-ASM.

The method by which customers exchange multicast routing has always been PIM. In Draft-Rosen, the PEs would form PIM neighbors inside the VRF and the tunnel-mesh would look like an emulated LAN. The same is true for basic mLDP MP2MP trees. This works well and most people are familiar with PIM operations on a LAN. To achieve better scalability, BGP was extended to do customer multicast (c-mcast) signaling. BGP introduces 2 new route-types under the IPv4/v6 MVPN SAFI to accomplish this; basically the PM equivalent of a (*,G) join and an (S,G) join. Receiving a PIM (*,G) or (S,G) join from the CE will trigger the creation of a BGP Type-6 or Type-7 route, respectively. Receiving a prune simply triggers the withdrawal of that route. BGP allows for massive scalability in MVPNs as the concept of a PIM “emulated LAN” for overlay signaling is removed.

Type 6: Shared Tree Join: Specifies the RP and group, and is meant to signal C-PIM-ASM interest in a particular group. This replaces the PIM (*,G) signaling.

Type 7: Source Tree Join: Looks identical to a Type-6 except the RP’s IP address is substituted for the source’s address. It can also be sent upon receipt of a Type-5 Source Active AD message. This replaces the PIM (S,G) signaling.

mLDP is also capable of carrying the c-mcast signaling in-band. That is, PIM/BGP is not needed to exchange customer multicast information since the actually (S,G) information is encoded in the mLDP label mapping messages as an opaque value. This only works with PIM-SSM, since there isn’t a

mechanism for (*,G) signaling nor carrying BSR messages across the VPN. It also scales poorly, but is a very simple solution that eliminates the need for an overlay protocol entirely. For customers using SSM that only have a few, high-bandwidth multicast flows (which is common), and this is a good solution.

A more rudimentary mechanism for transporting multicast includes performing the multicast replication at the head-end and reusing the unicast LSPs. This automatically gives all the flows FRR (provided the unicast LSPs were already protected), doesn't require new signaling, and also overcomes any vendor incompatibility issues. Ingress Replication (IR) is not commonly used (and is supported on XR only), but can be used in specific corner-cases. PBB-EVPN uses this by default for its inclusive multicast exchanges as it assumes that the core is not MVPN-capable by default, which is a good assumption.

In order for the router to know which kind of P-tunnel to use for a particular multicast flow (assuming BGP AD is used), it needs to look at the I-PMSI or S-PMSI to determine the tunnel type. Each transport method has a different tunnel type. This information is carried inside the PMSI attributes within BGP AD routes; once a BGP AD route is bound to a particular C(S,G), the tunnel type specified in the PMSI attribute is used for transport. A mismatch between endpoints of tunnel-types is not supported. This is how remote endpoints agree on how to encapsulate/decapsulate traffic traversing their local PMSIs.

Type 0: No tunnel specified

Type 1: RSVP-TE P2MP

Type 2: mLDP P2MP

Type 3: PIM-SSM

Type 4: PIM-ASM

Type 5: PIM-Bidir

Type 6: Ingress Replication (IR)

Type 7: mLDP MP2MP

As you can see, there are many options; many of the combinations of transport and overlay signaling are valid. **Note: This chapter lays the foundation for the MVPN tests. All of the detailed verification happens there.**

27.8 BGP Link State AF and Path Computation Element (PCE)

BGP-LS is designed to capture link state IGP and TE information and transport it across the network. Specifically, passing it to an SDN/PCE device allows the network to be controlled remotely, enabling network-wide TE and other features. BGP cannot actually use the IGP link-state information for any kind of path selection, but it is easily readable from the CLI. BGP is truly a transport mechanism as it scales much better than IGP and can peer directly with SDN controllers or PCE devices. The feature is simple to configure and only supported in IOS XR at present. The documentation says the peer address must be private but that isn't enforced in XR version 5.3.0. After identifying a domain-distinguisher, just enable the AF per neighbor as usual. The network diagram is shown below.

Below is the configuration of our simulated PCE server. Essentially, it is going to accept BGP-LS information from XRV12 and do nothing with it.

```
! XRV14
router bgp 10
  address-family link-state link-state
    domain-distinguisher 10:14.14.14.14

  neighbor 12.12.12.12
    address-family link-state link-state
```

The configuration is similar on XRV12, with the addition of the IS-IS LSP distribution into BGP. OSPFv2 is also supported, but OSPFv3 does not appear supported yet.

```
! XRV12
router isis 1
  distribute bgp-ls level 2

router bgp 10
  address-family link-state link-state
    domain-distinguisher 10:12.12.12.12

  neighbor 12.12.12.12
    address-family link-state link-state
```

A quick look at the BGP table for this AFI shows all of the IS-IS topology information from level 2 that was injected by XRV12. We will select a few different route types to examine. The BGP codes in the output are excellent and help to decipher the output. The [V] route represents the "vertex" for XRV12 itself. The [L2] is the IS-IS level, and since this isn't a link in the graph, there is a local node [N] but no remote node [R]. The NET is 0000.0000.0012.00 and the BGP RID that originated the prefix was 12.12.12.12 (XRV12). The [E] route, or "edge", is similar except it has a remote node, which is

0000.0000.0012.03. This is an IS-IS DIS for one of XRv12's links. The [T] route contains the prefix for XRv12's loopback0 which is 12.12.12.12/32. The prefix-codes are very useful; don't ignore them.

```
RP/0/0/CPU0:XRv14#show bgp link-state link-state
[snip]
Status codes: s suppressed, d damped, h history, * valid, > best
                i - internal, r RIB-failure, S stale, N Nexthop-discard

0000.0012.03]]/576
                        12.12.12.12          100      0 i
[snip]
*>i[T] [L2] [I0x0] [N[c10] [b12.12.12.12] [s0000.0000.0012.00]] [P[p12.12.12.12/32]]/400
                        12.12.12.12          100      0 i
[snip]
```

The details of the [V] route help to summarize our findings, also. The IS-IS area is not encoded anywhere in the summary information, so one would have to use the detailed show command for it. It is also nice to see the hostname (the LSP name for IS-IS at least) when trying to identify the prefixes. The TE-ID is also important since one of the main uses of this feature is MPLS TE.

```
RP/0/0/CPU0:XRv14#show bgp link-state link-state

PCE Vocabulary and Definitions

PCE: Path Computation Element is a network entity that can compute paths based on the topological graph and a set of constraints. It's basically an enhanced version of the "TE PCALC" and is often externally hosted (not composite). Paths that span multiple domains could be controlled by a single PCE (centralized) or multiple PCE (distributed).

PCC: The Path Computation Client generally represents an LSR who can request a path computation.

PCEP: PCE protocol is used between PCE and PCC and is defined in RFC 5440. It is just a TCP session whereby path requests, replies, commands, and error messages are exchanged.

TED: Traffic Engineering Database is what the PCE uses to determine paths through the network. The TED is not a new construct as RSVP-TE used the same information as input to the "TE PCALC" algorithm, ultimately generating an ERO to feed RSVP-TE PATH messages.

PCE systems can operate in one of two modes

Stateful PCE: The PCE has a strict synchronization with its PCC devices to include topology and resource information. This allows for optimal path computation network-wide. The downside is the significant control-plane overhead between PCE/PCC, and potentially multiple PCEs (more SDN-like). With the delegation option enabled, you also give PCE the authority to change your statically configured tunnels also, not just the automatically created PCE ones. The automatically created ones, like other auto-tunnels for TE, will be spawned and re-used based on the range of numbers you specify.

Stateless PCE: Each request for a path is computed independent of one another and the PCE does not remember any path information. Less control-plane overhead but much less capability. This is less SDN-like and might be better for PCE newcomers initially.

IGP extensions to support PCE discovery: IS-IS introduces "PCED sub-TLV type 5" while OSPF includes sub-TLVs inside the Router Information LSA (Opaque Type 4, Opaque ID 0) with TLV PCEC type 6. There are more sub-TLVs included to define specific PCE parameters covered in RFCs 5088 and 5089 for OSPF and IS-IS, respectively.

Three main PCE deployment models

Composite PCE: The PCE is hosted locally on an LSR. The PCE reads the TED and controls the LSP signaling within one box. I don't believe this is supported on XR as it would effectively turn the router into a TE controller.

External PCE: The PCE is hosted on an external platform like a server or out of band LSR. The TED is learned via BGP-LS and the PCE controls the LSP signaling using PCE protocol (PCEP) to control the PCCs. This seems like an appropriate model for a small SP or a test setup.

Multiple PCE: Typically uses external PCEs interconnected to share information, either for availability or scalability. This would be appropriate for a large, distributed SP.

The lab for this feature is very basic. In this case, the PCE source address for the TCP session is XRv12 loopback, and two peers are defined. The precedence value is self explanatory and lower numbers indicate higher priority. 14.14.14.14/32 is XRv14's loopback (remember, we have a BGP-LS peering with it, since it's our imitation PCE) and 15.15.15.15/32 is a non-existent address just for demonstration. PCE is operating in stateful mode with delegation of TE tunnels. The instantiation keyword allows the PCE to create new dynamic tunnels. The last stanza is outside of the PCE hierarchy but allows the PCC (this router) to generate auto-tunnels in a specified index range. Auto-tunnels come in many varieties and are discussed in detail in the MPLS TE section of this book.

```
! XRv12
mpls traffic-eng
  auto-tunnel pcc
    tunnel-id min 100 max 199
  pce
    peer source ipv4 12.12.12.12
    peer ipv4 14.14.14.14
      precedence 1

    peer ipv4 15.15.15.15
      precedence 2

  logging events peer-status
  stateful-client
  instantiation
  delegation
```

When we verify our PCE sessions, we see the session is pending, since we have no PCE. The remaining show commands for PCE are related to specific LSPs and tunnels, of which we have zero. I didn't actually set up the entire PCE environment as I believe it is beyond the scope of the CCIE SP exam.

```
RP/0/0/CPU0:XRv12#show mpls traffic-eng pce peer
```

Address	Precedence	State	Learned From
14.14.14.14	1	TCP Pending	Static config
15.15.15.15	2	TCP Pending	Static config

Additional Reading – Reference configurations "bgp-ls"

28. Describe, implement, and troubleshoot MVPN

This section walks through many advanced MVPN configurations. The topology is shown below; XRv3 and XRv4 are core routers, with the other six as VPNv4/v6 PEs. XRv2 is a BGP RR for VPNv4/v6 and MVPNv4/v6 (or IPv4/v6 MVPN, same thing). I tried to keep XRv away from the edge since its MVPN capabilities are limited, so most of the testing will occur on the five CSR PEs. CSR10 is the RP for all ASM groups, while the other nodes are senders and/or receivers. The SSM range of 232.0.0.0/8 is also used by the MVPN clients. All 6 sites have full IPv4 unicast reachability, and IPv6 reachability is limited to the top three CEs and bottom three CEs in a segmented fashion. The core runs IS-IS level 2 with MPLS TE enabled on all links.

For all profiles, the following (*,G) and (S,G) streams are joined by the specified CE devices:

XRv1: (, 225.0.0.1)*

CSR10: (2001:10:4:6::4, FF33::1),

CSR9: (, 225.0.0.1), (2001:10:4:6::4, FF33::1)*

CSR4: (, 225.0.0.1), (10.2.7.2, 232.0.0.5)*

CSR3: (, 225.0.0.1), (10.2.7.2, 232.0.0.5), (2001:10:4:6::4, FF33::1), (*, FF7E:240:2001:10:2:7:0:1)*

CSR2: (2001:10:4:6::4, FF33::1)

Anywhere MDT default groups are used, the format is as follows:

First octet: 239 for ASM, 238 for Bidir, and 232 for SSM. Remaining octets: X.255.0.1

Anywhere MDT data groups are used, the format is as follows:

First octet: 239 for ASM, 238 for Bidir, and 232 for SSM

Second octet: 4 for IPv4, 6 for IPv6

Third octet: Router number (1, 5, 6, 7, 8, 12) for each PE

Fourth octet: Variable, 0 - 255

The network diagram used in all profiles is shown below. The routers within the box make up the SP core. XRv2 is the BGP RR for all AFI that are in use. The 6 routers not inside the box are CE devices. Each of them has an IPv4/IPv6 static default route pointing towards the PEs, while the PEs redistribute connected PE-CE links into BGP for VPNv4/v6 reachability. VPNv4 and VPNv6 are always enabled. MVPNv4, MVPNv6, and IPv4 MDT will be enabled based on the profile being tested. The SP core runs PIM only for non-LSM profiles as a best practice.

28.1 Profile 0: Default MDT – GRE – PIM C–mcast Signaling (Traditional Draft-Rosen)

Because the type of PIM used in the core can vary and Profile 0 generally recommends SSM, we will look at all of the options. The baseline configuration has XRv4 as the RP for 239.0.0.0/8 groups using ASM and 238.0.0.0/8 groups using PIM-Bidir. BGP IPv4 MDT and IPv4/v6 MVPN families are disabled everywhere. PIM-SM is enabled on all transit links and MDT endpoints on PEs. The basic multicast configuration is not shown in this section. Rather than show the same basic verification over and over for the different flavors of profile 0, the baseline verifications are done here. First, we will check PIM neighbor counts on XRv3 and XRv4; because there are no neighbor filters, I make the assumption that the neighbors are bidirectional with all the PEs for brevity. There are 2 neighbors per link because XR considers the its own interface in the link (also why the loopback0 shows 1 neighbor as well).

```
RP/0/0/CPU0:XRv3#show pim neighbor count
PIM neighbors in VRF default
```

Interface	Nbr count
GigabitEthernet0_0_0_0.523	2
GigabitEthernet0_0_0_0.534	2
GigabitEthernet0_0_0_0.553	2
GigabitEthernet0_0_0_0.563	2
GigabitEthernet0_0_0_0.573	2
AMT	1
Loopback0	1

RP/0/0/CPU0:XRv4#show pim neighbor count

PIM neighbors in VRF default

Interface	Nbr count
GigabitEthernet0_0_0_0.514	2
GigabitEthernet0_0_0_0.534	2
GigabitEthernet0_0_0_0.554	2
GigabitEthernet0_0_0_0.574	2
GigabitEthernet0_0_0_0.584	2
AMT	1
Loopback0	1

Next, I check the status of the RP on a few select nodes. 239.0.0.0/8 is the ASM range, 238.0.0.0/8 is the Bidir range, and 232.0.0.0/8 is the default SSM range (no RP required). XRv4, the BSR/RP, shows the ranges. I spot-check XRv3 and CSR8 to ensure they learned the mappings properly, and are using the right type of PIM for each RP (ASM or Bidir). This completes the basic multicast transport verification for the core network.

28.1.1 PIM-ASM in the core

This variation starts with the baseline configuration and does not require any modification. The default MDT for VRF MC uses group 239.255.0.1 which, at present, is an ASM group. This default MDT is used for signaling between the nodes so C-PIM information, such as joins, prunes, hellos, and BSR messages can transit the SP core. Each PE loopback participating in this MDT is a source for group 239.255.0.1. We can check XRv4, the RP, and we should see a P(S,G) state entry for each PE using the default MDT group. Because this yields a lot of output, I will show a summary view. The P(*,G) entry is always in the table provided there is at least one receiver (we will discuss receivers next). Each P(S,G) is duplicated for a shortest path tree (SPT) and an RP tree (RPT, or root path tree).

Note: Cisco documentation clearly states the need to run BGP IPv4 MDT between sites for this profile to work. I found out that is not true as this entire section was done without this feature being configured. This may be because these ASM/Bidir variations are not technically compliant with Cisco's definition of the "profile", but they are functionally valid.

```

```

We will zoom in on CSR8's related state information on the P-RP. The RPT entries represent the state created when a source registered with the RP; this is why the RPF interface is a decapsulation tunnel since that is the mechanism by which "native" multicast is viewed by the router. The SPT is the P(S,G) state we normally see in XE that shows how native multicast is forwarded (not encapsulated register

messages). This traffic is forwarded out all of XRv4's other interfaces towards the remote PE's in the same MDT.

```

The reason XRv4 knows the forward the traffic to all receivers is because each PE loopback is also a receiver for the same group. This is part of the reason why PIM must be enabled on the MDT source; an IGMP join is automatically applied to that interface, which triggers a PIM P(*,G) join towards the SP-core's RP for that group. For completeness, I show some debug from CSR8 which shows the periodic join. CSR8 also tells the RP that it doesn't want traffic from the source 213.8.8.8, which is itself. All of the other PEs perform similar operations.

```

```

Focusing on CSR8, we can check its global MRIB to see how it treats this default MDT group. The summary view gives us most of the information, and I remove some of the expanded output because many entries are nearly identical. We can see the big 'Z' flag set on these groups which represents a multicast tunnel. The last group is the locally originated traffic which was locally registered (big 'F') after arriving on the loopback0 (MDT source). The OIL for these tunnels includes the MVRF MC, which is the VRF to which this MDT is bound.

```

With the multicast tunnels operational, we can check the C-PIM information to verify we have PIM neighbors across the tunnel (in the overlay) with the other five PEs. This PIM signaling is always carried by the default MDT and cannot be optimized into a data MDT, because it needs to go to all nodes. The default MDT is often called an “emulated LAN” since all of the multi-access PIM mechanisms, such as Assert, will occur over this tunnel mesh.

```
R8#show ip pim vrf MC neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
213.12.12.12      Tunnel2            00:04:22/00:01:21 v2     1 / DR B P G

```

The C-MRIB on CSR8 shows two interesting entries currently. The first is the IGMPv3 join for the SSM pair. The big ‘Y’ is set, meaning this group should be receiving traffic on a data MDT. We can specifically see a new data MDT was spawned using group 239.4.7.0 specifically to carry this traffic. The third octet represents the router that is sending the traffic, so we can see the CSR7 is the root (source) of this flow. This occurs because this C(S,G) was matched by the ACL defining what traffic was candidate for data

MDT transport. The second entry is the C(*,G) entry for customer ASM. CSR10 is the C-RP, and this information was learned via BSR across the default MDT. There hasn't been any traffic to this group yet.

```
R8#show ip mroute vrf MC | begin \  
(10.2.7.2, 232.0.0.5), 00:00:43/00:02:27, flags: sTIY  
  Incoming interface: Tunnel2, RPF nbr 213.7.7.7, MDT:239.4.7.0/00:02:26  
  Outgoing interface list:  
    GigabitEthernet2.538, Forward/Sparse, 00:00:33/00:02:27  
  
(* , 225.0.0.1), 00:08:05/00:02:16, RP 10.5.10.10, flags: SJC  
  Incoming interface: Tunnel2, RPF nbr 213.5.5.5  
  Outgoing interface list:  
    GigabitEthernet2.538, Forward/Sparse, 00:08:05/00:02:16
```

For verification, we will confirm our understanding of the data MDT by checking CSR6. It should have joined the same data MDT group.

```
R6#show ip mroute vrf MC 232.0.0.5 10.2.7.2 | begin \  
(10.2.7.2, 232.0.0.5), 00:00:38/00:02:43, flags: sTIY  
  Incoming interface: Tunnel0, RPF nbr 213.7.7.7, MDT:239.4.7.0/00:02:43  
  Outgoing interface list:  
    GigabitEthernet2.546, Forward/Sparse, 00:00:38/00:02:43
```

It is not a coincidence that both routers knew to pick the same group. This was carried inside the MDT signaling in the overlay. Although the debugs don't reveal the contents of the overlay, we can see that it happened. We can also look at the send/receive MDT information in a separate table. CSR7 was the originator, and CSR6 /CSR8 were the receivers.

```
! CSR6  
PIM(1): Receive MDT Packet (13613) from 213.7.7.7 (Tunnel0), length (ip: 44,  
udp: 24), ttl: 1  
PIM(1): TLV type: 1 length: 16 MDT Packet length: 16
```

```
R6#show ip pim mdt receive  
Joined MDT-data [group/mdt number : source]  uptime/expires for VRF: MC  
[239.4.7.0 : 213.7.7.7]  00:14:54/00:02:05
```

```
R8#show ip pim mdt receive  
Joined MDT-data [group/mdt number : source]  uptime/expires for VRF: MC  
[239.4.7.0 : 213.7.7.7]  00:15:06/00:02:53
```

```
R7#show ip pim mdt send  
MDT-data send list for VRF: MC  
  (source, group)                MDT-data group/num  ref_count  
  (10.2.7.2, 232.0.0.5)          239.4.7.0           1
```

An unfortunate drawback of the ASM model is that our data MDTs are also ASM groups. That means even though the overlay signaling was SSM, the underlying transport is not, so hopefully the SP is allowing SPT construction in the core for those flows.

```
R6#show ip mroute 239.4.7.0 | begin \  
(* , 239.4.7.0) , 00:13:51/stopped, RP 213.14.14.14, flags: SJCZ  
  Incoming interface: GigabitEthernet2.563, RPF nbr 213.6.13.13  
  Outgoing interface list:  
    MVRF MC, Forward/Sparse, 00:08:40/stopped
```

Now, we will sent traffic from CSR2 to group 232.0.0.5. We don't expect any additional PIM signaling to occur within the overlay, since the deliver trees have been built. However, in the underlay, CSR7 will have to register this new (S,G) with XRv4, and the SPT construction happens per normal PIM-SM rules. The S remains the MDT source (loopback0), but the G will be the new data MDT group assigned for this flow. XRv4 receives the register and sends a (S,G) join towards the source, CSR7's loopback. XR PIM debugs are extensive so I've only cherry-picked the valuable parts.

```
! CSR7  
PIM(0): Adding register encap tunnel (Tunnel3) as forwarding interface of  
(213.7.7.7, 239.4.7.0).  
PIM(0): Received v2 Join/Prune on GigabitEthernet2.574 from 213.7.14.14, to  
us  
PIM(0): Join-list: (213.7.7.7/32, 239.4.7.0), S-bit set  
PIM(0): Add GigabitEthernet2.574/213.7.14.14 to (213.7.7.7, 239.4.7.0),  
Forward state, by PIM SG Join
```

```
! XRv4  
pim[1152]: [13] VRF : default (213.7.7.7,239.4.7.0) Received Register from  
213.7.14.7 Register count 6, Register limit 20000  
pim[1152]: [13] Route create: VRF default (213.7.7.7,239.4.7.0)  
pim[1152]: [13] VRF : default (213.7.7.7,239.4.7.0) SEND J/P adding Join on  
Gi0/0/0/0.574, target 213.7.14.7  
pim[1152]: [13] Sending J/P message for neighbor 213.7.14.7 on Gi0/0/0/0.574  
for 1 groups, size 34 (MTU=1480)
```

XRv4 decapsulates the register message and sends it down the shared tree. CSR6 and CSR8 receive it and issue (S,G) joins towards CSR7 to leave the shared tree.

```
! CSR6  
PIM(0): Insert (213.7.7.7,239.4.7.0) join in nbr 213.6.13.13's queue  
PIM(0): Building Join/Prune packet for nbr 213.6.13.13  
PIM(0): Adding v2 (213.7.7.7/32, 239.4.7.0), S-bit Join  
PIM(0): Send v2 join/prune to 213.6.13.13 (GigabitEthernet2.563)  
  
! CSR8  
PIM(0): Insert (213.7.7.7,239.4.7.0) join in nbr 213.8.14.14's queue
```

```
PIM(0): Building Join/Prune packet for nbr 213.8.14.14
PIM(0): Adding v2 (213.7.7.7/32, 239.4.7.0), S-bit Join
PIM(0): Send v2 join/prune to 213.8.14.14 (GigabitEthernet2.584)
```

CSR7 receives the SPT join from XRv3 (originated by CSR6) and adds it to its delivery tree.

```
! CSR7
PIM(0): Received v2 Join/Prune on GigabitEthernet2.573 from 213.7.13.13, to
us
PIM(0): Join-list: (213.7.7.7/32, 239.4.7.0), S-bit set
PIM(0): Add GigabitEthernet2.573/213.7.13.13 to (213.7.7.7, 239.4.7.0),
Forward state, by PIM SG Join
```

CSR7 has not been told to stop registering, so it sends another one to the RP, along with native multicast. When XRv4 sees native multicast on the SPT, it issues the register-stop.

```
! CSR7
PIM(0): Received v2 Register-Stop on GigabitEthernet2.574 from 213.14.14.14
PIM(0): for source 213.7.7.7, group 239.4.7.0
PIM(0): Removing register encap tunnel (Tunnel3) as forwarding interface of
(213.7.7.7, 239.4.7.0).
PIM(0): Clear Registering flag to 213.14.14.14 for (213.7.7.7/32, 239.4.7.0)
PIM(0): Building Periodic (*,G) Join / (S,G,RP-bit) Prune message for
239.4.7.0
```

```
! XRv4
pim[1152]: [13] VRF : default (213.7.7.7,239.4.7.0) Received Register from
213.7.14.7 Register count 7, Register limit 20000
pim[1152]: [13] VRF : default (213.7.7.7,239.4.7.0) Send Register-Stop to
213.7.14.7
```

At this point, CSR7 should be delivering (213.7.7.7, 239.4.7.0) out of both interfaces towards CSR6 and CSR8. The little 'z' means this is the outer encapsulation for a data MDT group.

```
R7#show ip mroute 239.4.7.0 213.7.7.7 | begin \
(213.7.7.7, 239.4.7.0), 00:12:07/00:01:48, flags: FTz
Incoming interface: Loopback0, RPF nbr 0.0.0.0
Outgoing interface list:
GigabitEthernet2.573, Forward/Sparse, 00:12:05/00:03:19
GigabitEthernet2.574, Forward/Sparse, 00:12:07/00:03:22
```

We already know there is no new signaling in the overlay. Now, we can check packet counters on all three PEs; CSR7 sends packets to the MDT while CSR6 and CSR8 receive it from the MDT.

```
R6#show ip mroute 239.4.7.0 213.7.7.7 count | begin ^Group
Group: 239.4.7.0, Source count: 1, Packets forwarded: 412, Packets received:

406
```

```
Source: 213.7.7.7/32, Forwarding: 405/0/142/0, Other: 405/0/0
```

Fortunately, native multicast counters work in XRv. We can check the packet counters on XRv3 and XRv4 for extra verification. The “A” flag means accept (inbound), the “EG” flag means egress (outbound), and the “NS” flag means negate signal (not related to this).

```
RP/0/0/CPU0:XRv3#show mfib route 239.4.7.0 sources-only | begin 213

```

CSR6 will perform a final verification using EPC. It will capture traffic entering from the SP core (multicast ICMP inside GRE) and also exiting towards the customer (multicast ICMP only). Since the capture will look at both interfaces concurrently, the timestamps for the two packets should be very close together. It looks like the router was extremely fast in switching this packet (no time difference). In both packets, I highlighted the ICMP packet source/destination addresses. We can see the difference in length is exactly 24 (142-118=24), the length of a basic GRE header. This further strengthens our confidence that it is working.

```
3 142 2.000992 213.7.7.7 -> 239.4.7.0 GRE

```

Next we will examine IPv6 ASM. This is significantly more complex because we are doing ASM in both the customer and SP networks. XE routers only allowing debugging in one VRF at a time, so because we already examined what happens in the SP network, we will look at the C-PIM signaling for customer ASM traffic with IPv6. CSR2 is the embedded RP and only CSR3 is a receiver for the group specified below.

```

R8#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 | begin \
(*, FF7E:240:2001:10:2:7:0:1), 01:00:00/never, RP 2001:10:2:7::2, flags: SCJ
Incoming interface: Tunnel2
RPF nbr: ::FFFF:213.7.7.7
Immediate Outgoing interface list:
GigabitEthernet2.538, Forward, 01:00:00/never

```

Quickly checking for IPv6 PIM neighbors, we see that no PE has any neighbors over the MDT. Below is a spot check.

```

RP/0/0/CPU0:XRv2#show pim vrf MC ipv6 neighbor | begin mdt
mdtMC
Neighbor Address          Uptime    Expires   DR pri   DR

```

```

R6#show ipv6 pim vrf MC neighbor
No neighbors found.

```

```

R1#show ipv6 pim vrf MC neighbor
No neighbors found.

```

```

R8#show ipv6 pim vrf MC neighbor
No neighbors found.

```

Cisco requires IPv6 multicast enabled in the global process also; when this is enabled globally, it is enabled for all interfaces by default. Be sure to manually remove it (no ipv6 pim) from core-facing links so it only remains enabled on the loopback0 (MDT source). You can quickly check to see which interfaces have PIMv6 enabled. Below is a spot check of some routers, along with their newly-built PIM adjacencies.

```
RP/0/0/CPU0:XRv2#show pim vrf MC ipv6 neighbor | begin mdt
mdtMC

```

An interesting behavior of the CSR is that if the PIM DR is within a VRF and the RP is embedded, the register message never gets sent. Since CSR4 will be the source, we will tell CSR6 to use a static RP. We know embedded RP works from the receiver side since CSR2 has the C(*,G) join from CSR8. IPv6 (*,G) messages have an incoming interface of the PIM decapsulation tunnel for register messages as opposed to "null" for IPv4. The logic is the same, though.

```
! CSR6
ipv6 pim vrf MC rp-address 2001:10:2:7::2
```

```
ipv6 pim vrf MC register-source GigabitEthernet2.546
no ipv6 pim vrf MC rp embedded
```

```
R2#show ipv6 mroute FF7E:240:2001:10:2:7:0:1 | begin \
(*, FF7E:240:2001:10:2:7:0:1), 00:04:30/00:02:58, RP 2001:10:2:7::2, flags: S
  Incoming interface: Tunnel2
  RPF nbr: 2001:10:2:7::2
  Immediate Outgoing interface list:
    GigabitEthernet2.527, Forward, 00:04:30/00:02:58
```

```
R2#show ipv6 pim tunnel tunnel2
Tunnel2*
  Type   : PIM Decap
  RP     : 2001:10:2:7::2*
  Source: -
```

CSR4 will be sending traffic to this group. We expect CSR6 to register the source with CSR2, who will decapsulate the register message and send it down the shared tree, then immediately join the SPT. Given the location of CSR2 in the network, it sends a (S,G) prune to CSR7 instead, which is sufficient to build the (S,G) state there.

```
! CSR6
IPv6 PIM: [MC] (2001:10:4:6::4,FF7E:240:2001:10:2:7:0:1) Start registering to
2001:10:2:7::2

! CSR2
IPv6 PIM: J/P entry: Prune root: 2001:10:4:6::4 group:
FF7E:240:2001:10:2:7:0:1 Sender: FE80::7 flags: RPT S
IPv6 PIM: (2001:10:4:6::4,FF7E:240:2001:10:2:7:0:1)RPT Create entry
(2001:10:4:6::4,FF7E:240:2001:10:2:7:0:1) J/P adding Prune on
GigabitEthernet2.527
```

Upon receiving the traffic, CSR8 will join the SPT by sending a PIMv6 join directed to CSR6 over the default MDT.

```
! CSR8
IPv6 PIM: [MC] (2001:10:4:6::4,FF7E:240:2001:10:2:7:0:1) J/P adding Join on
Tunnel2
```

Whether triggered by CSR7's SPT join from CSR2 or CSR8's SPT join, CSR6 will switch over to the data MDT since this group is candidate for optimization. CSR6 will eventually receive joins from both. At this point, CSR6 sends multicast both as register messages to the C-RP and as native multicast.

```
! CSR6
IPv6 PIM: [MC] J/P entry: Join root: 2001:10:4:6::4 group:
FF7E:240:2001:10:2:7:0:1 Sender: ::FFFF:213.7.7.7 flags:
```

```
IPv6 PIM: [MC] J/P entry: Join root: 2001:10:2:7::2 group:
FF7E:240:2001:10:2:7:0:1 Sender: ::FFFF:213.8.8.8 flags:
```

CSR2 receives another register then tells CSR6 to stop registering. CSR6 stops sending traffic down its PIM encapsulation tunnel.

```
! CSR2
IPv6 PIM: (2001:10:4:6::4,FF7E:240:2001:10:2:7:0:1) Received Register from
2001:10:4:6::6

```

```
R6#show ipv6 pim vrf MC tunnel
Tunnel5*
Type : PIM Encap
RP : 2001:10:2:7::2
Source: 2001:10:4:6::6
```

At this point, CSR6 and CSR8 should have valid C(S,G) information. CSR6 claims to be forwarding traffic to multiple tunnels, but Tunnel2 doesn't exist. I am assuming this feature is not supported fully in a virtual environment. The router says it is forwarding to an MDT data group, which is correct (little 'y'). CSR8 specifically lists the MDT to which this C(S,G) is bound, which uses the SP-core group 239.6.6.0, rooted at CSR6.

```
R6#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 | begin \

```

A quick check of the packet counters indicates traffic is flowing from end to end. The reason for the 280 failures was a failure on my part; the “issue” I described regarding anycast RP in a VRF slowed me down, and I did not clear counters once I got things working. You can see the difference in packet size is exactly 24 (142 – 118) bytes also.

```
R6#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 count |
include HW
HW Forwarding: 903/0/118/0, Other: 280/0/280
```

```
R8#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 count |
include HW
HW Forwarding: 895/0/142/0, Other: 0/0/0
```

In the underlay, CSR6 has spawned a data MDT for this flow, which was carried over the default MDT in the PIM signaling information. CSR6 sends the MDT information and CSR8 receives it.

```
R6#show ipv6 pim mdt send
MDT-data send list for VRF: MC
  (source, group)                MDT-data group/num  ref_count
  (2001:10:4:6::4,
  FF7E:240:2001:10:2:7:0:1)      239.6.6.0          1
```

```
R8#show ipv6 pim mdt receive
Joined MDT-data [group/mdt number : source]  uptime/expires for VRF: MC
[239.6.6.0 : 213.6.6.6]  00:25:50/00:02:14
```

Quickly checking XRv3 and XRv4, we can see this new MDT group exists in the core and appears to be functional.

```
RP/0/0/CPU0:XRv3#show mfib route 239.6.6.0 sources-only | begin 213

```

We will configure EPC on CSR8 to look at GRE multicast incoming from the core and ICMP multicast going out towards the customer. Like with IPv4 SSM, the capture should show both packets almost simultaneously. The first packet is the GRE packet (0x2F is protocol 47) and the P(S,G) is (213.6.6.6, 239.6.6.0). This is how the service provider transports the packet across the core. The GRE payload is 0x86DD which is IPv6 that has C(S,G) equal to (2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1). The second packet is identical to the first except without the outer IPv4/GRE headers. If you count the difference in length, you will get 24 (0x8E - 0x76 = 0x18 = 24).

```

Additional Reading – Reference configurations “mvpn-0-asm”

28.1.2 PIM-SSM in the core

This variation starts with the baseline configuration and will require some additional BGP features, along with MDT updates. First, we must configure the IPv4 MDT AFI on all PEs. Once BGP converges with this new AF, we see routing information that looks like a normal IPv4 prefix. Normally this MDT AFI is used

for auto-discovery of MDT endpoints for SSM. The prefix is the MDT source and the MDT default group is carried inside the message; it's very straightforward and much less involved than LSM BGP-AD. This is just a way for MDT endpoints to discover one another without relying the ASM mechanism (i.e., the RP).

```
! Basic BGP MDT configuration on XE, apply to all PEs
router bgp 213
  address-family ipv4 mdt
  neighbor 213.12.12.12 activate

! XR2
router bgp 213
  address-family ipv4 mdt
  neighbor-group IBGP
  address-family ipv4 mdt
  route-reflector-client
```

Before continuing, we ensure the MDT capability was negotiated between neighbors. The fastest way to check this is on the RR, XRv2. It should be advertised and received for all five peers. We won't look at any of the routing information yet.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mdt neighbors | utility egrep 'MDT:|^BGP nei'
BGP neighbor is 213.1.1.1
  Address family IPv4 MDT: advertised and received
BGP neighbor is 213.5.5.5
  Address family IPv4 MDT: advertised and received
BGP neighbor is 213.6.6.6
  Address family IPv4 MDT: advertised and received
BGP neighbor is 213.7.7.7
  Address family IPv4 MDT: advertised and received
BGP neighbor is 213.8.8.8
  Address family IPv4 MDT: advertised and received
```

Next, we will update the MDT default/data group addresses to be within the SSM range. We will swap the first octet from 239 to 232, leaving everything else the same. Be sure to remove the default MDT configuration from all address-families before adding new ones.

```
! Changing from ASM to SSM on all XE PEs
vrf definition MC
  address-family ipv4
    no mdt default 239.255.0.1
    mdt default 232.255.0.1

A glance at CSR1's P-MRIB shows all of the expected P(S,G) entries for the MDT peers. The little 's' flag on each entry indicates SSM, which means there is no RP in use, and thus no P(*,G) or register messages in play. The big 'Z' indicates that this is a multicast tunnel, which is also correct. The big 'I' indicates that this entry is the result of having received a source-specific IGMP join, which happened on the loopback0.

The challenge at this point is answering how CSR1 knew to originate PIM P(S,G) joins for all of the remote peers. A quick debug of PIM shows us that CSR1 is, in fact, sending these joins.

```

! CSR1
PIM(0): Insert (213.7.7.7,232.255.0.1) join in nbr 213.1.14.14's queue
PIM(0): Building Join/Prune packet for nbr 213.1.14.14
PIM(0): Adding v2 (213.7.7.7/32, 232.255.0.1), S-bit Join
PIM(0): Send v2 join/prune to 213.1.14.14 (GigabitEthernet2.514)

PIM(0): Insert (213.8.8.8,232.255.0.1) join in nbr 213.1.14.14's queue
PIM(0): Building Join/Prune packet for nbr 213.1.14.14
PIM(0): Adding v2 (213.8.8.8/32, 232.255.0.1), S-bit Join
PIM(0): Send v2 join/prune to 213.1.14.14 (GigabitEthernet2.514)

PIM(0): Insert (213.5.5.5,232.255.0.1) join in nbr 213.1.14.14's queue
PIM(0): Building Join/Prune packet for nbr 213.1.14.14
PIM(0): Adding v2 (213.5.5.5/32, 232.255.0.1), S-bit Join
PIM(0): Send v2 join/prune to 213.1.14.14 (GigabitEthernet2.514)

```

The answer is BGP MDT. The MDT route carries the MDT endpoint, along with the RD, and the MDT group. This is a simple mapping that makes it very easy for remote routers to construct P(S,G) joins, which is why SSM is the preferred method of operation for this MVPN profile. Looking at CSR1, it learns all of the other endpoints this way. The route doesn't carry a route target because it's not bringing new routing information or targeting a specific device. We will look at CSR5 as an example.

```

R1#show bgp ipv4 mdt all | begin Network

  213:1:213.12.12.12   213.12.12.12      213.12.12.12

```

Note: Although not yet relevant (will become relevant for Inter-AS models), the BGP connector attribute has been added to the VPNv4 prefixes. This is the result of using any profile 0 variant for MVPN. This attribute is meant to override the BGP next-hop when performing RPF checks. Even if the BGP next-hop changes, the original address is maintained so there is a mechanism to “connect” potential multicast sources to their MDT endpoints.

```

R1#show ip rpf vrf MC 10.2.7.0

```

At this point, everything is the same with respect to normal multicast forwarding. Because both the default and data MDTs are SSM, the P-mcast signaling has been simplified and the customer can still use ASM. First, we will test IPv4 SSM across the customer network. CSR2 is the source and CSR3/CSR4 are receivers. This means that CSR6, CSR7, and CSR8 should all have C(S,G) state for this group. The group is also candidate for data MDT treatment, so that selective delivery tree should have been signaled. The little 'y' on the egress PE means the traffic is being sent to an MDT data group, while the big 'Y' on the receivers means it is receiving data from an MDT data group.

```
R6#show ip mroute vrf MC 232.0.0.5 10.2.7.2 | begin \
(10.2.7.2, 232.0.0.5), 06:40:59/00:02:25, flags: sTIY

Outgoing interface list:
GigabitEthernet2.538, Forward/Sparse, 06:47:22/00:02:18
```

```
R7#show ip mroute vrf MC 232.0.0.5 10.2.7.2 | begin \
(10.2.7.2, 232.0.0.5), 00:01:48/00:02:40, flags: sTY
Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0
Outgoing interface list:
Tunnel2, Forward/Sparse, 00:01:48/00:02:40
```

We can also verify the MDT signaling is correct by looking at the sent/received MDT information. This is used for signaling the dynamic data group assignments. The data MDT information is carried across the default MDT in a special PIM TLV that effectively notifies the egress LSR to join a specific data MDT.

```
R6#show ip pim mdt receive
Joined MDT-data [group/mdt number : source] uptime/expires for VRF: MC
[232.4.7.0 : 213.7.7.7] 00:40:22/00:02:01
```

```
R8#show ip pim mdt receive
Joined MDT-data [group/mdt number : source] uptime/expires for VRF: MC
[232.4.7.0 : 213.7.7.7] 00:40:57/00:02:26
```

```
R7#show ip pim mdt send
MDT-data send list for VRF: MC
```

(source, group)	MDT-data group/num	ref_count
(10.2.7.2, 232.0.0.5)	232.4.7.0	1

CSR2 will begin sending traffic now. There should be no more PIM signaling in either the provider or customer networks since all (S,G) trees are fully built. The counters have never been cleared on CSR6 or CSR8. CSR7 was rebooted in between tests to clear an error, but the counters continue to increment regardless, showing that data is flowing. We can also see the size difference is 24; when CSR7 measures the packet, it does so before GRE encapsulation. When the receivers measure it, they do so before GRE decapsulation.

```
R7#show ip mroute vrf MC 232.0.0.5 10.2.7.2 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 35, Packets received:
35
Source: 10.2.7.2/32, Forwarding: 35/1/118/0, Other: 35/0/0

Group: 232.0.0.5, Source count: 1, Packets forwarded: 732, Packets received:
732
Source: 10.2.7.2/32, Forwarding: 732/1/142/1, Other: 732/0/0
```

```
R8#show ip mroute vrf MC 232.0.0.5 10.2.7.2 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 730, Packets received:
730
Source: 10.2.7.2/32, Forwarding: 730/1/142/1, Other: 730/0/0
```

One final check involves using EPC on CSR8 to measure traffic entering from the SP and exiting to the customer. We should see GRE multicast entering and ICMP multicast exiting. The source/destination addresses have been identified in the buffer dump to prove the data MDT is working. The difference in size between the packets is exactly 24 and the time difference is immeasurable by the router.

```
R8#show monitor capture CAP buffer detailed

```

To ensure IPv6 multicast is working, we will test IPv6 SSM using the customer pair (2001:10:4:6::4, FF33::1). Let's check the C-MRIB on the ingress/egress PEs to ensure the C(S,G) state is there. Absent

from the C(S,G) states are 'y' or 'Y' flags; this group is not candidate for MDT treatment per the IPv6 ACL. This traffic will always transit the SP network along the default MDT, meaning all PEs will receive it.

```
R6#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 00:57:44/00:03:25, flags: sT  
  Incoming interface: GigabitEthernet2.546  
  RPF nbr: 2001:10:4:6::4  
  Immediate Outgoing interface list:  
    Tunnel0, Forward, 00:57:44/00:03:25
```

```
R7#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 07:17:33/never, flags: sTI  
  Incoming interface: Tunnel2  
  RPF nbr: ::FFFF:213.6.6.6  
  Immediate Outgoing interface list:  
    GigabitEthernet2.527, Forward, 07:17:33/never
```

```
R8#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 07:17:08/never, flags: sTI  
  Incoming interface: Tunnel2  
  RPF nbr: ::FFFF:213.6.6.6  
  Immediate Outgoing interface list:  
    GigabitEthernet2.538, Forward, 07:17:08/never
```

CSR4 begins sending traffic. There should be no change to the signaling, so next we verify the packet counters for each C(S,G) entry.

```
R6#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW  
  HW Forwarding: 73/1/118/0, Other: 0/0/0
```

```
R7#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW  
  HW Forwarding: 86/1/142/1, Other: 0/0/0
```

```
R8#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW  
  HW Forwarding: 81/1/142/1, Other: 0/0/0
```

Even routers like CSR1 and CSR5 are receiving (and dropping) this flow. This is the downside to using the default MDT for high-bandwidth flows; inefficient forwarding and wasted PE resources are allocated just to drop the traffic. The IPv6 VPN network is split so these other PEs don't even have unicast reachability to the source, so RPF fails.

```
R1#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 07:23:47/never, flags: sTI  
  Incoming interface: Null  
  RPF nbr: ::  
  Immediate Outgoing interface list:  
    GigabitEthernet2.519, Forward, 07:23:47/never
```

```
R1#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW
HW Forwarding: 0/0/0/0, Other: 215/215/0
```

```
R5#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \((
(2001:10:4:6::4, FF33::1), 07:25:14/never, flags: STI
Incoming interface: Null
RPF nbr: ::
Immediate Outgoing interface list:
GigabitEthernet2.550, Forward, 07:25:14/never
```

```
R5#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW
HW Forwarding: 0/0/0/0, Other: 224/224/0
```

Packet counting in the core is less effective, but is still another tool to add to our confidence. Checking XRv4, we see many more packets from CSR6 than we do from CSR1 along the default MDT. This is another good sign that the data is flowing along the path we suspect.

```
RP/0/0/CPU0:XRv4#show mfib route 232.255.0.1 213.6.6.6 | begin 213
(213.6.6.6,232.255.0.1), Flags:
Up: 01:15:09
Last Used: 00:00:05
SW Forwarding Counts: 1142/1142/128736
SW Replication Counts: 1142/2263/255640
[snip]
```

```
RP/0/0/CPU0:XRv4#show mfib route 232.255.0.1 213.1.1.1 | begin 213
(213.1.1.1,232.255.0.1), Flags:
Up: 00:52:02
Last Used: 00:00:04
SW Forwarding Counts: 286/286/24636
SW Replication Counts: 286/1144/98544
[snip]
```

Reusing the EPC configuration on CSR8, we validate that traffic is being successfully decapsulated from the default MDT in the SP network to the original ICMP packet, and forwarded to the customer. The GRE IPv4 header shows a source of 213.6.6.6 and a destination of 232.255.0.1 (Default MDT). The inner IPv6 ICMP header shows a source of 2001:10:4:6::4 and a destination of FF33::1.

Additional Reading – Reference configurations “mvpn-0-ssm”

28.1.3 PIM-Bidir in the core

Continuing on with the SSM configuration, we will use a hybrid of Bidir and SSM. Just like we saw in the ASM demonstration, it does not make (much) sense to use ASM or Bidir for data MDTs. The whole purpose of data MDTs is to optimize for bandwidth, so having an RP in the signaling path is not an effective way to do that. Since the data MDT receivers are known, SSM is the best option. Technically, ASM can offer benefits to data MDTs since ultimately the SPT is built, but for Bidir it makes no sense unless there were multiple Bidir RPs placed intelligently around the network where high-bandwidth flows were known to be (seems too complicated). Realistically, only these three models make sense:

1. **SSM for default and data MDTs.** This is the best design, is most common, but requires BGP. Since BGP is already running on all the PEs for VPNv4 or other MPLS services, activating another AF is not a big deal.
2. **ASM for default and SSM for data MDTs.** A valid combination that wouldn't require BGP. Allow PE endpoints to discover one another and use SSM paths for high-bandwidth flows.
3. **Bidir for default and SSM for data MDTs.** A valid combination that wouldn't require BGP. So long as the RP is central in the data plane, this reduces default MDT (S,G) state in the network if there are many PEs. Use SSM paths for high-bandwidth flows.

We did not explicitly test #2, but in this demonstration we will explore option #3. That means the data groups will remain 232.x.x.x while the default MDT will become 238.255.0.1. I will also disable BGP MDT to prove that it is not required for this model to function.

```

! Basic XE PE configuration to switch from SSM to Bidir default MDT
vrf definition MC
 address-family ipv4
   no mdt default 232.255.0.1
   mdt default 238.255.0.1
   mdt data 232.4.1.0 0.0.0.255 list ACL_DATA_MDT
 address-family ipv6
   no mdt default 232.255.0.1
   mdt default 238.255.0.1

```

```

mdt data 232.6.1.0 0.0.0.255 list ACL_DATA_MDT_IPV6

! XRv2 configuration to switch from SSM to Bidir default MDT
multicast-routing
vrf MC
  address-family ipv4
    no mdt default ipv4 232.255.0.1
    mdt default ipv4 238.255.0.1
  address-family ipv6
    no mdt default ipv4 232.255.0.1
    mdt default ipv4 238.255.0.1

```

Next, we disable BGP MDT on all routers. We should not need it to build the default MDT since all traffic flows to XRv4 as the Bidir-RP. Removing it from XRv2 is enough since it breaks the entire MDT route exchange, but to keep the configuration clean, I remove it everywhere.

```

! Removing BGP MDT from XE PEs
router bgp 213
  no address-family ipv4 mdt

! Removing BGP MDT from XRv2
router bgp 213
  no address-family ipv4 mdt
  neighbor-group IBGP
    no address-family ipv4 mdt
  address-family ipv4 mdt
  no route-reflector-client

```

Taking a cavalier attitude towards verifying PIM neighbors, I will check the neighbor counts on XRv2 and assume everyone has connectivity. I spot check a CSR1 as well. XRv2 reports 6 neighbors because it counts itself as another neighbor.

```

RP/0/0/CPU0:XRv2#show pim vrf MC neighbor count | include mdt
mdtMC 6

```

```

RP/0/0/CPU0:XRv2#sh pim vrf MC ipv6 neighbor count | include mdt
mdtMC 6

```

```

R1#show ip pim vrf MC neighbor | begin ^Neighbor

213.5.5.5       Tunnel2          00:07:13/00:01:27 v2      1 / B S P G

```

Seeing PIM neighbors within the customer VRF means the default MDT is working. Looking at CSR6 and XRv2, we can see the select their core interfaces as upstream (towards the root of the shared tree, the Bidir-RP) and their “VRF” interfaces as downstream, towards the customer. The big ‘Z’ on XE means this is a multicast tunnel, which is correct. The XR flags ‘LH’ and DSS’ mean “last hop” and “don’t signal sources”. The former means the router is a leaf in the delivery tree and the latter is self-explanatory when using Bidir. The ‘LI’ interface flag means local interest since this router is requesting the flow for itself; it was not signaled by a receiver.

```
R6#show ip mroute 238.255.0.1 | begin \

```

Because traffic on a Bidir tree always goes to the RP, there has to be a mechanism to send traffic upstream also (that’s why it’s called Bidir). This is comparable to an mLDP MP2MP tree where traffic flows upstream and downstream, where normal PIM ASM/SSM (or P2MP RSVP-TE) is comparable to an mLDP P2MP tree where traffic only flows downstream from the root. The designated forwarder (DF) is elected on each LAN and only this router is allowed to send traffic upstream to the root. This ensures the forwarding mechanism is loop-free. The output below shows XRv3 and CSR6 DF election results. The DF on the link between them is XRv3 since XRv3 is closer to the root (RP). CSR6 has a metric of 20 which is worse than XRv3’s metric of 10, so if Bidir multicast traffic is forwarded upstream to this LAN segment, only XRv3 is allowed to forward it upstream. This is what allows CSR6 to send traffic to the RP and ultimately have it be seen by the rest of the PEs. The XRv output is technically more correct since it shows the administrative distance also, which is evaluated before the metric.

```
RP/0/0/CPU0:XRv3#show pim df winner
```

RP	Interface	DF Winner	Metrics

(Non-DF)
PIM(0): RP 213.14.14.14, pref 115, metric 10
PIM(0): Metric is better
```

The data MDT information for the IPv4 SSM pair (10.2.7.2, 232.0.0.5) is signaled across the default MDT from CSR7 to CSR6 and CSR8. We quickly verify this is still working as it was with the prior tests. When the 'y' flag says the C(S,G) is sending to a data MDT, this is the mapping table that shows which C(S,G) goes to which data MDT group.

```
R7#show ip pim mdt send
MDT-data send list for VRF: MC
  (source, group)                MDT-data group/num  ref_count
  (10.2.7.2, 232.0.0.5)          232.4.7.0          1
```

```
R6#show ip pim mdt receive
Joined MDT-data [group/mdt number : source]  uptime/expires for VRF: MC
[232.4.7.0 : 213.7.7.7]  10:26:12/00:02:47
```

```
R8#show ip pim mdt receive
Joined MDT-data [group/mdt number : source]  uptime/expires for VRF: MC
[232.4.7.0 : 213.7.7.7]  10:25:16/00:02:43
```

Like earlier, the debugging shows this information being transmitted over the default MDT.

```
! CSR6
PIM(1): Receive MDT Packet (41878) from 213.7.7.7 (Tunnel0), length (ip: 44,
udp: 24), ttl: 1
PIM(1): TLV type: 1 length: 16 MDT Packet length: 16
```

All three of these routers should show C-MRIB entries for this IPv4 SSM group. The ingress PE (CSR7) has little 'y' to indicate sending to a data MDT group, while the egress PEs (CSR6 and CSR8) have a big 'Y' to indicate receiving from it. The egress PEs also show the MDT mapping in their C-MRIB entries. On CSR7, we saw earlier how the C(S,G) maps to a data MDT when we looked at the "sent MDT" listing.

```
R7#show ip mroute vrf MC 10.2.7.2 232.0.0.5 | begin \

Each router should have a corresponding P(S,G) of (213.7.7.7, 232.4.7.0) in their global MRIB also. This is how the traffic appears on the carrier's network. The little 'z' means this group is transport for a data MDT (true on CSR7), and on the others it is flagged as a multicast tunnel with a big 'Z'. Notice that the group is SSM, not Bidir, so this will have a positive performance impact on the customer multicast flow.

```
R7#show ip mroute 232.4.7.0 213.7.7.7 | begin \

For good measure, here is a PIM signaling packet transiting the default MDT. We know it is on the default MDT based on the destination group address 238.255.0.1. The TTL is 1 (0x01) and the protocol is 103/PIM (0x67). This packet in particular came from CSR5 destined to 224.0.0.13 (highlighted). It is probably a PIM Hello, BSR message, or periodic join/prune. We know that this packet transited the Bidir shared tree to reach CSR8.

```

Next we will test IPv6 SSM as we did earlier. The only difference with this delivery mechanism is that the IPv6 SSM pair (2001:10:4:6::4, FF33::1) is not candidate for MDT optimization as it does not match the ACL we applied. This means the traffic will always transit the default MDT. First, we verify that CSR7 and CSR8 receive the MLDv2 joins from their customers and that the C(S,G) tree was properly built back to the root, CSR6. The only significant difference between this set of outputs and the IPv4 SSM set is the lack of any 'y' or 'Y' flags. This is because the data MDT operation is not involved with this C(S,G) at all.

```
R6#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \
(2001:10:4:6::4, FF33::1), 10:58:30/00:03:05, flags: sT

RPF nbr: ::FFFF:213.6.6.6
Immediate Outgoing interface list:
GigabitEthernet2.538, Forward, 18:44:15/never
```

Since there is no data MDT, and the default MDT has been verified, we can safely assume this traffic will transport inside the default MDT. This means that XRv4 will always receive traffic for this flow. When CSR4 starts sending traffic, we check the packet counters on the three PEs to ensure it is working. The packet counters are all increasing as traffic flows.

```
R6#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW
HW Forwarding: 790/1/118/0, Other: 0/0/0

```

```
R8#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW
```

```
HW Forwarding: 792/1/142/1, Other: 0/0/0
```

To show the drawbacks of using PIM Bidir with default MDTs, I will instruct CSR3 to stop requesting this flow. CSR8 will send a C(S,G) prune towards CSR6 but it has no effect since CSR7 is still on the “emulated LAN” requesting traffic. When CSR7 sees the C(S,G) prune from CSR8, it immediately issues a C(S,G) join so that CSR6 will cancel its removal of the MDT from its OIL. Since there is no P(S,G) prune mechanism for the default MDT, traffic will still be sent to XRv4 and dropped. This is a prune override operation in action.

! CSR8

```
IPv6 PIM: [MC] (2001:10:4:6::4,FF33::1) GigabitEthernet2.538 Local state

```

Let’s ensure that CSR7 is still receiving the traffic while CSR8 is not. CSR8 doesn’t even have the C-MRIB entry anymore let alone statistical information for the data plane. CSR7 is still receiving traffic, though.

```
R7#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW
HW Forwarding: 1237/1/142/1, Other: 0/0/0
```

```
R8#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count | include HW
[no output]
```

To prove packets are entering CSR6, we will do two things. We will check the counters on the P(S,G) for the default MDT on CSR8 to show they are being received. This method isn’t fool-proof since you are basically trying to guess how many packets are along the default MDT that aren’t signaling, but the two outputs below were sampled 10 seconds apart. The source is sending 1 pps, so seeing ~12 packets in 10 seconds is probably an indication that the traffic is being received.

```
R8#show ip mroute 238.255.0.1 count | begin ^Group
```

```
Group: 238.255.0.1, Source count: 0, Packets forwarded: 20742, Packets

```

```
RP-tree: Forwarding: 20742/1/107/1, Other: 20745/3/0
```

```
R8#show ip mroute 238.255.0.1 count | begin ^Group
```

```
Group: 238.255.0.1, Source count: 0, Packets forwarded: 20754, Packets
received: 20757
```

```
RP-tree: Forwarding: 20754/1/107/1, Other: 20757/3/0
```

We can also use EPC to show the packets entering and not being sent down to the customer. Below we see two packets spaced exactly one second apart, but there is no raw ICMPv6 being sent to the customer. We can see the beginning of the IPv6 source address as 2001:10:4:6, which we know is the customer behind CSR6.

```
R8#show monitor capture CAP buffer detailed

Additional Reading – Reference configurations “mvpn-0-bidir”

28.2 Profile 1: Default MDT – MLDP MP2MP – PIM C–mcast Signaling (Basic mLDP)

This profile is the one most people think of when mLDP is discussed. It is a very simple configuration and is basically a one-for-one replacement with the GRE-Rosen method in terms of MDT methodology. The profile specifically calls out MP2MP trees, but we examine P2MP MDT trees also. The basic mLDP configuration is very straightforward, and I will configure support for the MP2MP tree and P2MP trees together. The MP2MP tree is a bidirectional tree that represents and emulated LAN. When used with C-PIM signaling, it forms a full-mesh of all VPN participants, which is determined by the VRF’s VPN-ID. This is not to be confused with the RD, which can (and does) vary between the PEs. An mLDP MP2MP tree is logically comparable to a PIM Bidir RP. Before doing anything, we should verify the routers are mLDP-capable. XRv lies and always says it is mLDP capable even when the process is disabled. Maybe this “capability” is loosely interpreted as the feature being supported, but this is advertised to LDP peers even when mLDP is off.

```
RP/0/0/CPU0:XRv4#show mpls ldp capabilities
```

Type	Description	Owner
0x50b	Typed Wildcard FEC	LDP
0x3eff	Cisco IOS-XR	LDP
0x508	MP: Point-to-Multipoint (P2MP)	mLDP
0x509	MP: Multipoint-to-Multipoint (MP2MP)	mLDP
0x703	P2MP PW	L2VPN-AToM

```
RP/0/0/CPU0:XRv4#show mpls mldp database
```

```
mLDP is not running (1082230272)
```

The configuration below enables mLDP in XR. I enable logging as well, but that is not required for mLDP to work.

```
! XRv4
mpls ldp
  mldp
  logging notifications
```

I have selected XRv4 to be the “root” of the mLDP “shared tree” and instructed the VRF to prefer mLDP over PIM. I also show a snippet for how to enable basic mLDP in XR because it is not on by default, as it is with XE. XR is much more complicated by introducing “core-trees”, which are essentially RPF lookup mechanisms. We specifically need to tell PIM to use the mLDP-based tree for RPF.

```

! XE basic PE configuration for all PEs
vrf definition MC
  vpn id 213:213
  address-family ipv4
    mdt preference mldp
    mdt default mpls mldp 213.14.14.14

! XRv2 basic PE configuration

  set core-tree mldp-default
end-policy

router pim
  vrf MC
    address-family ipv4
      rpf topology route-policy RPL_MLDP

```

As soon as a node is told about a root, the mLDP process adds this to its database. Behind the scenes, it creates an LSPvif for forwarding LSM. It automatically inherits the Loopback0 (LDP RID) configuration as the MDT source (XR needs to be explicitly told, XE does not) and enables PIM on it. A MP2MP default MDT is always identified by the number 0 contained within the opaque ID. This is the “MDT number” and as P2MP trees are spawned, the number increments.

```

R6#debug mpls mldp all
MLDP-MFI: Enabled MLDP MFI client on Lspvif0; status = ok
MLDP: Reclaimed success lsp vif: Lspvif0 address: 0.0.0.0 application: MDT

1
MLDP-MDT: [mdt 213:213 0] wavl insert success
MLDP: LDP root 213.14.14.14 added

```

Next, the router needs to signal to the root that it is a leaf in the tree. It does this by sending a label mapping message towards the root based on the shortest IGP path. This is not based on the multicast RPF lookups, but uses the actual unicast routing table. We see that shortest path to XRv4 is via XRv3. We also notice that mLDP allocated a local label of 6005. This is the downstream label that CSR6 advertises to XRv3 to say “when you want to send me traffic inside this specific VPN along the MP2MP tree, use this label”. ID:5 at the end is the LSM path ID, which is another way to reference the mLDP database entry.

```
! CSR6
MLDP: nhop 213.6.13.13 added
MLDP-NBR: 213.13.13.13:0 mapped to next_hop: 213.6.13.13
MLDP: Root 213.14.14.14 old paths: 0 new paths: 1
MLDP-DB: [mdt 213:213 0] Changing peer from none to 213.13.13.13:0
MLDP-DB: [mdt 213:213 0] Add accepting element nbr: 213.13.13.13:0
MLDP-MFI: For accepting element nbr: 213.13.13.13:0, [mdt 213:213 0] MFI
allocated label 6005

MLDP-DB: [mdt 213:213 0] path to peer: 213.13.13.13:0 changed None:0.0.0.0 to
GigabitEthernet2.563:213.6.13.13
MLDP-MFI: After the MFI call For accepting element nbr: 213.13.13.13:0, Bind
local label 6005 to PSM ID: 5, returned: 6005
```

If we have advertised our downstream local label to the upstream router, surely the upstream router will give us an upstream label so we can reach the root. This only occurs with MP2MP trees. This upstream label is a local label on the upstream router which says “when you want to send traffic through me to reach the root, use this label”.

```
! CSR6
MLDP-LDP: [mdt 213:213 0] label mapping from: 213.13.13.13:0 label: 93004
root: 213.14.14.14 Opaque_len: 14 sess_hdl: 0xF
MLDP-DB: [mdt 213:213 0] Set upstream label from no_label to 93004
```

We can look at the mLDP database for the MP2MP tree (ID=0) for the VPN in question to verify these labels mapping. We also see the LSM ID:5 which corresponds to the debug messages. Notice that the local label is downstream (XRv3 uses this to send traffic away from the root) and the outbound label is upstream (CSR6 uses this label to send traffic towards the root). The output also shows “replication clients” which are essentially downstream clients. In this case, it’s the customer VRF.

```
R6#show mpls mldp database opaque_type mdt 213:213 0
LSM ID : 5 (RNR LSM ID: 6) Type: MP2MP Uptime : 00:08:58
FEC Root : 213.14.14.14
Opaque decoded : [mdt 213:213 0]
Opaque length : 11 bytes
Opaque value : 02 000B 0002130000021300000000
RNR active LSP : (this entry)
```

```

Upstream client(s) :
  213.13.13.13:0    [Active]
    Expires         : Never           Path Set ID   : 5
    Out Label (U)   : 93004           Interface    : GigabitEthernet2.563*
    Local Label (D) : 6005            Next Hop     : 213.6.13.13
Replication client(s):
  MDT (VRF MC)
    Uptime          : 00:08:58        Path Set ID   : 6
    Interface       : Lspvif0

```

XRv3 also generates a log message which shows similar information. The log is incomplete in that it says no local label was assigned, but if we check the database, we clearly see it. The log also shows us the LSM-ID, a long hexadecimal number, which I use the reference the mLDP database entry. XRv3 also has a second downstream client, XRv2. The same process occurs for all clients, and the label mapping process happens all the way until the root is reached.

```

! XRv3
mpls_ldp[1042]: %ROUTING-MLDP-5-BRANCH_ADD : 0x00001 [mdt 213:213 0] MP2MP
213.14.14.14, Add LDP 213.6.6.6:0 branch remote label 6005, local label
no_label

```

```

RP/0/0/CPU0:XRv3#show mpls mldp database 0x00001
mLDP database
LSM-ID: 0x00001    Type: MP2MP    Uptime: 01:21:25

  Opaque decoded    : [mdt 213:213 0]
  Upstream neighbor(s) :
    213.14.14.14:0 [Active] Uptime: 00:22:10
      Next Hop       : 213.13.14.14
      Interface      : GigabitEthernet0/0/0/0.534
      Local Label (D) : 93005           Remote Label (U) : 94007
  Downstream client(s):
    LDP 213.6.6.6:0 Uptime: 00:17:55
      Next Hop       : 213.6.13.6
      Interface      : GigabitEthernet0/0/0/0.563
      Remote label (D) : 6005           Local label (U) : 93004
    LDP 213.12.12.12:0 Uptime: 00:22:31
      Next Hop       : 213.12.13.12
      Interface      : GigabitEthernet0/0/0/0.523
      Remote label (D) : 92003           Local label (U) : 93012

```

A quick way to see if the root is reachable with a properly built tree is to look at the root information directly. The output is similar in XE and XR. Recall that we never configured the root on XRv3, it learned it from the label mapping messages from the downstream clients (PEs).

```

R6#show mpls mldp root 213.14.14.14
Root node      : 213.14.14.14
Metric         : 20

```

```

Distance      : 115
Interface     : GigabitEthernet2.563 (via unicast RT)
FEC count     : 1
Path count    : 1
Path(s)       : 213.6.13.13          LDP nbr: 213.13.13.13:0
GigabitEthernet2.563

```

```

RP/0/0/CPU0:XRv3#show mpls mldp root 213.14.14.14
Root node     : 213.14.14.14
Metric        : 10
Distance      : 115
FEC count     : 1
Path count    : 1
Path(s)       : 213.13.14.14        LDP nbr: 213.14.14.14:0

```

The root also knows that is it the root using the same method as XRv3. When the metric/distance are 0, there are no LDP neighbors towards the root, and the router knows it is the root. At no time did we explicitly configure XRv4 to be root on XRv4 itself.

```

RP/0/0/CPU0:XRv4#show mpls mldp root 213.14.14.14
Root node     : 213.14.14.14 (We are the root)
Metric        : 0
Distance      : 0
FEC count     : 1
Path count    : 1
Path(s)       : 213.14.14.14        LDP nbr: none

```

The PEs are able to communicate over this MP2MP tree which allows them to form PIM adjacencies across their virtual interfaces within the VPN. On XRv3, when label 93005 comes in, the traffic is replicated towards both CSR6 and XRv2 (downstream clients). Label 93005 is the downstream label that XRv3 allocated and advertised towards XRv4.

```

RP/0/0/CPU0:XRv3#show mpls mldp database opaquetype mdt 213:213 0 | begin
Upst
Upstream neighbor(s) :
  213.14.14.14:0 [Active] Uptime: 00:33:08
    Next Hop       : 213.13.14.14
    Interface      : GigabitEthernet0/0/0/0.534
    Local Label (D) : 93005           Remote Label (U): 94007

```

```

RP/0/0/CPU0:XRv3#show mpls forwarding labels 93005

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
93005	6005	MLDP: 0x00001	Gi0/0/0/0.563	213.6.13.6	0
	92003	MLDP: 0x00001	Gi0/0/0/0.523	213.12.13.12	0

CSR6 and XRv2, upon receiving this, associate it with the proper VPN. That is why PHP cannot be used for LSM, since the label determines in which VPN the traffic belongs. XR takes a few show commands to verify that the traffic is part of a specific MDT.

```
R6#show mpls forwarding-table labels 6005
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Label	Outgoing interface	Next Hop
6005	[T] No Label	[mdt 213:213 0] [V]	\			
	0	aggregate/MC				

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92003
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92003	Unlabelled	MLDP: 0x00003			

```
RP/0/0/CPU0:XRv2#show mpls mldp database 0x00003 brief
```

LSM ID	Type	Root	Up	Down	Decoded	Opaque	Value
0x00003	MP2MP	213.14.14.14	1	1	[mdt 213:213 0]		

We can verify the PIM adjacencies over the tunnel also. This happens within the VRF since the global process is PIM-free.

```
RP/0/0/CPU0:XRv2#show pim vrf MC neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime	Expires	DR	pri	Flags
10.11.12.11	Gig0/0/0/0.512	02:00:40	00:01:33	1	B	P

213.8.8.8	Lspvif0	00:34:35/00:01:37	v2	1 / S P G

With the PIM neighbors up, the PEs should also learn that CSR10 is an RP. If you forget to change the core-tree on XR PEs, they will drop the BSR messages due to failed RPF. The “info source” is different but this is just cosmetic between XE and XR.

```
RP/0/0/CPU0:XRv2#show pim vrf MC rp mapping
```

Uptime: 00:40:26, expires: 00:01:31

At this point, I configure CSR4, CSR3, CSR9, and XRv1 to be receivers for 225.0.0.1. This is an ASM group so each PE should issues a C(*,G) join towards the C-RP, CSR10. I do not show the IGMP configuration because it is simple. Below is a quick check of the PEs to ensure they see the C-RP via the LSPvif0 interface with proper RPF information.

R1#show ip mroute vrf MC sparse

(*, 225.0.0.1), 01:37:11/00:02:48, RP 10.5.10.10, flags: SJC

Incoming interface: Lspvif0, RPF nbr 213.5.5.5

Outgoing interface list:

GigabitEthernet2.519, Forward/Sparse, 01:21:09/00:02:48

R6#show ip mroute vrf MC sparse

(*, 225.0.0.1), 01:37:29/00:02:46, RP 10.5.10.10, flags: SJC

Incoming interface: Lspvif0, RPF nbr 213.5.5.5

Outgoing interface list:

GigabitEthernet2.546, Forward/Sparse, 01:21:13/00:02:46

R8#show ip mroute vrf MC sparse

(*, 225.0.0.1), 01:37:23/00:02:17, RP 10.5.10.10, flags: SJC

Incoming interface: Lspvif0, RPF nbr 213.5.5.5

Outgoing interface list:

GigabitEthernet2.538, Forward/Sparse, 01:37:23/00:02:17

RP/0/0/CPU0:XRv2#show pim vrf MC topology 225.0.0.1

(*,225.0.0.1) SM Up: 00:00:35 RP: 10.5.10.10

JP: Join(00:00:14) RPF: LmdtMC,213.5.5.5 Flags: LH

GigabitEthernet0/0/0/0.512 00:00:35 fwd LI LH

Next, we check the ingress PE and C-RP, CSR5 and CSR10, to ensure they see the C(*,G) join. CSR5 is the only router that will have the LSPvif0 in the OIL since the RP is behind it. CSR10 has no incoming interface since it is the root of the shared tree, and is running PIM in the global table.

R5#show ip mroute vrf MC sparse

(*, 225.0.0.1), 01:45:03/00:03:11, RP 10.5.10.10, flags: S

```
Incoming interface: GigabitEthernet2.550, RPF nbr 10.5.10.10
Outgoing interface list:
  Lspvif0, Forward/Sparse, 01:45:03/00:03:11
```

```
R10#show ip mroute sparse
(*, 225.0.0.1), 01:45:53/00:02:54, RP 10.5.10.10, flags: S
  Incoming interface: Null, RPF nbr 0.0.0.0
  Outgoing interface list:
    GigabitEthernet2.550, Forward/Sparse, 01:45:53/00:02:54
```

Assuming CSR2 is the source and is sending traffic, we expect CSR7 to send a register message to the RP. The RP will forward the traffic down the shared tree until it can build the C(S,G) tree back to CSR7. Once it does that, it will prune itself from the C(S,G) tree since it is not in the transit path for any of those flows. All of the PEs will have C(S,G) state for the source.

```
CSR10#debug ip pim
PIM(0): Received v2 Register on GigabitEthernet2.550 from 10.2.7.7

PIM(0): Send v2 join/prune to 10.5.10.5 (GigabitEthernet2.550)
```

We will verify that the PEs are actually forwarding traffic towards the customers. XRv does not appear to work in the data plane, though.

```

XRv LSM LFIB counters don't appear to work, but the debugs do. On XRv3, we can see traffic arriving from CSR7 and being replicated towards XRv2 and CSR6. XRv3 spits out a nasty message that the P2MP traffic is being dropped, but it actually isn't. We saw the counters increment on CSR6 as it forward traffic towards the customer. The LFIB has this properly programmed but the counters don't increase. Notice that this MPLS packet came in from XRv4, not direct from CSR7. This is because we are using the MP2MP tree, so transit traffic goes through the root. There are ways to optimize this, which are examined later.

```
RP/0/0/CPU0:XRv3#debug mpls packet

```

```
RP/0/0/CPU0:XRv3#show mpls forwarding labels 93005
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
93005	6005	MLDP: 0x00001	Gi0/0/0/0.563	213.6.13.6	0
	92003	MLDP: 0x00001	Gi0/0/0/0.523	213.12.13.12	0

Additionally, I confirm it with EPC on CSR6. Immediately following the 0x8847 ethertype, label 0x1775 (6005) is seen entering the router, which is the correct local downstream label allocated by CSR6 towards XRv3. The packet has EXP 0 and is the bottom-most label. The IP packet has source 10.2.7.2 (green) and destination 225.0.0.1 (pink).

```

Although not strictly part of profile 1, data MDTs are optional. These are used to optimize bandwidth by only sending traffic to PEs that want it. The MP2MP tree is bidirectional and when traffic is sent onto that tree, the core routers consult their LFIB and deliver traffic to each node. PEs without C-multicast clients interested in that C-group will simply drop the traffic. The benefit of only using MP2MP trees is that it minimizes state since there is one delivery tree. It is best used for low-volume/inclusive traffic, whereas data MDTs are more appropriate for high-volume/selective traffic. In this example, only CSR4 and CSR3 request a high-volume SSM flow using C-group 232.0.0.5. This is the only high-volume flow in the network; all other SSM and ASM flows should use the MP2MP tree. We will instruct all PEs routers to allow a maximum of 10 data MDTs using only this C-group. I use SSM for variation, not out of necessity.

```
! XE PE configuration
ip access-list extended ACL_DATA_MDT
 permit ip any host 232.0.0.5

vrf definition MC
 address-family ipv4
  mdt data mpls mldp 10 list ACL_DATA_MDT immediate-switch

! XRV2 PE configuration
ipv4 access-list ACL_DATA_MDT
 10 permit ipv4 any host 232.0.0.5

multicast-routing
 vrf MC
  address-family ipv4
   mdt data mldp 10 ACL_DATA_MDT immediate-switch
```

This will spawn a new MDT in the core of the network, with a non-zero identifier. Since PIM is still used for C-multicast signaling, the PIM TLV process reviewed in profile 0 is used again. Looking at CSR6's MRIB topology, we can quickly figure out the new MDT number and look into the mLDp database. Notice that the RPF interface for the C(S,G) join is the same, but the RPF neighbor is CSR7 since this is an SSM join. The MDT number is 1. The Y/y flags mean joined/sending to MDT data groups, respectively.

```
R6#show ip mroute vrf MC ssm
(10.2.7.2, 232.0.0.5), 02:10:05/00:02:37, flags: sTIY
  Incoming interface: Lspvif0, RPF nbr 213.7.7.7, MDT: [1, 213.7.7.7]/

  Outgoing interface list:
    GigabitEthernet2.546, Forward/Sparse, 02:10:05/00:02:37
```

CSR6 indicates that traffic sent downstream from the root (CSR7) towards the customer should use label 6000. This was advertised to XRV3. Notice there is no outgoing/upstream label. Data MDTs are not only P2MP, they are unidirectional. A downstream LSR can never send data towards the root of the tree.

```

R6#show mpls mldp database opaque_type mdt 213:213 1
LSM ID : 7   Type: P2MP   Uptime : 01:33:18
FEC Root      : 213.7.7.7

Replication client(s):
  MDT (VRF MC)
    Uptime      : 01:33:18    Path Set ID : None
    Interface   : Lspvif0

```

On XRv3, we will look at its P2MP trees, since we know there is only one. The output doesn't even show an upstream label field, let alone a value. The remote label from CSR6 is 6000, which is what XRv3 will use to deliver LSM towards CSR6 (downstream away from the root). The local label 93002 is what XRv3 advertised to CSR7 to receive this downstream traffic. XRv3 doesn't need to replicate anything because there is only one client, CSR6. If there were more clients, their label mapping messages would intersect the existing P2MP tree somewhere and be grafted (like tree branches). The LFIB does not list XRv2 for this MDT as expected.

```

RP/0/0/CPU0:XRv3#show mpls mldp database p2mp

```

We will use a new command on CSR7 as a quick verification. Checking the mLDP bindings shows the downstream labels used to deliver traffic. CSR7 has to replicate it towards XRv3 and XRv4. Notice label 93002 in use for traffic sent towards XRv3 in this VPN as it matches the verification performed above.

We also check the mLDP database summary which shows us all the roots and their VPNs, along with client counts. There can be multiple roots in the network, even for the same VPN.

```
R7#show mpls mldp bindings opaque_type mdt 213:213 1

60
Source: 10.2.7.2/32, Forwarding: 60/1/122/0, Other: 60/0/0
```

Earlier, I mentioned there can be multiple roots. Specifically, we can manually configure multiple roots for the MP2MP tree also. Both of them use the MDT ID of 0. On CSR6 and CSR7, I temporarily configure CSR5 as a MP2MP root in addition to XRv4. Examining CSR7, we can prove this.

```
! CSR6 and CSR7
vrf definition MC
address-family ipv4
mdt default mpls mldp 213.5.5.5
address-family ipv6
mdt default mpls mldp 213.5.5.5
```

```
R7#show mpls mldp database summary
```

LSM ID	Type	Root	Decoded Opaque Value	Client
3	P2MP	213.7.7.7	[mdt 213:213 1]	3
4	MP2MP	213.5.5.5	[mdt 213:213 0]	1
1	MP2MP	213.14.14.14	[mdt 213:213 0]	1

CSR7 selects XRv4 as the root, not wanting to use CSR5. This is because the lowest cost to the root, when multiple roots are configured, is the default behavior. CSR5 is a hot-standby, since the label mapping exchange already occurred. This secondary root is listed as a “candidate”.

```
R7#show mpls mldp database opaque_type mdt 213:213 0 | include RNR|FEC_Root
LSM ID : 4 (RNR LSM ID: 2)    Type: MP2MP    Uptime : 00:01:51
    FEC Root                  : 213.5.5.5
    RNR active LSP            : 1 (root: 213.14.14.14)
LSM ID : 1 (RNR LSM ID: 2)    Type: MP2MP    Uptime : 03:11:48
    FEC Root                  : 213.14.14.14
    RNR active LSP            : (this entry)
    Candidate RNR ID(s) : 4
```

```
R7#show mpls mldp root 213.14.14.14 | include Metric
    Metric : 10
R7#show mpls mldp root 213.5.5.5 | include Metric
    Metric : 20
```

In the case of a tie, the highest IP address wins. In this case, XRv4 remains the root. The LSM-ID 8 output shows that “A” is the active LSP. This hexadecimal number 0xA represents the second database entry that maps to 213.14.14.14 as the root.

```
R6#show mpls mldp database opaque_type mdt 213:213 0 | include RNR|FEC_Root
LSM ID : 8 (RNR LSM ID: 6)    Type: MP2MP    Uptime : 00:15:40
    FEC Root                  : 213.5.5.5
    RNR active LSP            : A (root: 213.14.14.14)
LSM ID : A (RNR LSM ID: 6)    Type: MP2MP    Uptime : 00:01:45
    FEC Root                  : 213.14.14.14
    RNR active LSP            : (this entry)
    Candidate RNR ID(s) : 8
```

```
R6#show mpls mldp root 213.14.14.14 | include Metric
    Metric : 20
R6#show mpls mldp root 213.5.5.5 | include Metric
    Metric : 20
```

To make things complicated, I increase the IS-IS cost on XRv3’s link to XRv4 from 10 to 15. This makes CSR6 choose CSR5 as its root, while CSR7 still selects XRv4. In fact, every other router selects XRv4, since no one else is configured to use CSR5. At a glance, it appears like CSR6 will not have reachability to any other nodes since they cannot agree on the MP2MP root.

```
R6#show mpls mldp root 213.14.14.14 | include Metric
    Metric : 25
R6# show mpls mldp root 213.5.5.5 | include Metric
    Metric : 20

R6# show mpls mldp database opaque_type mdt 213:213 0 | include RNR|FEC_Root
```

```

LSM ID : 8 (RNR LSM ID: 6)    Type: MP2MP    Uptime : 00:17:30
  FEC Root      : 213.5.5.5
  RNR active LSP : (this entry)
Candidate RNR ID(s): A
LSM ID : A (RNR LSM ID: 6)    Type: MP2MP    Uptime : 00:03:36
  FEC Root      : 213.14.14.14
  RNR active LSP : 8 (root: 213.5.5.5)

```

From CSR6's perspective, nothing looks wrong as it sees all its PIM neighbors. Recall that PIM neighbors are unidirectional, and the reception of a PIM hello is sufficient to form a neighborhood. This implies that every other router is able to reach CSR6.

```

R6#show ip pim vrf MC neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
213.12.12.12      Lspvif0                          04:50:19/00:01:32 v2      1 / DR P G
213.5.5.5         Lspvif0                          04:50:20/00:01:42 v2      1 / S P G
213.7.7.7         Lspvif0                          04:50:20/00:01:43 v2      1 / S P G
213.1.1.1         Lspvif0                          04:50:20/00:01:19 v2      1 / S P G
213.8.8.8         Lspvif0                          04:50:20/00:01:18 v2      1 / S P G

```

The issue is that CSR6 is not able to reach all the other PEs. Specifically, it cannot reach XRv2, CSR1, or CSR8. Tracing the MP2MP tree from CSR6, CSR6 is using label 93007 to send traffic upstream towards CSR5 via XRv3. I use the ID number of 8, seen earlier, to reference this MP2MP tree.

```

R6#show mpls mldp database id 8 | section Upstream
Upstream client(s) :
  213.13.13.13:0    [Active]
    Expires         : Never          Path Set ID   : 8
    Out Label (U)   : 93007          Interface     : GigabitEthernet2.563*
    Local Label (D): 6002            Next Hop      : 213.6.13.13

```

XRv3 forwards this towards the root, which is CSR5, and also down to CSR7, which is part of the same MP2MP tree. XRv3 does not forward it to XRv2 since that PE never send a label mapping for the MP2MP tree using CSR5 as the root. Thus, XRv2 cannot see PIM hellos from CSR6.

```

RP/0/0/CPU0:XRv3#show mpls forwarding labels 93007
Local  Outgoing  Prefix          Outgoing        Next Hop        Bytes
Label  Label       or ID           Interface       Interface       Switched
-----
93007  5001         MLDP: 0x00003   Gi0/0/0/0.553  213.5.13.5      0
       7006         MLDP: 0x00003   Gi0/0/0/0.573  213.7.13.7      0

```

Knowing that CSR7 is a leaf in the tree, we normally expect CSR5 (the root) to forward the packet onward towards the other side of the network. However, CSR1 and CSR8 did not issue label mappings for this MP2MP tree, and thus no "branches" exist from CSR5. The only downstream client is XRv3 with

inbound traffic using label 5001 as expected. This means CSR1 and CSR8 will never see traffic from CSR6, but CSR7 will. CSR5 also will not see traffic from CSR6; even though it's the root, it did not configure itself as the root. In performing PE duties, it is not aware of that traffic coming from CSR6 within the MVPN as a result.

```
R5#show mpls mldp database summary
```

```

We verify our findings by checking PIM neighbors on all the PEs. As expected, only CSR7 have a PIM neighborship with CSR6. More correctly, the opposite is true regarding reachability, since CSR6 can only reach CSR7. Everyone can reach CSR6. A node only sends traffic upstream to one root, but is capable of receiving traffic from all configured roots. That is why using multiple roots works, so long as everyone has the same list of roots. The LSPs are signaled to each root at the time of configuration to enable this failover behavior.

```

```

To fix it, we will configure every node to agree on the list of roots. For simplicity, I will remove the CSR5 root from CSR6 and CSR7, as well as revert the IS-IS cost on XRv3. Multiple mLDP root testing is not the focus of this lab. Next, we will retest this MVPN profile with IPv6. We will use XRv4 as root on all devices and use Embedded RP for variety. CSR2 will be the Embedded RP for all IPv6 ASM traffic; for this test, we will use the ASM group FF7E:240:2001:10:2:7::1 and SSM group FF33::1. The SSM group will use the MP2MP default tree and the ASM group will use the P2MP data trees (opposite of what we tested

earlier). The VPN ID does not change but it shown again because without it, mLDP does not work at all. It is critical to identify a VPN-ID under the VRF. Because the MP2MP tree carries the FEC information of the VPN ID and root address, there is no differentiation between IPv4 and IPv6, so the roots must match between the two. If we wanted to use multiple roots, we would have to do so consistently between both AFs.

```
! XE PE configuration on all PEs

We should verify that our IPv6 PIM neighbors have formed. We see the “emulated LAN” behavior in play; even though the unicast RTs did not create this full-mesh of L3VPN reachability, the VPN ID is the same on all of the nodes.

```

We will configure MLD joins on all of the PEs to request traffic for FF33:1 from CSR4 and this will use the MP2MP default tree. CSR2 and CSR3 will issue MLD joins for FF7E:240:2001:10:2:7::1. The MLD configuration is not shown, but we verify the PIMv6 signaling between the PEs. First, we will verify the top three PEs (XRv2, CSR5, and CSR1). All of them receive the MLDv2 join from their CEs, but their RPF interface is null. The reason for this is that none of them have a unicast IPv6 route to 2001:10:4:6::4, because the unicast topology does not allow it. Their OILs are properly built, but ultimately traffic cannot flow towards the customers, even if it is flooded to the PEs via the MP2MP tree. There is nothing magical about MVPN as it still relies heavily on converged unicast VPN routing.

```

Next, we verify CSR7 and CSR8, which have unicast reachability back to CSR4. Their C(S,G) trees are properly constructed. A quick verification on CSR6 shows the LSPvif as the “LAN” interface in the OIL, as expected. This virtual interface represents the PMSI.

```

```

Traffic sent to LSPvif0 will be send down the MP2MP tree, ultimately reaching all destinations. We acknowledge this is wasteful in this scenario, because there is no connectivity between some receivers and the source. We can prove that mLDP is not smart enough to understand this by tracing the LSP. CSR6’s mLDP database uses upstream label 93004 to send traffic towards the root. XRv3 is the next-hop.

```
R6#show mpls mldp database opaque_type mdt 213:213 0 | section Upstream
```

```

Upstream client(s) :
  213.13.13.13:0    [Active]
    Expires          : Never          Path Set ID   : B
    Out Label (U)    : 93004          Interface     : GigabitEthernet2.563*
    Local Label (D)  : 6004           Next Hop      : 213.6.13.13

```

On XRv3, the mLDP database shows XRv2 as another downstream client of the MP2MP tree, and replicates traffic towards it using label 92003. We verify this by checking the LFIB also. At the same time, XRv3 sends traffic upstream to the root using XRv4's local label of 94007.

```

CSR4 will begin sending traffic now. Examining XRv2, CSR5, and CSR1, they show RPF failures when traffic arrives, since there is no RPF interface but the C(S,G) matches the C-MRIB. Because MVPN LSM isn't supported on egress XRv PEs, all the counters are zero, but normally it would show here. The RPF counters are proof that mLDP is flooding the traffic throughout the entire MP2MP tree.

```

Next, we test IPv6 ASM using the P2MP data MDT. Knowing that the top half of the network does not have a route to the Embedded RP, I won't configure the MLD join on them; we already tested the failures there. Instead, CSR3 joins the group FF7E:240:2001:10:2:7::1 and CSR8 sends a C(*,G) join towards the C-RP, which is CSR2.

```

R8#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 | begin \
(*, FF7E:240:2001:10:2:7:0:1), 00:00:26/never, RP 2001:10:2:7::2, flags: SCJ
Incoming interface: Lspvif0

tunnel destination 2001:10:2:7::2

```

At this point, no new mLDP P2MP trees have been built, despite us specifying so in the ACL. This is because a C(S,G) join is generally required for the P2MP tree to be built, since the intent is to build it directly to the source. This is why P2MP mLDP trees are better suited for SSM than ASM. As observed earlier, Embedded RP does not appear to work in a VRF when deployed with MVPN on XE. The PE never sends the register message. The configuration looks right, it just never works. There is no debug output on CSR2 (C-RP), nor any MPLS unicast packets seen in the core during this process.

```

CSR6#debug ipv6 pim

GigabitEthernet2.546
IPv6 PIM: [MC] (2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1) Create entry
IPv6 PIM: [MC] (2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1) RPF changed from
::/- to 2001:10:4:6::4/GigabitEthernet2.546
IPv6 PIM: [MC] (2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1) Connected status
changed from off to on
IPv6 PIM: [MC] (2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1) Start registering to
2001:10:2:7::2
```

```
R6#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 | begin \
(2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1), 00:03:43/00:00:51, flags: SFT
Incoming interface: GigabitEthernet2.546
RPF nbr: 2001:10:4:6::4, Registering
Immediate Outgoing interface list:
Tunnell, Forward, 00:03:43/never
```

For the sake of actually seeing this work, I configure the RP statically on CSR6 only, disable embedded RP support, and set a valid register source just to be certain. This was the same workaround conducted for profile 0.

```
! CSR6
ipv6 pim vrf MC rp-address 2001:10:2:7::2
ipv6 pim vrf MC register-source GigabitEthernet2.546
no ipv6 pim vrf MC rp embedded
```

Now, the first-hop router can successfully register traffic with the C-RP. The little 'y' flag means sending traffic to an MDT data group. This implies the P2MP MDT was built, but we will verify that later. We also know the MP2MP is not in use because the MDT ID is non-zero and a new LSM-ID was assigned. The counters show several packets forwarded also.

```
R6#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 | begin \
(2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1), 00:19:10/00:00:33, flags: SFTy
Incoming interface: GigabitEthernet2.546
RPF nbr: 2001:10:4:6::4
MDT TX nr: 2147483649 (0x80000001) LSM-ID: 0xD
Immediate Outgoing interface list:
Tunnell, Forward, 00:19:10/never
Lspvif0, Forward, 00:14:47/00:03:05
```

```
R6#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 count
Forwarding Counts: Pkt Count/Pkts per second/Avg Pkt Size/Kilobits per second
Other counts:      Total/RPF failed/Other drops(OIF-null, rate-limit etc)
VRF MC
54 routes, 6 (*,G)s, 46 (*,G/m)s
Group: FF7E:240:2001:10:2:7:0:1
```

```

HW Forwarding: 786/1/118/0, Other: 10/0/10
Totals - Source count: 1, Packet count: 786
```

Checking the C-RP quickly, we see the C(S,G) entry so we know registration was successful. Because CSR2 is not in the transit path between CSR4 and CSR3, it is pruned from the C(S,G) tree.

```
R2#show ipv6 mroute FF7E:240:2001:10:2:7:0:1 | begin \
(*, FF7E:240:2001:10:2:7:0:1), 00:45:09/00:03:22, RP 2001:10:2:7::2, flags: S
Incoming interface: Tunnel2
RPF nbr: 2001:10:2:7::2
Immediate Outgoing interface list:
GigabitEthernet2.527, Forward, 00:45:09/00:03:22
```

```

Immediate Outgoing interface list:
GigabitEthernet2.527, Null, 00:02:10/00:03:22
```

The egress PE shows traffic being received from the LSPvif and forwarded to the customer correctly. The same can be observed on CSR7. It is also considered an egress PE (tail-end of the P2MP tree), probably because the RP is behind it issuing C(S,G) joins, although the traffic is dropped due to a null OIL. It is awkward that the packet counters increase on CSR7 with a null OIL. The big 'Y' means traffic is being received from an MDT data group.

```
R8#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 | begin \
