    HW Forwarding: 404/1/126/0, Other: 1/1/0
  Totals - Source count: 1, Packet count: 404

```

Before all of this occurred, the new P2MP tree was signaled. We will examine the debugs from CSR8. One significant difference between these debugs and the MP2MP debugs is that there is no upstream label mapping message from the core, as expected.

```

! CSR8
MLDP-MDT: [mdt 213:213 2147483649] wavl insert success
MLDP: LDP root 213.6.6.6 added
MLDP-DB: [mdt 213:213 2147483649] Added P2MP branch for MDT label
MLDP: Root 213.6.6.6 old paths: 0 new paths: 1
MLDP-DB: [mdt 213:213 2147483649] Changing peer from none to 213.14.14.14:0
MLDP-DB: [mdt 213:213 2147483649] Add accepting element nbr: 213.14.14.14:0
MLDP-MFI: For accepting element nbr: 213.14.14.14:0, [mdt 213:213 2147483649]
MFI allocated label 8038
MLDP: [mdt 213:213 2147483649] label mapping msg sent to 213.14.14.14:0
success
MLDP-DB: [mdt 213:213 2147483649] path to peer: 213.14.14.14:0 changed
None:0.0.0.0 to GigabitEthernet2.584:213.8.14

```

MLDP-MFI: After the MFI call For accepting element nbr: 213.14.14.14:0, Bind local label 8038 to **PSM ID: 6, returned: 8038**

Next, we will trace the LSP. Checking CSR8, we confirm a new P2MP tree was built.

```
R8#show mpls mldp database summary
```

LSM ID Cnt.	Type	Root	Decoded Opaque Value	Client
4	P2MP	213.7.7.7	[mdt 213:213 1]	1
5	P2MP	213.6.6.6	[mdt 213:213 2147483649]	1
1	MP2MP	213.14.14.14	[mdt 213:213 0]	1

Looking at the mLDP database, CSR8 advertises label 8038 so XRv4 can send traffic downstream. There is no upstream label since mLDP P2MP trees are downstream only.

```
R8#show mpls mldp database opaque_type mdt 213:213 2147483649
```

```
LSM ID : 5    Type: P2MP    Uptime : 00:03:40
FEC Root      : 213.6.6.6
Opaque decoded : [mdt 213:213 2147483649]
Opaque length  : 11 bytes
Opaque value   : 02 000B 0002130000021380000001
Upstream client(s) :
  213.14.14.14:0 [Active]
    Expires      : Never      Path Set ID : 5
    Out Label (U) : None      Interface  : GigabitEthernet2.584*
    Local Label (D) : 8038    Next Hop   : 213.8.14.14
Replication client(s) :
  MDT (VRF MC)
    Uptime      : 00:03:40    Path Set ID : None
    Interface   : Lspvif0
```

On the other end, CSR6 is the root of the new P2MP MDT.

```
R6#show mpls mldp database summary
```

LSM ID Cnt.	Type	Root	Decoded Opaque Value	Client
B	P2MP	213.7.7.7	[mdt 213:213 1]	1
D	P2MP	213.6.6.6	[mdt 213:213 2147483649]	2
A	MP2MP	213.14.14.14	[mdt 213:213 0]	1

There are no upstream clients from the root, and CSR6 replicates the traffic downstream to XRv3 using label 93007.

```
R6#show mpls mldp database opaque_type mdt 213:213 2147483649
```

```
LSM ID : D    Type: P2MP    Uptime : 00:03:52
FEC Root      : 213.6.6.6 (we are the root)
Opaque decoded : [mdt 213:213 2147483649]
```

```

Opaque length      : 11 bytes
Opaque value       : 02 000B 0002130000021380000001

94019  8038        MLDP: 0x00005  Gi0/0/0/0.584 213.8.14.8    0

```

Last, we will examine OAM for MP2MP and P2MP trees in this profile. Unlike Profile 12 where we were limited only to unidirectional P2MP trees (the root specified had to be local), with MP2MP pings we can test from any endpoint; the tree is bidirectional. We specify the FEC and opaque type and can quickly discover all the endpoints in the MVPN on this MDT.

```

Additional Reading – Reference configurations "mvpn-1"

28.3 Profile 3: Default MDT – GRE – BGP-AD – PIM C-mcast Signaling

For this test, begin with the MVPN Profile 0 configuration using the Bidir model where PIM is set up already for both the customer and provider networks. The default MDT uses PIM-Bidir while the data MDTs use PIM-SSM. This will allow us to see more varieties in the P-tunnel types. The only significant difference here is enabling BGP auto-discovery (AD). This modification similar to jumping from profile 1 to profile 9 (using mLDP, not GRE). I do not anticipate seeing much benefit to this since the default MDT is still specified statically and signaling is done via PIM. IPv4 MDT SAFI is no longer needed; instead we configure MVPN.

```

! Basic XE configuration to enable BGP AD
vrf definition MC

After configuring BGP, we look at CSR1 to see if it learned any BGP AD routes. It sees a Type-1 I-PMSI route from every PE in the MVPN (IPv4) and the same type of route for the “south-side” routers on IPv6. This is because the VPNv6 L3VPN is split horizontally. We also see a Type-3 S-PMSI route from CSR7 which describes a data MDT.

```
R1#show bgp ipv4 mvpn vrf MC | begin Network

```

Looking at the I-PMSI and S-PMSI for CSR7 side by side, we see one uses type 5 and one uses type 3 provider tunnels (green). Type-5 is PIM-Bidir and Type-3 is PIM-SSM, which is correct given our multicast group allocations defined for MDT default/data within this MVPN. If we were using ASM, we would have seen Type-4 also. In this case, both trees are rooted at CSR7 (yellow). The only difference is the destination group (cyan) encoded in the tunnel parameters. This is essentially the same information that IPv4 MDT carries, except it is more verbose and capable.

```

```

Because the Type-3 S-PMSI was created once CSR7 received a C(S,G) join for a flow candidate for MDT optimization, this implies the entire signaling path is already set up. Assuming CSR2 is the source with CSR3 and CSR4 as receivers, we can verify the C-MRIB entries on the three relevant PEs. The “verbose” option on the egress PE shows us the GRE MDT to which this is bound; the S-PMSI route told us the P-tunnel was PIM (GRE) and the group was 232.4.7.0. We also see a little ‘y’ which means this is sending to a data MDT group. The ingress PEs, CSR6 and CSR7, also show the MDT to which they are bound (using the Type-3 S-PMSI from CSR7). The big ‘Y’ means they are joined to (receiving) an MDT data group.

```

R7#show ip mroute vrf MC 232.0.0.5 10.2.7.2 verbose | begin \(
(10.2.7.2, 232.0.0.5), 00:05:18/00:03:06, flags: sTyp

Outgoing interface list:  
GigabitEthernet2.538, Forward/Sparse, 00:36:18/00:02:48
```

We can verify the data MDT is in play by checking the routers MDT caches. This information is derived from BGP and helps device the binding between BGP AD routes (PMSI) and C-MRIB entries. All of them know about the data MDT. CSR7 originated the message so the next-hop (last column) is blank.

```
R7#show ip pim mdt bgp all | section 232  
MDT group 232.4.7.0  
213:7:213.7.7.7                213.7.7.7                0.0.0.0

```

We can also quickly verify the P(S,G) creation of the MDT data group. We also must ensure XRv3 and XRv4, core routers, have this P(S,G) state. CSR7 is performing replication to both XRv3 and XRv4 and the little 'z' means this is a multicast tunnel bound to an MDT data group in the MVPN. The core routers show that they are sending the traffic only two their downstream clients and not all PEs in the MVPN, which is the whole point of data MDTs. The core routers have no special MVPN-style flags for the P(S,G) state because they are not aware of anything special. Last, the egress PEs accept this traffic from the core and forward it to their MVPN customers.

```

```

As a final check, we can use EPC to measure packets coming in from the core and going out towards the customer. The two packets are shown below in that sequence. The difference in length is exactly 24 bytes (142-118) and the IP addresses are shown plainly in the output. The outer IP addressing is highlighted in yellow and the inner IP addressing is green.

```
R8#show monitor capture CAP buffer detailed

```

Next, we will test IPv6 SSM. ASM introduces much more complex signaling in the MVPN customer network and is tested many times in many profiles. IPv6 SSM is interesting because the C(S,G) we use, which is (2001:10:4:6::4, FF33::1), is not candidate for MDT optimization per our IPv6 ACL. This means that it will transit the default MDT, which uses PIM-Bidir in the underlay. All PEs will receive the traffic in

their underlay (core) networks and many will drop it, which can be wasteful both on bandwidth and router resources. First, we verify the C-PIM signaling is working by checking the three relevant PEs. CSR6 should have received the C(S,G) join from CSR7 and CSR8, then added its MDT interface to the OIL.

```
R6#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 00:37:09/00:03:19, flags: sT  
  Incoming interface: GigabitEthernet2.546  
  RPF nbr: 2001:10:4:6::4  
  Immediate Outgoing interface list:  
    Tunnel3, Forward, 00:37:09/00:03:19
```

```
R7#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 01:06:42/never, flags: sTI  
  Incoming interface: Tunnel2  
  RPF nbr: ::FFFF:213.6.6.6  
  Immediate Outgoing interface list:  
    GigabitEthernet2.527, Forward, 01:06:42/never
```

```
R8#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \  
(2001:10:4:6::4, FF33::1), 01:06:41/never, flags: sTI  
  Incoming interface: Tunnel3  
  RPF nbr: ::FFFF:213.6.6.6  
  Immediate Outgoing interface list:  
    GigabitEthernet2.538, Forward, 01:06:41/never
```

We can verify that the default MDT is in use a few ways. First, none of the routers claim to be doing any kind of data MDT. CSR6 does not send and CSR7/CSR8 do not receive and data MDT information. No one has entry idea about any 232 groups; in our case, we can correlate this with no data MDTs.

```
R6#show ipv6 pim mdt bgp all | section 232  
[no output]
```

```
R7#show ipv6 pim mdt bgp all | section 232  
[no output]
```

```
R8#show ipv6 pim mdt bgp all | section 232  
[no output]
```

We check BGP IPv6 MVPN for a matching S-PMSI route for this specific C(S,G) on the router who would have originated it, which is CSR6. There is no such network. However, we do have an I-PMSI match using CSR6 as the root (green) using a type-5 Bidir tunnel (yellow) to group 238.255.0.1 (cyan).

```
R6#show bgp ipv6 mvpn vrf MC route-type 3 2001:10:4:6::4 FF33::1 213.6.6.6  
% Network not in table
```

```
R6#show bgp ipv6 mvpn vrf MC route-type 1 213.6.6.6  
BGP routing table entry for [1][213:6][213.6.6.6]/12, version 32

```

Because the default MDT is working (if it were not, none of the C-MRIB state would be exchanged), we need not validate it in the core again. It is a basic PIM-Bidir configuration with XRv4 as the root and the core has no knowledge about the MDT traffic at all. At this point, we begin sending traffic from CSR4. We check packet counters on the ingress/egress PEs to ensure it is working.

```

```

A quick EPC effort on CSR8 from the core and to the customer shows the encapsulations plainly. In summary, this profile is almost identical to profile 0 except replaces IPv4 MDT with IPv4/v6 MVPN using BGP AD. This is the “new way” of configuring PIM/GRE-based MVPN.

Additional Reading – Reference configurations “mvpn-3”

28.4 Profile 6: VRF MLDP – In-band Signaling

For this test, begin with the MVPN Profile 1 configuration where all of the MVPN BGP is set up already, plus the MP2MP/P2MP trees are built. We will be disabling the MDT model and transporting the C-multicast state inside mLDP. The XR configuration is more logical than XE for this profile; in XE, none of the configuration goes under the VRF at all. In XR, the configuration still goes under the VRF and the core-tree is updated to reflect the usage of in-band signaling for mLDP. The configuration in XE uses global PIM commands and references the VRF in question, which is difficult to follow.

```
! Basic XE configuration to enable mLDP in-band signaling
vrf definition MC
  address-family ipv4
    no mdt default mpls mldp 213.14.14.14
    no mdt preference mldp

      mdt mldp in-band-signaling ipv4
    address-family ipv6
      no mdt default mldp ipv4 213.14.14.14
      mdt mldp in-band-signaling ipv4

route-policy RPL_MLDP
  set core-tree mldp-inband
end-policy
```

There is no BGP AD, BGP c-mcast signaling, or PIM c-mcast signaling used in this model. A quick check on CSR6 and XRv2 confirms this. XRv2 shows some self-neighbors that I assume are an internal function of the mLDP in-band signaling. Suffice it to say that there is no more “overlay” across the MVPN.

```
R6#show bgp ipv4 mvpn all
[no output]
```

```
R6#show ip pim vrf MC neighbor | begin ^Neighbor

```

Many other MVPN profiles use “out of band” signaling via some kind of c-mcast overlay (PIM or BGP). In this model, the C(S,G) information is directly encoded inside the opaque value. **Note that only SSM is supported for this profile, as there currently is no mechanism to dynamically discover sources.** A quick look at CSR6 shows an IGMP join received from the customer but the C(*,G) goes nowhere, lacking a C-RP. With an overlay in place, CSR6 would have learned this via PIM or BGP c-mcast signaling.

```
R6#show ip mroute vrf MC 225.0.0.1 | begin \
(*, 225.0.0.1), 01:11:02/00:02:01, RP 0.0.0.0, flags: SJC
Incoming interface: Null, RPF nbr 0.0.0.0
Outgoing interface list:
GigabitEthernet2.546, Forward/Sparse, 01:11:02/00:02:01
```

```
R6#show ip pim vrf MC rp mapping
PIM Group-to-RP Mappings
[no output]
```

However, CSR6 does have a customer requesting traffic for (10.2.7.2, 232.0.0.5), which is a valid SSM group. We can check the C-MRIB to verify the entry was installed properly. A new LSPvif was spawned which is used for RPF. Because BGP AD did not advertise any PMSI information and there are no traditional MDTs, we don’t fully see how the traffic is actually being transported yet (the P-tunnel is a mystery at this point).

```
R6#show ip mroute vrf MC 232.0.0.5 | begin \
(10.2.7.2, 232.0.0.5), 01:13:19/00:02:46, flags: sTI
Incoming interface: Lspvif2, RPF nbr 213.7.7.7
Outgoing interface list:
GigabitEthernet2.546, Forward/Sparse, 01:13:19/00:02:46
```

Looking at the current P2MP trees that have been built, we see one rooted in CSR6 and one rooted in CSR7. As discussed earlier, the entire C(S,G) information is carried inside the opaque value, so we can see the IPv4 SSM and IPv6 SSM groups mapped here. The opaque type is VPNv4/v6 since that is the mechanism by which the routes were learned. In this case, we know the source is behind CSR7, so we look at the details for that tree. We can see the mapping to LSPvif2 and also the incoming downstream (local) label of 6008. The length of the opaque makes this less desirable to decode in hex like we did for

other profiles (the global-ID ones, for example), but it's still possible. The C-S, C-G, and RD are shown in cyan, green, and yellow respectively. The length is 16 (0x10) bytes and the type is 0xFA.

```
R6#show mpls mldp database summary
```

LSM ID	Type	Root	Decoded Opaque Value	Client
1	P2MP	213.7.7.7	[vpn4 10.2.7.2 232.0.0.5 213:7]	
2	P2MP	213.6.6.6	[vpn6 2001:10:4:6::4 FF33::1 1]	

```
R6#show mpls mldp database opaque_type vpn4 10.2.7.2 232.0.0.5 213:7
```

```

```

Interface : Lspvif2

Clearing the mLDP neighbors on CSR6 and debugging mLDP at the same time reveals the process. CSR6 receives the IGMP join for (10.2.7.2, 232.0.0.5) and adds an entry to its database for the VPNv4 opaque containing the C-S, C-G, and RD. Various other multicast components, such as RPF interfaces, are also updated. The process is identical for IPv6 SSM groups.

```
! CSR6
MLDP-MRIB-RW: RW Tracking started for: 10.2.7.2

    Interface     : Lspvif2
```

Next, we can check CSR7 to see if it has the information about this tree. mLDP should have carried the C(S,G) information in-band upstream towards the root in the label mapping messages. A quick look at the database confirms this. We see that both XRv3 and XRv4 are downstream in the path to CSR6 and CSR8 respectively. It also has the appropriate C(S,G) entry; using the “verbose” keyword we can see it is using LSM-ID 6, which is correct.

```

```

Checking the LFIBs on XRv3 and XRv4, we see normal MPLS forwarding without any replication. This is because there aren't clients on other PEs, such as CSR1, that are interested in this flow.

```

RP/0/0/CPU0:XRv3#show mpls forwarding labels 93000

```

When CSR2 begins sending traffic, there is no more signaling that occurs. The tree has been fully signaled (as is common when using SSM in most profiles) so routers must only forward the LSM.

```

R6#show ip mroute vrf MC 232.0.0.5 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 103, Packets received:

Round-trip min/avg/max = 111/155/200 ms

Next we will test IPv6 SSM. We expect the behavior to be identical to IPv4 SSM. We will use different method of verifying the flows. First, we will ensure all of the PEs have the proper C-MRIB information. Ingress PE CSR6 sends traffic to the PMSI while the egress PEs (CSR7 and CSR8) accept information arriving from the PMSI.

R6#show ipv6 mroute vrf MC FF33::1 | begin \((

(2001:10:4:6::4, FF33::1), 00:28:46/never, flags: sT

Incoming interface: GigabitEthernet2.546

RPF nbr: 2001:10:4:6::4

Immediate Outgoing interface list:

Lspvif3, Forward, 00:28:46/never

R7#show ipv6 mroute vrf MC FF33::1 | begin \((

(2001:10:4:6::4, FF33::1), 01:55:08/never, flags: sTI

Incoming interface: Lspvif1

RPF nbr: ::FFFF:213.6.6.6

Immediate Outgoing interface list:

GigabitEthernet2.527, Forward, 01:55:08/never

R8#show ipv6 mroute vrf MC FF33::1 | begin \((

(2001:10:4:6::4, FF33::1), 00:29:46/never, flags: sTI

Incoming interface: Lspvif3

We will send traffic from CSR4. We already know the downstream label is 93015. XRv3 will replicate this to CSR7, and endpoint, and also towards CSR8 via XRv4.

```
R4#ping FF33::1 rep 10000
Output Interface: GigabitEthernet2.546
```

```
RP/0/0/CPU0:XRv3#show mpls forwarding labels 93015
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
93015	7010	MLDP: 0x0002d	Gi0/0/0/0.573	213.7.13.7	0
	94003	MLDP: 0x0002d	Gi0/0/0/0.534	213.13.14.14	0

Upon receipt, CSR7 delivers the traffic to the customer in accordance with the VPNv6 opaque value carried inside the mLDP mapping messages. XRv4 forwards it down to CSR8. The byte counter increases on the XE boxes, which is another verification method. These LFIB counters do not appear to work for MVPN traffic on XRv.

```
R7#show mpls forwarding-table labels 7010
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
7010	[T] No Label	[vpn6 2001:10:4:6::4 FF33::1 213:6]	11834	[V] \	aggregate/MC

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94003
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94003	8011	MLDP: 0x0002f	Gi0/0/0/0.584	213.8.14.8	0

Finally, Like CSR7, CSR8 forwards it to its customer based on the VPNv6 opaque information. We also see packet matches, like on CSR7.

```
R8#show mpls forwarding-table labels 8011
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
8011	[T] No Label	[vpn6 2001:10:4:6::4 FF33::1 213:6]	15738	[V] \	aggregate/MC

We will quickly check the IPv6 C-multicast counters on all of the PEs to ensure there are no issues there. I also use EPC to validate the traffic entering on CSR7 to ensure it is using the correct label and has the correct C(S,G) information. The label is 0x1B62 highlighted in yellow (7010) and the IPv6 information is correct also. The source address is highlighted in cyan and the group is in green.

```

Additional Reading – Reference configurations “mvpn-6”

28.5 Profile 7: Global MLDP In-band Signaling

This profile is very similar to Profile 6 except performs mLDP in-band signaling within the global table. BGP VPNv4/v6 and MVPN v4/v6 have been disabled which should obviate the need for carrying an RD within the opaque. Normal IPv6 unicast and IPv6 labeled-unicast (6PE) reachability is provided between the customer sites in this design. PIM is not enabled on the core routers (XRv3 and XRv4). There was significant rework to BGP to support this, but that rework was not technically challenging and is not shown here. Only the significant components of mLDP in-band signaling are shown. The same 4 commands are used to enable the feature for IPv4 and IPv6, except the “VRF” modifier is not used. This is a very simple configuration. XR still uses the same core tree RPL; it is shown again for reference only.

```
! Basic XE configuration to enable mLDP in-band signaling
ip multicast mpls mldp
ip pim mpls source lo0
ipv6 multicast mpls mldp
ipv6 multicast mpls source loopback 0
```

```
! Basic XR configuration to enable mLDP in-band signaling
multicast-routing
address-family ipv4
 mdt mldp in-band-signaling ipv4
address-family ipv6
 mdt mldp in-band-signaling ipv4

route-policy RPL_MLDP
 set core-tree mldp-inband
end-policy
```

Because mLDP in-band signaling carries the C(S,G) information inside of its opaque, only PIM-SSM is supported. There is no signaling mechanism in the overlay to carry information like the BSR mappings or PIM hellos; this is identical to profile 6 seen earlier. A quick check on CSR8 shows no PIM neighbors and no RP information. CSR5 learns the RP only because they are connected, but it is not used for anything significant in this test.

```
R8#show ip pim neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires    Ver    DR
Address                                     Prio/Mode
[no output]
```

```
R8#show ip pim rp mapping
PIM Group-to-RP Mappings
[no output]
```

```
R5#show ip pim rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4
  RP 10.5.10.10 (?), v2
    Info source: 10.5.10.10 (?), via bootstrap, priority 0, holdtime 150
    Uptime: 00:24:25, expires: 00:02:23
```

As a final verification to prove PIM-ASM is broken, CSR10 is the RP and does not have the C(*,G) join for group 225.0.0.1. CSR8 receives the IGMP join for this group but has no RP assigned.

```
R8#show ip mroute 225.0.0.1 | begin \
(*, 225.0.0.1), 00:24:54/00:02:12, RP 0.0.0.0, flags: SJC
  Incoming interface: Null, RPF nbr 0.0.0.0
  Outgoing interface list:
    GigabitEthernet2.538, Forward/Sparse, 00:24:54/00:02:12
```

```
R5#show ip mroute 225.0.0.1
Group 225.0.0.1 not found
```

PIM-SSM, however, appears to be functioning from a PIM standpoint. Both CSR6 and CSR8 have clients joining (10.2.7.2, 232.0.0.5) and have PIM C(S,G) tries that indicate a valid incoming interface (PMSI). The incoming interface will be mapped to the mLDP delivery tree inside the mLDP database (shown later).

```
R6#show ip mroute 232.0.0.5 10.2.7.2 | begin \
(10.2.7.2, 232.0.0.5), 00:28:06/00:02:55, flags: sTI
  Incoming interface: Lspvif6, RPF nbr 213.7.7.7
  Outgoing interface list:
    GigabitEthernet2.546, Forward/Sparse, 00:28:06/00:02:55
```

```
R8#show ip mroute 232.0.0.5 10.2.7.2 | begin \
(10.2.7.2, 232.0.0.5), 00:26:37/00:02:20, flags: sTI
```

```
Incoming interface: Lspvif3, RPF nbr 213.7.7.7
Outgoing interface list:
  GigabitEthernet2.538, Forward/Sparse, 00:26:37/00:02:20
```

Looking at the mLDP trees on CSR6, we see that each one has two P2MP trees. These are unidirectional (downstream only) trees rooted at CSR7. mLDP in-band signaling clearly shows us what the opaque values are, and we see the IPv4 and IPv6 multicast (S,G) embedded inside. This in-band signaling mechanism creates a P2MP tree for every PIM-SSM sender in the network, and all the leaves join it via label-mapping messages. The output is very similar to the VPNv4/v6 opaque messages seen earlier except without an RD.

```
R6#show mpls mldp database summary
LSM ID      Type      Root      Decoded Opaque Value      Client
Cnt.
7           P2MP      213.7.7.7      [ipv4 10.2.7.2 232.0.0.5]      1
8           P2MP      213.6.6.6      [ipv6 2001:10:4:6::4 FF33::1]  1
```

CSR8 shows an IPv6 ASM group only because the RP is embedded. The C(*,G) join actually does make it to the C-RP, which is CSR2. The issue is that there is no way to prune specific sources from the shared tree once the flow starts without an out-of-band signaling protocol. So technically, some components of PIM-ASM could work, but its general operation is compromised due to the lack of an overlay. For now, we will focus on the IPv4 (S,G).

```
R8#show mpls mldp database summary
LSM ID      Type      Root      Decoded Opaque Value      Client
Cnt.
3           P2MP      213.7.7.7      [ipv4 10.2.7.2 232.0.0.5]      1
1           P2MP      213.7.7.7      [ipv6 :: FF7E:240:2001:10:2:7:1]  1
2           P2MP      213.6.6.6      [ipv6 2001:10:4:6::4 FF33::1]  1
```

Looking into more detail on the IPv4 entry for CSR8, we see the low-level opaque type is 0x03, the field is 8 bytes long, and the information is simply the concatenated string of C-S and C-G (yellow and green, respectively). From CSR8's perspective, there is no traffic going outbound (upstream) towards CSR7 since this tree is unidirectional, so no upstream labels are allocated. CSR8 should be receiving traffic with label 8010 for this C(S,G). Notice that the replication client lists Lspvif3, which is the same interface shown above in the C-MRIB output.

```
R8#show mpls mldp database opaque_type ipv4 10.2.7.2 232.0.0.5
LSM ID : 3      Type: P2MP      Uptime : 00:06:47
  FEC Root      : 213.7.7.7
  Opaque decoded : [ipv4 10.2.7.2 232.0.0.5]
  Opaque length  : 8 bytes
  Opaque value   : 03 0008 0A020702E8000005
  Upstream client(s) :
    213.14.14.14:0 [Active]
    Expires       : Never      Path Set ID : 3
```

```

Out Label (U) : None           Interface : GigabitEthernet2.584*
Local Label (D): 8010         Next Hop  : 213.8.14.14
Replication client(s):
MRIBv4(0)
Uptime          : 00:06:47      Path Set ID   : None
Interface       : Lspvif3

```

The same output exists on CSR6 since it joined the same P2MP tree for the same opaque value. The only differences (potentially) will be the incoming label and replication interfaces. Traffic arriving to CSR6 will use label 6007.

```

R6#show mpls mldp database opaque_type ipv4 10.2.7.2 232.0.0.5
LSM ID : 7   Type: P2MP   Uptime : 00:52:36

Uptime          : 00:52:36      Path Set ID   : None
Interface       : Lspvif6

```

CSR7 also has a single entry for this tree. CSR7 replicates the traffic towards both XRv3 and XRv4 since there are clients behind each of the core routers. Note the outgoing downstream labels of 93002 and 94002 as we will use these to verify the LFIB on the core routers.

```

R7#show mpls mldp database opaque_type ipv4 10.2.7.2 232.0.0.5

```

Local label (U): None

Next Hop : 213.7.14.14

A quick OAM check from CSR7 helps us discover the neighbors. Recall that MPLS OAM is only valuable at the root when probing P2MP mLDP trees as they are unidirectional. I demonstrate the “easy” way using built-in commands and the “hard” way using hexadecimal codes. The hex method is required for some verification as the XE parser does not list all supported opaque types (seen later).

```
R7#ping mpls mldp p2mp 213.7.7.7 ipv4 10.2.7.2 232.0.0.5

Because the C-PIM trees and subsequent LSPs are built, sending traffic from CSR2 should trigger no additional signaling. We check C-MRIB packet counters on all three routers to ensure the multicast process is able to send packets to (CSR7) and receive packets from (CSR6 and CSR8) the PMSI.

```
R7#show ip mroute 232.0.0.5 10.2.7.2 count | begin ^Group

Source: 10.2.7.2/32, Forwarding: 30/1/122/0, Other: 30/0/0
```

The LFIBs of the core routers indicate that this traffic is being sent downstream towards the egress PEs. The transport is efficient since these are P2MP trees only; there is no MP2MP tree in use. The outbound downstream labels from CSR7 are 93002 and 94002, which we saw from CSR7's mLDP database. Unfortunately, XRv packet counters do not appear to work for LSM. We can see labels 6007 and 8010 in use which we verified to be the local labels for this LSP on CSR6 and CSR8, respectively.

```
RP/0/0/CPU0:XRv3#show mpls forwarding labels 93002
Local   Outgoing   Prefix           Outgoing   Next Hop        Bytes
Label   Label       or ID            Interface
-----
93002   6007        MLDP: 0x0002f    Gi0/0/0/0.563 213.6.13.6      0

RP/0/0/CPU0:XRv4#show mpls forwarding labels 94002
Local   Outgoing   Prefix           Outgoing   Next Hop        Bytes
Label   Label       or ID            Interface
-----
94002   8010        MLDP: 0x00030    Gi0/0/0/0.584 213.8.14.8      0
```

When CSR6 receives the packet it removes all MPLS encapsulation. The LFIB entry is bound to the mLDP opaque value which defines the (S,G), so when the packet is passed to the PIM process, there is no question as to which C-MRIB entry this flow belongs.

```
R6#show mpls forwarding-table labels 6007
Local      Outgoing   Prefix           Bytes Label   Outgoing   Next Hop
Label      Label       or Tunnel Id     Switched      interface
6007 [T] No Label   [ipv4 10.2.7.2 232.0.0.5] \
                                     35624      aggregate
```

On CSR8, we will verify with EPC. Capturing inbound, we see the LSM arriving with label 8010 (0x1F4A). Going outbound to the customer, we see the raw ICMP multicast packet. The difference in packet size is exactly 4 bytes which accounts for the MPLS shim header containing one label (yellow). The (S,G) information of (10.2.7.2, 232.0.0.5) is highlighted in green.

```

```

Next, we test IPv6 SSM. CSR4 is the source and CSR2/CSR3 are the receivers. We saw earlier from our summary view that some of the routers had IPv6 opaque state for certain flows. Revisiting that in detail, we see the egress PEs (CSR7 and CSR8) both received MLDv2 joins from their clients for this group.

These get written to the C-MFIB as (S,G) entries and the router, knowing that it is enabled for mLDP in-band signaling for IPv6, originates a label mapping message for this (S,G) towards the root, which is CSR6. Debugging mLDP on CSR8 reveals this process. First, there are IPv6-specific things that occur with respect to the C(S,G). The join is received and RPF is updated.

```
! CSR8
```

```
MLDP-MRIB-IPv6: (2001:10:4:6::4,FF33::1/128) update (t=1) RPF:
```

```

```

```
MLDP-MRIB-IPv6: (2001:10:4:6::4,FF33::1/128) update idb = Lspvif2, (f=2,c=2)
```

```
MLDP-MRIB-IPv6: add accepting interface: Lspvif2 root: ::FFFF:213.6.6.6
```

```
MLDP-MRIB-IPv6: change interface from NULL to Lspvif2
```

Next, mLDP builds the tree, which is universal for any mLDP tree. The only difference is the opaque value (that mLDP doesn't care about) represents IPv6 versus IPv4. The router allocates label 8009 and sends this in a label-mapping message upstream to XRv4. This tells XRv4 which label to use when sending traffic down the mLDP P2MP delivery tree.

```
! CSR8
MLDP: LDP root 213.6.6.6 added
mLDP-RW: Sending RW notification message to process: mLDP Process

MLDP: [ipv6 2001:10:4:6::4 FF33::1] label mapping msg sent to 213.14.14.14:0
success
```

Checking the C-MRIB on all three routers, we can see the proper (S,G) information. CSR6 receives multicast traffic from the customer and sends it to the PMSI, while CSR7 and CSR8 do the opposite. Even though this is a P2MP tree, it is technically not an MDT-data group. There are no "MDT" mechanisms in play, so the 'Y' or 'y' flags do not apply.

```
R6#show ipv6 mroute FF33::1 2001:10:4:6::4 | begin \

GigabitEthernet2.538, Forward, 00:04:42/never

In terms of labels, CSR7 allocates 7005 and CSR8 allocates 8009 upstream towards the core as they build their trees. This makes XRv3 a branch point since it has two downstream clients: CSR7 and XRv4. Notice that CSR7 has bound its LSM path to Lspvif4 and CSR8 did the same with Lspvif2. This must match what the C-MRIB says. Decoding the IPv6 opaque is also simple. The hex code is now 0x04 (versus 0x03 for IPv4) with the concatenation of the C(S,G) information.

```

```

Tracing the full mLDP signaling path, XRv4 will receive the label mapping from CSR8 specifying the FEC root, so XRv4 sends a label mapping message upstream to XRv3. The mLDP database tells us that XRv4 allocated downstream label 94005 to XRv3 for incoming traffic.

```

RP/0/0/CPU0:XRv4#show mpls mldp database opaque type ipv6 2001:10:4:6::4
FF33::1
mLDP database
LSM-ID: 0x00032   Type: P2MP   Uptime: 00:12:11
  FEC Root       : 213.6.6.6
  Opaque decoded  : [ipv6 2001:10:4:6::4 ff33::1]
  Upstream neighbor(s) :
    213.13.13.13:0 [Active] Uptime: 00:12:11
    Local Label (D) : 94005
  Downstream client(s):
    LDP 213.8.8.8:0   Uptime: 00:12:11

      Interface       : GigabitEthernet0/0/0/0.584
      Remote label (D) : 8009

```

At the branch point, XRv3 replicates the traffic to CSR7 using label 7005 and to XRv4 using label 94005. The LFIB confirms the replication also. XRv3 allocates downstream label 93000 to CSR6, which is the root (upstream).

```

	94005	MLDP: 0x0002e	Gi0/0/0/0.534	213.13.14.14	0

CSR6 sees the label mapping from XRv3 and uses this for all downstream traffic in this P2MP tree. No upstream label is allocated by CSR6. CSR6 is the root of the tree, so the signaling path ends.

When CSR4 sends data, no additional signaling should take place. The C-MRIB packet counters on CSR6 shows packet exiting to the PMSI, while CSR7/CSR8 show them arriving from the PMSI.

Additional Reading – Reference configurations “mvpn-7”

28.6 Profile 8: Global Static – P2MP-TE

P2MP RSVP-TE is another technique used to transport LSM across an MPLS network. The benefits of this approach were discussed during the general MVPN comparison, but overall the feature is used in few-to-many scenarios where bandwidth reservations and/or FRR are required. **No other MVPN solutions can provide bandwidth reservations.** FRR is also inherent in this design without any special modifications, provided the sub-LSPs request FRR treatment. The feature is not supported on the CSR (or any XE platform) at all even though RSVP-TE was extended further to support it. The MPLS network consists only of XRV devices with CSRs as CE devices. Even though there are no VRFs anywhere in this test, it is still considered an MVPN profile, much like global mLDP in-band. The diagram is shown below.

The CSRs run RIPv2 with the XrV PEs at the pseudo PE-CE connections. Regular IPv4 BGP transports the IP prefixes while 6PE is used to transport IPv6. Only the connected transit PE-CE links are redistributed into BGP and each CSR has an IPv6 default route pointing towards the provider. The CSRs have joined two SSM (S,G) pairs on their loopbacks: (10.5.5.5, 232.1.1.1) and (FF33::1, 2001:10:5:11::5). The tunnel configuration for the IPv4 tunnel is shown below. A single P2MP tunnel could support both IPv4 and IPv6, but I demonstrate wanting them to be separate, with different tail-ends.

```
! Xrv1
interface tunnel-mte134
  ipv4 unnumbered Loopback0
  destination 213.12.12.12
  path-option 10 dynamic

  destination 213.13.13.13
  path-option 10 dynamic

  destination 213.14.14.14
  path-option 10 dynamic
```

```
signalled-bandwidth 20000
```

The normal TE process begins whether unicast/multicast routing is set up or not. This relies on the TED as any TE tunnel would. The basic MPLS configurations in the core, to include IGP, MPLS-TE, and BGP, are not discussed in detail here. For each sub-LSP, a separate RSVP PATH message is created. Between both tunnels (MTE134 and 136), we have 5 sub-LSPs. Looking at XRv2, it receives those sub-LSPs.

```
RP/0/0/CPU0:XRv2#show rsvp sender
```

Destination Add	P2MPID	Source Add	SPort	Input IF	Rate	Burst	Prot
213.12.12.12	134	213.11.11.11	10002	Gi0/0/0/0.512	20M	1K	Off
213.13.13.13	134	213.11.11.11	10002	Gi0/0/0/0.512	20M	1K	Off
213.14.14.14	134	213.11.11.11	10002	Gi0/0/0/0.512	20M	1K	Off

It appears as if all of them are requesting bandwidth individually. This is technically true, but RSVP-TE was extended to account for this by using the P2MP-ID. Below I show all of the sub-LSP path messages and their requests for bandwidth. Bandwidth is not summed when PATH messages contain requests for bandwidth if the P2MP-ID matches between them. We confirm that XRv2 has only allocated 20 Mbps (not 60) on its interfaces facing downstream.

```

Gi0/0/0/0.524	100M	100M	20M (35%)	0

We can also ask XRv2 about its label bindings for these LSPs. Because XRv2 is downstream from the root (XRv1), the incoming local label is considered downstream. Notice the label is the same for all sub-LSPs; this implies replication occurs when label 92008 arrives inbound. The first sub-LSP terminates locally on XRv2 so there is no label swap operation. The other two are replicated down the tree to XRv3 and XRv4 using labels 93000 and 94001 respectively. The LFIB confirms this.

```
RP/0/0/CPU0:XRv2#show rsvp reservation p2mp-id 134 detail | utility egrep
'Destination|Label'
```

Destination addr: 213.12.12.12. Subgroup: 1/213.11.11.11.

Labels: Local downstream: 92008.
 Destination addr: 213.13.13.13. Subgroup: 2/213.11.11.11.
 Labels: Local downstream: 92008, Outgoing downstream: 93000.
 Destination addr: 213.14.14.14. Subgroup: 3/213.11.11.11.
 Labels: Local downstream: 92008, Outgoing downstream: 94001.

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92008
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92008	93000	P2MP TE: 134	Gi0/0/0/0.523	213.12.13.13	0
	94001	P2MP TE: 134	Gi0/0/0/0.524	213.12.14.14	0

Rather than trace the signaling path on every single router, we will check to see if XRv1 receives the RSVP RESV messages inbound, which would bring the tunnels up.

```
RP/0/0/CPU0:XRv1#show mpls traffic-eng tunnels p2mp 134 brief
```

TUNNEL NAME	DESTINATION	STATUS	STATE
tunnel-mte134	213.12.12.12	up	up
tunnel-mte134	213.13.13.13	up	up
tunnel-mte134	213.14.14.14	up	up

Displayed 1 (of 2) heads, 0 (of 0) midpoints, 0 (of 0) tails
 Displayed 1 up, 0 down, 0 recovering, 0 recovered heads

In terms of multicast, we must enable PIM on the MTE interfaces on the head-end, as well as statically join SSM groups to the tunnel. Below are configuration snippets for both head and tail ends. I do not show enabling multicast on interfaces because it's very basic. The tail ends must be told how to perform RPF lookups for multicast sources by referencing the LSP somehow. This is accomplished one of two ways: the old way involves using "static-rpf" and specifying a host route and BGP next-hop, and the new way involves just specifying the BGP next-hop inside an RPL. I use the old way on XRv2 and XRv3, while deploying the new way on XRv4. The concept of a "core-tree" is a way for PIM to have an idea of how to perform RPF lookups. In this case, we use RSVP-TE. In other profiles, we can select other options such as mLDP, in-band signaling, etc.

```
! XRv1
router igmp
 interface tunnel-mte134
   static-group 232.1.1.1 10.5.5.5

router mld
 interface tunnel-mte136
   static-group ff33::1 2001:10:5:11::5

! XRv2 and XRv3 (old method)
multicast-routing
 address-family ipv4
   core-tree-protocol rsvp-te
```

```

static-rpf 10.5.5.5 32 mpls 213.11.11.11
address-family ipv6
  core-tree-protocol rsvp-te
static-rpf 2001:10:5:11::5 128 mpls 213.11.11.11

! XRv4 (new method)
multicast-routing
  address-family ipv4
    core-tree-protocol rsvp-te
  address-family ipv6
    core-tree-protocol rsvp-te

route-policy RPL_LSM_ROOT
  set lsm-root 213.11.11.11
end-policy

router pim
  address-family ipv4
    rpf topology route-policy RPL_LSM_ROOT
  address-family ipv6
    rpf topology route-policy RPL_LSM_ROOT

```

Note: You must use an IPv4/32 or IPv6/128 mask with static RPF. It scales poorly as a result, and which is why the LSM-root method covers all multicast for this MVPN.

```

! Erroneous example
multicast-routing
  address-family ipv6
    static-rpf 2001:10:5:11:: 64 mpls 213.11.11.11
!!% Invalid prefix length: Prefix length should be host mask length.

```

Let's verify that XRv1 accepts traffic coming from its LAN facing CSR5 and forwards it out the MTE tunnel for both IPv4 and IPv6. Both of these MTEs are in the OIL for the (S,G) pairs because of the static IGMP/MLD joins we applied on the head-end. This is the only way to force traffic into the MTE tunnel.

```

RP/0/0/CPU0:XRv1#show pim topology 232.1.1.1 | begin 232
(10.5.5.5,232.1.1.1)SPT SSM Up: 00:57:27
JP: Join(00:00:38) RPF: GigabitEthernet0/0/0/0.551,10.5.11.5 Flags:
tunnel-mte134 00:57:27 fwd LI LH

RP/0/0/CPU0:XRv1#show pim ipv6 topology FF33::1 | begin ff33
(2001:10:5:11::5,ff33::1) SPT
SSM Up: 00:06:38 JP: Join(00:00:32) Flags:
RPF: GigabitEthernet0/0/0/0.551,fe80::5*
tunnel-mte136 00:06:38 fwd LI LH

```

Next, we verify the three tail-ends all have valid RPF lookups for the multicast sources. We will verify XRv2 without touching XRv3 since their configuration is identical. I cannot explain why all of these RPF

lookups are resulting in “null” despite first recursing to a valid MPLS-related entry. I have to assume this is an XRv issue.

```
RP/0/0/CPU0:XRv2#show pim rpf 10.5.5.5
Table: IPv4-Unicast-default
* 10.5.5.5/32 [200/10]
    via MPLS with SPE 213.11.11.11
    via Null with rpf neighbor 0.0.0.0

RP/0/0/CPU0:XRv2#show pim ipv6 rpf 2001:10:5:11::5
Table: IPv6-Unicast-default
2001:10:5:11::5/128 [200/0]
    via SPE ::ffff:213.11.11.11, MPLS
    via ::ffff:213.11.11.11, Null
```

XRv4’s output doesn’t look much better, but it’s a little different with the LSM-root syntax.

```
RP/0/0/CPU0:XRv4#show pim rpf 10.5.5.5
Table: IPv4-Unicast-default
* 10.5.5.5/32 [200/20]
    via MPLS with rpf neighbor 0.0.0.0

RP/0/0/CPU0:XRv4#show pim ipv6 rpf 2001:10:5:11::5
Table: IPv6-Unicast-default
2001:10:5:11::5/128 [200/0]
    via ::ffff:213.11.11.11MPLS, Null
```

When we check the PIM topology, all of the entries show what appears to be a valid RPF interface. I am not sure if this is another XRv issue, but it appears inconsistent.

```
RP/0/0/CPU0:XRv2#show pim topology 232.1.1.1 | begin 232
(10.5.5.5,232.1.1.1)SPT SSM Up: 00:57:31

RPF: MPLS (SPE), ::ffff:213.11.11.11
GigabitEthernet0/0/0/0.574 00:42:54 fwd Join(00:02:35)
```

We will use CSR5 to send traffic from its loopback (10.5.5.5) to the proper SSM group (232.1.1.1). Using debugging on any of the tail end routers, we see packets being dropped by the MFIB process due to not being able to determine the egress interface. I suspect there is an RPF problem still. Debugging on XRv2 at least reveals that packets are making it into the MTE and being label-switched correctly. Packets arriving from XRv1 with label 92008 are being replicated correctly down to XRv3 and XRv4. This indicates that the MPLS encapsulation process is working correctly at the head-end, and the midpoints are able to swap labels.

```
! Any tail end router
RP/0/0/CPU0:XRv4#debug mfib ipv4 netio drop
netio[309]: MFIB : TID 0xe0000000 Pkt (10.5.5.5, 232.1.1.1) dropped [Cannot
get input IF handle in packet 0xb0c22e84]: Null input I/F
```

```
! XRv2

mpls_rewrite
mpls_rewrite: tos 0 eos 1 ttl 254, out_label 94001, #labels 1, RA - 0,
out_intf GigabitEthernet0_0_0_0.524
```

This is a tricky pitfall. The router describes multicast-routing being enabled on some specific interfaces, but “interface all enable” is thrown in there quietly. If you enable multicast-routing on the upstream facing MPLS interface, the RPF check “looks” better. On XRv2, XRv3, and XRv4, I just enabled multicast on all interfaces in an effort to see this work (not shown). With that in place, the RPF show commands appear complete for IPv4 only. I theorize that IPv6 RPF is still broken since the core is not IPv6 capable, and 6PE cannot help mask this.

```
RP/0/0/CPU0:XRv2#show pim rpf 10.5.5.5
Table: IPv4-Unicast-default
* 10.5.5.5/32 [200/10]
    via MPLS with SPE 213.11.11.11
    via GigabitEthernet0/0/0/0.512 with rpf neighbor 213.11.12.11

RP/0/0/CPU0:XRv2#show pim ipv6 rpf 2001:10:5:11::5
Table: IPv6-Unicast-default
2001:10:5:11::5/128 [200/0]
```

```

via SPE ::ffff:213.11.11.11, MPLS
via ::ffff:213.11.11.11, Null

RP/0/0/CPU0:XRv4#show pim rpf 10.5.5.5
Table: IPv4-Unicast-default
* 10.5.5.5/32 [200/20]
  via MPLS GigabitEthernet0/0/0/0.524 with rpf neighbor 213.12.14.12

RP/0/0/CPU0:XRv4#show pim ipv6 rpf 2001:10:5:11::5
Table: IPv6-Unicast-default
2001:10:5:11::5/128 [200/0]
  via ::ffff:213.11.11.11MPLS, Null

```

Testing reveals that it still doesn't matter, as the debug still shows dropped packets and the MFIB counters do not change on any tail-end router. The head-end shows them being sent into the tunnel, and debugs from XRv2 show it being label-switched. I believe this is an XRv data-plane limitation.

```

RP/0/0/CPU0:XRv1#show mfib route 10.5.5.5 | include Forwarding

```

Additional Reading – Reference configurations “mvpn-8”

28.7 Profile 9: Default MDT – MLDP – MP2MP – BGP-AD – PIM C-mcast Signaling

For this test, begin with the MVPN Profile 1 configuration where all of the MVPN BGP is set up already, plus the MP2MP/P2MP trees are built. XRv4 is the MP2MP root and there are some other P2MP roots related to SSM joins. Enabling BGP AD is very easy, and the snippets are below.

```

! BGP AD on XE
vrf definition MC
  address-family ipv4
    mdt auto-discovery mldp
  address-family ipv6
    mdt auto-discovery mldp

! BGP AD on XR

```

```
multicast-routing
vrf MC
  address-family ipv4
    bgp auto-discovery mldp
  address-family ipv6
    bgp auto-discovery mldp
```

I admit, the use-case of using BGP AD with mLDP MP2MP trees and PIM c-mcast signaling is very limited. It does not appear capable of dynamically distributing MP2MP root information, so all nodes still need to have roots configured. Each PE generates a Type 1 MVPN route, which is Intra-AS I-PMSI AD. This route contains the currently selected root and lists its tunnel type. Looking at CSR5, we see a Type 1 router for every PE, in the VPN. This membership is controlled by the traditional unicast route-target.

```
R5#show bgp ipv4 mvpn vrf MC | begin Network
      Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 213:5 (default for vrf MC)
*>i [1] [213:5] [213.1.1.1]/12
                213.1.1.1                0      100      0 ?
*> [1] [213:5] [213.5.5.5]/12
                0.0.0.0                32768 ?

*>i [3] [213:5] [10.2.7.2] [232.0.0.5] [213.7.7.7]/22
                213.7.7.7                0      100      0 ?
```

Looking into CSR5's specific route, we can see the root information encoded in hex. Tunnel-type 7 is an mLDP MP2MP tunnel, and the root address is 213.14.14.14. Also notice that the no-export community is set because we did not configure inter-AS AD. The importance of this route is to signal membership in an I-PMSI; that is to say, others who receive this route know that this PE is reachable via an MP2MP tunnel rooted at 213.14.14.14 for this MVPN instance.

```
R5#show bgp ipv4 mvpn vrf MC route-type 1 213.5.5.5
BGP routing table entry for [1][213:5][213.5.5.5]/12, version 18

0000
rx pathid: 0, tx pathid: 0x0

```

There is also a single Type 3 BGP route, which is an S-PMSI AD route. This is originated by a PE that has a source behind it and someone else has expressed interest. This entry is permanent because the C(S,G) shown in the group is from an IGMPv3 SSM join from CSR3 and CSR4. It only takes one node to request multicast, and then the ingress PE (CSR7) announces that there is interest for a C(S,G). Notice the show command requires the route type, C-S, C-G, and BGP next-hop. You cannot shortcut this. The tunnel type is 2 to signal an mLDP P2MP tree and the root is 213.7.7.7 inside the tunnel message.

```

R5#show bgp ipv4 mvpn vrf MC route-type 3 10.2.7.2 232.0.0.5 213.7.7.7
BGP routing table entry for [3][213:5][10.2.7.2][232.0.0.5][213.7.7.7]/22,

      rx pathid: 0, tx pathid: 0x0

```

Testing IPv6 is a little more interesting. There are no Type 3 routes by default, because in order to have a router originate one, it needs to have received a C(S,G) join to indicate there is a source behind it, and someone is interested.

```

R8#show bgp ipv6 mvpn vrf MC | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 213:8 (default for vrf MC)
*>i [1][213:8][213.6.6.6]/12
      213.6.6.6      0      100      0 ?
*>i [1][213:8][213.7.7.7]/12
      213.7.7.7      0      100      0 ?
*> [1][213:8][213.8.8.8]/12

```

::

32768 ?

In this case, CSR6 originates a Type 3 route for the traffic sourced by CSR4 to the embedded RP group. This route was not generated until CSR4 started sending traffic, because CSR3 did not know the source ahead of time. The route was not generated when CSR4 started sending, but when CSR6 received the PIM join from CSR8.

```
R4#ping FF7E:240:2001:10:2:7::1 repeat 10000 time 1
Output Interface: GigabitEthernet2.546
```

```
R6#debug bgp ipv6 mvpn updates
BGP(16): nettable_walker
[3] [213:6] [2001:10:4:6::4] [FF7E:240:2001:10:2:7:0:1] [213.6.6.6]/46 route
sourced locally
```

```
BGP(16): (base) 213.12.12.12 send UPDATE (format)
[3] [213:6] [2001:10:4:6::4] [FF7E:240:2001:10:2:7:0:1] [213.6.6.6]/46, next
213.6.6.6, metric 0, path Local, extended community RT:213:6
```

Debugging CSR8 shows similar results. The update is received from CSR6 and added to the MVPN RIB. Notice the tunnel type is 2, which is an mLDP P2MP tunnel using S-PMSI, versus 7 which was used in the Type 1 route to detail the I-PMSI information (MP2MP tree).

```
R8#debug bgp ipv6 mvpn updates
BGP(16): 213.12.12.12 rcvd UPDATE w/ attr: nexthop 213.6.6.6, origin ?,
localpref 100, metric 0, originator 213.6.6.6, clusterlist 213.12.12.12,
community no-export, extended community RT:213:6
. BGP(16): 213.12.12.12 rcvd
[3] [213:6] [2001:10:4:6::4] [FF7E:240:2001:10:2:7:0:1] [213.6.6.6]/46

BGP(16): add RIB route
[3] [213:8] [2001:10:4:6::4] [FF7E:240:2001:10:2:7:0:1] [213.6.6.6]/46
Flags: 0x0, Tunnel type: 2, label: exp-null, tunnel parameters: 0600 0104
FFFFFFFFFFFFFFFFD506 0606 000E 0200 0B00 0213 0000 0213 FFFFFFFFFFFFFFFFFF8000 0001
```

We can clearly see the route in the table with the proper next hop. Looking at the route details confirms the debug, as we can see the root encoded in the tunnel data. The show command is rather long, so it is highlighted for emphasis.

```
R8#show bgp ipv6 mvpn vrf MC | begin Network
      Network      Next Hop      Metric LocPrf Weight Path

Because the unicast architecture is split in half for IPv6 VPN, BGP AD routes from one half do not leak into the other. Again, this is controlled by the route-target. When we looked at the bottom half routers, we did not see I-PMSI AD messages (Type 1 routes) from any top half routers. Likewise, checking a top router shows nothing from the bottom half, and the dynamic Type 3 announcement is likewise not seen.

Last, we will examine OAM for MP2MP and P2MP trees in this profile. Unlike Profile 12 where we were limited only to unidirectional P2MP trees (the root specified had to be local), with MP2MP pings we can test from any endpoint; the tree is bidirectional. We specify the FEC and opaque type and can quickly discover all the endpoints in the mVPN on this MDT.

```

Additional Reading – Reference configurations “mvpn-9”

28.8 Profile 10: VRF Static – P2MP TE - BGP-AD

This is very similar to profile 8 except now the CSRs are MPLS L3VPN customers, so their routing is carried by VPNV4/v6. Because XRv only supports MVPN from the headend, the tunnel tail ends cannot deliver multicast to the end clients, but we can verify the control-plane and some parts of the data-plane. **Note: This profile does not appear to be supported for IPv6 since the “mdt static” command is not available under that AF. The remaining relevant IPv6 configuration is left in the configuration files (as close as I could get) for reference.**

The configuration for a static multipoint TE (MTE) tunnel is very simple. Each destination gets its own set of path options, etc.

! XRV1

```

interface tunnel-mte134
  ipv4 unnumbered Loopback0
  destination 213.12.12.12
  path-option 10 dynamic

  destination 213.13.13.13
  path-option 10 dynamic

  destination 213.14.14.14
  path-option 10 dynamic

  signalled-bandwidth 20000

```

In terms of signaling, P2MP RSVP-TE requires a lot of “core state”. This is because each sub-LSP (tunnel destination within the overall multipoint tunnel) is signaled independently. That is, for N destinations, N RSVP PATH messages are generated from the head-end, and N RSVP RESV messages are generated from the tail-ends. In this case, XRv1 generates three separate PATH messages, one for each destination. Just like ordinary P2P RSVP TE, each PATH message has a label request object (LRO).

```

RP/0/0/CPU0:XRv1#show rsvp sender

```

Destination Add	P2MPId	Source Add	SPort	Input IF	Rate	Burst	Prot
213.13.13.13	134	213.11.11.11	10003	No	20M	1K	Off
213.14.14.14	134	213.11.11.11	10003	No	20M	1K	Off
213.12.12.12	134	213.11.11.11	10003	No	20M	1K	Off

The difference comes at the branch points, such as XRv2; the router can determine if multiple sub-LSPs as part of the same LSP (same P2MP-ID) share an upstream interface. In this case, XRv1 is upstream from XRv2 for all three of the sub-LSPs that terminate on XRv2 (local), XRv3, and XRv4. XRv2 will still issue (N) RSVP RESV messages to XRv1, but they contain the same label object. Even though XRv2 is one hop away, PHP cannot be used for LSM for several reasons. Since there is only one label in the stack to begin with, the core is not multicast enabled, and even if it were, the C-multicast information is unknown to the P routers. Besides, XRv2 still has to account for the other downstream neighbors also, so PHP doesn’t make sense for P2MP TE.

```

RP/0/0/CPU0:XRv1#show rsvp reservation

```

Destination Add	P2MPId	Source Add	SPort	Input IF	Sty	Serv	Rate	Burst
213.13.13.13	134	213.11.11.11	10003	Gi0/0/0/0.512	SE	LOAD	20000K	1K
213.14.14.14	134	213.11.11.11	10003	Gi0/0/0/0.512	SE	LOAD	20000K	1K
213.12.12.12	134	213.11.11.11	10003	Gi0/0/0/0.512	SE	LOAD	20000K	1K

From XRv1’s perspective, it will use this label to send traffic out (it’s XRv2’s local label) and downstream (away from the root). From XRv2’s perspective, the label is oriented the other way, incoming and upstream-facing.

```
RP/0/0/CPU0:XRv1#show rsvp reservation detail | utility egrep 'Destin|Label'
Destination addr: 213.13.13.13. Subgroup: 1/213.11.11.11.
Labels: Outgoing downstream: 92006.
Destination addr: 213.14.14.14. Subgroup: 2/213.11.11.11.
Labels: Outgoing downstream: 92006.
Destination addr: 213.12.12.12. Subgroup: 3/213.11.11.11.
Labels: Outgoing downstream: 92006.
```

On XRv2, traffic arriving with label 92006 is replicated down the individual trees using the RSVP-bound labels from the next downstream router. Notice that the path terminating on XRv2 does not have an outgoing downstream label since it is the tail end of the LSP. The LFIB shows the replication for leaves past the branch point. Be careful not to confuse this with load sharing. Again, no PHP is allowed here because XRv3 and XRv4 need to know in which VPN this traffic belongs. I am not sure why the unlabelled path to CSR8 is not shown in the LFIB.

```
RP/0/0/CPU0:XRv2#show rsvp reservation detail | utility egrep 'Destin|Label'
Destination addr: 213.13.13.13. Subgroup: 1/213.11.11.11.
Labels: Local downstream: 92006, Outgoing downstream: 93005.
Destination addr: 213.14.14.14. Subgroup: 2/213.11.11.11.
Labels: Local downstream: 92006, Outgoing downstream: 94005.
Destination addr: 213.12.12.12. Subgroup: 3/213.11.11.11.
Labels: Local downstream: 92006.
```

```
RP/0/0/CPU0:XRv2#show mpls forwarding labels 92006
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92006	93005	P2MP TE: 134	Gi0/0/0/0.523	213.12.13.13	0
	94005	P2MP TE: 134	Gi0/0/0/0.524	213.12.14.14	0

The tail-end routers LFIB output does not look promising, much like XRv2's (lack of) customer LFIB entry, but I believe this is correct. Traffic arrives via the P2MP tunnel and is delivered to the customer unlabelled. Looking at XRv4, we see the LFIB then check the VRF-aware PIM topology (mroutetable).

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94005
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94005	Unlabelled	P2MP TE: 134			

```
RP/0/0/CPU0:XRv4#show pim vrf RIP topology 232.1.1.1
(10.5.5.5,232.1.1.1)SPT SSM Up: 00:32:29
JP: Join(never) RPF: MPLS(SPE),213.11.11.11 Flags:
GigabitEthernet0/0/0/0.574 00:32:29 fwd Join(00:02:32)
```

P2MP RSVP-TE only supports SSM, which is why I used 232.1.1.1. The tail-end devices need to instruct the multicast process to use a different “core-tree” for RPF lookups, specifically using the TE tunnel. We also enable BGP AD for signaling of S-PMSI messaging specifically.

```
! All tail end routers
multicast-routing
vrf RIP
  address-family ipv4
    bgp auto-discovery p2mp-te
    core-tree-protocol rsvp-te
```

We can verify that RPF is correct another way also. The PIM topology said MPLS(SPE) followed by XRv1’s loopback which wasn’t very descriptive. We expect the RPF next-hop to be the BGP connector attribute, which is XRv1’s loopback0 213.11.11.11/32. The connector attribute is useful in Inter-AS scenarios.

```
RP/0/0/CPU0:XRv4#show pim vrf RIP rpf 10.5.5.5
Table: IPv4-Unicast-default
* 10.5.5.5/32 [200/1]
  via MPLS with rpf neighbor 213.11.11.11
  Connector: 213:11:213.11.11.11, Nexthop: 213.11.11.11
```

```
RP/0/0/CPU0:XRv4#show bgp vpnv4 unicast rd 213:11 10.5.5.5 | include
Connector
  Connector: type: 1, Value:213:11:213.11.11.11
```

The headend configuration is also awkward and took me a long time to understand. The MTE tunnel itself cannot be inside a VRF (the parser does not let you enable PIM on it), but we must configure a VRF-aware IGMP static-group for the SSM traffic we want to force downstream. This then creates a PIM join towards the CE (in the VRF), which is upstream towards the c-multicast source. Be sure to enable PIM on the global loopback0 (same address used for BGP peerings) and set the MDT source to that interface for all AFs; remember only IPv4 appears to work in v5.3.0. In the VRF, the only interface is the PE-CE link, but the MTE is statically assigned within that VRF. Interestingly, configuring IGMP parameters on an interface not enabled for multicast and not in the same VRF still works because of the “mdt static” assignment which maps an MTE tunnel to a VRF.

```
! XRv1
vrf RIP
  address-family ipv4
    bgp auto-discovery p2mp-te
    mdt static p2mp-te tunnel-mte134

router igmp
vrf RIP
  interface tunnel-mte134
    static-group 232.1.1.1 10.5.5.5
```

When we check the multicast state, we see the VRF on the PE shows the proper information, and issues an SSM (S,G) join towards CSR5. **Pitfall: I cannot get it working on the head-end unless I use “interface all enable” under the VRF.** PIM must be enabled on the MTE but you cannot do this explicitly, and if you only enable PIM on the PE-CE link, it simply does not work. Fortunately, you don’t have to enable PIM on the PE-P link, because the core is PIM-free. XRv PIM output accounts for the PIM DR as a neighbor, so if PIM is enabled on a multi-access link and the neighbor count is 1, don’t assume another router is there. Obviously there are no PIM neighbors on loopback0 or the MTE tunnel.

```

I enabled a 20 Mbps bandwidth reservation on this tunnel since this capability is the biggest benefit of RSVP-TE P2MP tunnels. When we checked the RSVP reservations on XRv1, we saw three reservations with 20 Mbps each. If we check the RSVP interface parameters, we see only 20 Mbps was allocated, and this is because it’s a single flow, not N different flows. This is desirable, and leads us to believe that the head-end router will not be replicating traffic.

```
RP/0/0/CPU0:XRv1#show rsvp interface
*: RDM: Default I/F B/W % : 75% [default] (max resv/bc0), 0% [default] (bc1)
Interface  MaxBW (bps)  MaxFlow (bps) Allocated (bps)  MaxSub (bps)
-----
Gi0/0/0/0.512 100M        100M          20M ( 20%)      0
```

From CSR5, I will generate some traffic and enable MPLS debugging on the XRv routers to watch it transit the network. Although the tunnel tail-ends won't deliver it to the final customer (XRv data-plane limitation), we can verify the LSP. This at least proves that MPLS imposition for MVPN works, or else XRv2 would have never seen LSM. MPLS packet debugging on XRv2 shows that when a packet along the P2MP LSP arrives, it is replicated to both routers as the LFIB directs. No messages are shown about its delivery to CSR8, presumably because it's broken. Even with these debugs and proper forwarding, the LFIB counters do not increment in the LFIB on XRv2.

```

```

At this point, we will perform some additional control-plane verifications, specifically examining the Type-4 Leaf AD message. We haven't used this in many profiles. This message is used by leaves (tail ends) to tell the originator of a Type-3 S-PMSI route (root) that they are interested in a particular C(S,G). Leaves will only send this if the Type-3 message has the "leaf information requested" flag inside the route. Without the command, we have no Leaf AD messages, because XRv1 did not signal it.

```
RP/0/0/CPU0:XRv1#show bgp ipv4 mvpn route-type 4
[no output]
```

```
RP/0/0/CPU0:XRv1#show bgp ipv4 mvpn vrf RIP
[3][32][10.5.5.5][32][232.1.1.1][213.11.11.11]/120 | include PMSI
PMSI: flags 0x00, type 1, label 0, ID 0x00000008600000086d50b0b0b
```

We can enable this flag per VRF, per address-family under the BGP AD stanza. Nothing else within the PMSI attributes changes; it is still an RSVP P2MP tunnel (type 1) and still has root 213.11.11.11. When we make the configuration change below and verify, we see that the other three XRv routers all signal to XRv1 their interest in the particular S-PMSI.

```

```

Looking into the details of the Leaf AD message, we see that it contains a lot of information; the information needs to specify all the attributes of the S-PMSI to which the leaf has signaled interest, plus additional information. The first part of the Leaf AD NLRI is the “route key” which contains the exact Type-3 route. The last piece is the originating router’s IP address, which is XRv2’s loopback. The route otherwise looks identical to the Type-3 on the surface. It also contains two extended communities. The dynamic RT (aka VRF-import) is set to the root’s IP address followed by a random number. Because none of XRv1’s VPNv4 routes match this dynamic RT (yet it was imported), I am assuming that the “0” on the end of it means that it doesn’t have to map directly to a VPNv4 route as the Type-6/7 c-mcast signaling messages do. I show the output from the two local VPNv4 routes on XRv1 to prove that the numbers don’t match. I also cannot find any documentation on what exactly “SEG-NH” means, but my guess is “S-PMSI Egress Next-Hop”, which would make sense considering it is XRv2’s loopback (tail end).

```

Another interesting behavior in this profile is that only the head-end seems to originate a Type-1 I-PMSI. We were led to believe all routers do this so they can establish some kind of “default MDT” to communicate. There is no such concept here since all the multicast joins and RPF information has been pre-configured and BGP is not terribly involved. The Type-1 originating head-end router doesn’t even have a PMSI attribute, so only the S-PMSI route (Type-3) has it, and it specified P2MP TE. This makes sense since only SSM is supported.

Additional Reading – Reference configurations “mvpn-10”

28.9 Profile 11: Default MDT – GRE – BGP-AD – BGP C-mcast Signaling

For this test, begin with the MVPN Profile 3 configuration where PIM is set up already for both the customer and provider networks. The default MDT uses PIM-Bidir while the data MDTs use PIM-SSM. This will allow us to see more variety in the P-tunnel types. The only significant difference here is enabling BGP c-mcast signaling since BGP AD is already enabled per profile 3. This modification is similar to jumping from profile 9 to profile 13 (using mLDP, not GRE). The main benefit/use-case of this model is to gradually transition to next-generation MVPN. An SP can still use the existing PIM/GRE core for forwarding, along with existing QoS and MoFRR, while taking advantage of the newer BGP control-plane in the overlay for additional scalability.

```
! Enable BGP c-mcast signaling in XE
vrf definition MC
  address-family ipv4
    mdt overlay use-bgp
  address-family ipv6
```

```

mdt overlay use-bgp

! Enable BGP c-mcast signaling in XR
router pim
vrf MC
  address-family ipv4
    mdt c-multicast-routing bgp
  address-family ipv6
    mdt c-multicast-routing bgp

```

Because I cannot find a way to disable PIM on the MDT interface on XRv2, we will check for PIM neighbors on the segment and ensure there are none, except XRv2. XRv2 should see no neighbors, meaning that the XE routers are not sending PIM hellos. This means that PIM signaling is not being used over the MDT interfaces.

```

RP/0/0/CPU0:XRv2#show pim vrf MC neighbor | include mdt

```

As a quick check, and without even thinking about the topology, we can check the RR (XRv2) for any Type 6 or Type 7 BGP routes. These represents the Shared Tree Join and Source Tree Join (basically (*,G) and (S,G) messages) within the MVPN. If we see any of these routes, we know BGP c-mcast signaling is configured correctly. Specifically, we see three Type-6 joins which represent C(*,G) joins for a PIM-ASM group 225.0.0.1 and RP 10.5.10.10. We also see two Type-7 SPT joins for the C(S,G) PIM-SSM group 232.0.0.5 with source 10.2.7.2. CSR6 and CSR8 are requesting both the ASM and SSM flows, while CSR1 is only requesting the ASM flow.

We will perform the same drill for IPv6. There is a single receiver, CSR8, requesting PIM-ASM traffic for the embedded-RP group FF7E:240:2001:10:2:7:0:1 with C-RP 2001:10:2:7::2. There are two routers, CSR7 and CSR8, requesting PIM-SSM traffic for the group FF33::1 from source 2001:10:4:6::4. Because the VPNv6 network is segmented horizontally, many IPv6 MVPN functions will be broken. This was intended to highlight unicast/multicast coordination issues as discussed in previous profiles.

```

First, we will test IPv4 SSM with a C(S,G) of (10.2.7.2, 232.0.0.5). CSR6 and CSR8 receive IGMPv3 joins for these C(S,G) pairs, then add C-MRIB entries. For brevity, we will focus on CSR8 only. The IGMPv3 join carries the source in “INCLUDE” mode, which is effectively a request for SSM multicast. The C-MRIB entry references a specific data MDT. The reason for this is because a data MDT was signaled for this group as a result of it being candidate for MDT optimization in the MDT data ACL for IPv4. This is signaled by the big ‘Y’.

```

```

It seems impossible that this MDT information could be exchanged between remote PEs within PIM running between them. As seen in profile 3, this is a function of BGP AD. The Type-3 S-PMSI route originated from CSR7 that describes this C(S,G) was received by CSR6 and CSR8. So long as the egress routers are importing the unicast RT of the ingress router (RT:213:7 in this case), the Type-3 is imported to the MVPN. We can see by the tunnel-type that this is a PIM-SSM tunnel inside GRE, rooted at CSR7, using group address 232.4.7.0. The summary view is shown on CSR6 and the details are shown on CSR8.

```

Once the C-MRIB entry is added in the egress router's C-MRIB, a BGP Type-7 SPT join is sent back towards the source. Because this is a BGP route send to a RR, other routers might try to import it when only CSR7 should. This is solved by the "VRF Import" or "dynamic RT"; CSR7 affixes a new extended-community to its unicast VPNv4 routes that effectively says "If you have BGP joins for this source/RP, use this RT". On CSR8, we can see the dynamic RT signaled by CSR7 for the customer prefix 10.2.7.0/24 is "RT:213.7.7.7:2". Note that while this has the same characteristics as a normal RT, it is technically a separate community field when attached to the unicast VPN routes. When originating the Type-7 SPT join to CSR7 (originated by CSR6 and CSR8), this is the export RT that is applied, allowing only CSR7 to import it.

```

```

At this point, CSR7 should have added a C-MRIB entry directing traffic for (10.2.7.2, 232.0.0.5) out towards the PMSI with RPF facing towards its customer LAN. This traffic has the small 'y' as it is sending traffic to an MDT data group and a big 'G' as the C-MRIB entry was derived from a BGP Type 7 SPT join. A quick verification of the "send" MDT shows that the C(S,G) was bound to a P-tunnel MDT data group.

```
R7#show ip mroute vrf MC 232.0.0.5 10.2.7.2 | begin \
(10.2.7.2, 232.0.0.5), 21:37:00/stopped, flags: sTyG
Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0
Outgoing interface list:
Tunnel2, Forward/Sparse, 21:37:00/stopped
```

```
R7#show ip pim mdt send
MDT-data send list for VRF: MC
  (source, group)                                MDT-data group/num    ref_count
(10.2.7.2, 232.0.0.5)                            232.4.7.0             1
```

With all of the c-mcast signaling complete, we now verify that the P-tunnel has been built. Because the data MDTs rely on SSM, CSR6 and CSR8 should have issued P(S,G) joins for (213.7.7.7, 232.4.7.0) towards CSR7. Checking all routers, we can see the P-PIM delivery tree is built properly. The big 'Z' means the MRIB entry represents a multicast tunnel while the little 'z' represents sending data on behalf of a customer MDT data group. The egress PEs forward this traffic to the "MVRF", which is essentially a decapsulation software process.

```
R7#show ip mroute 232.4.7.0 213.7.7.7 | begin \

```

Outgoing interface list:

MVRF MC, Forward/Sparse, 21:44:00/00:00:59

We will begin sending traffic on CSR2. Tracing hop by hop, CSR7 should see packet counter increases on its C-MRIB and P-MRIB entries. This indicates traffic is being properly encapsulated and forwarded to the core. On CSR7, we check the C(S,G) and P(S,G) entries at the same time. The packet counts are identical and only a 24-byte (GRE) packet difference is observed.

```
R7#show ip mroute vrf MC 232.0.0.5 10.2.7.2 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 45, Packets received:
45
Source: 10.2.7.2/32, Forwarding: 45/1/118/0, Other: 45/0/0
```

```
R7#show ip mroute 232.4.7.0 213.7.7.7 count | begin ^Group

```

A quick EPC verification on CSR8, capturing inbound facing the core and outbound facing the customer, shows the encapsulation of the packet. We can clearly see the GRE multicast arriving with the ICMP multicast being forwarded to the customer. The difference in length is exactly 24 bytes and the timestamp is identical.

```

Last, we will examine IPv6 SSM. ASM is covered in detail in several other profiles and the complexity in the customer network isn't the primary focus of MVPN. This is interesting because despite being SSM, there is no corresponding S-PMSI mapping. This is because the C(S,G) is not matched by the IPv6 data MDT ACL. We can check the ingress PE for (2001:10:4:6::4, FF33::1), which is CSR6, for any kind of data MDT information regarding this group. We do not see any Type-3 routes and subsequently no sent MDTs.

On the egress PEs (CSR8 for example), the only real match we have for this C(S,G) is the I-PMSI, signaled by the BGP Type-1 route. Looking at the details, we see this is a type 5 tunnel, which indicates PIM-Bidir. The root of the tree is XRv4, and the group address is 238.255.0.1.

```

The corresponding C-MRIB entry doesn't show a big 'Y' flag to indicate it is receiving traffic for a data MDT, but the little 'g' indicates that it sent a BGP c-mcast route (Type 6 or 7, but in this case, 7) to signal interest in this group. We can confirm these flags by checking the data MDTs received (none) and the originated BGP Type-7 route.

A quick check on CSR6 confirms that this Type-7 route was imported. Again, this is because of the dynamic RT that CSR8 attached to the route targeting CSR6. This is derived from the VPNv6 route originated by CSR6 for the prefix 2001:10:4:6::/64. We confirm the dynamic RT added by CSR7 matches what CSR6 advertised in its VPNv6 route.

Knowing that the default MDT is built, we will not verify that. When CSR4 starts sending traffic, we verify that CSR6 is encapsulating those packets using the P-tunnel default MDT group. This shows that the C-MRIB is forwarding the traffic towards the PMSI correctly.

```

```

We can see this traffic enters CSR1 by virtue of C(S,G) presence there. The packet counters show that all packets have been discarded due to RPF failure. This is because CSR1 has no route to the source as the unicast RT was never imported in the VPNv6 topology. In an optimized network, this traffic would not be transported via the I-PMSI in the first place, which means CSR1 would not have this C-mcast state.

```

R1#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 count

A final check involves EPC on CSR8 to capture incoming P-tunnel traffic along the default MDT and customer IPv6 traffic after decapsulation. For brevity, we can see the headers and be reasonably sure the design is working. The IPv4 GRE packets along the default MDT are decapsulated (24 bytes removed) and the IPv6-ICMP packets are forwarded to the customer.

Additional Reading – Reference configurations “mvpn-11”

28.10 Profile 12: Default MDT – MLDP – P2MP – BGP-AD – BGP C-mcast Signaling

For this test, begin with the MVPN Profile 9 configuration where all of the MVPN BGP AD is set up already, plus the MP2MP/P2MP trees are built. We need to do two things: remove the MP2MP tree, and enable BGP C-multicast signaling. Both are very straightforward. **In XE, be sure to remove all of the MP2MP tree configuration for both IPv4/IPv6 before enabling P2MP. When you remove the MDT default, all the MDT data configuration also disappears.** We need to reapply our ACLs on XE only.

```
! Enable BGP c-mcast signaling and mLDP P2MP default trees in XE PEs
vrf definition MC
address-family ipv4
no mdt default mpls mldp 213.14.14.14

    mdt c-multicast-routing bgp

```

This profile helps demonstrate the value of using BGP-AD for an entirely dynamic solution, as well as using BGP for mcast signaling.. Because we did not specify a bidirectional MP2MP root, some replacement for a “default MDT” still needs to be built. This would carry key information like C-PIM BSR messages, for example. Without BGP-AD, this would not be possible, since the endpoints of the particular MVPN instance are unknown. In this configuration, every PE is the root of its own P2MP tree, and all other nodes within the MVPN instance join as leaves to every other tree. Compared to MP2MP trees, this introduces significantly more state into all routers (P and PE) within the SP network. The benefit is a fully dynamic construct with semi-optimal transmission paths by default. This has the same effect as the MP2MP “emulated LAN” in terms of C-signaling but does so with better SP core forwarding.

Taking a quick look at CSR6, we see several P2MP trees. Without actually proving/verifying anything, we can make some educated guesses based on this output. The first 6 entries relate to the IPv4 MDTs since they include all of the PEs within the MVPN (yellow). The last 3 entries are related to the IPv6 MDTs since they only include the “south-side” routers (green). A quick look at CSR1 helps confirm this estimate as CSR1 sees all of the IPv4 MDTs but only the “north-side” routers for IPv6 MDT.

One interesting thing to notice is that opaque-type is no longer MDT; it is global-ID, or GID. This is a different type of opaque value (specifically type 0x01 as we will see in OAM), but mLDP doesn't care about this opaque value. It just gets transported. Notice that the GIDs are the same for the entire IPv4 and IPv6 MVPNs, with the exception of XRv2. Its GID numbering scheme starts from 1 while the others to do. It would be valuable to understand where this GID came from, and how is it possible that all the routers agreed on it. I tried to find a way to set this on IOS XE and XR, but was unable to. This value is encoded in the BGP Type-1 I-PMSI message in hexadecimal. Looking at the IPv4 and IPv6 Type-1 routes on CSR1, we can see the values of 65536 (0x10000) and 131072 (0x20000) in the tunnel information for IPv4 and IPv6 Type-1 AD routes, respectively.

rx pathid: 0, tx pathid: 0x0

```

Let's trace a few mLDP P2MP trees to make sure things look correct. As an example, all 6 PEs should be joined to CSR6's delivery tree. Since mLDP P2MP trees are receiver-driven, we will trace it back from the leaves first. Rather than use the GID for the show commands (which shows N-1 trees, generally), I will use the LSP ID. CSR6 instructs XRv4 to use label 1011 when delivering traffic downstream.

```

R1#show mpls mldp database summary | include 213.6.6.6
5          P2MP      213.6.6.6          [gid 65536 (0x00010000)]      1

```

```

R1#show mpls mldp database id 5 | section Upstream
Upstream client(s) :
  213.14.14.14:0    [Active]
    Expires         : Never          Path Set ID   : 5

    Local Label (D) : 1011           Next Hop      : 213.1.14.14

```

Because we expect CSR8 to route through XRv4 also, we will check its downstream label mapping. Notice that CSR8 has two trees rooted at CSR6, but the second is IPv6. This is not present on CSR1 because the north/south routers do not have IPv6 connectivity over the VPN. CSR8 uses label 8003.

```

R8#show mpls mldp database summary | include 213.6.6.6
8          P2MP      213.6.6.6          [gid 65536 (0x00010000)]      1
B          P2MP      213.6.6.6          [gid 131072 (0x00020000)]      1

```

```

    Local Label (D) : 8003           Next Hop      : 213.8.14.14

```

XRv4 also sees two tunnels rooted in CSR6. We check the IPv4 one and see both CSR1 and CSR8 as downstream clients with the correct label mappings (1011 and 8003). XRv4 advertises label 94013 towards XRv3 who is upstream towards CSR6. The numbers "1 2" highlighted in the summary output shows the number of upstream and downstream clients, respectively.

Before checking XRv3, we will check CSR5, CSR7, and XRv2. We expect their shortest paths to be via XRv3, so they should all advertise downstream labels to XRv3, similar to how CSR1 and CSR8 did so with XRv4. We see labels 5010, 7006, and 92017 advertised to XRv3. These should be downstream from XRv3's perspective, along with XRv4.

As expected, XRv3 has 4 downstream clients for this P2MP tree and one upstream client towards CSR6. Notice the “1 4” indicates this in brief form. A quick validation of the remote downstream labels shows our trace is correct so far. XRv3 advertises label 93000 towards CSR6.

```

On CSR6, we see the label 93000 from XRv3 with no upstream (local) label. P2MP trees are always unidirectional from the root towards the leaves, which is why there is a “full mesh” of P2MP trees in this profile.

```

At this point, we will begin testing multicast traffic. The details of BGP c-mcast signaling are described in detail in Profile 13. It is tested here but documented in less detail. First, we ensure the Type-6 C(*,G) join made its way to the C-RP. Each router will have originated this provided there was a client in the customer network interested in a C-group. Checking XRv2 first, we can see three interested PEs: CSR1, CSR6, and CSR8. CSR5 sends a C(*,G) PIM join towards the C-RP (CSR10) having installed it by receiving a BGP Type-6 route (big 'G').

```

```

All of the PEs with interested clients (egress PEs) generate BGP Type-7 SPT joins at this point. CSR5 does it because it actually received a C(S,G) prune from CSR10. The others do it because they received traffic down the C(*,G) shared tree and assume that they should join this SPT. The debugs from CSR5 and CSR6 both show local generation of the Type-7 route. Checking XRv2, we can see 4 copies of it; one from the PE connected to the RP and three from remote clients. If XRv were working, we would have seen one from XRv2. In the interest of brevity, the highlighted RD at the top of this output varies between routes, so this exact output is from CSR5. The RD of the route originated is CSR7, which is the PE towards the C-source.

```

I've also highlighted the dynamic RT of 213.7.7.7:1. This was derived from the extended community carried within CSR7's VPNv4 route to the C-source. We can verify that below, and all routers use this in their Type-7 joins to target CSR7.

```

R5#show bgp vpnv4 unicast vrf MC 10.2.7.0/24

```

CSR7 also receives the Type-7 SPT join, which is technically the best-path from XRv2. They all contain the same information so it doesn't matter which one the RR picks as best. In this case, CSR5's route was best. Upon receipt, once the BGP route is processed and installed, PIM takes over and enters the C(S,G) state into the PIM topology (MRIB). This means the C-SPT has been built back to the source so multicast can now travel our mLD P2MP tree. Technically this is not S-PMSI since no Type-3 S-PMSI AD routes were generated, and we did not configure "Data MDT" support for this group. The I-PMSI is still used, but the C-SPT is still invoked on the ingress PE.

```

PIM(1): Clear Registering flag to 10.5.10.10 for (10.2.7.2/32, 225.0.0.1)
```

Before verifying mLDp operation, we check the MRIB state and counters on the ingress PE. CSR7 shows traffic entering from the customer LAN and being forwarded out the PMSI. The big 'G' means the entry was installed due to receiving a BGP Type-7 SPT join, and the little 'q' means that router originated a Type-5 SA message for this C(S,G).

```
R7#show ip mroute vrf MC 225.0.0.1 10.2.7.2 | begin \  
(10.2.7.2, 225.0.0.1), 00:28:50/00:02:32, flags: FTGq  
  Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0  
  Outgoing interface list:  
    Lspvif0, Forward/Sparse, 00:28:49/stopped  
  
R7#show ip mroute vrf MC 225.0.0.1 10.2.7.2 count | section ^Group  
Group: 225.0.0.1, Source count: 1, Packets forwarded: 861, Packets received:  
862  
  Source: 10.2.7.2/32, Forwarding: 861/0/117/0, Other: 862/1/0
```

The egress PEs should show incoming traffic on the PMSI and outgoing on their customer LANs. Their flags show a little 'g' indicating they sourced a BGP Type-7 SPT join and a big 'Q' indicating they received a Type-5 Source Active.

```

Source: 10.2.7.2/32, Forwarding: 920/0/122/0, Other: 920/0/0

The PE facing the C-RP has interesting output. Since only two packets were sent in native multicast to the RP, the counter stops incrementing as the C(S,G) is pruned. This is the correct operation. The route was still installed from having sent a BGP Type-7 route (little 'g'), but the Type-5 SA is not bound to this C(S,G) since CSR5 did not join the C-SPT. The "other drops" column is incrementing as the OIL is null.

```

Since the source is behind CSR7, we know that CSR7 is the root of the mLDP P2MP tree. I perform a quick EPC on CSR7 outbound towards XRv3 to ensure the proper label bindings are used. CSR7 should

use label 93011 (0x16B53) to send MVPN traffic for VRF MC downstream towards XRv3. The packet capture shows this, along with the source/destination IP addresses highlighted.

```

Since testing ASM is much more involved and the concepts are identical between IPv4 and IPv6, we will quickly test IPv6 SSM only. Our baseline configuration does not signal S-PMSI for our IPv6 SSM group FF33::1, but we will modify the ACLs on our PEs to account for it. This deviation allows us to add some variety to the testing.

```
! Modification to XE/XR PE routers (same syntax)
ipv6 access-list ACL_DATA_MDT_IPV6
 permit ipv6 any host FF33::1
```

Adding this to ACL entry CSR6 (ingress PE), with BGP IPv6 MVPN debugging enabled, shows the immediate creation of the Type-3 S-PMSI route. Technically, the data MDT configurations only need to be added to the ingress PE connected to sources, but I add it everywhere for completeness.

```
! CSR6
BGP(16): nettable_walker [3][213:6][2001:10:4:6::4][FF33::1][213.6.6.6]/46
route sourced locally
BGP(16): (base) 213.12.12.12 send UPDATE (format)
[3][213:6][2001:10:4:6::4][FF33::1][213.6.6.6]/46, next 213.6.6.6, metric 0,
path Local, extended community RT:213:6
```

As an interesting test, if you delete the ACL entry, the route is immediately withdraw and downstream PEs will switch over to using the default MDT (I-PMSI) again. The lack of S-PMSI advertisement by the “root” of the P2MP, in the case of mLDP, means that there is no selective behavior for this C(S,G). The ACL is corrected and the entry is re-added before continuing.

```
R6(config-ipv6-acl)#no permit ipv6 any host FF33::1
```

```

```

Looking at the route from XRv2’s perspective, it was received from CSR6 and advertised to the other PEs in the update-group. With an RT of 213:6, we know that CSR1 and CSR5 will not import this Type-3 route, but CSR7 and CSR8 should. There are two other key components of this Type-3 route worth discussing. The first is the tunnel-type, which is 2, just like the P2MP default MDTs. It’s the same delivery mechanism in the data plane, but a more “selective” tunnel as not all nodes in the MVPN instance are required to join it. The 0x20001 is the global-id (GID) which is 131073 in decimal.

```
RP/0/0/CPU0:XRv2#show bgp ipv6 mvpn rd 213:6

```

Even without the Type-3 route, CSR7 and CSR8 originated Type-7 SPT joins to CSR6 to request traffic for this C(S,G). The Type-3 route just allows the core to transport it more efficiently. The way to tell if the C-traffic is actually utilizing the data MDT is to check the C-MRIB entry. On CSR7, we can see the MDT with GID 131073 which we saw in the Type-3 route. We also see the big ‘Y’ flag which means this entry receives traffic from a data MDT (learned via Type-3 S-PMSI route). The little ‘g’ means it was installed by having sent a Type-7 SPT join. Because the GID is carried in the Type-3 route, it will be common for all subscribers to the S-PMSI. A quick check of the incoming interface and OIL shows us that the PMSI is upstream and the customer LAN is downstream, which is correct.

```
R7#show ipv6 mroute vrf MC FF33::1 | begin \
(2001:10:4:6::4, FF33::1), 1d04h/never, flags: sTIYg
Incoming interface: Lspvif0, MDT: [131073] (0x00020001), 213.6.6.6]/never
RPF nbr: ::FFFF:213.6.6.6
Immediate Outgoing interface list:
GigabitEthernet2.527, Forward, 1d04h/never
```

```
R8#show ipv6 mroute vrf MC FF33::1 | begin \
(2001:10:4:6::4, FF33::1), 1d05h/never, flags: sTIYg
Incoming interface: Lspvif0, MDT: [131073] (0x00020001), 213.6.6.6]/never
RPF nbr: ::FFFF:213.6.6.6
Immediate Outgoing interface list:
GigabitEthernet2.538, Forward, 1d05h/never
```

CSR6’s output is very similar but reversed in many ways. The flag cases have been inverted; little ‘y’ means the router originated a Type-3 S-PMSI route for this C(S,G) and is sending to an MDT data group. The big ‘G’ means it received a Type-7 SPT join for this C(S,G). Traffic enters from the customer LAN and

is sent to the PMSI using MDT 131073 (global-id). The MDT is “TX” only, where the others are receive-only; mLDP P2MP trees are always unidirectional.

```
R6#show ipv6 mroute vrf MC FF33::1 | begin \  
(2001:10:4:6::4, FF33::1), 04:36:09/never, flags: sTyG  
Incoming interface: GigabitEthernet2.546  
RPF nbr: 2001:10:4:6::4  
MDT TX nr: 131073 (0x00020001) LSM-ID: 0x12  
Immediate Outgoing interface list:  
Lspvif0, Forward, 04:36:09/never
```

Unlike ASM, there is no more BGP/C-PIM signaling that has to occur for traffic to flow. Once CSR4 starts sending traffic, CSR6 pushes the proper labels and sends it down the delivery tree. We will quickly trace the delivery tree to see if there is any obvious benefit. Remember that we already have several mLDP P2MP trees in the network, and we have just added another for S-PMSI supporting a C(S,G). Since P2MP trees are receiver-driven, we start with CSR7 and CSR8. Since we know the GID, we will use that as a filter to find the P2MP tree we want to trace. We find downstream label mappings of 7016 and 8016, one of which goes to XRv3 and one of which goes to XRv4.

```

```

Checking those two routers, we see that XRv4 uses label 8016 to send traffic to CSR8 and tells XRv3 to use label 94000 to send traffic towards itself. XRv3 acknowledges that label from XRv4 as well as the one from CSR7, and tells CSR6 to use label 93001 to send traffic towards it. Notice that XRv4 has one upstream and one downstream client, while XRv3 has one upstream and two downstream clients.

```

CSR6 is the root, using label 93001 to send traffic towards XRv3 for further distribution. Because all of the clients in the south-side of the network are requesting this data, the default MDT is identical to the data MDT. This is not an effective use of the data MDT since all PE's are requesting traffic. From a design perspective, it would not make sense to signal S-PMSI for this flow. We will test it quickly to verify it works. We just recently checked the C-MRIB, and knowing that the C(S,G) state won't change, we will just check the forwarding counters.

```

R6#show ipv6 mroute vrf MC FF33::1 count | include HW
  HW Forwarding: 37/0/118/0, Other: 0/0/0

R7#show ipv6 mroute vrf MC FF33::1 count | include HW

```

To show a more efficient design, we temporarily remove CSR3 as a client of this C-multicast feed. Upon doing this, CSR8 immediately withdraws the Type-7 SPT join, which makes sense since it no longer wants the traffic. There is no significant change on CSR6 since CSR7's route was the best-path and there is still at least one client.

```
! CSR8
BGP[16] MVPN: withdraw c-route, type 7, bs len 0 asn=213, remote-rd=213:6,

```

XRv4 also generates syslog saying that it has deleted a branch to CSR8. This is because CSR8 is no longer part of this P2MP S-PMSI tree. Because XRv4 has no clients, XRv3 prunes XRv4 from the tree also.

```
RP/0/0/CPU0:XRv4#mpls_ldp[1042]: %ROUTING-MLDP-5-BRANCH_DELETE : 0x00010
[global-id 131073] P2MP 213.6.6.6, Delete LDP 213.8.8.8:0 branch remote label
8016

RP/0/0/CPU0:XRv3#mpls_ldp[1042]: %ROUTING-MLDP-5-BRANCH_DELETE : 0x00010
[global-id 131073] P2MP 213.6.6.6, Delete LDP 213.14.14.14:0 branch remote
label 94000
```

A quick check of XRv3's LFIB shows that the traffic is only going to CSR7, as expected. Now the S-PMSI has some benefit since using the I-PMSI from CSR6 would send traffic to CSR8 also, only to be dropped. Assuming there was full IPv6 connectivity in the VPN, like IPv4, the I-PMSI would span all PE's. We also check the mLDP database to verify the LFIB is correct. By removing this one client from the S-PMSI, both XRv4 and CSR8 were removed from the S-PMSI delivery tree.

```

As always, we finish with looking at OAM. Because mLDP P2MP trees are unidirectional, we must test them from the root. This is awkward because it looks like we are pinging the root from the root, but in reality we are just identifying the mLDP FEC and opaque values. XE does not have a keyword for “global-id”. Referencing “draft-bishnoi-mpls-mldp-opaque-types-01.txt” indicates that this opaque type is 0x01, so we can use that. From CSR6, we can test one-way connectivity from CSR6 to all of its leaves on the I-PMSI. We see three trees rooted at CSR6. The first one is the I-PMSI for the IPv4 MVPN. We verify that the remaining 5 PEs are connected on this I-PMSI. The “ping” command requires the exact hex data of the GID since there isn’t a more graceful way to test this in XE currently.

```

Quickly testing XRv2, we look at the IPv4 I-PMSI and IPv6 I-PMSI. XR has a nice keyword for “global-id”, but you can also do it the hard way using the hex data. I demonstrate both below. It doesn’t seem to work, though, possibly due to a GID mismatch or XRv LSM limitations. I do not troubleshoot this further.

```
RP/0/0/CPU0:XRv2#show mpls mldp database brief | include 213.12.12.12
0x0000B P2MP 213.12.12.12 0 2 [global-id 1]
0x00005 P2MP 213.12.12.12 0 2 [global-id 262145]
```

```
RP/0/0/CPU0:XRv2#ping mpls mldp p2mp 213.12.12.12 hex 0x1 00000001
Sending 1, 100-byte MPLS Echos to mldp p2mp 213.12.12.12 hex fec (0x1,
00000001),
    timeout is 2.2 seconds, send interval is 0 msec, jitter value is 200

28.11 Profile 13: Default MDT – MLDP – MP2MP – BGP-AD – BGP C-mcast Signaling

For this test, begin with the MVPN Profile 9 configuration where all of the MVPN BGP AD is set up already, plus the MP2MP/P2MP trees are built. XRv4 is the MP2MP root and there are some other P2MP roots related to SSM joins. Enabling BGP C-multicast signaling is very easy, and the snippets are below.

```
! Enable BGP c-mcast signaling in XE PEs
vrf definition MC
  address-family ipv4
    mdt overlay use-bgp
  address-family ipv6
    mdt overlay use-bgp

! Enable BGP c-mcast signaling in XRv2
router pim
  vrf MC
    address-family ipv4
      mdt c-multicast-routing bgp
    address-family ipv6
      mdt c-multicast-routing bgp
```

Pitfall: There does not appear to be a way to stop XRv from sending PIM hellos over the emulated LAN.

Every router will still see XRv2 as a PIM neighbor. The real power of using BGP AD and C-mcast signaling together is that now (with the exception of the XRv issue) there is no PIM anywhere in the carrier network, other than PE-CE links. First, let's ensure some of the remote PEs still know who the RP is. After all, there is no PIM adjacency on the LSPvif0 anymore, so there must be a mechanism for the BSR messages to flow. CSR6, for example, still learns the RP. The debug confirms it came from the LSPvif0 interface.

```
R6#show ip pim vrf MC rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4
  RP 10.5.10.10 (?), v2
    Info source: 10.5.10.10 (?), via bootstrap, priority 0, holdtime 150
    Uptime: 00:53:56, expires: 00:02:14
```

```

R6#debug ip pim vrf MC
PIM(1): Received v2 Bootstrap on Lspvif0 from 213.5.5.5
(1): pim_add_prm:: 224.0.0.0/240.0.0.0, rp=10.5.10.10, repl = 0, ver =2,
is_neg =0, bidir = 0, crp = 0
PIM(1): Update
prm_rp->bidir_mode = 0 vs bidir = 0 (224.0.0.0/4, RP:10.5.10.10), PIMv2

```

Double checking RPF and PIM neighbors, we clearly see the correct RPF to CSR5, but no PIM neighbor with CSR5. This seems to violate some fundamental PIM rules.

```

R6#show ip rpf vrf MC 10.5.10.10
RPF information for ? (10.5.10.10)
RPF interface: Lspvif0
RPF neighbor: ? (213.5.5.5)
RPF route/mask: 10.5.10.0/24
RPF type: unicast (bgp 213)
Doing distance-preferred lookups across tables
RPF topology: ipv4 multicast base, originated from ipv4 unicast base

```

```

R6#show ip pim vrf MC neighbor lspvif 0 | begin ^Neighbor
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
213.12.12.12      Lspvif0          01:43:02/00:01:34 v2      1 / DR P G

```

This is where the Type 1 AD route is key. Remember that because all the PEs have discovered one another via the I-PSMI BGP AD routes, they know to use the bidirectional MP2MP tree. The Type-1 route signaled this with the tunnel-type 7 option and including the root address in the tunnel parameters, as discussed in Profile 9. Thus, ASM can still work with this design even without PIM in the overlay. Using MP2MP root 213.14.14.14 (0xD50E0E0E), we can reach CSR5.

```

R5#show bgp ipv4 mvpn vrf MC route-type 1 213.5.5.5

0000
      rx pathid: 0, tx pathid: 0x0

```

Also recall that CSR4 is issuing IGMP joins for an ASM group 225.0.0.1 and an SSM group 232.0.0.5. In order to send the C(*,G) join to the C-RP, CSR6 must know the C-RP address first, which was just discussed. Once it knows that, it generates a Type 6 Shared-Tree Join route which is directly comparable to a PIM (*,G) join. This route information contains many pieces of information, and the RP address is included as the “source”. In this way, it looks just like the Type 7 Source-Tree Join route which is examined later.

```
R6#show bgp ipv4 mvpn vrf MC route-type 6 213:5 213 10.5.10.10 225.0.0.1

    rx pathid: 0, tx pathid: 0x0
```

Looking at this BGP Type-6 route on CSR5, we can see it was iBGP learned from CSR6 through the route-reflector, XRv2. The RT is the MDT source address of the PE who is closest to the RP, in this case, and the “2” at the end is a random number used to differentiate the RTs for different C(*,G) joins. This allows CSR6 to “target” CSR5; since XRv2 reflects this route to many peers, those other peers should not import it.

```
R5#show bgp ipv4 mvpn vrf MC route-type 6 213:5 213 10.5.10.10 225.0.0.1

    Originator: 213.6.6.6, Cluster list: 213.12.12.12
    rx pathid: 0, tx pathid: 0x0
```

With this route in the BGP RIB, the MRIB process for this VPN also needs to update itself so multicast traffic can flow. The C(*,G) entry looks normal, with the exception of the big “G” flag, which means the entry was installed by a received BGP c-mcast route. Normally, MRIB entries are the results of PIM signaling (joins, prunes, etc). In this case, the MRIB entry was BGP-signaled.

```

R5#show ip mroute vrf MC sparse
(*, 225.0.0.1), 00:00:37/00:02:22, RP 10.5.10.10, flags: SG
  Incoming interface: GigabitEthernet2.550, RPF nbr 10.5.10.10
  Outgoing interface list:
    Lspvif0, Forward/Sparse, 00:00:37/00:02:22

```

This raises the question of why CSR5 only has one Type 6 route when CSR1 and CSR8 should have also generated these routes. The answer is because XRv2 is a RR, it only advertises its best route. CSR6 is best because the IGP metric to the BGP next-hop is lowest. I've highlighted the show command because it is very long. This "loss" of information does not negatively affect forwarding; the LSPvif is in the OIL of the C(*,G) if at least one BGP Type 6 route is received. It does not matter which one, and BGP can be used to help scale MVPNs in this way. XRv2 should have generated one too, but I don't think it is fully supported.

```

There is a lot of upcoming activity once CSR2 starts sending traffic. I have enabled IPv4 MVPN debugging on CSR7 (first hop router), CSR6 (last hop router), and CSR5 (PE towards RP). CSR7 sends a PIM register message, which is unicast, towards the RP. I enabled this debugging after the fact, so registration is complete, but we can see the registration process continuing so the RP is aware of the active source.

```

! CSR7
PIM(2): Send v2 Data-header Register to 10.5.10.10 for 10.2.7.2, group
225.0.0.1
PIM(2): Received v2 Register-Stop on GigabitEthernet2.574 from 10.5.10.10
PIM(2): for source 10.2.7.2, group 225.0.0.1
PIM(2): Clear Registering flag to 10.5.10.10 for (10.2.7.2/32, 225.0.0.1)

```

The RP tries to join to SPT and sends a C(S,G) join to CSR5. CSR5 then creates a BGP Type-7 route and sends it to the RR. RR rules still apply, and when XRv2 reflects it back, it gets rejected on ingress.

```

! CSR5

```

Upon receiving this Type-7 Source-Tree Join, CSR7 issues a Type-5 Source Active AD route. This announces that there is a source actively sending traffic behind the originating PE. CSR7 adds the Type-7 to its MVPN RIB, then generates the Type 5 route and sends it to the RR.

```

```

Like CSR10, when CSR4 saw multicast traffic, it immediately tries to switch to the SPT and issues a PIM (S,G) join to CSR6. CSR6 then generates a Type 7 BGP route to indicate interest in this C(S,G). This goes to the RR, along with the Type 7 routes from CSR5, CSR1, and CSR8. All of their CEs do the same thing.

```

! CSR6
BGP[15] MVPN: add c-route, type 7, bs len 0 asn=0, rd=213:6,

Local, extended community RT:213.7.14.7:2

```

CSR6 receives a Type 7 route from CSR5 for (10.2.7.2, 225.0.0.1). Clearly this source is NOT behind CSR6, and CSR6 should not accept this route. This is the purpose of the dynamic RTs; CSR6 is not importing RT:213.7.14.7:2, only CSR7 is, because the source is behind CSR7 only. The route is rejected. However, the Source Active AD route (Type-5) is accepted from the RR and installed. The RT on the Type 5 route, since this is an AD route (not C-mcast signaling, technically) is the standard unicast RT.

```
! CSR6
BGP(15): 213.12.12.12 rcvd UPDATE w/ attr: nexthop 213.5.5.5, origin ?,
localpref 100, metric 0, originator 213.5.5.5, clusterlist 213.12.12.12,
extended community RT:213.7.14.7:2

BGP(15): add RIB route [7][213:7][213][10.2.7.2/32][225.0.0.1/32]/22
```

As a quick check, let's identify why CSR7 only saw, and subsequently installed, the Type-7 route from CSR5. This is because XRv2 only advertised the best path, which won against CSR6 due to lowest RID. As long as the first-hop router receives one Type 7, that is all that matters.

```

```

Let's verify the Type-7 installation on CSR7. These parameters should match up with the debugs. The route is from CSR5 (doesn't really matter) and describes C(10.2.7.2, 225.0.0.1). CSR7 also originates the Type-5 route. Again, notice the difference between the dynamic RT on the Type-7 and the standard RT on the Type-5.

```

CSR6, as the last hop router, acknowledges the Type-5 and originates a Type-7. CSR6's Type-7 loses best-path on XRv2 and is not advertised further, but it doesn't matter since an identical C(S,G) route from CSR5 was advertised on.

For completeness, we take a quick look at CSR1 and CSR8 also. Their process was identical to CSR6. The Type-7 routes (the C(S,G) joins) were sourced locally and the Type-5 route (Source Active) was learned via the RR with next-hop CSR7, the first-hop router.

```

Now that all the signaling was verified, we can check the multicast routing. First, we check CSR7 to ensure traffic is arriving from the VPN customer and going towards the core via LSPvif0. We see some new flags here. The big “G” means the entry was installed from a received BGP c-mcast route, in this case, a Type-7 Source-Tree Join from CSR5. The little ‘q’ means that this router issues a Type-5 Source Active route for this C(S,G). The packet counters for CSR7 continue to increase, indicating a functional data-plane.

```
R7#show ip mroute vrf MC 225.0.0.1 10.2.7.2 | begin \  
(10.2.7.2, 225.0.0.1), 00:01:25/00:01:37, flags: FTGq  
Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0  
Outgoing interface list:  
Lspvif0, Forward/Sparse, 00:01:25/00:01:34
```

```
R7#show ip mroute vrf MC 225.0.0.1 10.2.7.2 count | begin ^Group  
Group: 225.0.0.1, Source count: 1, Packets forwarded: 87, Packets received:  
88  
Source: 10.2.7.2/32, Forwarding: 87/1/117/0, Other: 88/1/0
```

CSR6, CSR8, and CSR1 should have identical outputs with the exception of minor differences like packet counters, since I checked their outputs at different times. The flags are “inverted” on these entries: the little ‘g’ signifies that a BGP c-mcast route was sent representing this C(S,G), which is true because CSR6 did originate a Type-7 route for it. The big ‘Q’ means that a Type-5 Source Active route was received for this C(S,G). This is also true because CSR7 originated that message. Notice the counters are increasing.

```
R6#show ip mroute vrf MC 225.0.0.1 10.2.7.2 | begin \  
(10.2.7.2, 225.0.0.1), 00:01:02/00:01:57, flags: JTgQ  
Incoming interface: Lspvif0, RPF nbr 213.7.7.7

```

Last, let's check CSR5. Very few multicast packets should be shown here, since the C-RP will prune itself from the SPT when it realizes it is not in the transit path anymore. The big 'P' indicates a prune and the little 'g' indicates the entry is the result of a sent BGP c-mcast message, specifically a Type-7 SPT join. The LSPvif is still a "LAN" in terms of forwarding, because this traffic is using the MP2MP mLDP tree.

```
R5#show ip mroute vrf MC 225.0.0.1 10.2.7.2 | begin \  
(10.2.7.2, 225.0.0.1), 00:02:42/00:00:17, flags: PTXg  
Incoming interface: Lspvif0, RPF nbr 213.7.7.7  
Outgoing interface list: Null
```

```
R5#show ip mroute vrf MC 225.0.0.1 10.2.7.2 count | begin ^Group  
Group: 225.0.0.1, Source count: 1, Packets forwarded: 5, Packets received:  
154  
Source: 10.2.7.2/32, Forwarding: 4/0/122/0, Other: 153/1/148
```

Earlier examples showed us the MDT information inside the MRIB entries, but no longer. One way we know this traffic is using the MP2MP mLDP tree is the lack of an S-PMSI AD route (Type-3). When this route is present, as it is currently for SSM traffic, the P2MP root is encoded in the same manner as the MP2MP tunnel, except the tunnel type is changed to 2, which is mLDP P2MP. We explore this next. First, we will do an inbound capture on CSR6 to see if the downstream label 6001 is used. We select CSR6 because it participates in both a P2MP tree (SSM) and the MP2MP tree. Assuming we were confused as to which one was in use, we check the incoming label. If the label is 6013, that means the P2MP tree is used.

```
R6#show mpls mldp database summary
```

LSM ID	Type	Root	Decoded Opaque Value	Client
Cnt.				
1C	P2MP	213.7.7.7	[mdt 213:213 1]	1
19	MP2MP	213.14.14.14	[mdt 213:213 0]	1

```
R6#show mpls mldp database opaque_type mdt 213:213 0 | section Upstream
```

```
Upstream client(s) :
```

213.13.13.13:0	[Active]		
Expires	: Never	Path Set ID	: 1F
Out Label (U)	: 93004	Interface	: GigabitEthernet2.563*
Local Label (D)	: 6001	Next Hop	: 213.6.13.13

```
R6#show mpls mldp database opaque_type mdt 213:213 1 | section Upstream
```

```
Upstream client(s) :
```

213.13.13.13:0	[Active]		
Expires	: Never	Path Set ID	: 23
Out Label (U)	: None	Interface	: GigabitEthernet2.563*
Local Label (D)	: 6013	Next Hop	: 213.6.13.13

We use EPC to verify the packet, and also check the LFIB for sanity. Label 0x1771 is 6001. The counters for this LSP constantly increase.

```

			570724	aggregate/MC	

The process for SSM is a little more straightforward since there is no RP, and therefore no registration. Looking deeper at the Type-7 BGP SPT join, we see that for SSM, it is originated by both CSR6 and CSR8. Both of them have SSM clients (CSR3 and CSR4) that are requesting traffic for 232.0.0.5. On XRv2, we see both routes have an RD of 213:7. Note that CSR6 is the best path.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mvpn rd 213:7 route-type 7 | begin Network
```

Network	Next Hop	Metric	LocPrf	Weight	Path
Route Distinguisher: 213:7					
*>i[7][213:7][213][32][10.2.7.2][32][232.0.0.5]/184					
	213.6.6.6	0	100	0	?

```
* i                213.8.8.8                0    100    0 ?
```

Normally, the RD of a VPN route is equal to that of the originator. In this case, it is set to the RD of the destination. The only way CSR6 and CSR8 can determine this is by using the BGP AD messaging. This is where the Type 1 I-PMSI message is used. CSR8 reports learning this Type 1 from CSR7 which simply carries the RD, VPN next-hop for BGP, and tunnel information (seen earlier). The BGP next-hop determines what the dynamic RT will be (shown shortly).

```
R8#show bgp ipv4 mvpn rd 213:7 | begin Network
      Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 213:7

      213.7.7.7                0    100    0 ?
*>i [3] [213:7] [10.2.7.2] [232.0.0.5] [213.7.7.7]/22
      213.7.7.7                0    100    0 ?
*> [7] [213:7] [213] [10.2.7.2/32] [232.0.0.5/32]/22
      0.0.0.0                32768 ?
```

Upon receiving it, CSR7 creates a Type 3 S-PMSI route that states it has a C(S,G) of (10.2.7.2, 232.0.0.5) reachable via PE 213.7.7.7. The tunnel type 2 indicates mLDP P2MP tree and the root is 213.7.7.7, which is not the same as the MP2MP root of 213.14.14.14 seen in the Type-1 I-PMSI messages. **The only reason CSR7 (ingress PE) generated this was because the ACL specified that this group was candidate for data MDT construction.** The Type 3 just informs egress PEs know about the existing P2MP tree.

```
R7#show bgp ipv4 mvpn vrf MC route-type 3 10.2.7.2 232.0.0.5 213.7.7.7

CSR8 then assigns the RD of CSR7 along with a dynamic RT so that only CSR7 imports it. Notice the RD on the Type 7 route below, along with the RT. This RT was learned via the regular VPNv4 unicast route as an

extended community. This is also true for ASM but is detailed here instead. No extra configuration is needed to VPNv4/v6 to enable this, as long as extended communities are supported (they must be).

```

A quick check of the VPN MRIBs on CSR8 and CSR7 confirm our understanding. CSR6 claims the C(S,G) entry was installed by having sent a BGP route (Type 7), and CSR7 indicates the entry was installed by

having received it from an interested receiver. This is indicated by the little ‘g’ and big ‘G’, respectively. CSR6 has joined a “data MDT”, meaning a specific tree built for this flow, and CSR7 is sending to this MDT. The data MDT directions are indicated by the big ‘Y’ and little ‘y’, respectively. CSR6’s RPF faces the PMSI interface while CSR7’s RPF faces the source. We know this is definitely not using the default MDT since the command shows an MDT ID of 1. Everything appears correct.

```
R6#show ip mroute vrf MC ssm
(10.2.7.2, 232.0.0.5), 1d01h/00:02:49, flags: sTIYg
  Incoming interface: Lspvif0, RPF nbr 213.7.7.7, MDT: [1, 213.7.7.7]/never
  Outgoing interface list:
    GigabitEthernet2.546, Forward/Sparse, 1d01h/00:02:49
```

```
R7#show ip mroute vrf MC ssm
(10.2.7.2, 232.0.0.5), 1d01h/stopped, flags: sTyG
  Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0
  Outgoing interface list:
    Lspvif0, Forward/Sparse, 1d01h/stopped
```

When CSR2 starts sending, there is no more BGP AD or c-mcast signaling that must occur, since the trees are already fully built. CSR7 reports sending traffic successfully out to the LSPvif.

```
R7#show ip mroute vrf MC 232.0.0.5 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 96, Packets received:
96
  Source: 10.2.7.2/32, Forwarding: 96/1/118/0, Other: 96/0/0
```

CSR6 and CSR8 also show it being sent towards their respective customers. Just for extra verification, I used EPC on egress on CSR6 to show the IP data being sent. Because it’s not encapsulated, we can see the nicely formatted IP addresses in the header without digging through the hex. I highlighted the IP protocol, source, and destination IP addresses as a sanity check.

```
R6#show ip mroute vrf MC 232.0.0.5 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 76, Packets received:
76

Next, we will test IPv6. The concepts are identical to IPv4 but for completeness, we will test it. First, I recommend checking to ensure there are no PIM neighbors over the PMSI. XRv appears stubborn here, so we will ignore that.

```

R1#show ipv6 pim vrf MC neighbor | begin ^Neighbor
Neighbor Address      Interface      Uptime      Expires      Mode DR pri
::FFFF:213.12.12.12   Lspvif0       1d03h       00:01:36 B G   DR 1

```

```

R5#show ipv6 pim vrf MC neighbor | begin ^Neighbor
Neighbor Address      Interface      Uptime      Expires      Mode DR pri
::FFFF:213.12.12.12   Lspvif0       1d03h       00:01:18 B G   DR 1

```

```

R6#show ipv6 pim vrf MC neighbor | begin ^Neighbor
Neighbor Address      Interface      Uptime      Expires      Mode DR pri
::FFFF:213.12.12.12   Lspvif0       1d03h       00:01:17 B G   DR 1

```

```

R7#show ipv6 pim vrf MC neighbor | begin ^Neighbor
Neighbor Address      Interface      Uptime      Expires      Mode DR pri
FE80::2               Gi2.527       1d09h       00:01:37 B G     1
::FFFF:213.12.12.12   Lspvif0       1d08h       00:01:15 B G   DR 1

```

```

R8#show ipv6 pim vrf MC neighbor | begin ^Neighbor
Neighbor Address      Interface      Uptime      Expires      Mode DR pri

Flags
::ffff:213.12.12.12*  1d08h       00:01:17 1          (DR)   P

```

A quick snapshot of the BGP IPv6 MVPN table is warranted. We check from CSR6; immediately we see far less information than we did for IPv4. The answer is twofold. First, the network is segmented with the top three PEs not having reachability to the bottom three PEs. Recall that these Type-1 I-PMSI routes have a standard unicast RT in accordance with the RT-export policies of the VRF. Normal RT rules dictate a router cannot accept VPN routes that are not imported locally. The debugs confirm this basic fact. Other dynamic RT's not destined to CSR6 are also rejected, but that is the normal operation for BGP c-mcast signaling.

```

R6#show bgp ipv6 mvpn vrf MC | begin Network
      Network          Next Hop          Metric LocPrf Weight Path

```

The table is also missing a Type-3 S-PMSI AD route for the SSM group FF33::1. This is potentially confusing, because for IPv4, once CSR7 received a Type-7 SPT join for the SSM group we tested, it immediately issued a Type-3 S-PMSI announcement. In this case, CSR6 receives a Type-7 indicating interest in C(S,G) pair (2001:10:4:6::4, FF33::1) but does not originate a Type-3 S-PMSI AD route. Again, this is because this particular IPv6 C(S,G) is not candidate for data MDT optimization per the ACL rules in the VRF. As a quick test, if we add the C-G to the ACL, even without clearing anything, CSR6 immediately creates a Type-3 S-PMSI route to announce the presence of an S-PMSI (specifically, a tunnel-type 2 mLDP P2MP transport) for this group.

```

213.12.12.12 100 0 i

```

Looking specifically at IPv6 SSM, both CSR2 and CSR3 originated C(S,G) joins towards their PEs requesting traffic for (2001:10:4:6::4, FF33::1). CSR7 and CSR8 both originated Type-7 SPT joins for this C(S,G) and sent it to XRv2, the RR. The RR picks CSR7 because it has a lower IGP cost to the BGP next-hop.

```

* i 213.8.8.8 0 100 0 ?

```

Looking specifically at this best-path on CSR6, we can see why CSR6 imported it. The dynamic RT assigned to the C-S is what CSR7 used to set the dynamic RT on the Type-7 route it advertised towards CSR6. This way, only CSR6 imports it. This behavior is protocol agnostic and is true for IPv4 and IPv6.

Before sending traffic, we can verify that the C-PIM control-plane is correct. The group is mapped to the I-PMSI, or the mLDP MP2MP tree, which explains the absence of any 'Y' or 'y' flags on these groups. The "data MDT" is not in use here. Again, the big 'G' means the entry was installed from having received a BGP Type 6 or 7 route. The little 'g' means the entry was installed from having sent one. Packets exit to the PMSI on CSR6 and enter from it on CSR7 and CSR8.

```

When CSR4 starts sending traffic, there is no Type-5 Source Active AD message. This is because the group is SSM and CSR6 has already received a Type-7 join for it. We can quickly verify if the traffic is working by checking the counters on CSR6, CSR7, and CSR8.

For variety, we will capture inbound on CSR7 facing the mLDP MP2MP root of XRv4. Even though this isn't the shortest path back to CSR6, we know that we are not using S-PMSI since no Type 3 routes exist within this MVPN instance anywhere currently. The incoming label is 0x1B5E (7006) which is the correct MDT 0 local downstream label allocated by CSR7 for the I-PMSI. I also highlighted the IPv6 source/destination addresses as proof.

```

```

Last, we will test IPv6 ASM. Since the ACL we defined under the VRF accounts for our ASM groups which use Embedded RP, at some point we expect to see some additional route types, like Type-3 and Type-5

floating around the network. Since CSR3 is the only router requesting multicast for this group, let's trace the signaling path quickly. CSR3 sends a C(*,G) join to CSR8 who advertises a Type 6 Shared Tree Join towards the C-RP, which is CSR2. Notice the little 'g' to signify the C(*,G) entry was installed due to having sent a BGP c-mcast signaling route. Also note that the "show" command for a Type 6 route asks for the "multicast source"; this is the C-RP address. The "RT-import" process is also shown for completeness.

```

XRv2 reflects this to CSR7, who imports it based on the dynamic RT that was set by CSR8, highlighted above. Again, CSR8 knows this because the ordinary VPNv6 unicast route to the RP contained this dynamic RT as an extended community when IPv6 MVPN AF was activated. The big 'G' on the C(*,G) state indicates this entry was installed due to having received a BGP Type-6 route.

```

CSR4 starts sending traffic to this group. The first thing that happens is that CSR6 sends a C-PIM register message to the C-RP, which is CSR2. Many of the routes are running “debug bgp ipv6 mvpn updates” and “debug ipv6 pim group FF7E:240:2001:10:2:7:0:1” for the upcoming verification.

```

R4#ping FF7E:240:2001:10:2:7:0:1 repeat 10000
Output Interface: GigabitEthernet2.546

```

```

! CSR6

2001:10:2:7::2

```

Upon receipt, CSR2 creates C(S,G) state and forwards the decapsulated register message down the shared tree towards CSR8. At present, CSR7’s path to CSR8 for multicast traffic using the I-PMSI (mLDP MP2MP tree), so these initial packets use this as transport. After some more register messages, CSR2 sends the register stop once the trees are built. CSR2 also sends a C(S,G) prune to CSR7 since CSR2 is not in the SPT transit path.

```

```

CSR7 adds C(S,G) state receiving the join from CSR2, and then sends a Type-7 SPT join to into the BGP network targeting CSR6. The entry uses the S-PMSI (data MDT).

```
R7#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 | begin \

RPF nbr: ::FFFF:213.6.6.6
Outgoing interface list: Null
```

CSR8 does the exact same thing, except it has a legitimate OIL. We will examine the debugging on CSR8 specifically. The traffic is detected on the I-PMSI, which was multicast coming down the shared tree which was originally encapsulated in the C-PIM register messages. CSR8 responds with a BGP Type-7 SPT join towards CSR6.

```

```

CSR6 receives one of the joins (XRv2 only forwards one, which is fine), creates a Type-5 Source Active message, under the assumption that a source behind it has started sending traffic. CSR7 and CSR8 will both install this in their BGP RIBs, but only CSR8 will bind it to the C(S,G) state entry.

```

CSR8 is informed about an available S-PMSI for this multicast flow by CSR6. The debugs reveal the contents of the S-PMSI route, which shows a tunnel-type 2 (mLDP P2MP) and a root of 213.6.6.6 in hex. CSR8 sends mLDP label mapping messages, not shown, to advertise its downstream label mappings to XRv4 and ultimately towards CSR6. When this process is complete, mLDP reports it via syslog.

```

```

A quick check of the C-MRIB state information on CSR6, CSR7, and CSR8 is warranted to ensure the proper flags are set. CSR6 is the root of the mLDP P2MP tree, which is why it specifies “MDT TX” in the C-MRIB state. The MDT ID is 2147483649, which is non-zero, indicating a P2MP tree. The ‘F’ flag means this router was the C-PIM DR responsible for registering sources with the C-RP. The little ‘y’ indicates that this router is sending (TX) to a data MDT tree. The big ‘G’ indicates this route was installed from having received a BGP Type 6/7 route (7 in this case). The little ‘q’ indicates that this router originated a Type 5 Source Active message for this C(S,G). The RPF information appears correct also; the device closest to the source, CSR6, points upstream towards the source, and the remote PEs point to the BGP next-hop towards the source over the S-PMSI that was built as a result of a Type-3 S-PMSI BGP message.

```
R6#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 | begin \
(2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1), 00:43:22/00:02:27, flags: SFTyGq
Incoming interface: GigabitEthernet2.546
RPF nbr: 2001:10:4:6::4
MDT TX nr: 2147483649 (0x80000001) LSM-ID: 0x5
Immediate Outgoing interface list:
Lspvif0, Forward, 00:43:22/never
```

CSR7 shows the MDT as part of the incoming interface, which makes sense. The big ‘Y’ is set to indicate having joined a Data MDT, and the little ‘g’ is set to indicate having installed this entry by sending a BGP Type 7 route.

```
R7#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 | begin \
(2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1), 00:43:40/00:02:12, flags: STYg
Incoming interface: Lspvif0, MDT: [2147483649 (0x80000001),
213.6.6.6]/never
RPF nbr: ::FFFF:213.6.6.6
Outgoing interface list: Null
```

CSR8 has the “Yg” flags like CSR7 but with an additional big ‘Q’, signifying that this entry is mapped to a Type 5 Source Active route for the same C(S,G). Because CSR7 doesn’t have an interested receiver, the Type-5 isn’t bound to the C(S,G) state. CSR7 remains joined on the SPT since the RP is behind it.

```
R8#show ipv6 mroute vrf MC FF7E:240:2001:10:2:7:0:1 2001:10:4:6::4 | begin \
(2001:10:4:6::4, FF7E:240:2001:10:2:7:0:1), 00:43:42/00:02:08, flags: SJTYgQ
Incoming interface: Lspvif0, MDT: [2147483649 (0x80000001),
213.6.6.6]/never
RPF nbr: ::FFFF:213.6.6.6
Inherited Outgoing interface list:
GigabitEthernet2.538, Forward, 03:11:51/never
```

Validating the packet counters shows us that forwarding appears to be working.

```

Because CSR7 joined the P2MP tree also, we expect it to be receiving traffic directly from XRv3 now, not XRv4, since the shortest path to the P2MP root is via XRv3. This is more optimal for bandwidth, but not for state. A quick capture inbound on CSR7 from XRv3 confirms this. We also verify the proper downstream label is used, which is 7010 (0x1B62). The source/destination addresses are also highlighted.

```

We also expect CSR8 to be receiving this flow. We will capture outbound on CSR8 within the VRF so we can see the raw IPv6 packets being forwarded to the customer without MPLS encapsulation. We clearly see the 0x86DD ethertype to represent IPv6. The IP protocol number is 0x3A which is 58 for IPv6 ICMP. The parser gives you some summarized information also.

Just to verify that the top routers have broken connectivity (and for extra review), we can clear BGP updates for IPv6 MVPN inbound on CSR5 and look at the debugs. The RT values on BGP AD routes (Types 1-5) are regular VPN RTs (213:6, etc) that CSR5 is not importing. The dynamic RT's apply only to BGP c-mcast signaling (Type 6-7) which are also not imported by CSR5 in this topology. I've grouped the BGP routes in order from 1 to 7 for easier reading. CSR5 cannot establish I-PMSI with CSR6, CSR7, or CSR8 due to the Type-1 routes not being imported.

```

The Type-3 S-PMSI route and Type-5 Source Active are also not imported since CSR5 does not have unicast reachability to CSR6, so it doesn't make sense to import it. The RT is the same as the Type-1 routes shown above.

The BGP c-mcast signaling routes use the dynamic RTs. Seeing these rejected can be normal in many cases since the RT specifically targets a device for a C(*,G) or C(S,G) Join. The prune is expressed by withdrawing these messages.

Last, we will examine OAM for MP2MP and P2MP trees in this profile. Unlike Profile 12 where we were limited only to unidirectional P2MP trees (the root specified had to be local), with MP2MP pings we can test from any endpoint; the tree is bidirectional. We specify the FEC and opaque type and can quickly discover all the endpoints in the MVPN on this MDT.

```
R6#show mpls mldp database summary
```

We can also check the S-PMSI P2MP tree to CSR7, but to do so, we have to test it from CSR7. We should be able to verify connectivity to CSR6 and CSR8 since they have joined this P2MP tree. CSR6 is also the root of another P2MP tree but for brevity, we do not verify that.

Additional Reading – Reference configurations “mvpn-13”

28.12 Profile 14: Partitioned MDT – MLDP P2MP – BGP-AD – BGP C-mcast signaling

For this test, begin with the MVPN Profile 12 configuration where all of the MVPN BGP AD is set up already, plus the P2MP trees are built (no MP2MP trees anywhere). We need to make sure the MDT trees are “partitioned” (described later) versus “default”. We also need to enable a “strict” RPF check (described later). Removing the default MDT also removes the data MDT configuration, so it must be added again.

```
! Basic XE configuration to enable partitioned MDT
vrf definition MC
  address-family ipv4
    no mdt default mpls mldp p2mp
    mdt partitioned mldp p2mp
    mdt data mpls mldp 10 list ACL_DATA_MDT immediate-switch
    mdt strict-rpf interface
  address-family ipv6
    no mdt default mpls mldp p2mp
    mdt partitioned mldp p2mp
    mdt data mpls mldp 10 list ACL_DATA_MDT_IPV6 immediate-switch
    mdt strict-rpf interface

route-policy RPL_MLDP
  set core-tree mldp-partitioned-p2mp
end-policy
```

BGP-AD is used to more aggressively shape what traffic is allowed to traverse the core so as to minimize flooding multicast to PEs with no interest. Specifically, there are many Type-3 S-PMSI routes that use wildcards now. A Type-3 can specify C(*,G) or C(*,*) wildcards. This is accomplished by setting the length

field to 0 in the S-PMSI route. A quick look at CSR6 shows some of these new routes. Notice that all six PEs originated a C(*,*) route saying that they are willing to construct S-PMSI trees for any multicast flow.

```
R6#show bgp ipv4 mvpn vrf MC | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
*>i  [3] [213:6] [*] [*] [213.1.1.1]/14

      213.5.5.5      0      100      0 ?
*>i  [3] [213:6] [10.2.7.2] [232.0.0.5] [213.7.7.7]/22
      213.7.7.7      0      100      0 ?
```

This output shows us all three possible combinations: C(S,G), C(*,G), C(*,*). The C(S,G) is something we have seen before and this shows a router (CSR7 in this case) advertising that it is capable of delivering traffic to this C(S,G) via an S-PMSI. The same logic is true for the remaining two variations; all of them are candidates for S-PMSI tree construction. The partitioned nature of this MVPN profile means that trees are built-on demand, which means the concept of I-PMSI isn't appropriate. We can even see that CSR5 has originated an entry for group 224.0.0.13, the All-PIM-Routers group. This exists so CSR5 can distribute the BSR messaging from CSR10. The lack of an I-PMSI in general implies that we will see much more S-PMSI state as a result.

Because BSR is being distributed to all nodes (presumably), CSR5 should have an S-PMSI tree rooted at itself to serve this control traffic. We can check the mLDP database summary, but this doesn't tell us which tunnel is used for distributing this information. The BGP Type-3 C(*,224.0.0.13) route should tell us the tunnel information. Anyone importing RT 213:5 should show interest in this. We see it is a type 2 mLDP P2MP tunnel with GID value 0x1FFFF rooted at CSR5. A quick OAM check shows us that everyone else has joined this delivery tree.

First, we will test IPv4 SSM, since it already has a Type3 C(S,G) S-PMSI route in the network. CSR7 originated this because CSR2 is the source. CSR6 and CSR8 originated Type-7 SPT joins towards CSR7, and XRv2 picked CSR6 as best-path due to the IGP metric being lower. As long as CSR7 receives one of them, that is enough. CSR7 imports the route based on its dynamic RT matching the VPNv4 MVPN RT assigned locally. This is how CSR7 knows that the Type-7 join is destined for it.

```

We can verify the PMSI binding in two ways. We can check the BGP Type-3 C(S,G) route to look at the tunnel opaque information, or we can look at the C-MRIB details. Both are shown below. The MDT is 0x10001 (65537) which is carried in the BGP route. The C-MRIB uses this for delivering the packet to the PMSI. The little 'y' and big 'G' mean the entry is sending to a data MDT (this group is permitted by the ACL) and was installed upon receipt of a BGP Type-7 route, respectively.

R7#show bgp ipv4 mvpn vrf MC route-type 3 10.2.7.2 232.0.0.5 213.7.7.7

```

Now that we know the tunnel being used, we will send traffic from CSR2. There should be no change in the BGP control-plane at this point as the S-PMSI and C-PIM delivery trees are complete. We will verify the C-MRIB state and packet counters concurrently on the relevant PEs. Looking at the egress PEs, they claim they are receiving traffic from a data MDT (big 'Y') and had the C-MRIB entry installed by having sent a BGP Type-7 route (little 'g'). Traffic arrives from the PMSI on the egress devices and is sent to the PMSI from the ingress device.

A quick OAM ping can tell us who else is attached to the S-PMSI. It should only be CSR7 and CSR8. Additionally, we look at the downstream label mappings and expect to see replication towards XRv3 and XRv4. EPC proves this; the decimal label mappings in the show command match what EPC captured.

We progress to IPv6 SSM. The pair C(2001:10:4:6::4, FF33::1) is not candidate for data MDT treatment but still technically travels along a P2MP S-PMSI path. CSR2 and CSR3 are receivers, so CSR7 and CSR8 both originate Type-7 SPT joins towards the ingress PE, CSR6. XRv2 (RR) sees both routes. When we look at the paths, we can see the dynamic RT applied. This value was derived from CSR7's VPNv6 route for the C-S. XR calls this the "VRF Route import", but it's the same as the MVPN RT shown in XE. This is the mechanism by which a receiver PE targets a sender PE.

Notice that CSR6 is not originating a specific Type-3 S-PMSI route for this specific C(S,G). The group is not candidate for data MDT optimization and thus will match the next most specific Type-3 route for tunnel binding, which is the C(*,*). CSR6 originates this and identifies the GID as 0x20000 (131072 in decimal). The tunnel is mLDP P2MP (type 2) and it is rooted at CSR6, as expected.

```

Using OAM, we can quickly test for leaves in this delivery tree, despite the “double wildcard” nature of this tunnel. Only CSR7 and CSR8 respond, and this is technically still S-PMSI operation since I-PMSI tunnels are not in use. In fact, the BGP Type-1 I-PMSI routes aren’t even carrying PMSI attributes at all.

Before sending traffic, we quickly validate the C-PIM signaling at the ingress/egress PEs. We don't see any 'y' or 'Y' flags since this group is not using data MDTs. We do see 'g' flags on the egress PE's to signify that these C-MRIB entries were installed as a result of having sent a BGP Type-7 SPT join. Conversely, the ingress PE shows a big 'G' to signify that the entry was installed by receiving the route. Forwarding-wise, the ingress PE forwards towards the PMSI while the egress PEs accept traffic incoming from the PMSI.

```

R6#show ipv6 mroute vrf MC FF33::1 2001:10:4:6::4 | begin \

```

Next, we will check the PMSI tunnel binding and mLDP P2MP tree. Both CSR7 and CSR8 import the Type-3 S-PMSI C(*,*) route from CSR6. We saw the GID earlier as being 131072 and we know the root is CSR6; we craft a regex to match this specific P2MP tree and view it based on the LSM-ID. As such, LSM packets should be arriving on CSR7 and CSR8 using the downstream labels allocated by those egress PEs.

```
R7#show mpls mldp database summary | include 213.6.6.6.*131072
29          P2MP      213.6.6.6          [gid 131072 (0x00020000)]      1
```

```
R7#show mpls mldp database id 29 | section Upstream

    Local Label (D) : 8017            Next Hop     : 213.8.14.14
```

We can reasonably assume traffic is entering by using the LFIB counters. A more thorough examination would use EPC, capturing incoming traffic on those upstream facing links for each PE (CSR7 captures facing XRv3 and CSR8 captures facing XRv4). CSR7 shows label 0x1B68 (7016) and CSR8 shows label 0x1F51 (8017) entering from the SP core.

Next, we examine IPv4 ASM. As always, this model of multicast (in general) is much more complex than SSM both in terms of signaling and forwarding. First, we verify that the C-RP has the C(*,G) join having derived it from the Type 6 Shared tree join received by the PE in front of the C-RP (CSR5). The big 'G' on CSR5's C(*,G) entry means that the route was installed from having received a Type-6 shared tree join. I also show the dynamic RT matching between the unicast VPNv4 route and the BGP Type-6 route.

When CSR2 starts sending, CSR7 registers the C(S,G) with the RP. It also sends a C(*,G) prune for the specific C-S back towards the RP. The C-RP will send a C(S,G) join towards CSR5. Upon receipt, CSR5 updates its C-MRIB and translates this C-PIM join into a BGP Type-7 SPT join towards CSR7. We also see the MDT was changed from null to E, so this is the LSM-ID that the flow currently uses on CSR5.

```

len left = 0
```

XRv2 collects all of these routes, selects the best-path (doesn't matter which one), and reflects it to CSR7. Since they all have the same "RT import", CSR7 can import any of them, as it is the target of the C(S,G) join. XRv2 selected CSR5's join as best.

```

[snip]
```

CSR7 receives this best-path Type-7 route from XRv2 (originated from CSR5) and imports it to the VRF since the "RT import" (dynamic RT) is targeting CSR7. The PIM process interprets the C(S,G) information and begins forwarding native multicast towards the PMSI. Finally, since CSR7 is now aware that there must be a source behind it, it originates a Type-5 Source Active message to notify other PE's of an active source. PE's that come online and request multicast later can use this, since the C(S,G) entry will be in the C-MRIB when a Type-5 is received, even without receivers.

```

```

At this point, egress PEs can receive traffic. As an optimization, the C-RP prunes itself from the shared tree when it realizes it is not in the transit path. CSR5 receives this prune message and removes the customer LAN from the forwarding tree. The C-RP only does this after telling the DR (CSR7) to stop registering the C(S,G). CSR7 also notices that the C(S,G) is not candidate for data MDT treatment.

```

! CSR7
PIM(1): Received v2 Register-Stop on GigabitEthernet2.574 from 10.5.10.10
PIM(1): for source 10.2.7.2, group 225.0.0.1
PIM(1): Removing register encap tunnel (Tunnel2) as forwarding interface of
(10.2.7.2, 225.0.0.1).
PIM(1): Clear Registering flag to 10.5.10.10 for (10.2.7.2/32, 225.0.0.1)
PIM(1): MDT ACL not matched for (10.2.7.2,225.0.0.1)

! CSR5
PIM(1): Received v2 Join/Prune on GigabitEthernet2.550 from 10.5.10.10, to us
PIM(1): Prune-list: (10.2.7.2/32, 225.0.0.1)
PIM(1): Prune GigabitEthernet2.550/225.0.0.1 from (10.2.7.2/32, 225.0.0.1) -
deleted

```

Quickly verifying the C-MRIB entries on all relevant PEs, we see the signaling is working. There is some awkwardness in this output since we now have many LSPvif interfaces (enumerations are numbers greater than 0 on some routers). This is due to the partitioned nature of the MVPN profile; it is also the reason for needing the “strict” RPF check because now there are multiple interfaces representing the PMSI. The ingress PE (CSR7) shows the familiar ‘G’ flags to indicate receiving a BGP Type-7 route and originator a Type-5 Source Active. The egress PEs (CSR1, CSR7, CSR8) show ‘gQ’ to indicate the inverse of what was just stated; BGP joins were advertised while Source Actives were received. CSR5’s output shows traffic entering and exiting the PMSI in hairpin fashion; we will look at this shortly.

A quick check of packet counters shows that the traffic appears to be working somewhat poorly. We see tons of RPF failures (50% of the traffic) and many more packets arriving than we should on most of the egress PEs. CSR8 appears to be the exception. I suspect this has something to do with CSR5 hairpinning traffic back into the network.

```

Strange situations like this warrant more detailed verification. We begin at CSR7 to trace the S-PMSI tree used for delivering this flow. Through a quick process of elimination, we don't see a C(S,G) or C(*,G) Type-3 route, so the C(*,*) matches. The tunnel GID is 0x1000 (65536), is rooted at CSR7, and is an mLDP P2MP tunnel.

```

XRv3 replicates the traffic to CSR5, CSR6, and XRv2. It is interesting to note that suddenly XRv2 wants the traffic; this is technically correct since XRv1 is joining the group, but BGP c-mcast signaling did not actually make a Type-7 join. I believe this is an XRv-specific behavior. XRv4 replicates the traffic to CSR1 and CSR8. Because we know CSR1, CSR6, CSR8, and XRv2 are legitimate endpoints, we won't trace the tree farther in those directions. I am more curious about what is happening at CSR5.

```

```

CSR5's LFIB claims that the packet is being decapsulated and send to the customer. I suspect that the traffic is actually being re-encapsulated and sent down CSR5's S-PMSI C(*,*) tree to other spokes. Earlier debug output told us that LSM-ID "E" was used by CSR5 to send traffic downstream initially while the SPT was under construction. This reveals labels 93000 and 94013 used for downstream traffic.

Using EPC outbound on CSR5's links, we can see if CSR5 is sending LSM originally sourced at CSR2 back down into the network. We can clearly see that is the case; notice the IP header information shows traffic from 10.2.7.2 to 225.0.0.1. The labels 0x16F3B and 0x16B48 are 94013 and 93000, respectively. This is a highly undesirable situation.

```

```

A quick OAM check will reveal all the endpoints of this tree. This explains why we saw RPF failures on every node except CSR8; every other node is joined to CSR5's tree which means duplicate packets are being received. Considering CSR8 has an identical configuration as CSR6, I cannot explain this behavior, but at least the result of the behavior is predictable.

My speculation is that because a partitioned MDT is in use, traffic received by CSR5 is send back into the network because CSR5 still has a Type-6 Shared Tree join towards the C-RP. That never gets pruned unless the PE's have no more end hosts that send IGMP joins for the ASM groups in question. The traffic is not following the C(*,G) entry because the C(S,G) exists, but I don't believe the MDT is smart enough to assume anything, even though the active source is behind CSR7 (CSR5 knows it from the Type-5). The logic still doesn't explain why CSR8 is not part of this delivery tree.

```

A hard-clear of BGP IPv4 MVPN makes CSR8 join the tree, so I am assuming are some race conditions behind the scenes. We can now see the RPF failures on CSR8 as well as the OAM results from CSR5.

Many of the routers (ingress and egress PE) are also complaining about coordination issues between the PIM and MRIB processes. I don't pretend to understand this, but I would say this feature is still somewhat tricky.

```

In summary, partitioned MDTs seem best deployed when paired with SSM. Only S-PMSI is used (XE only supports P2MP trees while XR supports MP2MP and P2MP trees) with wildcards in the BGP Type-3 routes to direct traffic into certain P-tunnels. If the C-RP is not in the same site as the sources when using ASM, you can end up with duplicated traffic in the network as I have illustrated above.

Additional Reading – Reference configurations “mvpn-14”

28.13 Profile 17: Default MDT – MLDP P2MP – BGP-AD – PIM C-mcast signaling

For this test, begin with the MVPN Profile 12 configuration where all of the MVPN BGP AD is set up already, plus the P2MP trees are built (no MP2MP trees anywhere). All we need to do is remove BGP c-multicast signaling and use PIM instead. The I-PMSI P2MP trees will still exist due to BGP AD, but we will never see Type 6 or 7 routes in this test.

```
! Basic XE configuration to disable BGP (enable PIM) c-mcast signaling
vrf definition MC
  address-family ipv4
    no mdt overlay use-bgp
  address-family ipv6
    no mdt overlay use-bgp

! Basic XR configuration to disable BGP (enable PIM) c-mcast signaling
router pim
  vrf MC
    address-family ipv4
      no mdt c-multicast-routing
    address-family ipv6
      no mdt c-multicast-routing
```

We will verify CSR1 as a sanity check. It still has all the appropriate I-PMSI P2MP trees, as well as the appropriate BGP AD routes. Specifically, it has Type-1 I-PMSI routes from all PEs for IPv4, and only the “north-side” routers for IPv6. The Type-3 S-PMSI route is an AD message originated from CSR7 to allow PEs with interested receivers for this C(S,G) to join this S-PMSI P2MP tree.

We also expect to see a “full-mesh” of C-PIM neighbors over the I-PMSI. In the interest of brevity, we will check CSR6 and XRv2 for extra validation, then continue with the test.

R1#show ip pim vrf MC neighbor | begin ^Neighbor

Because C-PIM signaling is used, we expect to see C(*,G) joins making their way through the PMSI towards the C-RP, with C(S,G) SSM joins making their way towards their respective C-S. In this case, CSR10 is the R-CP which should have the (*, 225.0.0.1) join. CSR2 is an SSM source, which means CSR7 should have the (10.2.7.2, 232.0.0.5) join.

Outgoing interface list:

Lspvif0, Forward/Sparse, 22:22:54/00:02:56

The output on CSR7 indicates that this group is “sending” to an MDT data group (little ‘y’ flag). We can find out the S-PMSI tunnel binding by checking the BGP-AD messages for a matching Type-3 associated with this C(S,G). CSR7 originated this Type-3 S-PMSI route to tell other PEs about this C(S,G). The tunnel-type 2 field means this is an mLDP P2MP tunnel and the root is 213.7.7.7 (0xD5070707). The MDT number is 65537 (0x10001).

```

R7#show bgp ipv4 mvpn vrf MC route-type 3 10.2.7.2 232.0.0.5 213.7.7.7

```

Using the “verbose” modifier, we can see the binding between the S-PMSI and the C(S,G) MRIB entry. The little ‘p’ means that it was signaled from a C-PIM join, which is expected.

```

R7#show ip mroute vrf MC 232.0.0.5 10.2.7.2 verbose | begin \((
(10.2.7.2, 232.0.0.5), 22:37:25/00:03:08, flags: sTyp

```

When CSR2 starts sending traffic, it will be delivered to all endpoints of the P2MP tree. We could trace the tree to verify, but since that has been demonstrated many times, I will use show commands on CSR6 and CSR8. If the GID is 65537 is it highly likely this is part of the same mLDP P2MP tree.

```

R6#show mpls mldp database summary | include 65537
23          P2MP      213.7.7.7          [gid 65537 (0x00010001)]      1

R8#show mpls mldp database summary | include 65537
22          P2MP      213.7.7.7          [gid 65537 (0x00010001)]      1

```

We quickly verify the C-MRIB entries on CSR6 and CSR8. The RPF interface is the PMSI (MDT is shown without the verbose keyword here) and OIL includes the customer LAN. The big ‘Y’ indicates that these routers have “joined” a Data MDT.

```

R6#show ip mroute vrf MC 232.0.0.5 10.2.7.2 | begin \((
(10.2.7.2, 232.0.0.5), 22:42:35/00:02:26, flags: sTIY

```

We will quickly trace the LSPs that make up the P2MP tree used for this flow. We will use a different method this time; we know that P2MP trees are unidirectional (downstream only) and are receiver-driven, but we can still verify it from the root downwards. On CSR7, we will check the downstream labels learned from XRv3 and XRv4. CSR7 should use labels 93015 and 94020 for XRv3 and XRv4 respectively when sending traffic down this tree.

```
R7#show mpls mldp database opaque_type gid 65537 | section Replic
```

Replication client(s):

MDT (VRF MC)

Uptime : 22:48:55 Path Set ID : None

Interface : Lspvif0

213.14.14.14:0

Uptime : 22:48:55 Path Set ID : None

Out label (D) : 94020 Interface : GigabitEthernet2.574*

Local label (U): None Next Hop : 213.7.14.14

213.13.13.13:0

Uptime : 22:48:42 Path Set ID : None

Out label (D) : 93015 Interface : GigabitEthernet2.573*

Local label (U): None Next Hop : 213.7.13.13

Using EPC on CSR7 outbound concurrently on both core links, we can verify the packets are actually using the labels we just traced. Assuming the root node pushes the right MVPN label onto the packet, the core routers will perform swap operations until it gets to the leaves. Notice the identical timestamps, source MAC address, and IP header information. This is the router performing replication as expected. The labels are highlighted (93015 and 94020) which are the downstream labels for XRv3 and XRv4.

Next, we will examine the more complex ASM setup. CSR10 is the R-CP, so when CSR2 starts sending traffic, CSR7 will register this C(S,G) with the C-RP. CSR10 decapsulates the payload and sends this traffic down the C(*,G) tree towards CSR6 and CSR8.

```
! CSR7
PIM(1): Check RP 10.5.10.10 into the (*, 225.0.0.1) entry
PIM(1): Building Triggered (*,G) Join / (S,G,RP-bit) Prune message for
225.0.0.1
PIM(1): Adding register encap tunnel (Tunnel2) as forwarding interface of
(10.2.7.2, 225.0.0.1).
```

```
! CSR10
PIM(0): Received v2 Register on GigabitEthernet2.550 from 10.2.7.7
for 10.2.7.2, group 225.0.0.1
PIM(0): Adding register decap tunnel (Tunnel1) as accepting interface of
(10.2.7.2, 225.0.0.1).
PIM(0): Insert (10.2.7.2,225.0.0.1) join in nbr 10.5.10.5's queue
PIM(0): Building Join/Prune packet for nbr 10.5.10.5
PIM(0): Adding v2 (10.2.7.2/32, 225.0.0.1), S-bit Join
PIM(0): Send v2 join/prune to 10.5.10.5 (GigabitEthernet2.550)
```

CSR5 receives that join from CSR10 and sends it towards the C(S,G), CSR7. CSR7 then updates the MDT in use from 0 (null in this case, since there is no MP2MP default MDT) to LSM-ID 0x17. We can see this is the I-PMSI P2MP tunnel rooted at CSR7, which is correct.

```
! CSR5
PIM(1): Received v2 Join/Prune on GigabitEthernet2.550 from 10.5.10.10, to us
PIM(1): Join-list: (10.2.7.2/32, 225.0.0.1), S-bit set
PIM(1): Add GigabitEthernet2.550/10.5.10.10 to (10.2.7.2, 225.0.0.1), Forward
state, by PIM SG Join
PIM(1): Insert (10.2.7.2,225.0.0.1) join in nbr 213.7.7.7's queue
PIM(1): Building Join/Prune packet for nbr 213.7.7.7
PIM(1): Adding v2 (10.2.7.2/32, 225.0.0.1), S-bit Join
PIM(1): Send v2 join/prune to 213.7.7.7 (Lspvif0)
```

```
! CSR7
Received v2 Join/Prune on Lspvif0 from 213.5.5.5, to us

      rx pathid: 0, tx pathid: 0x0
```

At this point CSR7 can start sending native multicast traffic down the C(S,G) tree. The C-RP will want to see traffic on the SPT before telling the DR to stop registering. Once it does, we see the big 'T' flag to indicate having seeing traffic along the SPT. The C-RP then issues a prune for this C(S,G) towards CSR5 as it no longer wants the traffic. It also sends a register-stop to the DR (CSR7) so that router stops sending both unicast-encapsulated traffic inside register messages and native multicast concurrently. Notice that CSR7 also tells us that this group will continue to use the default MDT since there was no match in the data MDT ACL.

```
R10#show ip mroute 225.0.0.1 10.2.7.2 | begin \

PIM SG Join
```

Unlike some other examples, no Type-5 Source Active route is created. Although technically an AD route, the Type 5 is mostly to inform other PEs of an active source when BGP c-mcast signaling is in use. There has been no change in BGP AD signaling since CSR2 started sending traffic. No Type-3 was generated by CSR7 since this group is not candidate for S-PMSI treatment.

We can verify the C-MRIB entries for this C(S,G) on all receiver PEs. Because these all use the I-PMSI, there is no special MDT for them, and thus they do not reveal any MDT details, even with the “verbose” command. Only CSR7, the ingress PE, reveals some MDT information. It’s also clear that the ingress PE sends traffic out the PMSI while the egress PEs receive it from the PMSI.

```

Note that the PE facing the R-CP also forwarded a few multicast packets before it was pruned. This is why the 'T' flag is set on the C(S,G). Another 818 packets were dropped due to having a null OIL; since I-PMSI is used, all the PEs will receive this traffic, including CSR5 and XRv2.

```
R5#show ip mroute vrf MC 225.0.0.1 10.2.7.2 verbose | begin \((
(10.2.7.2, 225.0.0.1), 00:32:29/00:02:54, flags: PTX

Source: 10.2.7.2/32, Forwarding: 2/0/122/0, Other: 821/1/818
```

We already determined that the LSM-ID of the I-PMSI for this MVPN is 17 (on CSR7, at least). We will use that to look at the mLDP bindings to see the downstream labels. Traffic towards XRv3 uses label 93011 while traffic to XRv4 uses label 94015.

```
R7#show mpls mldp database id 17 | section Replic

```

Using the same EPC configuration on CSR7, we verify the LSM leaving CSR7's upstream interfaces. We can see the proper labels encoded in hex below. Again, the timestamps, source MAC address, and IP payload are identical as CSR7 is replicating this traffic. These labels are different than the ones used for the IPv4 SSM flow (10.2.7.2, 232.0.0.5) so we know we are using a different delivery tree.

```
R7#show monitor capture CAP buffer detailed

```

For brevity, we will check the LFIBs of XRv3 and XRv4 and move on. Because this is the I-PMSI tree, the traffic is delivered to all PEs. We can also see that CSR5 selected XRv3 as the preferred path to CSR7 (ECMP). This is where it sent its label mapping message.

```
RP/0/0/CPU0:XRv3#show mpls forwarding labels 93011

```

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94015
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94015	1011	MLDP: 0x0001a	Gi0/0/0/0.514	213.1.14.1	0
	8017	MLDP: 0x0001a	Gi0/0/0/0.584	213.8.14.8	0

Last, we will test IPv6 SSM. This does not have an S-PMSI associated with it, so we expect it to use the I-PMSI tunnel rooted at CSR6. We can verify this by checking the BGP AD information. There are no Type-3 routes anywhere in the “south-side” of the IPv6 MVPN network.

```
R6#show bgp ipv6 mvpn vrf MC | begin Network
```

Network	Next Hop	Metric	LocPrf	Weight	Path
Route Distinguisher: 213:6 (default for vrf MC)					
*> [1] [213:6] [213.6.6.6]/12					
	::			32768	?
*>i [1] [213:6] [213.7.7.7]/12					
	213.7.7.7	0	100	0	?
*>i [1] [213:6] [213.8.8.8]/12					
	213.8.8.8	0	100	0	?

Verifying the current C-MRIB information, we can see the C(S,G) tree has already been built within an RP for (2001:10:4:6::4, FF33::1). Traffic enters CSR6 from the customer (CSR4) and goes to the PMSI, and the receivers accept traffic from the PMSI and deliver to remote customers.

```
R6#show ipv6 mroute vrf MC FF33::1 | begin \((
(2001:10:4:6::4, FF33::1), 23:59:45/00:02:57, flags: sT
Incoming interface: GigabitEthernet2.546
RPF nbr: 2001:10:4:6::4
Immediate Outgoing interface list:

```

```
R8#show ipv6 mroute vrf MC FF33::1 | begin \((
(2001:10:4:6::4, FF33::1), 00:00:04/never, flags: sTI
Incoming interface: Lspvif0
RPF nbr: ::FFFF:213.6.6.6
Immediate Outgoing interface list:
GigabitEthernet2.538, Forward, 00:00:04/never
```

CSR4 begins sending traffic and we check the packet counters.

```
R4#ping FF33::1 repeat 10000
Output Interface: GigabitEthernet2.546

R6#show ipv6 mroute vrf MC FF33::1 count | include HW
  HW Forwarding: 22/0/118/0, Other: 0/0/0

R7#show ipv6 mroute vrf MC FF33::1 count | include HW
  HW Forwarding: 30/0/126/0, Other: 0/0/0

R8#show ipv6 mroute vrf MC FF33::1 count | include HW
  HW Forwarding: 24/0/126/0, Other: 0/0/0
```

To determine the outgoing label, we can look at the tunnels rooted at CSR6 with a GID of 65536. We know that is the I-PMSI from this MVPN as it was shown many times earlier as the opaque information inside the BGP Type-1 I-PMSI route. We will check the database to extract the LSM-ID. CSR6 sends LSM to XRv3 using label 93002.

```
R6#show mpls mldp database summary | include 213.6.6.6.*65536
17      P2MP      213.6.6.6      [gid 65536 (0x00010000)]      2

R6#show mpls mldp database id 17 | section Replic
Replication client(s):
  MDT   (VRF MC)
    Uptime      : 1d00h          Path Set ID   : None

    Local label (U): None        Next Hop      : 213.6.13.13
```

We can see that XRv3 replicates this along the I-PMSI towards XRv2, CSR5, XRv4, and CSR7. CSR5 and CSR7 are receivers and do not forward it on, while XRv4 replicates it towards CSR1 and CSR8. Only CSR7 and CSR8 really needed the traffic, so S-PMSI could have optimized the bandwidth usage here (at the expense of state). Because there are few receivers but many PEs, using the I-PMSI for this flow is highly inefficient.

```
RP/0/0/CPU0:XRv3#show mpls forwarding labels 93002
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched

	8016	MLDP: 0x00019	Gi0/0/0/0.584	213.8.14.8	0

Last, we test OAM. I described earlier how there is no easy keyword for GID in XE, so we have to manually specify the opaque type of 0x01 in hexadecimal. By specifying the root of the LSP, and also testing this from the root (tree is unidirectional and downstream), we can quickly see all of the endpoints. This tests the LSPs for any oddities that may occur in the path. From CSR1, we will test the IPv4 and IPv6 I-PMSI tunnels. Notice that the IPv4 one has 5 peers while the IPv6 only has 2, due to VPNv4/v6 topology differences. I also quickly test the IPv4 S-PMSI for the SSM group from the root, CSR7. Notice that the opaque value changes to reflect the different GID.

```

Additional Reading – Reference configurations “mvpn-17”

29. Describe and optimize multicast scale and performance

29.1 Inter-AS Multicast and Multicast Source Discovery Protocol (MSDP)

This section uses a large BGP topology with multiple ASes to demonstrate how multicast can flow across Internet boundaries. The basic topology is shown below. AS 7 and AS 9 use route-reflection to reduce the number of iBGP peerings, while AS 8 and AS 11 do not because they contain only 2 routers each. Every BGP peering negotiates four AFIs: IPv4 unicast, IPv4 multicast, IPv6 unicast, and IPV6 multicast. This allows us to quickly adjust the path attribute, next-hops, and other features without having to change the BGP topology mid-stride. Each AS also uses its own IGP or set of IGPs to achieve reachability for IPv4 and IPv6 as shown in the diagram.

Before doing any advanced MSDP or multicast configuration, we will verify the configurations. The basic configuration is very long only because there are many protocols running, but there is nothing complex yet. As an example, I show the BGP configurations on CSR10 and XRV1 only. I create a pair of peer groups (XR neighbor-groups) for IPv4 and IPv6 peers; an alternative approach would be peer-session and peer-policy templates. IPv4 unicast and IPv4 multicast are enabled on the "IBGP" group with IPv6 unicast and IPv6 multicast enabled on the "IBGPV6" group. I chose to show CSR10 and XRV1 because they are the route-reflectors within their respective AS boundaries and would have the most interesting configuration. Notice there are no advanced features configured, and I do not show the IGP configuration because it is very simple.

Because all of the IPv4 BGP sessions use IPv4 peer loopbacks, and all of the IPv6 BGP sessions use IPv6 peer loopbacks, we can simply verifying BGP sessions being up rather than verify IGP reachability. The BGP sessions wouldn't be up if IGP was dysfunctional within any AS for IPv4 or IPv6. For brevity, I copy/paste the commands below on all BGP speakers. I only show some of the output (XRv1 and CSR10) for brevity. The benefit of the speeding verification approach is that the commands are valid on XE and XR platforms.

```

```

At this point, all test host routers (CSR1 through CSR4) should be able to ping one another. Using a TCL script, I test this quickly on these four routers (ping results not shown for brevity).

```

! CSR1 through CSR4
tclsh
foreach i {
9.2.5.2
7.1.7.1
8.3.8.3
11.4.13.4
} { ping $i timeout 1 repeat 3 }

```

Additionally, all BGP loopbacks should have reachability between one another. This will be important for the MSDP testing later. We will initiate this from the XE BGP speakers only, but that will give us a good picture as to which loopbacks are reachable since we can probe the XR loopbacks as well.

```

! All XE BGP speakers
tclsh
foreach i {
7.0.0.7
7.0.0.11
7.0.0.14
8.0.0.12
8.0.0.8
11.0.0.9
11.0.0.13
9.0.0.5
9.0.0.10
9.0.0.6
} { ping $i timeout 1 repeat 3 source loopback 0 }

```

PIMv2 is enabled on all interfaces in the topology except for on the four test hosts. We can quickly test this by looking at the IPv4 and IPv6 PIM neighbors by using copy/paste again. This is critical for multicast transport, and PIM must also be enabled on all inter-AS transit links for multicast to flow between AS boundaries.

```

Next, we will configure the rendezvous points (RP). Each AS has at least one RP to support PIM sparse mode (PIM-SM). Routers not contained with the AS boundaries are used to simulate hosts that can send and receive multicast traffic. Rather than simulate this using router loopbacks, this lab will try to make the testing more realistic by having PIM designed routers (DR) perform their natural roles on the LAN segments they serve. AS 7 uses PIM bootstrap router (BSR) which is built into PIMv2; XRv1 is the RP for that AS. AS 9 uses Cisco's AutoRP which was used in PIMv1 for RP discovery and dissemination; CSR10 is the RP for that AS. AS 8 and AS 11 use the static RP method given their small size. CSR9 is the RP for AS 11 and XRv2 is the RP for AS 8. Because the focus of this lab is inter-AS multicast and MSDP, we will not be examining all of the advanced PIM features here. I configure the RPs for IPv4 only; IPv6 inter-AS multicast is a very different topic and is examined later.

```
! XRv1
router pim
 address-family ipv4
   bsr candidate-bsr 7.0.0.11 hash-mask-len 30 priority 1
   bsr candidate-rp 7.0.0.11 priority 192 interval 60
```

```
! CSR10
ip pim autorp listener
ip pim send-rp-announce Loopback0 scope 1
ip pim send-rp-discovery Loopback0 scope 2
```

```
! CSR6 and CSR5
ip pim autorp listener
```

```

! CSR9
ip pim rp-address 11.0.0.9

! XRv3
router pim
 address-family ipv4
   rp-address 11.0.0.9

! XRv2
router pim
 address-family ipv4
   rp-address 8.0.0.12

! CSR8
ip pim rp-address 8.0.0.12

```

First, we will verify the routers in AS 7 have all learned the RP through BSR. In this case, the RP and BSR address is 7.0.0.11; I highlight the RP address in yellow and the BSR address in green. This is straightforward with no surprises.

```

R7#show ip pim rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4
  RP 7.0.0.11 (?), v2
    Info source: 7.0.0.11 (?), via bootstrap, priority 192, holdtime 150

    Info source: 7.11.14.11 (?), elected via bsr, priority 192, holdtime 150
    Uptime: 00:04:16, expires: 00:02:28

```

Next, we verify the RP mappings in AS 9. The immediate problem we find with PIM and AutoRP is that this dynamic RP signaling leaks beyond AS boundaries. This is generally undesirable unless the ASes share an RP, which is highly unlikely in real life and certainly not the case in this lab. The most obvious solution would be to ensure ASes did not have reachability between RPs at all, but that would break inter-AS multicast entirely. Since the loopbacks are advertised into BGP, reachability exists and RPF

passes, which is why RP information is currently allowed to leak. On CSR10, we can see two RP mappings, both from BSR and AutoRP.

```
R10#show ip pim rp mapping
PIM Group-to-RP Mappings
This system is an RP (Auto-RP)
This system is an RP-mapping agent (Loopback0)

Group(s) 224.0.0.0/4
  RP 9.0.0.10 (?), v2v1
    Info source: 9.0.0.10 (?), elected via Auto-RP
    Uptime: 00:06:30, expires: 00:02:28
  RP 7.0.0.11 (?), v2
    Info source: 7.0.0.11 (?), via bootstrap, priority 192, holdtime 150
    Uptime: 00:05:23, expires: 00:02:18
```

To see which one is actually preferred, we can test it with the RP-hash command. We can see that the AutoRP is preferred, which would technically work for intra-AS multicast in AS 9, but it is very sloppy. The reason AS 7 did not learn the AutoRP mappings is because they were not configured to listen for it. Additionally, those mappings are flooded in dense-mode (which is what the listen command facilitates) which isn't operational on the XR boxes presently.

```
R10#show ip pim rp-hash 224.1.1.1
  RP 9.0.0.10 (?), v2v1
    Info source: 9.0.0.10 (?), elected via Auto-RP
    Uptime: 00:09:43, expires: 00:02:14
PIMv2 Hash Value (mask 255.255.255.252)
  RP 9.0.0.10, via Auto-RP
  RP 7.0.0.11, via bootstrap, priority 192, hash value 930306691
```

We can look at CSR9 to see that it learns XRv1 as the RP, which overrides the static configuration. This is a bigger deal since their intra-AS multicast would now be broken as the local RP would not be used. We could use the "override" keyword on CSR9 so that the static mapping (of equal prefix length) overrides any dynamic mappings. This is also a sloppy solution and is not preferable in this situation.

```
R9#show ip pim rp mapping
PIM Group-to-RP Mappings
Group(s) 224.0.0.0/4
  RP 7.0.0.11 (?), v2
    Info source: 7.0.0.11 (?), via bootstrap, priority 192, holdtime 150
    Uptime: 00:11:59, expires: 00:01:44
Group(s): 224.0.0.0/4, Static
  RP: 11.0.0.9 (?)
```

The better solution is to filter the BSR messages bi-directionally on all inter-AS links where BSR is enabled. We only need to do this on XRv1 and XRv4, but for extra protection, it makes sense to

configure it on all transit interfaces. This way, it protects the non-BSR AS from accidentally learning BSR information. We do not have the granularity to selectively filter group/RP mappings from the BSR message; we can only turn the filter off or on. I show the configuration on XRv4 and CSR6 for brevity, but I apply the “bsr-border” command on all transit links.

```
! XRv1
router pim
  address-family ipv4
    interface GigabitEthernet0/0/0/0.524
      bsr-border

    interface GigabitEthernet0/0/0/0.594
      bsr-border

! CSR6
interface GigabitEthernet2.562
  ip pim bsr-border

interface GigabitEthernet2.569
  ip pim bsr-border
```

On XE, we can verify it by checking the PIM interface summary to find an asterisk after the PIM operating mode on each interface. Alternatively, we can look at the interface details to see it confirmed more explicitly. There does not appear to be an XR show command to verify this.

```
R6#show ip pim interface gig2.569
Address      Interface          Ver/   Nbr    Query  DR      DR
              Interface          Mode   Count  Intvl  Prior
10.6.9.6     GigabitEthernet2.569 v2/S * 1      30     1       10.6.9.9

R6#show ip pim interface gig2.569 detail

Multicast Tagswitching: disabled
```

Quickly checking CSR10 and CSR9, we can see their RP mapping tables look correct now. The RP addresses are shown in yellow and the information sources are shown in green. They no longer learn the BSR information from AS 7.

```
R10#show ip pim rp mapping
PIM Group-to-RP Mappings
This system is an RP (Auto-RP)
This system is an RP-mapping agent (Loopback0)
Group(s) 224.0.0.0/4
  RP 9.0.0.10 (?), v2v1
    Info source: 9.0.0.10 (?), elected via Auto-RP
      Uptime: 00:29:07, expires: 00:02:53
```

```
R9#show ip pim rp mapping
PIM Group-to-RP Mappings
Group(s): 224.0.0.0/4, Static
  RP: 11.0.0.9 (?)
```

Although less of a problem, the AutoRP announcements are still being sent out of AS 9. Looking at CSR6, we can confirm this, as these groups are secretly operating in dense mode. Group 224.0.1.39 is used by candidate-RPs to notify the mapping agent (MA) about their candidacy, and group 224.0.1.40 is used to disseminate the RP information to clients. CSR6 sees traffic from 9.0.0.10 towards 224.0.1.40 which are the mapping advertisements and floods these out of the AS.

```
R6#show ip mroute 224.0.1.40 9.0.0.10 | begin \((
(9.0.0.10, 224.0.1.40), 00:30:09/00:02:31, flags: LT
  Incoming interface: GigabitEthernet2.560, RPF nbr 9.6.10.10
  Outgoing interface list:
    Loopback0, Forward/Sparse, 00:30:09/stopped
    GigabitEthernet2.562, Forward/Sparse, 00:30:09/stopped
    GigabitEthernet2.569, Forward/Sparse, 00:30:09/stopped
```

These isn't an easy button to solve this, so we can manually remove groups 224.0.1.39 and 224.0.1.40 from the mroute OIL using a multicast boundary. We apply this to all transit links on all routers, but like BSR, it is most important to do it on the AS 9 ASBRs. I show the configuration on CSR6 and XRv1.

```
! CSR6
ip access-list extended ACL_DENY_AUTORP
deny ip any host 224.0.1.39
deny ip any host 224.0.1.40
permit ip any any
```

```

interface GigabitEthernet2.562
 ip multicast boundary ACL_DENY_AUTORP

interface GigabitEthernet2.569
 ip multicast boundary ACL_DENY_AUTORP

! XRv1
ipv4 access-list ACL_DENY_AUTORP
 10 deny ipv4 any host 224.0.1.39
 20 deny ipv4 any host 224.0.1.40
 30 permit ipv4 any any

multicast-routing
 address-family ipv4
   interface GigabitEthernet0/0/0/0.501
     boundary ACL_DENY_AUTORP

```

First, we check the configuration to make sure the list was applied properly. We can see the filter as a multicast boundary inbound and outbound, and we see hits against the ACL entries matching those groups. This is a good indication that the filter is working.

```

R6#show ip multicast interface gig2.569
GigabitEthernet2.569 is up, line protocol is up
 Internet address is 10.6.9.6/24
 Multicast routing: enabled
 Multicast switching: fast
 Multicast packets in/out: 0/36
 Multicast boundary: ACL_DENY_AUTORP (in/out)
 Multicast TTL threshold: 0
 Multicast Tagswitching: disabled

```

```

R6#show access-l ACL_DENY_AUTORP
Extended IP access list ACL_DENY_AUTORP
 10 deny ip any host 224.0.1.39 (2 matches)
 20 deny ip any host 224.0.1.40 (4 matches)
 30 permit ip any any

```

This is also true for XRv1, though the commands are slightly different. Looking at the MRIB before the AutoRP group times out, we can see that XRv1 did see traffic from 9.0.0.10 for 224.0.1.40. This times out soon after the filters are applied and the entry is removed.

```

RP/0/0/CPU0:XRv1#show mrib route 224.0.1.40 9.0.0.10
[snip]
(9.0.0.10,224.0.1.40) RPF nbr: 0.0.0.0 Flags: RPF
 Up: 00:04:18
 Outgoing Interface List

```

```
GigabitEthernet0/0/0/0.514 Flags: F, Up: 00:04:18
GigabitEthernet0/0/0/0.571 Flags: F, Up: 00:04:18
```

```
RP/0/0/CPU0:XRv1#show mrib route 224.0.1.40 9.0.0.10
```

```
No matching route in MRIB route-DB
```

We can further confirm it worked by checking the (S,G) state for the AutoRP mapping group to ensure it is only being locally consumed (forwarded to loopback0 only) or forwarded within the AS. This ensures that AS 9, the AS using AutoRP, doesn't leak information out of its AS in the first place.

```
R6#show ip mroute 224.0.1.40 9.0.0.10 | begin \((
(9.0.0.10, 224.0.1.40), 00:35:15/00:02:22, flags: LT
  Incoming interface: GigabitEthernet2.560, RPF nbr 9.6.10.10
  Outgoing interface list:
    Loopback0, Forward/Sparse, 00:35:15/stopped
```

With multiple disparate RPs servicing overlapping ASM groups, we must use MSDP to build a topology in which they can be tied together. MSDP is very similar to BGP as it is TCP based (port 639) and is designed to notify neighboring ASes about active sources within the local AS. These source active (SA) messages are like "long-range" PIM register messages. The general value of this is that any RPs with existing (*,G) trees in a remote AS will be notified of active sources in the local AS. These remote RPs can issue (S,G) joins back to the source in another AS, which may not even transit the MSDP peers (doesn't matter; MSDP is used for signaling only). The original intent of MSDP is that it would mirror the BGP topology exactly, at least with respect to RPs. Though MSDP can be configured on non-RPs, this only makes sense in hierarchical architectures where some aggregation nodes might reduce the overall amount of MSDP peers required. For now, we will configure MSDP peers between the four ASes in a near-full mesh except AS 8 and AS 11 will not have a direct peering. The basic MSDP peer configuration is simple, and the remote-AS field is optional. If not configured, it can be derived from BGP or set to zero, depending on software versions. I personally prefer to set the value for completeness.

```
! CSR10
ip msdp peer 7.0.0.11 connect-source Loopback0 remote-as 7
ip msdp peer 8.0.0.12 connect-source Loopback0 remote-as 8
ip msdp peer 11.0.0.9 connect-source Loopback0 remote-as 11

! CSR9
ip msdp peer 7.0.0.11 connect-source Loopback0 remote-as 7
ip msdp peer 9.0.0.10 connect-source Loopback0 remote-as 9

! XRv1
router msdp
  peer 8.0.0.12
    connect-source Loopback0
    remote-as 8

  peer 9.0.0.10
```

```

connect-source Loopback0
remote-as 9

peer 11.0.0.9
connect-source Loopback0

router msdp
peer 7.0.0.11
connect-source Loopback0
remote-as 7

peer 9.0.0.10
connect-source Loopback0
remote-as 9

```

When the peers start to come up, MSDP prints syslog messages to inform us. Below are the log messages on CSR10 and XRv1 from their mutual peering being established.

```

! CSR10
%MSDP-5-PEER_UPDOWN: Session to peer 7.0.0.11 going up

! XRv1
msdp[1045]: %ROUTING-MSDP-5-INIT_PEER_UP_DOWN : MSDP peer up: 9.0.0.10

```

To see the status of all peers, the MSDP summary table displays it clearly on both XE and XR. Since AS 8 and AS 11 don't peer directly, we can conclude that all peer are up by checking CSR10 and XRv1. The "peer name" is the DNS-resolved name for the peer, and the question mark means that resolution was not performed. This is not an error condition and has no effect on MSDP operations.

```
R10#show ip msdp summary

```

We can look at the details on each peer, much like we would with the “show bgp neighbor” command. There is not much interesting traffic at present, but we learn some new things about MSDP. We can see that the SA filtering options are very flexible as we can apply route-maps in/out to filter RP information and (S,G) information. The outputs on both routers also show us detailed statistics for messages exchanged. One of the most important message counters is the MSDP RPF failure, which is discussed in detail later. Last, MSDP is also capable of MD5 authentication, much like BGP. Notice that XR shows the keep-alive timer at 30 seconds with a dead timer of 2.5 times that (75 seconds).

```

```

To confirm that MSDP uses TCP port 639, we can check the TCP details to see the sessions established. Both CSR10 and XRv1 show 3 MSDP sessions, each to the proper peer. We also note that the lower IP address is responsible for opening the MSDP session (that is, the lower peer IP is the TCP client).

```

R10#show tcp brief | include 639
7FBC42BF0C40  9.0.0.10.639      8.0.0.12.65296      ESTAB
7FBC42BF7E20  9.0.0.10.30326      11.0.0.9.639        ESTAB
7FBC42BF15C0  9.0.0.10.639      7.0.0.11.30561      ESTAB

RP/0/0/CPU0:XRv1#show tcp brief | include :639
0x10151770 0x60000000  0  0  7.0.0.11:24200  8.0.0.12:639      ESTAB
0x101b1638 0x60000000  0  0  7.0.0.11:30561  9.0.0.10:639      ESTAB
0x101c71fc 0x60000000  0  0  7.0.0.11:23252  11.0.0.9:639      ESTAB
0x101b32a8 0x60000000  0  0  0.0.0.0:639     0.0.0.0:0         LISTEN
0x101b1a84 0x00000000  0  0  0.0.0.0:639     0.0.0.0:0         LISTEN

```

We will configure MD5 authentication between CSR10 and XRv1. Normally, one would configure this everywhere, but for brevity I limit it to one connection. Key-chains are not supported. We can verify this by checking the peer detailed and filtering for the important output.

```

! CSR10
ip msdp password peer 7.0.0.11 AS7AS9_MSDP

! XRv1
router msdp
peer 9.0.0.10
password clear AS7AS9_MSDP

R10#show ip msdp peer 7.0.0.11 | include MD5
MD5 signature protection on MSDP TCP connection: enabled

RP/0/0/CPU0:XRv1#show msdp peer 9.0.0.10 | include Password
Password: Configured, set on active socket

```

We can also verify this with low-level TCP commands. Recovering the TCB from the TCP brief for a particular TCP session, we look at the option detailed to find MD5 negotiated. This does not appear visible on XR.

```
R10#show tcp brief | include 7.0.0.11
7FBC42BF6068 9.0.0.10.639 7.0.0.11.45268 ESTAB
```

```
R10#show tcp tcb 7FBC42BF6068 | begin ^Option
Option Flags: md5, Retrans timeout
[snip]
```

Next, we will adjust the session timers between CSR10 and XRv1. For faster dead-peer detection, I will reduce the keep-alive timer to 15 seconds and the maximum time to wait for a message (dead-timer, basically) to 35 seconds.

```
! CSR10
ip msdp keepalive 7.0.0.11 15 35

! XRv1
router msdp
 peer 9.0.0.10
  keepalive 15 35
```

This information does not appear visible on XE, so we will verify it on XR only.

```
RP/0/0/CPU0:XRv1#show msdp peer 9.0.0.10 | include timer period
KeepAlive timer period: 15
Peer Timeout timer period: 35
```

Next, we will actually send some multicast data between sites. CSR3 will request traffic for group 225.0.1.3, which will trigger a (*,G) join from the PIM-DR (CSR8) to the local RP (XRv2). XRv2 is the root of the shared tree and is waiting to hear about active sources via PIM register messages (intra-AS) or MSDP SA messages (inter-AS).

```
! CSR3
interface GigabitEthernet2.538
 ip igmp join-group 225.0.1.3
```

```

```

CSR2 will be the first sender for this group. Before starting, we enable some PIM and MSDP debugging on various to understand the process.

```
! CSR5
debug ip pim 225.0.1.3

! CSR10
debug ip pim 225.0.1.3
debug ip msdp 8.0.0.12 peer
debug ip msdp 8.0.0.12 detail

! XRv2
debug msdp peer 9.0.0.10
debug mrrib route

! CSR2
R2#ping 225.0.1.3 repeat 10000
```

As the PIM DR, CSR5 senses traffic on the LAN and originates a PIM register message towards the local RP, which is CSR10. CSR10 is not aware of any receivers for this group and would normally reply immediately with a PIM register-stop message. This time, CSR10 first originates an MSDP source-active (SA) message to notify XRv2 that there is an active source. After that, it continues with its normal PIM operation of sending a register-stop. We can see that, generally speaking, the MSDP actions happen before the PIM ones as indicated by the debug.

```
! CSR5
PIM(0): Check RP 9.0.0.10 into the (*, 225.0.1.3) entry
PIM(0): Building Triggered (*,G) Join / (S,G,RP-bit) Prune message for
225.0.1.3
PIM(0): Adding register encap tunnel (Tunnel1) as forwarding interface of
(9.2.5.2, 225.0.1.3).

! CSR10
MSDP(0): 8.0.0.12: Building SA message from SA cache
MSDP(0): start_index = 0, sa_cache_index = 0, Qlen = 0
MSDP(0): Sent entire sa-cache, sa_cache_index = 0, Qlen = 0
PIM(0): Received v2 Register on GigabitEthernet2.550 from 9.5.10.5
```

```

    for 9.2.5.2, group 225.0.1.3
PIM(0): Check RP 9.0.0.10 into the (*, 225.0.1.3) entry
PIM(0): Adding register decap tunnel (Tunnel2) as accepting interface of (*,
225.0.1.3).
PIM(0): Adding register decap tunnel (Tunnel2) as accepting interface of
(9.2.5.2, 225.0.1.3).
MSDP(0): 8.0.0.12: Send 100-byte SA encapsulated data for (9.2.5.2,
225.0.1.3), RP 9.0.0.10

```

Multiple things are happening concurrently now, so we will look at CSR10 first. After sending the MSDP SA message, it doesn't wait to receive an (S,G) join from the remote AS and immediately sends a PIM register-stop to CSR5. CSR5 receives this and, as far as it knows, there are no receivers for this group, so the DR stops sending register messages. As seen above, the SA message carries that 100-byte ICMP ping as a payload, much like a register message does.

```

! CSR10
PIM(0): Send v2 Register-Stop to 9.5.10.5 for 9.2.5.2, group 225.0.1.3

! CSR5
PIM(0): Received v2 Register-Stop on GigabitEthernet2.550 from 9.0.0.10
PIM(0):   for source 9.2.5.2, group 225.0.1.3
PIM(0): Removing register encap tunnel (Tunnel1) as forwarding interface of
(9.2.5.2, 225.0.1.3).
PIM(0): Clear Registering flag to 9.0.0.10 for (9.2.5.2/32, 225.0.1.3)

```

On the other side of the network, XRv2 receives the MSDP SA message from CSR10. The MSDP debugging doesn't reveal much human-readable output, but we can see that a message was received from MSDP and an MRIB (S,G) entry of (9.2.5.2, 225.0.1.3) was created. This is a good indication that it successfully processed the SA message from CSR10.

```

! XRv2

```

In lieu of cryptic debug, we can verify the SA-cache on XRv2 to ensure it sees the entry. We can see the (S,G), followed the RPF source (more on this later) and the remote AS. The encapsulated data received is

a byte counter for the amount of traffic carried inside of the SA message; like PIM register messages, the payload is transferred to MSDP SA messages when they are originated. The 100-byte ICMP echo was tunneled across while the inter-AS SPT was first built.

```
RP/0/0/CPU0:XRv2#show msdp sa-cache 225.0.1.3
MSDP Flags:
E - set MRIB E flag , L - domain local source is active,
EA - externally active source, PI - PIM is interested in the group,
DE - SAs have been denied. Timers age/expiration,
Cache Entry:
(9.2.5.2, 225.0.1.3), RP 9.0.0.10, MBGP/AS 9, 00:08:55/00:01:50
  Learned from peer 9.0.0.10, RPF peer 9.0.0.10
  SAs recvd 10, Encapsulated data received: 100
  grp flags: PI, src flags: E, EA, PI
```

It is important to note that the SA cache shows received SA messages. As such, CSR10 has no entries, despite originating one. Like BGP, we can see the advertised SAs by invoking the peer command with a special option. This shows the SAs advertised to a certain peer. SA messages are categorized by whether they were advertised by their presence in the MRIB (local origination) or forwarded on from the SA cache (like a string of MSDP peers).

```
R10#show ip msdp sa-cache 225.0.1.3
MSDP Source-Active Cache
Group not found

R10#show ip msdp peer 8.0.0.12 advertised-SAs
MSDP SA advertised to peer 8.0.0.12 (?) from mroute table

225.0.1.3      9.2.5.2 (?)
MSDP SA advertised to peer 8.0.0.12 (?) from SA cache
```

We can further verify the MSDP statistics on XRv2. We can see that 30 SAs have been received (periodic updates) while none of have been sent. The output is similar on CSR10 which shows 30 outbound SAs and none received. CSR10 also shows a single “data” packet out, which is the 100-byte ICMP echo that was MSDP-encapsulated as a carry-over from the original PIM register message from CSR5.

```
RP/0/0/CPU0:XRv2#show msdp statistics peer 9.0.0.10
MSDP Peer Statistics :- default
Peer 9.0.0.10 : AS is 9, State is Up, 1 active SAs
  TLV Rcvd : 33 total
              3 keepalives, 0 notifications
              30 SAs, 0 SA Requests
              0 SA responses, 0 unknowns
  TLV Sent : 59 total
              59 keepalives, 0 notifications
              0 SAs, 0 SA Requests
```

```
0 SA responses
SA msgs : 30 received, 0 sent
```

```
R10#show ip msdp peer 8.0.0.12 | begin Message_count
Message counters:
  RPF Failure count: 0
  SA Messages in/out: 0/30
  SA Requests in: 0
  SA Responses out: 0
  Data Packets in/out: 0/1
```

The more significant effect of having received this SA message is that now XRv2 can originate an (S,G) join back to 9.2.5.2 since it is aware of a new source. We will casually glaze over the MSDP RPF rules for now, but we see that the RPF peer for the originating RP is CSR6, and MSDP instructs the router to consult the RIB for this information.

```
P/0/0/CPU0:XRv2#show msdp rpf 9.0.0.10
RPF peer for 9.0.0.10 is 9.0.0.10 AS 9, rule: 1
  bgp/rib lookup: nexthop: 9.0.0.10, asnum: 9
```

```
RP/0/0/CPU0:XRv2#show route 9.0.0.10
Routing entry for 9.0.0.10/32
  Known via "bgp 8", distance 20, metric 0
  Tag 9, type external
  Routing Descriptor Blocks
    10.6.12.6, from 10.6.12.6, BGP external
    Route metric is 0
  No advertising protos.
```

With this information, XRv2 sends the (S,G) join to CSR6. The MRIB entry also has the 'E' flag set which means MSDP external, equivalent to the 'M' flag in XE.

```
RP/0/0/CPU0:XRv2#show pim topology 225.0.1.3 9.2.5.2 | begin 9.2
(9.2.5.2,225.0.1.3)SPT SM Up: 00:19:10
JP: Join(00:00:39) RPF: GigabitEthernet0/0/0/0.562,10.6.12.6 Flags:
KAT(00:02:04) E RA
  GigabitEthernet0/0/0/0.582 00:19:09 fwd Join(00:03:02)
```

CSR6 and CSR10 continue building the SPT by sending the (S,G) join towards CSR5. Notice that CSR10 has the "A" flag set to indicate that this was a candidate for MSDP advertisement, implying that an SA may have been advertised for it. CSR6 and CSR5 have no idea MSDP is even in use, and they do not need to know.

```
R6#show ip mroute 225.0.1.3 9.2.5.2 | begin \

```

Incoming interface: GigabitEthernet2.525, RPF nbr 0.0.0.0

Outgoing interface list:

GigabitEthernet2.550, Forward/Sparse, 00:22:16/00:02:48

As a final check, we look at CSR8. I do not trace the SPT switchover process, which also occurs, but suffice it to say that CSR8 has the (S,G) entry as well due to SPT switchover. Counting packets forwarding to CSR3, we can see the feature is working as expected. I issue the command a few times to ensure the packet counters continue to increment.

```
R8#show ip mroute 225.0.1.3 9.2.5.2 count | begin ^Group
```

```
Group: 225.0.1.3, Source count: 1, Packets forwarded: 1372, Packets received: 1372
```

Source: 9.2.5.2/32, Forwarding: 1371/1/118/0, Other: 1371/0/0

```
R8#show ip mroute 225.0.1.3 9.2.5.2 count | begin ^Group
```

```
Group: 225.0.1.3, Source count: 1, Packets forwarded: 1422, Packets received: 1422
```

Source: 9.2.5.2/32, Forwarding: 1421/1/118/0, Other: 1421/0/0

To test a more complex example, we will originate traffic from CSR4 for group 225.0.1.3 at the same time. Since AS 11 and AS 8 do not have a direct MSDP connection, AS 7 and AS 9 will need to forward the SA generated by CSR9, the local RP. This behavior is the MSDP default; this is different than iBGP which doesn't reflect iBGP-learned routes by default. MSDP is very liberally with SA advertisements and relies on RPF for loop prevention. To test, we can simply start the ping and after enabling some debug. I use different MSDP debugs on XRv2 to try and get more valuable information. I also disable the PIM debugging since that process is the same, essentially, and we are trying to learn MSDP.

```
! CSR9, CSR10
```

```
debug ip msdp detail
```

```
debug ip msdp peer
```

```
! XRv2, XRv1
```

```
debug msdp cache
```

```
debug msdp events
```

```
! CSR4
```

```
ping 225.0.1.3 repeat 10000 timeout 1
```

Upon received the PIM register message from XRv3, CSR9 originates the MSDP SA for (11.4.13.4, 225.0.1.3). CSR9 sends it to both XRv1 and CSR10 as we can see from peer advertised-SA output.

```
! CSR9

```

```
MSDP SA advertised to peer 9.0.0.10 (?) from SA cache
```

First, we will look at CSR10. It receives the message from CSR9 with encapsulation data inside. This passes the MSDP RPF check (discussed in detail later), which means it is added to the SA cache and forwarded to other MSDP peers, except the one from which the SA was received. Because XRv1 also received this SA from CSR9 directly, it performs the same action; install the SA into the cache and advertise it onward.

```
! CSR10
```

```
MSDP(0): 11.0.0.9: Received 120-byte msg 506 from peer
```

```
MSDP(0): 11.0.0.9: SA TLV, len: 120, ec: 1, RP: 11.0.0.9, with data
```

```
MSDP(0): 11.0.0.9: Peer RPF check passed for 11.0.0.9, peer is RP
```

```
MSDP(0): WAVL Insert SA Source 11.4.13.4 Group 225.0.1.3 RP 11.0.0.9  
Successful
```

```
MSDP(0): 7.0.0.11: Forward 120-byte SA (11.4.13.4, 225.0.1.3) from 11.0.0.9  
to 7.0.0.11
```

```
MSDP(0): 8.0.0.12: Forward 120-byte SA (11.4.13.4, 225.0.1.3) from 11.0.0.9  
to 8.0.0.12
```

```
! XRv1
```

```
msdp[1045]: [1] default cache: adding remote RP 11.0.0.9
```

```
msdp[1045]: [1] default (11.4.13.4, 225.0.1.3) cache: new entry - rpf: 11.0.0.9
```

This means that CSR10 and XRv1 are both going to advertise the SA for (11.4.13.4, 225.0.1.3) to one another as well. When CSR10 receives it, this packet is rejected due to failing the MSDP RPF check. The same is true on XRv1 for the SA received from CSR10. This is perfectly logical and is loosely analogous to the BGP AS-path loop-prevention mechanism. Even without understanding the details of MSDP RPF yet, we can look at the diagram and generally understand its purpose. CSR10 and XRv1 both received the SA directly from CSR9, so accepting the same SA from a second-hand peer is less desirable.

```
! CSR10
MSDP(0): Received 120-byte TCP segment from 7.0.0.11
MSDP(0): Append 120 bytes to 0-byte msg 507 from 7.0.0.11, qs 1
MSDP(0): 7.0.0.11: Received 120-byte msg 507 from peer
MSDP(0): 7.0.0.11: SA TLV, len: 120, ec: 1, RP: 11.0.0.9, with data
MSDP(0): 7.0.0.11: Peer RPF check failed for 11.0.0.9, EBGp route/peer in AS 7/0
```

```
! XRv1
msdp[1045]: [1] default cache: rejecting SA from peer 9.0.0.10 for RP 11.0.0.9
```

To prove that each router installed the proper SA entry, we can check the caches. Both of them show 11.0.0.9 as the RPF peer (as opposed to one another) which is correct given the BGP topology.

```
RP/0/0/CPU0:XRv1#show msdp sa-cache 225.0.1.3
MSDP Flags:
E - set MRIB E flag , L - domain local source is active,
EA - externally active source, PI - PIM is interested in the group,
DE - SAs have been denied. Timers age/expiration,
Cache Entry:
(9.2.5.2, 225.0.1.3), RP 9.0.0.10, MBGP/AS 9, 00:48:42/00:02:07

R10#show ip msdp sa-cache 225.0.1.3
MSDP Source-Active Cache - 1 entries for 225.0.1.3
(11.4.13.4, 225.0.1.3), RP 11.0.0.9, BGP/AS 11, 00:10:02/00:05:49, Peer 11.0.0.9
```

There is a problem on XRv2, however. Despite both XRv1 and CSR10 advertising their SA messages to XRv2, XRv2 rejects them both. The debug reveals this and the SA cache has no entries originating in AS

11. The only entry is the first one we tested earlier from AS 9. XRv2 is claiming that both of these SAs are failing RPF.

```
! XRv2
msdp[1045]: [1] default cache: rejecting SA from peer 7.0.0.11 for RP
11.0.0.9

  grp flags: PI, src flags: E, EA, PI
```

XR has a special debug command for troubleshooting MSDP RPF issues. I enable it on XRv2 to get more details, along with MSDP TLV debugging which will reveal the contents of the SA TLVs. The router is indicating that there is an RPF route towards 11.0.0.9 (via BGP) but there isn't an MSDP peer. This is by design as we never configured a peer between those ASes.

```
RP/0/0/CPU0:XRv2#debug msdp rpf
RP/0/0/CPU0:XRv2#debug msdp tlv
```

```
msdp[1045]: [1] default 7.0.0.11 tlv: ReadQ: 20 bytes in buffer

msdp[1045]: [1] default 9.0.0.10 tlv:
msdp[1045]: [1] 11.0.0.9 RPF: Found RPF but no rpf peer for 11.0.0.9 - Failed
msdp[1045]: [1] 11.0.0.9 RPF: RPF lookup for 11.0.0.9 failed for peer
9.0.0.10: No Peer preferred
```

The debug also reveals a semi-frightening error message that isn't exactly intuitive. Clearly there are BGP routes for this remote RP, but the debug seems to indicate there is an error.

```
! XRv2
msdp[1045]: [2] 11.0.0.9 RPF: BGP route not found for 11.0.0.9: 'sysdb'
detected the 'warning' condition 'A SysDB client tried to access a
nonexistent item or list an empty directory'
```

To better understand MSDP RPF, we will discuss its operation and purpose. There are three rules to MSDP and they are applied depending on the BGP topology. First, the MSDP process tries to find a BGP neighbor that has the same IP address as the MSDP peer.

1. If the MSDP peer is also an iBGP peer, apply Rule 1.
2. If the MSDP peer is also an eBGP peer, apply Rule 2.
3. If the MSDP peer is not a BGP peer at all, apply Rule 3.

The rules are all very similar in nature. I describe them in detail below, and then summarize them afterwards. To identify some terms initially, the “originating RP” is the RP that originated the SA message. In our case, this would be 11.0.0.9. The “advertising peer” is the MSDP peer that advertised the SA message in question, which may or not be the same as the originating RP. In this case, 9.0.0.10 and 7.0.0.11 are the advertising peers.

Rule 1 (iBGP peer): Check the BGP MRIB for the best path to the originating RP. If no match exists, check the BGP URIB instead. If no match exists, RPF fails. If a path is found, the receiving RP compares the BGP neighbor address (not the next-hop) to the MSDP peer address; they must match. In summary, this rule means that the BGP and MSDP topologies should match within an AS.

Rule 2 (eBGP peer): Check the BGP MRIB for the best path to the originating RP. If no match exists, check the BGP URIB instead. If no match exists, RPF fails. If a path is found, the first AS in the path towards the originating RP must match the peer AS of the eBGP peer. If it doesn't, RPF fails. In summary, the BGP and MSDP topologies should match between ASes. Compared to rule 1, the MSDP peer address and BGP peer address do not have to match, but the general AS advertisement path must match.

Rule 3 (no BGP peer): Check the BGP MRIB for the best path to the originating RP. If no match exists, check the BGP URIB instead. If no match exists, RPF fails. If a path is found, the BGP MRIB is searched for the best path to the advertising peer, followed by the BGP URIB if a path isn't found. If a path is found, the first AS in the path towards the originating RP must match the AS of the MSDP peer. In summary, this rule is similar to rule 2 but performs two different lookups; one for the originating RP and one for the advertising peer.

Summary of rules: All of them check the BGP MRIB for a path to the originating RP, followed by the BGP URIB if a path is not found. For all lookups, this is the order of operations. The difference is in the follow-on activities which may introduce additional checks depending on the peer type.

Troubleshooting XRv2, we check the BGP neighbor tables for IPv4 unicast and multicast. 11.0.0.9 is not a BGP peer of any kind, so we assume MSDP rule 3 is invoked.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 unicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer    InQ  OutQ  Up/Down  St/PfxRcd
8.0.0.8        0     8    170     160        20     0     0  00:24:11      2
10.6.12.6       0     9     46     43         20     0     0  00:24:49     11
10.12.14.14     0     7     45     43         20     0     0  00:24:49     11

RP/0/0/CPU0:XRv2#show bgp ipv4 multicast summary | begin ^Neigh
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer    InQ  OutQ  Up/Down  St/PfxRcd
8.0.0.8        0     8    170     161         13     0     0  00:24:20      1
10.6.12.6       0     9     46     43         13     0     0  00:24:58      3
10.12.14.14     0     7     45     43         13     0     0  00:24:58      3
```

First, we check the BGP MRIB (IPv4 multicast) for a path to the originating RP (11.0.0.9). We find no match there, but we do in the BGP URIB (IPv4 unicast). The best path is via XRv4 due to being the oldest eBGP route. The first AS in the best path is AS 7.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 multicast 11.0.0.9
% Network not in table

RP/0/0/CPU0:XRv2#show bgp ipv4 unicast 11.0.0.9
[snip]
  Path #1: Received by speaker 0
  Not advertised to any peer
  9 11
    10.6.12.6 from 10.6.12.6 (9.0.0.6)
      Origin incomplete, localpref 100, valid, external, group-best
      Received Path ID 0, Local Path ID 0, version 0
      Origin-AS validity: not-found
  Path #2: Received by speaker 0
  Advertised to update-groups (with more than one peer):
    0.3
  Advertised to peers (in unique update groups):
    8.0.0.8
    7 11
      10.12.14.14 from 10.12.14.14 (7.0.0.14)
        Origin incomplete, localpref 100, valid, external, best, group-best
        Received Path ID 0, Local Path ID 1, version 14
        Origin-AS validity: not-found
```

Since we found a path, XRv2 progresses to run the same checks against the advertising peer (7.0.0.11). XRv4 is the best path due to the shortest AS-path length.

```

RP/0/0/CPU0:XRv2#show bgp ipv4 multicast 7.0.0.11
% Network not in table

RP/0/0/CPU0:XRv2#show bgp ipv4 unicast 7.0.0.11
[snip]
  Path #1: Received by speaker 0
  Not advertised to any peer
  9 7
    10.6.12.6 from 10.6.12.6 (9.0.0.6)
      Origin IGP, localpref 100, valid, external, group-best
      Received Path ID 0, Local Path ID 0, version 0
      Origin-AS validity: not-found
  Path #2: Received by speaker 0
  Advertised to update-groups (with more than one peer):
    0.3
  Advertised to peers (in unique update groups):
    8.0.0.8
  7
    10.12.14.14 from 10.12.14.14 (7.0.0.14)
      Origin IGP, localpref 100, valid, external, best, group-best
      Received Path ID 0, Local Path ID 1, version 6
      Origin-AS validity: not-found

```

Last, the router verifies that the first AS in the best-path to the originating RP (11.0.0.9) is the same as the advertising MSDP peer (7.0.0.11). Both of them are 7, so RPF should pass according to the rules above. We saw earlier that it did not, which leads us to question the aforementioned RPF rule logic. In an attempt to repair this, I will make the MSDP RPF check “more correct” by advertising CSR9’s loopback (the originating RP address) into the BGP MRIB.

```

! CSR9
router bgp 11
  address-family ipv4 multicast
    redistribute connected route-map RM_CONN_TO_BGP

```

This means that XRv2 will learn BGP MRIB routes for the originating RP now instead of relying on the BGP URIB. This shouldn’t be required per the rules described earlier, but perhaps XR assumes that because IPv4 multicast is running, that is the only AFI it checks. Now, it prefers CSR6 as the best-path due to being the oldest eBGP route.

```

RP/0/0/CPU0:XRv2#show bgp ipv4 multicast 11.0.0.9/32
[snip]
  9 11
    10.6.12.6 from 10.6.12.6 (9.0.0.6)
      Origin incomplete, localpref 100, valid, external, best, group-best
      Received Path ID 0, Local Path ID 1, version 14
  Path #2: Received by speaker 0

```

```

Not advertised to any peer
7 11
10.12.14.14 from 10.12.14.14 (7.0.0.14)
Origin incomplete, localpref 100, valid, external, group-best
Received Path ID 0, Local Path ID 0, version 0

```

Suddenly, RPF passes on XRv2. Everything else we verified above is still correct, but the route to the originating RP changed from being unicast to multicast. Examining the debug on XRv2, we no longer see the “scary” BGP messages about missing routes. Based on this, I assert that the XR debug message was referring to the lack of an IPv4 multicast BGP route specifically, but didn’t make that entirely clear. We will later prove that **when XR BGP is running multicast and unicast AFIs, the RPF process expects to always have a routing entry in the multicast BGP RIB for RPF**. Without it, RPF will fail, as BGP unicast routes are not considered in this case.

```

```

When we check the RPF details on XRv2, we see that MSDP rule 4 is used. This appears very confusing and the word “rule” in XR not does correlate with the MSDP “rules” we just discussed. We can at least see that 9.0.0.10 is the next-hop which has a valid BGP URIB route (the BGP peer and MSDP peer), which allows RPF to work.

```

RP/0/0/CPU0:XRv2#show msdp rpf 11.0.0.9
RPF peer for 11.0.0.9 is 9.0.0.10 AS 9, rule: 4
bgp/rib lookup: nexthop: 9.0.0.10, asnum: 11

```

The XR “rules” are specific to RFC3618 which describe conditions for RPF checks but this is not made clear in the documentation. This is enabled on XR and cannot be disabled, yet the default on IOS and XE platforms is to use the Cisco “rules” discussed earlier. Unfortunately, both RFC3618 and Cisco call them “MSDP RPF rules” so there isn’t an easy way to distinguish them in the show commands or debug outputs. One would have to simply know the difference, the rule descriptions, and the defaults per platform. XE platforms can optionally use RFC3618 rules which we will investigate later. The RFC3618 rules are also processed in top-down fashion with lower number rules being the more preferred RPF mechanisms. RFC3618, and the debug output on XR, list the rules in Roman numeral format.

- i. The advertising MSDP peer is the same address as the originating RP.
- ii. The advertising MSDP peer is the eBGP next-hop for the RPF route.
- iii. The advertising MSDP peer is the BGP peer that advertised the route towards the originating RP, but it isn’t the same BGP peer address as the next-hop.
- iv. The advertising MSDP peer resides in the closest AS towards the originating RP.
- v. The advertising MSDP peer RPF was statically configured.

This raises the question of how RPF passed on the original SA when the originating RP (9.0.0.10) wasn’t in the MRIB either. This was from our first test where CSR2 was the sender and CSR10 was the originating RP. We can examine XRv2 MSDP RPF debugs to see which RFC3618 rule was used to accept this SA from CSR10. This debug can be confusing because it suggests “rule 1” was used, when clearly the routes to CSR10 are eBGP, not iBGP as the “Cisco MSDP RPF rules” specify. Again, this is because XR is following “RFC3618 RPF rule 1”; when the originating RP and advertising peer are the same address, RPF passes immediately. Under Cisco’s rules, RPF isn’t even checked in this case, as this is a special case clearly documented. The debug clearly shows that the advertising peer and originating RP are the same.

```

msdp[1045]: [1] 9.0.0.10 RPF: Accepting SA from peer 9.0.0.10 for RP 9.0.0.10
due to Matched RP Address (i)
```

Going back to the second test with CSR4 as a sender, we can verify the SA cache on XRv2 to see the new entry. The AS is 11 with the remote RP being 11.0.0.9. Although there is no MSDP or BGP peering with this address, RPF passes due to the IPv4 multicast route for the originating RP advertised by CSR6 and XRv4 (best path dependent).

```
RP/0/0/CPU0:XRv2#show msdp sa-cache
MSDP Flags:
```

E - set MRIB E flag , L - domain local source is active,
 EA - externally active source, PI - PIM is interested in the group,

 SAs recvd 19, Encapsulated data received: 0
 grp flags: PI, src flags: E, EA, PI

A quick check of multicast counters on CSR8 shows this working. CSR2 has many more packets than CSR4 because of the RPF problems we had to resolve. Both CSR2 and CSR4 have been sending the whole time which is why the packet counts are high.

```
R8#show ip mroute 225.0.1.3 count | begin ^Group
Group: 225.0.1.3, Source count: 2, Packets forwarded: 3945, Packets received:
3945

```

Because the eBGP peers have MSDP connections between their loopbacks (which are also RPs), we bypass many of the complex RPF issues and rules. On XE, the special case of not checking RPF applies, and on XR, RFC3618 rule 1 is always applied. We can introduce some of this complexity for additional practice. On XRv1 and CSR10, I reconfigure the MSDP session slightly. XRv1 will peer with CSR10's direct connected transit link while CSR10 continues to peer with XRv1's loopback. This is analogous with modifying the BGP update-source, except we modify the MSDP connect-source. From XRv1's perspective, this means that SA messages from CSR10 will be sourced from 10.10.11.10 (transit link) with an RP of 9.0.0.10 (loopback). Since the MSDP peer address (10.10.11.10) and RP (9.0.0.10) differ, this does not qualify for RFC3618 rule 1. The topology doesn't change much, so the general design is the same, but XR will have to select another RFC3618 RPF rule to accept SA messages from 9.0.0.10.

```
! CSR10
ip msdp peer 7.0.0.11 connect-source gig2.501 remote-as 7

! XRv1
```

```

router msdp
  no peer 9.0.0.10
  peer 10.10.11.10
  password clear AS7AS9_MSDP
  connect-source Loopback0
  remote-as 9
  keepalive 15 35

```

Since CSR2 is still sending traffic, CSR10 is still originating periodic SA messages. XRv1 will receive this whether there are clients in AS 7 or not. On XRv1, the MSDP RPF rule used in this case is RFC3618 rule 3. Despite the route to 9.0.0.10/32 being eBGP-learned, rule 3 is used. At a glance, the logic for RFC3618 rule 2 holds true since the eBGP next-hop is 10.10.11.10 which is the advertising peer as well. The debug shows RFC3618 rule 3 being matched for that particular SA received from 9.0.0.10. The reason for failing to match RFC3618 rule 2 is similar to the error on XRv2. The RFC3618 definitions, and XR in general, assume that the routes in question are BGP IPv4 multicast. Since XRv1 does not have an IPv4 multicast route to 9.0.0.10, it “falls back” to the unicast route which qualifies it for RFC3618 rule 3 RPF. We confirm this with the show command also.

```

! XRv1
msdp[1045]: [1] default 10.10.11.10 tlv: ReadQ: TLV parsed length = 20, type
= 1
msdp[1045]: [1] default 10.10.11.10 tlv: 10.10.11.10: recvd <SourceActive,20>

msdp[1045]: [1] default 10.10.11.10 tlv: -- (9.2.5.2/32 225.0.1.3)
msdp[1045]: [1] default 10.10.11.10 tlv:
msdp[1045]: [1] 9.0.0.10 RPF: Found RPF peer 10.10.11.10 for RP 9.0.0.10 -
Matched Next Hop (iii)
msdp[1045]: [1] 9.0.0.10 RPF: Accepting SA from peer 10.10.11.10 for RP
9.0.0.10 due to Matched Next Hop (iii)

RP/0/0/CPU0:XRv1#show msdp rpf 9.0.0.10
RPF peer for 9.0.0.10 is 10.10.11.10 AS 9, rule: 3
  bgp/rib lookup: nexthop: 10.10.11.10, asnum: 0

```

If we want XRv1 to see this as candidate for matching RFC3618 rule 2, we would need to advertise 9.0.0.10 inside BGP IPv4 multicast. We can re-use the route-map from IPv4 unicast for this.

```

! CSR10
router bgp 9
  address-family ipv4 multicast
  redistribute connected route-map RM_CONN_TO_BGP

```

With debugging still enabled on XRv1, we can see the new match. This debug clearly shows that the next-hop was the eBGP peer which is expected. The SA is exactly the same, but since XRv1 now has an IPv4 multicast route towards the originating RP, rule 2 can be used. I also verify with the show command.

```

! XRv1
msdp[1045]: [1] default 10.10.11.10 tlv: ReadQ: 20 bytes in buffer
msdp[1045]: [1] default 10.10.11.10 tlv: ReadQ: TLV parsed length = 20, type

  bgp/rib lookup: nexthop: 10.10.11.10, asnum: 9

```

By now, it should be clear that the MSDP RPF rules can be confusing and often inconsistent between platforms. Fortunately, the debug messaging is helpful, especially on XR where the matched rules are shown. To demonstrate more differences between Cisco's version and RFC3618, we can use CSR9. It is currently using Cisco's method, which means our verifications are limited to debugs. The equivalent show command only works when RFC3618 is enabled.

```

R9#show ip msdp rpf-peer 8.0.0.12
This command requires "ip msdp rpf rfc3618" to be configured.

```

To test it, I will originate traffic for a bogus group on CSR3. Even if AS 11 doesn't have receivers, CSR9 should accept the SA message from XRv2. We saw that, in the same topology but in the reverse order, XRv2 rejected these messages under the RFC3618 construct. CSR9, however, accepts them, based on Cisco's MSDP RPF rule 3.

```

R9#debug ip msdp peer
MSDP Peer debugging is on

```

```

MSDP(0): 7.0.0.11: Received 120-byte msg 1017 from peer

SAs received: 1, Encapsulated data received: 1

```

The path via CSR6 was chosen as the BGP best-path due to being the oldest route. Notice that CSR9 doesn't care about the lack of an IPv4 multicast route for the originating RP, as XRv2 did.

```

R9#show bgp ipv4 multicast 8.0.0.12
% Network not in table

R9#show bgp ipv4 unicast 8.0.0.12
BGP routing table entry for 8.0.0.12/32, version 47
Paths: (2 available, best #2, table default)
  Advertised to update-groups:
    3          4
  Refresh Epoch 1
  7 8
    10.9.14.14 from 10.9.14.14 (7.0.0.14)
      Origin IGP, localpref 100, valid, external
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 1
  9 8
    10.6.9.6 from 10.6.9.6 (9.0.0.6)
      Origin IGP, localpref 100, valid, external, best
      rx pathid: 0, tx pathid: 0x0

```

Per Cisco's rule 3, the router then checks the path to the advertising peer to ensure the AS of that peer matches the first AS of the best path, which is 9. They match, so the SA is installed as we saw above. CSR9 actually has an IPv4 multicast route for this since we advertised it on CSR10 earlier, but this is irrelevant.

```

R9#show bgp ipv4 multicast 9.0.0.10
BGP routing table entry for 9.0.0.10/32, version 28
Paths: (2 available, best #2, table 8000)

      Origin incomplete, localpref 100, valid, external
      rx pathid: 0, tx pathid: 0
  Refresh Epoch 1
  9

```

```
10.6.9.6 from 10.6.9.6 (9.0.0.6)
  Origin incomplete, localpref 100, valid, external, best
  rx pathid: 0, tx pathid: 0x0
```

Personally, I would prefer to have all MSDP speakers playing by the same “rules” in a real network design. We enable RFC3618 for RPF rules on CSR9 and observe the differences. We now expect more XR-like behavior with respect to the debug outputs and show commands. The XE platforms don’t tell you rules 1 through 5, but instead give you a brief description of why it was selected. For example, if we look at the MSDP RPF towards 9.0.0.10, we can see that the advertising peer equals the originating RP (“Peer is RP”), which is RFC3618 rule 1. Under Cisco’s rules, this would also “pass” by not even triggering the RPF check. If we repeat the show command for XRv2’s loopback on CSR9, the RFC3618 rule is 4 (“Peer is best in the closest AS”), which is consistent with how XRv2 views CSR9 (reciprocity, in a way). There is no BGP or MSDP peer with this address, and the path to 8.0.0.12 is consistent with the SA received from the MSDP peer in that AS.

```
! CSR9
ip msdp rpf rfc3618

R9#show ip msdp rpf-peer 9.0.0.10
RPF peer information for ? (9.0.0.10)
  RPF peer: ? (9.0.0.10)
  RPF route/mask: 9.0.0.10/32
  RPF rule: Peer is RP
  RPF type: mbgp

R9#show ip msdp rpf-peer 8.0.0.12
RPF peer information for ? (8.0.0.12)
  RPF peer: ? (9.0.0.10)
  RPF route/mask: 9.0.0.10/32
  RPF rule: Peer is best in the closest AS
  RPF type: mbgp
```

Examining the debugs, we can confirm these findings. From CSR10, SA messages originating from XRv2 are accepted since this is the best-path back to the originating RP. When CSR9 receives SAs from XRv1 from CSR10, these are rejected, since CSR9 is expecting to learn these directly from CSR10. This makes sense because CSR10 and CSR9 have a direct MSDP peering, so RFC3618 rule 4 is used as shown above. In order for the XE debugging to be particularly useful, one would have to memorize the five RFC3618 rules since it doesn’t give you the Roman numeral as XR does. Then again, if RPF passes and everything is functional, an administrator may have less of a reason to reveal these details.

```
! CSR9

MSDP(0): 7.0.0.11: Peer RPF check failed for 9.0.0.10, EMBGP route/peer in AS
7/0

```

I view MSDP as being a combination of PIM and BGP in some ways. It has RPF rules for control-plane SAs just like PIM has RPF rules for register messages. It is like BGP based on its ability to relay information across ASes, along with its TCP transport and rich filtering options. We notice that MSDP peers, upon receipt of a valid SA (one that passes RPF), will automatically re-send that SA to all other MSDP peers except the peer from which it was received. While this doesn't cause any loops due to RPF rules, it can be very inefficient, especially in a meshed network. For example, when CSR9 receives SAs from CSR10, there is no reason for it to re-send them to XRv1, since XRv1 and CSR10 have a direct MSDP session. The same is true on XRv2's reception of SAs from CSR10. In BGP, the iBGP "split-horizon" rule effectively prevents this re-advertisement of routes within an AS; we can relax this rule with route-reflectors. Note: The MSDP AS information is not relevant for MSDP advertisement in terms of "split-horizon" like BGP. In MSDP, the opposite logic is used; SAs are flooded liberally by default and we can restrict their advertisement using mesh-groups. Mesh-groups are generally used for intra-AS flood reduction but we can use it for inter-AS as well. The concept is simple; SAs received from a peer in a given mesh-group can never be advertised to a peer in the same mesh-group. The assumption is that the sending MSDP peer always has a direct connection to all other peers in the mesh-group. Enabling this feature can reduce SA flooding, saving routing resources (less RPF lookups and guaranteed failures) and bandwidth (less flooding). We will configure this on all MSDP peers in accordance with the example I gave above.

```

! CSR9
ip msdp mesh-group MG9 7.0.0.11
ip msdp mesh-group MG9 9.0.0.10

! XRv2
router msdp
 peer 7.0.0.11
   mesh-group MG12

 peer 9.0.0.10
   mesh-group MG12

```

Before observing the operational effect of this feature, we will verify the configuration by checking the peer details on each router. Mesh groups are only locally significant and are not signaled in MSDP. They can be any text string and every peer can belong to a maximum of one mesh group. The way I've configured it, it is similar to a BGP route-reflector design where XRv2 and CSR9 should be clients only; that is, not route-reflectors. They should not advertise anything other than logically originated SA messages.

```

R9#show ip msdp peer | include ^MSDP_Peer|mesh

```

```
MSDP Peer 7.0.0.11 (?), AS 7 (configured AS)
  Peer is member of mesh-group MG9
MSDP Peer 9.0.0.10 (?), AS 9 (configured AS)
  Peer is member of mesh-group MG9
```

```
RP/0/0/CPU0:XRv2#show msdp peer | utility egrep '^MSDP Peer|mesh'
MSDP Peer 7.0.0.11 (?), AS 7
  Peer is a member of mesh group MG12
MSDP Peer 9.0.0.10 (?), AS 9
  Peer is a member of mesh group MG12
```

First, we will verify the behavior on CSR9. With CSR2 sending traffic, CSR10 (9.0.0.10 as the RP address and MSDP peer) will advertise SAs to all MSDP peers since there are no mesh groups configured there. When CSR9 receives it, it can only advertise it to peers in a different mesh group than CSR10. Since all peers are in the same mesh group as CSR10, CSR9 does nothing beyond process it locally. It is interesting to note that enabling mesh groups for a peer totally bypasses the MSDP RPF checks as the debug reveals. This could be a workaround for RPF issues as well. Since both messages bypass RPF, CSR9 installs the one it receives first, which came directly from CSR10. It doesn't really matter which one gets installed since the (S,G) join will traverse the shortest path to the originating RP anyway.

```
! CSR9
debug ip msdp peer
debug ip msdp detail
```

```
MSDP(0): Received 120-byte TCP segment from 9.0.0.10

```

As further proof, we can check CSR9 to ensure it is not advertising the SA or (9.2.5.2, 225.0.1.3) towards XRv1 (7.0.0.11). Being in the same mesh group, this should never happen. It is, however, advertising its locally originated SA which is a result of CSR4 sending traffic into the network. This is the desired result, which effectively allows CSR9 to be a “non-transit” MSDP node.

```
R9#show ip msdp peer 7.0.0.11 advertised-SAs
```

```
MSDP SA advertised to peer 7.0.0.11 (?) from mroute table

```
225.0.1.3      11.4.13.4 (?)
```

```
MSDP SA advertised to peer 7.0.0.11 (?) from SA cache
[no output]
```

There is a third way to bypass RPF in MSDP as well; this is the default-peer feature. This is valuable for environments where SAs should be accepted from a peer no matter what. You can specify multiple default-peers in a router, but they are processed top-down assuming the peers are up and a prefix-list is not used. We can optionally apply a prefix list to each default peer to specify which sources apply to which peer. For example, on CSR9 we could configure CSR10 and XRv1 as default peers given the sources in each of their ASes. Although this will remain in the configuration for demonstration purposes, this feature only makes sense when MSDP and BGP are not deployed together. This can be used for stub ASes that may not be running BGP, or perhaps a multi-homed customer to two ISPs with two static default routes. The current network does not fit this design without significant rework, so we don't test this further.

```
! CSR9
ip msdp default-peer 9.0.0.10 prefix-list PL_AS9
ip msdp default-peer 7.0.0.11 prefix-list PL_AS7
ip prefix-list PL_AS7 seq 5 permit 7.0.0.0/8 le 32
ip prefix-list PL_AS9 seq 5 permit 9.0.0.0/8 le 32
```

XR is less flexible than XE with respect to this feature, so I show a snippet below but do not commit it to the configuration. XR only allows for one default peer (good in a single-homed PE-CE environment without BGP) and thus no prefix-list support is needed. The snippet shows XRv1 as an example.

```
! XRv2 (example only)
router msdp
  default-peer 7.0.0.11
```

There are other minor options used for fine-tuning SA advertising. One of them is setting a basic SA-limit, which is loosely analogous to OSPF's "max-lsa" command. Only a certain amount of SAs can be received from a peer, regardless of what (S,G) pairs they represent, and this is a security mechanism to prevent DoS attacks against the MSDP control-plane. The syntax differs slightly between XE and XR, and we configure this between CSR10 and XRv1 for demonstration with a limit of 500 SAs. XE clearly shows this new limit in the peer output but XR does not.

```
! XRv1
router msdp
  peer 10.10.11.10
    maximum external-sa 500
```

```
! CSR10
ip msdp sa-limit 7.0.0.11 500
```

```
R10#show ip msdp peer 7.0.0.11 | include limit
  SAs learned from this peer: 0, SAs limit: 500
```

We can also filter SAs based on sources, groups, or both together. On CSR9 and XRv1, we configure them to reject sending SAs sourced from their own major networks to any administratively-scoped

addresses towards CSR9 and XRv2. In a real deployment, a feature like this would make sense on all external peers, but I demonstrate it towards CSR9 and XRv2. The filters on CSR9 use a combination of route-maps and ACLs while XRv1 only uses ACLs. XR RPLs are not supported for SA-filtering in MSDP.

```
! CSR10
ip access-list extended ACL_SA_FILTER
  deny ip 9.0.0.0 0.255.255.255 239.0.0.0 0.255.255.255
  permit ip any any

route-map RM_FILTER_SA permit 10
  match ip address ACL_SA_FILTER

ip msdp sa-filter in 8.0.0.12 list ACL_SA_FILTER
ip msdp sa-filter out 8.0.0.12 list ACL_SA_FILTER
ip msdp sa-filter in 11.0.0.9 route-map RM_FILTER_SA
ip msdp sa-filter out 11.0.0.9 route-map RM_FILTER_SA

! XRv1
ipv4 access-list ACL_SA_FILTER
  10 deny ipv4 9.0.0.0 0.255.255.255 239.0.0.0 0.255.255.255
  20 permit ipv4 any any

router msdp
  peer 11.0.0.9
    sa-filter in list ACL_SA_FILTER
    sa-filter out list ACL_SA_FILTER

  peer 8.0.0.12
    sa-filter in list ACL_SA_FILTER
    sa-filter out list ACL_SA_FILTER
```

We quickly verify that the configurations were applied successfully on both routers for both peers. On CSR10, the output changes slightly based on whether a route-map or ACL is used, since XE gives us the option.

```
R10#show ip msdp peer 8.0.0.12 | section Filtering
SA Filtering:
  Input (S,G) filter: ACL_SA_FILTER, route-map: none
  Input RP filter: none, route-map: none
  Output (S,G) filter: ACL_SA_FILTER, route-map: none
  Output RP filter: none, route-map: none

R10#show ip msdp peer 11.0.0.9 | section Filtering
SA Filtering:
  Input (S,G) filter: none, route-map: RM_FILTER_SA
  Input RP filter: none, route-map: none
  Output (S,G) filter: none, route-map: RM_FILTER_SA
  Output RP filter: none, route-map: none
```

```
RP/0/0/CPU0:XRv1#show msdp peer 11.0.0.9 | begin Filtering
SA Filtering:
```

```
Input (S,G) filter: ACL_SA_FILTER
```

```

SA Filtering:
```

```
Input (S,G) filter: ACL_SA_FILTER
```

```
Input RP filter: none
```

```
Output (S,G) filter: ACL_SA_FILTER
```

```
Output RP filter: none
```

To demonstrate this in action, I will source traffic from CSR2 to group 239.1.1.1, which will be (9.2.5.2, 239.1.1.1). This will match the outgoing filter on CSR10 and the SA will not be advertised to XRv2 or CSR9 at all, but XRv1 will receive it. XRv1 is likewise not allowed to send it to XRv2 or CSR9, so they shouldn't have the SA via any means. We enable debugging on CSR10 and XRv1 to confirm this. Of note, it seems like the XE route-map doesn't work since the message was filtered to XRv2 (ACL) but not to CSR9 (route-map).

```
R2#ping 239.1.1.1 repeat 1000000 timeout 1
```

```
! CSR10
```

```
MSDP(0): 7.0.0.11: Building SA message from SA cache
```

```
MSDP(0): start_index = 0, sa_cache_index = 0, Qlen = 0
```

```
MSDP(0): Sent entire sa-cache, sa_cache_index = 0, Qlen = 0
```

```
MSDP(0): Received 3-byte TCP segment from 7.0.0.11
```

```
MSDP(0): Append 3 bytes to 0-byte msg 9190 from 7.0.0.11, qs 1
```

```
MSDP(0): 7.0.0.11: Received 3-byte msg 9190 from peer
```

```
MSDP(0): 7.0.0.11: Keepalive TLV
```

```
MSDP(0): 7.0.0.11: Sending Keepalive message to peer
```

```
MSDP(0): 8.0.0.12: Filtered encapsulated message to peer
```

```
MSDP(0): 11.0.0.9: Send 100-byte SA encapsulated data for (9.2.5.2, 239.1.1.1), RP 9.0.0.10
```

```
MSDP(0): 7.0.0.11: Send 100-byte SA encapsulated data for (9.2.5.2, 239.1.1.1), RP 9.0.0.10
```

The XR debug isn't nearly as valuable since it doesn't show the filtering in real-time, but we do see the SA arriving from 9.0.0.10.

```
! XRv1
```

```
msdp[1045]: [1] default 10.10.11.10 tlv: ReadQ: 120 bytes in buffer
```

```
msdp[1045]: [1] default 10.10.11.10 tlv: ReadQ: TLV parsed length = 120, type = 1
```

```
msdp[1045]: [1] default 10.10.11.10 tlv: 10.10.11.10: rcvd
<SourceActive,120>
msdp[1045]: [1] default 10.10.11.10 tlv: RP 9.0.0.10 has 1 entries
msdp[1045]: [1] default 10.10.11.10 tlv: -- (9.2.5.2/32 239.1.1.1)
msdp[1045]: [1] default 10.10.11.10 tlv: -- 100 bytes of encap'd data
remain
```

We confirm the error by checking CSR10 to see if it actually advertised SAs. We also check XRv2 and CSR9 for further confirmation. We can conclude the route-map mechanism isn't working in XE in version 3.13.2S. I would recommend to use the ACL only, primarily because it always works and because it is consistent with XR.

```
R10#show ip msdp peer 8.0.0.12 advertised-SAs | include 239
[no output]
```

```
R10#show ip msdp peer 11.0.0.9 advertised-SAs | include 239
239.1.1.1          9.2.5.2 (?)
```

```
RP/0/0/CPU0:XRv2#show msdp sa-cache 239.1.1.1
[no output]
```

```
R9#show ip msdp sa-cache 239.1.1.1
MSDP Source-Active Cache - 1 entries for 239.1.1.1
(9.2.5.2, 239.1.1.1), RP 9.0.0.10, MBGP/AS 9, 00:03:49/00:05:14, Peer
9.0.0.10
```

Continuing on, XRv1 correctly processes this SA from CSR10 and adds it to the SA cache. XRv1 is allowed to learn this SA as it was not filtered outbound on CSR10 or inbound on XRv1.

```
RP/0/0/CPU0:XRv1#show msdp sa-cache 239.1.1.1
MSDP Flags:
E - set MRIB E flag , L - domain local source is active,
EA - externally active source, PI - PIM is interested in the group,
DE - SAs have been denied. Timers age/expiration,
Cache Entry:
(9.2.5.2, 239.1.1.1), RP 9.0.0.10, MBGP/AS 9, 00:01:16/00:01:54
  Learned from peer 10.10.11.10, RPF peer 10.10.11.10
  SAs rcvd 2, Encapsulated data received: 100
  grp flags: none, src flags: EA
```

Both XE and XR show ACL hits which are revealed when the SAs are matched against a filter. Of course, on CSR10, these hits only increment when advertising SAs to XRv2 since the route-map applied to CSR9 is dysfunctional and never matches.

```
RP/0/0/CPU0:XRv1#show access-lists ACL_SA_FILTER
ipv4 access-list ACL_SA_FILTER
10 deny ipv4 9.0.0.0 0.255.255.255 239.0.0.0 0.255.255.255 (28 matches)
```

```
20 permit ipv4 any any (24 matches)
```

```
R10#show access-list ACL_SA_FILTER  
Extended IP access list ACL_SA_FILTER
```

```
10 deny ip 9.0.0.0 0.255.255.255 239.0.0.0 0.255.255.255 (4 matches)  
20 permit ip any any (43 matches)
```

TTL scoping is a simple mechanism to help confine multicast traffic within a certain AS. This becomes very significant in IPv6 since it is one of the main mechanisms for performing inter-AS ASM; there is no MSDP for IPv6. MSDP can also identify TTL-thresholds per peer which will cause it not to encapsulate data traffic into SA messages to peers if the TTL of the multicast data packet is less than or equal to the configured value. For example, XE has no default here, but XR has a default threshold value of 2. This makes sense because in terms of inter-AS multicast, it's highly likely that the source and destination and less than 2 hops away. Building an inter-AS multicast tree would be useless since the data-plane traffic would expire before reaching the receivers. We quickly verify the defaults before adjusting the values.

```
R10#show ip msdp peer 7.0.0.11 | include ttl  
Peer ttl threshold: 0
```

```
RP/0/0/CPU0:XRv1#show msdp peer 10.10.11.10 | include ttl  
Peer ttl threshold: 2
```

On XRv1 and CSR10, on the peering they share, I adjust the TTL-threshold value to 8. This means that multicast packets with TTL <= 8 cannot be encapsulated into SA messages and sent to the peer in question. A higher threshold implies a more strict filtering policy. After configuring the feature, we quickly verify the change, although testing this is difficult given our inability to adjust ping TTLs.

```
! CSR10  
ip msdp ttl-threshold 7.0.0.11 8
```

```
! XRv1  
router msdp  
peer 10.10.11.10  
ttl-threshold 8
```

```
R10#show ip msdp peer 7.0.0.11 | include ttl  
Peer ttl threshold: 8
```

```
RP/0/0/CPU0:XRv1#show msdp peer 10.10.11.10 | include ttl  
Peer ttl threshold: 8
```

MSDP also has a concept of redistribution. This is totally unrelated to route redistribution used in unicast routing protocols. The word “redistribution” in this context relates to the redistribution of sources within the MSDP topology. In other words, it is a first-stage filter that is used by an MSDP speaker to determine for which (S,G) an SA is created at all. For example, local multicast traffic

(239.0.0.0/8 groups, RFC1918 sources, etc) shouldn't even have an SA built at all in many cases; there is little reason to announce this traffic outside of an AS boundary. MSDP speakers that aren't RPs have no reason to originate SAs at all, only forward them. MSDP redistribution can achieve both goals. This feature is only supported in XE, and we will configure it on CSR9. CSR9 has no other filtering configured, so when CSR4 sends traffic to group 239.1.1.2, CSR9 should not even create an SA message. The feature accepts a route-map, ACL, or AS-path ACL. For simplicity, I use an ordinary ACL below.

```
! CSR9
ip access-list extended ACL_MSDP_REDISTRIBUTE
deny ip 11.0.0.0 0.255.255.255 239.0.0.0 0.255.255.255
permit ip any any

ip msdp redistribute list ACL_MSDP_REDISTRIBUTE
```

To test it, I will use two test groups. One is a global group of 225.0.1.3, the group CSR4 is using currently. I also send traffic to 239.1.1.2; both of these groups are successfully registered with the RP. The 'A' flag means these are candidates for MSDP advertisement and the SAs will be redistributed unless we manually filter them. The reason 239.1.1.2 is pruned is because there are no receivers, but 225.0.1.3 actually has real receivers from earlier.

```
! CSR9
ping 225.0.1.3 repeat 1
ping 239.1.1.2 repeat 1
```

```
R9#show ip mroute 239.1.1.2 11.4.13.4 | begin \
(11.4.13.4, 239.1.1.2), 00:03:22/00:02:57, flags: PA
Incoming interface: GigabitEthernet2.593, RPF nbr 11.9.13.13
Outgoing interface list: Null
```

```
R9#show ip mroute 225.0.1.3 11.4.13.4 | begin \
(11.4.13.4, 225.0.1.3), 00:02:04/00:03:29, flags: A
Incoming interface: GigabitEthernet2.593, RPF nbr 11.9.13.13
Outgoing interface list:
GigabitEthernet2.594, Forward/Sparse, 00:02:04/00:03:25
```

Checking CSR9's advertised SAs to CSR10 as an example, we only see group 225.0.1.3 and not 239.1.1.2. Like the SA filter ACLs, we can also see matches for (S,G) entries that match a particular ACL entry. We cannot confirm this with MSDP debug on CSR9 because it displays no output. The filtering likely occurs before the MSDP debug processes see it. This concludes the MSDP section of this book.

```
R9#show ip msdp peer 9.0.0.10 advertised-SAs
MSDP SA advertised to peer 9.0.0.10 (?) from mroute table

225.0.1.3 11.4.13.4 (?)
```

```
R9#show access-lists ACL_MSDP_REDISTRIBUTE
```

Extended IP access list ACL_MSDP_REDISTRIBUTE

```
10 deny ip 11.0.0.0 0.255.255.255 239.0.0.0 0.255.255.255 (17 matches)
20 permit ip any any (14 matches)
```

As mentioned earlier, setting multicast TTL-thresholds on administrative boundaries can help scope multicast as well. It is cruder than ACL-based filtering and not often used with IPv4; XE no longer supports the command and it is hidden in the parser. XR does support the command, and I enable it on the link to CSR10 for demonstration purposes. Earlier we used a multicast boundary to filter AutoRP advertisements, so we don't demonstrate that again, but that is a preferred method for inter-AS filtering.

```
R10(config-subif)#ip multicast ttl 8
```

This command is no longer supported.

```
! XRv1
multicast-routing
 address-family ipv4
   interface GigabitEthernet0/0/0/0.501
     ttl-threshold 8
```

One of the simplest methods to do inter-AS multicast is to use SSM. This obviates the need for PIM RPs and MSDP entirely, relying only on RPF back to the sources directly. We quickly enable SSM for a custom range 238.0.0.0/8 on all multicast routers in the network. By default, XR uses 232.0.0.0/8 and XE doesn't have SSM enabled at all. We have tested SSM in other chapters using 232.0.0.0/8 but using a custom group is good for variety.

```
! All XE multicast routers
ip pim ssm range ACL_SSM
ip access-list standard ACL_SSM
 permit 238.0.0.0 0.255.255.255
```

```
! All XR multicast routers
ipv4 access-list ACL_SSM
 10 permit ipv4 any 238.0.0.0/8
```

```
multicast-routing
 address-family ipv4
   ssm range ACL_SSM
```

For SSM to work, the PIM routers connecting to receivers must support IGMPv3, which is not the XE default. We enable it on CSR5, CSR7, and CSR8 under their appropriate LAN interfaces. The receivers could potentially be CSR1 through CSR4, so they must also support IGMPv3. Only CSR5 is shown for brevity.

```
! CSR5
```

```
interface GigabitEthernet2.525
 ip igmp version 3
```

To test this, CSR3 will request traffic for 238.3.3.3 from 9.2.5.2 which resides in AS 9. We ensure that CSR8 receives the IGMPv3 membership report in INCLUDE mode, which “includes” specific sources, namely 9.2.5.2.

```
R8#show ip igmp groups 238.3.3.3 detail
```

```
Flags: L - Local, U - User, SG - Static Group, VG - Virtual Group,
       SS - Static Source, VS - Virtual Source,
       Ac - Group accounted towards access control limit
```

```
Interface:      GigabitEthernet2.538
```

```
Group:          238.3.3.3
```

```
Flags:          SSM
```

```
Uptime:         00:00:29
```

```
Group mode:     INCLUDE
```

```
Last reporter:  8.3.8.3
```

```
Group source list: (C - Cisco Src Report, U - URD, R - Remote, S - Static,
                   V - Virtual, M - SSM Mapping, L - Local,
                   Ac - Channel accounted towards access control limit)
```

Source Address	Uptime	v3 Exp	CSR Exp	Fwd	Flags
9.2.5.2	00:00:29	00:02:31	stopped	Yes	R

CSR8 creates (S,G) state for this SSM group. Interestingly, the RPF check to 9.2.5.2 is via multicast BGP because we advertised that LAN route into BGP for MSDP testing earlier. The ‘s’ flag implies SSM is in use and the ‘l’ flag implies that a host-specific join was received.

```
R8#show ip mroute ssm
```

```
(9.2.5.2, 238.3.3.3), 00:01:28/00:02:01, flags: sTI
```

```

Outgoing interface list:
GigabitEthernet2.550, Forward/Sparse, 00:09:02/00:03:20
```

Checking the packet counters on CSR8 for brevity, we can see traffic is successfully being delivered to CSR3. There was no additional complexity with PIM RPs or MSDP in this design, and once the SPT is built, there is no additional signaling required once the source starts sending traffic.

```
R2#ping 238.3.3.3 repeat 10000 timeout 1
```

```
R8#show ip mroute 238.3.3.3 9.2.5.2 count | begin ^Group
Group: 238.3.3.3, Source count: 1, Packets forwarded: 18, Packets received:
18
Source: 9.2.5.2/32, Forwarding: 18/1/118/0, Other: 18/0/0
```

```
R8#show ip mroute 238.3.3.3 9.2.5.2 count | begin ^Group
Group: 238.3.3.3, Source count: 1, Packets forwarded: 28, Packets received:
28
Source: 9.2.5.2/32, Forwarding: 28/1/118/0, Other: 28/0/0
```

Next, we will examine IPv6 inter-AS multicast routing. Because there is no concept of MSDP, we can achieve intelligent scoping in one of three ways. I list them in order of my personal preference, and probably from most straightforward to most difficult.

1. Use SSM as we did for IPv4. The signaling logic is identical for IPv4 SSM and IPv6 SSM.
2. Use embedded RP for ASM, which does not apply in IPv4. The IPv6 data packet embeds the IPv6 RP information and provided there is a common RP for this group, the proper trees can be built.

3. Use the scope bits inside the IPv6 group address for ASM. These were discussed in the IPv6 general architecture section and allow the administrator to define arbitrary boundaries. We could also use these to scope SSM traffic as they are independent from the multicast transport type.

First, we will use IPv6 SSM similar to how we did for IPv4. We will use the default IPv6 SSM range of FF33::/32 since XE does not appear capable of specifying a custom range. Technically, FF3x::/32 where 3 <= x <= F are valid IPv6 ranges, but we will use FF33::/32 for simplicity (scope bits of link-local or node-local don't make sense for SSM). CSR4 will be a receiver for group FF33::4 and CSR1 will be the source (2007:7:1:7::1). Just like IPv4 SSM requires IGMPv3 at the receiver, IPv6 SSM requires MLDv2 at the receiver. Both XE and XR have this enabled by default, so we don't have to modify this. CSR4 issues the INCLUDE mode membership report to XRv3 who processes it locally.

```
! CSR4
interface GigabitEthernet2.543
  ipv6 mld join-group FF33::4 2007:7:1:7::1

RP/0/0/CPU0:XRv3#show mld groups ff33::4 gig0/0/0/0.543 detail

XRv3 now creates (S,G) create within the IPv6 MRIB and PIM topology. The SPT is built as follows: XRv3 > CSR9 > XRv4 > CSR7. Just like with IPv4, the little 's' flag on XE indicates this is an SSM group, where XR actually uses the string "SSM".

```
RP/0/0/CPU0:XRv3#show pim ipv6 topology ff33::4 | begin ff33
(2007:7:1:7::1, ff33::4) SPT
SSM Up: 00:04:27 JP: Join(00:00:21) Flags:

```

We begin pinging on CSR1 to test reachability. We can check the counters on XRv3 to ensure traffic is being delivered to CSR4. We can see packets in/packets out on XRv3, and the numbers are equal which means there is only one OIL interface (no replication). I issue the command a few seconds apart so we can see the counters increment. The 'A' flag on Gig0/0/0/0.593 shows that packets were "accepted" from this interface (valid RPF) and the 'EG' flag on Gig0/0/0/0.543 shows that packets were "egressing" towards CSR4.

```

```

Next, we will test embedded RP in an inter-AS environment. We first need to identify the RPs and statically configure them (and only them) as RPs. Because this information is contained within the IPv6 data traffic, we don't necessarily need to be fancy with per-group RP assignments. The RP will look like a

static RP on these nodes (because it is). We begin with CSR10 and CSR9, then verify the RP configuration afterwards.

```
! CSR10
ipv6 pim rp-address 2009::a
```

```
! CSR9
ipv6 pim rp-address 200b::9
```

```
R10#show ipv6 pim range-list 2009::a
Static SM RP: 2009::A Exp: never Learnt from : ::
FF00::/8 Up: 00:00:26
```

```
R9#show ipv6 pim range-list 200b::9
Static SM RP: 200B::9 Exp: never Learnt from : ::
FF00::/8 Up: 00:00:12
```

We configure the same feature on XRv1 and XRv2. The configuration is similar and we verify the RP mappings before continuing. The difference is that in XR, you cannot simply specify a static RP; you must use the specified embedded-RP command. Additionally, you must specify a group-list, but I permit all globally-scoped groups for each RP. The ACL is commonly used for scoping since we can permit/deny certain ranges within a given scope. The breakdown of the group addresses is discussed next. At this point, every AS has an RP.

```
! XRv1
ipv6 access-list ACL_EMBEDDED_RP
10 permit ipv6 any ff7e:b40:2007::/96
```

```
router pim
address-family ipv6
embedded-rp 2007::b ACL_EMBEDDED_RP
```

```
! XRv2
ipv6 access-list ACL_EMBEDDED_RP
10 permit ipv6 any ff7e:c40:2008::/96
```

```
router pim
address-family ipv6
embedded-rp 2008::c ACL_EMBEDDED_RP
```

```
RP/0/0/CPU0:XRv1#show pim ipv6 group-map ff7e:b40:2007::
IP PIM Group Mapping Table
(* indicates group mappings being used)
(+ indicates BSR group mappings active in MRIB)
```

Group Range	Proto	Client	Groups
ff7e:b40:2007::/96*	SM	embd-cfg	0

```
RP: 2007::b
RPF: De6tunnel2, 2007::b (us)
```

```
RP/0/0/CPU0:XRv2#show pim ipv6 group-map ff7e:c40:2008::
IP PIM Group Mapping Table
(* indicates group mappings being used)
(+ indicates BSR group mappings active in MRIB)
```

Group Range	Proto	Client	Groups
ff7e:c40:2008::/96*	SM	embd-cfg	0
RP: 2008::c			
RPF: De6tunnel2, 2008::c (us)			

Before continuing, we will specify the appropriate embedded RP group-ranges supported by each embedded RP. For simplicity I will use global scope (0xE) for now. The RP host address is limited to 4 bits, which is why I used hexadecimal characters for the router loopback low-order bits rather than decimal numbers. This is relevant particularly on CSR10 and the XR routers. In the examples below, yellow highlights the scope, green highlights the RP host ID, pink highlights the prefix length (0x40 = 64), grey highlights the prefix, and cyan highlights the available groups.

```
CSR9:  FF7E:0940:200B:0:0:0:0:0/96
CSR10: FF7E:0A40:2009:0:0:0:0:0/96
XRv1:  FF7E:0B40:2007:0:0:0:0:0/96
XRv2:  FF7E:0C40:2008:0:0:0:0:0/96
```

A very quick way to verify this is to ping an IPv6 multicast group in each of these ranges from any of our test clients provided embedded RP is supported (it is enabled by default on XE and XR). The PIM DR that registers these sources will be smart enough to know the RP is embedded based on the flags in the group address header (these flags were discussed in the IPv6 architecture section). I will conduct this test on CSR2 using CSR5 as the PIM DR. We enable debugging on CSR5 to watch it create range-list (RP mapping) entries for the proper RPs, then confirm it creates (S,G) state for each entry.

```
! CSR9 is RP
R2#ping FF7E:0940:200B:0:0:0:0:0
Output Interface: GigabitEthernet2.525
```

```
! CSR10 is RP

```

We can confirm the MRIB to ensure the (S,G) state exists for each one. Since CSR5 should be registering each (S,G) to each remote RP, the entries should exist for each (S,G) that CSR2 used.

```
R5#show ipv6 mroute | begin FF7
(2009:9:2:5::2, FF7E:940:200B::), 00:01:40/00:01:49, flags: SFT

Embedded SM RP: 200B::9 Exp: never Learnt from : ::
  FF7E:940:200B::/96 Up: 00:02:23
```

It appears that register messages are never being sent. None of the remote RPs show any indication of receiving a register message. To prove it, below I show two PIM tunnels. One is the register tunnel for the IPv4 RP within AS 7 and the other is for the embedded RP in AS 8. This is the same behavior seen in the MVPN section with embedded RP as well.

```
R5#show ip pim tunnel
Tunnel1
  Type      : PIM Encap
  RP        : 9.0.0.10
  Source    : 9.5.10.5
  State     : UP
  Last event : Created (1d02h)
```

```
R5#show ipv6 pim tunnel
Tunnel0*
  Type : PIM Encap
  RP   : Embedded RP Tunnel
  Source: 2009::5
```

Despite the embedded RP destination being known, the tunnel destination is unspecified. One may think this is just a cosmetic issue because the RP isn't learned ahead of time and the tunnel is built dynamically. Having testing embedded RP before, this is actually a normal case.

```
R5#show derived-config interface tunnel1
```

```

interface Tunnel1
  description Pim Register Tunnel (Encap) for RP 9.0.0.10
  ip unnumbered GigabitEthernet2.550
  tunnel source GigabitEthernet2.550
  tunnel destination 9.0.0.10
  tunnel tos 192

```

```

R5#show derived-config interface tunnel0
interface Tunnel0
  description Pim Register Tunnel (Encap) for Embedded RP
  no ip address
  ipv6 unnumbered Loopback0
  ipv6 enable
  tunnel source Loopback0
  tunnel destination ::
  tunnel tos 224
  tunnel ttl 65

```

Furthermore, tunnel0 shows no outbound packets while tunnel1 does. Tunnel0 doesn't even show output drops or any sign of activity. Debugging CEF drops and IPv6 packets also reveals no indication of PIMv6 register messages being sent. Unfortunately, this is also the case in a working embedded RP design, making the problem difficult to troubleshoot.

```

R5#show interfaces tunnel1 | include output
Last input never, output never, output hang never
Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
5 minute output rate 0 bits/sec, 0 packets/sec
  10 packets output, 1280 bytes, 0 underruns
  0 output errors, 0 collisions, 0 interface resets
  0 output buffer failures, 0 output buffers swapped out

```

```

R5#show interfaces tunnel0 | include output
Last input never, output never, output hang never
Input queue: 0/375/0/0 (size/max/drops/flushes); Total output drops: 0
5 minute output rate 0 bits/sec, 0 packets/sec
  0 packets output, 0 bytes, 0 underruns
  0 output errors, 0 collisions, 0 interface resets
  0 output buffer failures, 0 output buffers swapped out

```

The feature actually works if traffic is sourced from CSR5's loopback and sent out of the interface as well. I assume that because this local traffic is processed-switched, the registration process happens successfully. I quickly test a group for each of the 4 embedded RPs to make sure the registers are working now. All of the OILs are null since there are no receivers in the network for any of these groups.

```

R5#ping FF7E:A40:2009:: source loopback0
Output Interface: loopback0

```

```
R10#show ipv6 mroute FF7E:A40:2009:: | begin \  
(2009::5, FF7E:A40:2009::), 00:00:25/00:03:04, flags: SP  
    Incoming interface: GigabitEthernet2.550  
    RPF nbr: FE80::5  
    Outgoing interface list: Null
```

```
R5#ping FF7E:940:200B:: source loopback0  
Output Interface: loopback0
```

```
R9#show ipv6 mroute FF7E:940:200B:: | begin \  
(2009::5, FF7E:940:200B::), 00:00:12/00:03:16, flags: SP  
    Incoming interface: GigabitEthernet2.569  
    RPF nbr: FE80::6  
    Outgoing interface list: Null
```

For additional verification, IPv6 PIM debugs on CSR9 (one of the RPs) shows that a register was received. We never saw this before when trying to make CSR5 register sources on its LAN interface to CSR2.

```
! CSR9  
IPv6 PIM: (2009::5,FF7E:940:200B::) Received Register from 2009::5  
IPv6 PIM: (2009::5,FF7E:940:200B::) Create entry  
IPv6 PIM: (2009::5,FF7E:940:200B::) RPF changed from ::/- to  
FE80::6/GigabitEthernet2.569
```

When testing this with XRv1 and XRv2, they receive the registers, but RPF appears to be failing despite both routers have valid unicast BGP routes.

```
R5#ping FF7E:B40:2007:: source loopback0  
Output Interface: loopback0
```

```
RP/0/0/CPU0:XRv1#show pim ipv6 topology ff7e:b40:2007:: | begin 2009

  Route metric is 0
  No advertising protos.

```

This is because whenever XR is running IPv4/v6 multicast in BGP, the IPv4/v6 unicast routes are not allowed to satisfy RPF. This is stricter than XE where any route can satisfy RPF if the multicast BGP entries do not exist. This is part of the reason why the MSDP RPF rules were so difficult earlier; XR assumes that if BGP multicast is available it must be used; unicast BGP routes are ignored. We will quickly advertise CSR5's IPv6 loopback into IPv6 BGP multicast, and then start the pings again.

```

! CSR5
router bgp 9
 address-family ipv6 multicast
   network 2009::5/128

```

```

R5#ping FF7E:B40:2007:: source loopback0

SM Up: 00:00:05 JP: Null(never) Flags: KAT(00:03:27) RA RR (00:04:29)
RPF: GigabitEthernet0/0/0/0.562,fe80::6
  No interfaces in immediate olist

```

Despite the RPF next-hops being the same as the unicast routes, XR simply didn't accept the unicast BGP routes for RPF when multicast AFIs were available. A quick look at the PIM RPF information confirms the

valid entries. CSR9 and CSR10, also running BGP IPv6 multicast, accepted the RPF derived from the BGP IPv6 unicast route to 2009::5.

```
RP/0/0/CPU0:XRv1#show pim ipv6 rpf 2009::5
Table: IPv6-Multicast-default
2009::5/128 [20/0]
  via fe80::10, GigabitEthernet0/0/0/0.501
```

```
RP/0/0/CPU0:XRv2#show pim ipv6 rpf 2009::5

2009::5/128 [20/0]
  via fe80::6, GigabitEthernet0/0/0/0.562
```

To actually test a real flow, I will join a group in AS8 from CSR3. This is an ASM join so no sources are included, as CSR8 shows.

```
! CSR3
interface GigabitEthernet2.538
  ipv6 mld join-group FF7E:C40:2008::3

R8#show ipv6 mld groups FF7E:C40:2008::3 detail
Interface:      GigabitEthernet2.538
Group:          FF7E:C40:2008::3
Uptime:         03:51:31
Router mode:    EXCLUDE (Expires: 00:03:23)
Host mode:      INCLUDE
Last reporter:  FE80::3
Source list is empty
```

CSR8 originates the (*,G) join towards the RP, which is 2008::C (XRv2). It gleans this from the group itself just like the first-hop routers did during the source registration process. XRv2 receives the join, sees itself as the RP, and becomes the root of the (*,G) tree. It is standing by to receive register messages on its decapsulation PIM tunnel.

```
R8#show ipv6 mroute ff7e:c40:2008::3 | begin \
(*, FF7E:C40:2008::3), 03:52:45/never, RP 2008::C, flags: SCJ
Incoming interface: GigabitEthernet2.582
RPF nbr: FE80::12
Immediate Outgoing interface list:
  GigabitEthernet2.538, Forward, 03:52:45/never
```

```
RP/0/0/CPU0:XRv2#show pim ipv6 topology ff7e:c40:2008::3 | begin ::3
(*,ff7e:c40:2008::3)
SM Up: 03:50:33 JP: Join(never) Flags:
RP: 2008::c*
RPF: Decaps6tunnel2,2008::c
  GigabitEthernet0/0/0/0.582 03:50:33 fwd Join(00:02:58)
```

We will send traffic from CSR5 (sourcing from the loopback so it works reliably) towards this new group. When XRv2 receives the register message, it does nothing special, and the signaling follows the same PIM ASM process we have reviewed many times.

```
R5#ping FF7E:C40:2008::3 source loopback0 repeat 100000 timeout 1
Output Interface: loopback0
```

XRv2 sends the (S,G) back towards 2009::5, which goes through CSR6 and CSR10 on the way. This is based on the BGP IPv6 multicast route which describes the RPF back to the source in question.

```

Immediate Outgoing interface list:
    GigabitEthernet2.560, Forward, 00:04:26/00:03:03
```

CSR8 switches over to the SPT (not terribly relevant in this design or for embedded RP) and is actively receiving packets along this tree. I issue the command a few seconds apart to ensure the counters are incrementing, which shows packets being forwarded towards the client, CSR3.

```
R8#show ipv6 mroute FF7E:C40:2008::3 2009::5 count | begin ^Group

Totals - Source count: 1, Packet count: 137

The last technique for inter-AS multicast is scoping. XE makes it easy with a custom command that automatically blocks all traffic at the configuration scope or less. XR requires manual multicast boundaries, which is similar to the IPv4 multicast boundary method. Let's assume that AS7 and AS9 are part of the same organization but are different geographical sites. They should be able to share organization-local traffic, but not site-local traffic. Their links to ASes 8 and 11 should block organizational traffic since those ASes are not within the organization. First, we will configure the XE routers in AS 9 since they are simpler. CSR10 limits scope 5 (site-local) and below within the AS, while CSR6 limits scope 8 (organization-local) and below within the AS. This means that global traffic can use any of these three links and organization-local traffic can use Gig2.501 on CSR10. I also show the context-sensitive help; we can use numbers or textual macros (which get converted into numbers).

```
R10(config-subif)#ipv6 multicast boundary scope ?
<3-15>                               Scope identifier for this zone
admin-local                          Admin-local(4)
organization-local                   Organization-local(8)
site-local                           Site-local(5)
subnet-local                         Subnet-local(3)
vpn                                  Virtual Routing/Forwarding(14)

! CSR10

  ipv6 multicast boundary scope 5

! CSR6
interface GigabitEthernet2.562
  ipv6 multicast boundary scope 8

interface GigabitEthernet2.569
  ipv6 multicast boundary scope 8
```

On XR, we have to create exhaustive ACLs. Since wildcards are not supported for IPv6 ACLs on either XE or XR, we enumerate all of the possible group ranges. Since the 'R', 'P', and 'T' bits have some dependencies upon one another, we don't need to enumerate all 16 combinations for the third hex digit, but we do need to account for the combinations shown below (there are four). We also should account for lesser, routable scopes, such as scopes 3 (subnet-local) and 4 (admin-local). The ACL on XRv4 is even longer since it has to account for all routable scopes at value 8 or less.

```
! XRv1

250 permit ipv6 any any
```

```
multicast-routing
address-family ipv6
  interface GigabitEthernet0/0/0/0.524
    boundary ACL_ORG_BOUNDARY

  interface GigabitEthernet0/0/0/0.594
    boundary ACL_ORG_BOUNDARY
```

We can see the effect of this within our existing topology. Earlier, when we tested IPv6 SSM, we used group FF33::4. This group is subnet-local with a scope value of 3, which is relatively low. XRv3 and CSR9 both have the (S,G) join for this as they are trying to build the tree back towards CSR1.

```
RP/0/0/CPU0:XRv3#show pim ipv6 topology | begin ff33
(2007:7:1:7::1,ff33::4) SPT
SSM Up: 08:18:21 JP: Join(00:00:15) Flags:
RPF: GigabitEthernet0/0/0/0.593,fe80::9
GigabitEthernet0/0/0/0.543 08:18:21 fwd LI LH

R9#show ipv6 mroute ff33::4 | begin \
(2007:7:1:7::1, FF33::4), 07:47:26/00:03:17, flags: sT
Incoming interface: GigabitEthernet2.594
RPF nbr: FE80::14
Immediate Outgoing interface list:
GigabitEthernet2.593, Forward, 07:47:26/00:03:17
```

However, XRv4 should not have this (S,G) due to the multicast-boundary applied. Only traffic scoped 9 or higher can be exchanged with AS 11. We see no multicast state for this group, and furthermore the boundary shows hits against the FF33::/32 entry. This proves that the boundary is functioning as expected, and this breaks connectivity from CSR1 to CSR4 using this group.

```
RP/0/0/CPU0:XRv4#show pim ipv6 topology ff33::4
No PIM topology table entries found.
```

```
RP/0/0/CPU0:XRv4#show access-list ipv6
ipv6 access-list ACL_ORG_BOUNDARY
10 deny ipv6 any ff08::/32
[snip, other entries are not interesting]
210 deny ipv6 any ff03::/32
220 deny ipv6 any ff13::/32
230 deny ipv6 any ff33::/32 (8 matches)
240 deny ipv6 any ff73::/32
250 permit ipv6 any any
```

To test the XE scope-based boundaries, we will try to join a new group on CSR4 via CSR2 as the source. The group is FF38::4 which is exactly equal to the scope configured on the AS 9 border routers; we expect the (S,G) join from CSR9 to be rejected by CSR6.

```
! CSR4
interface GigabitEthernet2.543
ipv6 mld join-group FF38::4 2009:9:2:5::2

RP/0/0/CPU0:XRv3#show pim ipv6 topology | begin ff38
(2009:9:2:5::2,ff38::4) SPT
SSM Up: 00:00:18 JP: Join(00:00:57) Flags:
```

```

RPF: GigabitEthernet0/0/0/0.593, fe80::9
    GigabitEthernet0/0/0/0.543  00:00:18  fwd LI LH

R9#show ipv6 mroute ff38::4 | begin \
(2009:9:2:5::2, FF38::4), 00:00:30/00:02:59, flags: sT
    Incoming interface: GigabitEthernet2.569
    RPF nbr: FE80::6
    Immediate Outgoing interface list:
        GigabitEthernet2.593, Forward, 00:00:30/00:02:59

```

Looking at CSR6, it has no entry for this group. There aren't many positive-logic show commands for this feature. The best way to verify is by confirming the absence of the groups in question on a given router. IPv6 PIM debugging on XE does reveal that the (S,G) join from CSR9 is rejected due to multicast scope, but there does not appear to be a comparable show command.

```

R6#show ipv6 mroute ff38::4
No mroute entries found.

! CSR6
IPv6 PIM: Received J/P on GigabitEthernet2.569 from FE80::9 target: FE80::6
(to us)
IPv6 PIM: J/P Group FF38::4 is a scoped boundary or denied, skipping

```

Configuring another SSM join on CSR1 with a group of similar scope towards CSR2, we can confirm that this works. CSR7 receives the INCLUDE-mode join which contains the source of CSR2. This is because AS 7 and AS 9 are allowed to share organization-scope IPv6 multicast.

```

! CSR1
interface GigabitEthernet2.517
    ipv6 mld join-group FF38::1 2009:9:2:5::2

R7#show ipv6 mld groups FF38::1 detail
Interface:      GigabitEthernet2.517
Group:          FF38::1
Uptime:         00:00:23
Router mode:    INCLUDE
Host mode:      INCLUDE
Last reporter:  FE80::1
Group source list:
Source Address              Uptime    Expires    Fwd  Flags
2009:9:2:5::2              00:00:23  00:03:56  Yes  Remote 4

```

CSR7 originates an (S,G) join towards CSR2, which is via XRv1. XRv1 then sends the (S,G) join towards CSR10 which is the RPF neighbor for the source. It passes the filter outbound on XRv1 since the scope is organization-local. If the multicast boundary denied this group, the link to CSR10 would not be in the OIL.

```

R7#show ipv6 mroute FF38::1 | begin \
(2009:9:2:5::2, FF38::1), 00:02:02/never, flags: sTI
Incoming interface: GigabitEthernet2.571
RPF nbr: FE80::11
Immediate Outgoing interface list:
GigabitEthernet2.517, Forward, 00:02:02/never

RP/0/0/CPU0:XRv1#show pim ipv6 topology | begin ff38
(2009:9:2:5::2, ff38::1) SPT
SSM Up: 00:02:20 JP: Join(00:00:14) Flags:
RPF: GigabitEthernet0/0/0/0.501, fe80::10
GigabitEthernet0/0/0/0.571 00:02:20 fwd Join(00:03:16)

```

The received (S,G) join likewise passes the filter inbound on CSR10 since the groups scope of 8 is greater than the boundary scope of 5. CSR10 passes the join to CSR5 who is the root of the SPT.

```

R10#show ipv6 mroute FF38::1 | begin \
(2009:9:2:5::2, FF38::1), 00:03:27/00:02:38, flags: sT
Incoming interface: GigabitEthernet2.550
RPF nbr: FE80::5
Immediate Outgoing interface list:
GigabitEthernet2.501, Forward, 00:03:27/00:02:38

R5#show ipv6 mroute FF38::1 | begin \
(2009:9:2:5::2, FF38::1), 00:03:42/00:02:50, flags: sT
Incoming interface: GigabitEthernet2.525
RPF nbr: 2009:9:2:5::2
Immediate Outgoing interface list:
GigabitEthernet2.550, Forward, 00:03:42/00:02:50

```

To confirm that organization-local multicast works, we ping from CSR2 and check the counters on CSR7 to ensure they increment.

```

R7#show ipv6 mroute FF38::1 count | begin ^Group

Totals - Source count: 1, Packet count: 22

```

In summary, there are several key lessons from this chapter:

- It is bad practice to let local RP information (BSR, AutoRP) leak in/out of a multicast domain/AS
 1. Use BSR border at the boundaries
 2. Filter AutoRP groups manually at the boundaries
 3. Last ditch effort: Use static RP “overrides”
- Cisco and RFC3618 MSDP RPF rules are different. XE uses Cisco’s rules by default while XR uses RFC3618. I recommend enabling RFC3618 RPF rules on XE routers because they are simpler to understand and consistent with XR platforms. This also enables the “show ip msdp rpf-peer” command within XE which returns the RFC3618 RPF rule used to match the RP input.
- When XR has BGP multicast AFIs configured, the RPF lookup always uses this table over the corresponding BGP unicast AFI. Existing BGP unicast routes, however valid they may be, cannot be used for RPF unless the corresponding multicast AFI is totally disabled on the router.
- For IPv4, inter-AS ASM almost always requires MSDP. SSM is much simpler as it removes the need for RPs and MSDP entirely.
- By default, MSDP is very liberal with its SA advertisement and relies heavily on RPF to prevent loops. A well-tuned MSDP network makes use of mesh-groups, TTL-thresholds, redistribution filters, and SA filters to minimize SA flooding in the first place.
- For IPv6, there are three main design options for enabling inter-AS multicast service:
 1. SSM: Simplest and most reliable
 2. Embedded RP ASM: Works well when used in conjunction with RP ACLs and scopes
 3. Scoping with globally-reachable RPs: Difficult to manage but possible

Additional Reading – Reference configurations “inter-as-mcast”

29.2 Multicast Only Fast Re-Reroute (MoFRR)

MoFRR is a feature used to ensure high availability for multicast traffic. It does not introduce any new protocols but adjusts how RPF works with traditional PIM. It is also not specific to MVPN or MPLS in general. When the PIM last hop router (LHR) receives an IGMP join, whether ASM or SSM, it will originate some kind of PIM join. ASM joins will be (*,G) PIM joins sent to the RP while SSM joins will be (S,G) PIM joins sent to the first hop router (FHR) connected to the source. In either case, the LHR and all intermediate routers towards the root of the given tree select exactly one RPF interface. This will normally follow the shortest IGP path to the root, and in the case of ECMP, select the PIM neighbor with the highest IP address. MoFRR allows a router to send multiple PIM joins towards the root of the tree for diversity; this technique works best when the two ECMP paths are separate networks or “planes” that are totally independent, but this is not a requirement. We can test it using an existing topology. Specifically, this section uses the MVPN profile 0 with PIM-SSM basic configuration as a starting point. The diagram is shown again for reference.

The only initial modification is that the direct link between XRv3 and XRv4 has been adjusted to an IS-IS metric of 20. In this way, there are 3 ECMPs between XRv3 and XRv4; MoFRR requires ECMP to operate. We can check the FIB on each core router towards one another to verify this configuration change.

```
! XRv3 and XRv4
router isis 1
interface GigabitEthernet0/0/0/0.534
point-to-point
address-family ipv4 unicast
metric 20

address-family ipv6 unicast
metric 20
```

```

  via 213.7.14.7, GigabitEthernet0/0/0/0.574, 8 dependencies, weight 0,
class 0 [flags 0x0]
```

Next, we will configure some new SSM groups within the customer VPN. Since the core of the network is purely using SSM, that is what will be tested. Using SSM in the customer VPN will simplify the design and allow us to focus on MoFRR, not basic PIM-ASM processes. To support data MDTs for sources behind it, CSR1's data MDT ACL will be extended to the entire SSM range, since CSR9 will be an IPv4 multicast source for this test. We will join a new SSM group on CSR4 as this will be the receiver.

```
! CSR1
ip access-list extended ACL_DATA_MDT
  no 10
  10 permit ip any 232.0.0.0 0.255.255.255

! CSR4
interface GigabitEthernet2.546
  ip igmp join-group 232.42.51.8 source 10.1.9.9
```

Before continuing, we will verify that the proper MDT has been built. CSR6 receives the IGMPv2 join operating in INCLUDE mode; we verify the proper source is carried in the membership report. A corresponding C(S,G) entry is created for this source/group pair.

```
R6#show ip igmp vrf MC groups 232.42.51.8 detail
[snip]
Interface:      GigabitEthernet2.546
Group:         232.42.51.8
Flags:         SSM
Uptime:        00:19:39
Group mode:    INCLUDE
Last reporter: 10.4.6.4
[snip]
```

Source Address	Uptime	v3 Exp	CSR Exp	Fwd	Flags
10.1.9.9	00:19:39	00:02:30	stopped	Yes	R

CSR6 translates this into a C-PIM join and sends it to CSR1. The join is sent within the default MDT which is used for C-PIM signaling.

```
R6#debug ip pim vrf MC
PIM(1): Insert (10.1.9.9,232.42.51.8) join in nbr 213.1.1.1's queue
PIM(1): Building Join/Prune packet for nbr 213.1.1.1
PIM(1): Adding v2 (10.1.9.9/32, 232.42.51.8), S-bit Join
PIM(1): Send v2 join/prune to 213.1.1.1 (Tunnel3)
```

Upon receipt, CSR1 adds the C(S,G) state to its C-MRIB and notifies CSR6, via PIM MDT TLV, that a data MDT is available for this C(S,G).

```
R1#debug ip pim vrf MC
PIM(17): Received v2 Join/Prune on Tunnel3 from 213.6.6.6, to us
PIM(17): Join-list: (10.1.9.9/32, 232.42.51.8), S-bit set
PIM(17): Add Tunnel3/213.6.6.6 to (10.1.9.9, 232.42.51.8), Forward state, by
PIM SG Join
PIM(17): MDT next_hop change from: 232.255.0.1 to 232.4.1.0 for (10.1.9.9,
232.42.51.8) Tunnel3
```

```
R1#show ip pim mdt send
MDT-data send list for VRF: MC
      (source, group)                MDT-data group/num  ref_count
(10.1.9.9, 232.42.51.8)            232.4.1.0          1
```

CSR6 receives this update, updates its C-MRIB entry with the MDT data to bind it to the proper P(S,G) entry. Without this data MDT, the traffic would be forwarded within the default MDT. The big 'Y' implies this entry is joined to a data MDT, and the information is embedded within the C-RIB entry. So far, this is all review, and nothing specific to MoFRR has occurred.

```
R6#debug ip pim vrf MC
PIM(1): Receive MDT Packet (11649) from 213.1.1.1 (Tunnel3), length (ip: 44,
udp: 24), ttl: 1
PIM(1): TLV type: 1 length: 16 MDT Packet length: 16
```

```
R6#show ip pim mdt receive
Joined MDT-data [group/mdt number : source]  uptime/expires for VRF: MC
[232.4.1.0 : 213.1.1.1]  00:24:13/00:02:45
[232.4.7.0 : 213.7.7.7]  03:55:34/00:02:25
```

```
R6#show ip mroute vrf MC 232.42.51.8 10.1.9.9 | begin \
(10.1.9.9, 232.42.51.8), 00:26:17/00:02:50, flags: sTIY
  Incoming interface: Tunnel3, RPF nbr 213.1.1.1,
MDT: [213.1.1.1,232.4.1.0]/00:02:11
  Outgoing interface list:
    GigabitEthernet2.546, Forward/Sparse, 00:07:08/00:02:50
```

As a final verification, we will check the P(S,G) entry on CSR6 to ensure it has been created. The RPF interface points towards XRv3 as expected. The big 'Z' identifies this as a multicast tunnel, and the OIL includes the multicast VRF being serviced.

```
R6#show ip mroute 232.4.1.0 213.1.1.1 | begin \  
(213.1.1.1, 232.4.1.0), 00:28:08/stopped, flags: sTIZ  
Incoming interface: GigabitEthernet2.563, RPF nbr 213.6.13.13  
Outgoing interface list:  
MVRF MC, Forward/Sparse, 00:10:28/00:01:31
```

We know that this join must transit XRv3 since that is the only path CSR6 has to reach CSR1. XRv3 has three options to reach 213.1.1.1, which is the result of our IS-IS metric adjustment earlier. Based on this, XRv3 will select the PIM neighbor with the highest IP address, which is XRv4.

```
RP/0/0/CPU0:XRv3#show route ipv4 213.1.1.1 | include via  
Known via "isis 1", distance 115, metric 30, type level-2  
213.13.14.14, from 213.1.1.1, via GigabitEthernet0/0/0/0.534  
213.5.13.5, from 213.1.1.1, via GigabitEthernet0/0/0/0.553  
213.7.13.7, from 213.1.1.1, via GigabitEthernet0/0/0/0.573
```

```
RP/0/0/CPU0:XRv3#show pim ipv4 rpf 213.1.1.1  
Table: IPv4-Unicast-default  
* 213.1.1.1/32 [115/30]  
via GigabitEthernet0/0/0/0.534 with rpf neighbor 213.13.14.14
```

Although both CSR7 and CSR5 are viable alternative paths, they do not receive the P(S,G) join from XRv3 since they are not in the reverse path towards the root of the tree. We can confirm this issue by checking the P-MRIB entry on CSR5 and CSR7; this group is not found. XRv3 also makes no mention of any attempt to involve those routers in the multicast delivery path, either. So far, this is all expected PIM behavior.

```
R5#show ip mroute 232.4.1.0 213.1.1.1  
Group 232.4.1.0 not found
```

```

To enable MoFRR, we must have ECMP on the router on which MoFRR will be configured. In this case, XRv3 has ECMP to 213.1.1.1, and we will configure MoFRR there. The configuration is very straightforward, and we can use an ACL to select which groups to enable for MoFRR. Since MoFRR

essentially duplicates the multicast flow along alternative paths, it can be wasteful of bandwidth, and should be used sparingly for critical flows.

```
! XRv3
ipv4 access-list ACL_MOFRR
 10 permit ipv4 any 232.0.0.0 0.255.255.255

router pim
 address-family ipv4
   mofrr
     flow ACL_MOFRR
```

To verify this, we can look at the detailed P-MRIB output on XRv3. While the summary P-MRIB information does identify this as MoFRR capable, it doesn't tell us anything about the alternate path. Instead, towards the bottom of this command we can see a secondary RPF neighbor identified as CSR7. This router was selected over CSR5 since it has the next highest IP address. This means that XRv3 issues a P(S,G) join to CSR7 and XRv4 at the same time.

```
RP/0/0/CPU0:XRv3#show pim ipv4 topology 232.4.1.0 213.1.1.1 detail | begin
232
(213.1.1.1,232.4.1.0)SPT SSM Up: 00:19:06

```

We check the P-MRIB tables on CSR5 and CSR7 again. CSR5 still doesn't have the entry, but CSR7 does, and nothing looks fancy about it. CSR7 is totally unaware that MoFRR is in effect. CSR7 identifies XRv4 as its RPF neighbor to CSR1, which is correct.

```
R5#show ip mroute 232.4.1.0 213.1.1.1

```

Because both XRv3 and CSR7 identified XRv4 as their RPF neighbor towards 213.1.1.1, that means XRv4 is a "merge point", and a single point of failure, for this flow. More importantly, it means that XRv4 should have both links to CSR7 and XRv3 in its OIL for this P(S,G). Like CSR7, and every other router

besides XRv3, XRv4 is totally unaware that MoFRR is enabled in the network. XRv4 will duplicate multicast traffic towards XRv3 and CSR7 concurrently. When XRv3 receives multiple copies, it will discard the ones from CSR7 (the alternate path) until the main path fails. In XR, failure is determined by a loss of traffic for 30 ms; after this time, switchover occurs, and the entire process takes about 50 ms on real hardware routers.

```
RP/0/0/CPU0:XRv4#show pim ipv4 topology 232.4.1.0 213.1.1.1 | begin 232
(213.1.1.1,232.4.1.0)SPT SSM Up: 00:23:10
JP: Join(00:00:43) RPF: GigabitEthernet0/0/0/0.514,213.1.14.1 Flags:

GigabitEthernet0/0/0/0.574 00:04:44 fwd Join(00:03:06)
```

We begin sending traffic on CSR9 to test this. Since all PIM signaling is complete, CSR4 should be receiving this traffic. For brevity, we will verify that traffic is arriving on CSR6 within the P(S,G) entry, and being transferred to the C(S,G) group for forwarding. We can see the packet counts are identical between the two, as expected.

```
R9#ping 232.42.51.8 repeat 10000 time 1
```

```
R6#show ip mroute 232.4.1.0 213.1.1.1 count | begin Group
Group: 232.4.1.0, Source count: 1, Packets forwarded: 85, Packets received:
85
Source: 213.1.1.1/32, Forwarding: 85/1/142/1, Other: 85/0/0
```

```
R6#show ip mroute vrf MC 232.42.51.8 10.1.9.9 count | begin Group

85
Source: 10.1.9.9/32, Forwarding: 85/1/142/1, Other: 85/0/0
```

XRv3 has very interesting output. I include the forwarding legend for clarity since the counters are different than a normal setup. We can see that 446 packets have arrived, but exactly half of them have been forwarded. The other half are identified as RPF failures.

```
RP/0/0/CPU0:XRv3#show mfib ipv4 route 232.4.1.0 213.1.1.1 | begin ^Forwarding
Forwarding/Replication Counts: Packets in/Packets out/Bytes out

GigabitEthernet0/0/0/0.563 Flags: NS EG, Up:00:29:12
GigabitEthernet0/0/0/0.573 Flags: A2, Up:00:10:46
```

Looking at the P-MRIB, which shows slightly different information than the P-PIM topology, we see the interface towards XRv4 is identified as 'A' for accept. This is the RPF interface. The interface towards CSR7 is identified as 'A2' because this is the secondary RPF, and this is where the packets are being dropped. We can see the MoFRR is reported as "inactive", which is expected in a stable network.

```
RP/0/0/CPU0:XRv3#show mrib ipv4 route 232.4.1.0 | begin 232

Outgoing Interface List
  GigabitEthernet0/0/0/0.563 Flags: F NS, Up: 00:31:08
```

We can further confirm that both XRv4 and CSR7 are forwarding equal quantities of packets to XRv3, which would explain the exact 50% drop rate. The CSR only updates its counters every 10 seconds which explains the tiny discrepancy in the packet counts. Notice that on XRv4, the software replication process has twice as many packets going out as coming in; this proves that XRv4 is replicating packets properly.

```

To test MoFRR, we will shutdown XRv4's interface to XRv3 (not shown). MoFRR determines that the link has failed when the PIM neighbor fails (in the graceful shutdown I did, it happens immediately). MoFRR is still receiving packets from CSR7 and makes this the primary RPF interface, marked with an 'A' below. Because a third path exists, XRv3 signals a P(S,G) join to CSR5 to use it for a backup path now, marked 'A2'. Also note that while MoFRR is still technically inactive, the sequence number is 2, which counts the number of MoFRR triggers per (S,G). MoFRR is only active for the time it takes PIM to reconverge its forwarding state in the network. This is similar to TE-FRR except RSVP is used, not PIM.

```
RP/0/0/CPU0:XRv3#show mrib ipv4 route 232.4.1.0 | begin 232

```

Before continuing, we will bring the link between XRv3 and XRv4 back. We will also stop the pings from CSR9 to reset the network to an idle state. We quickly verify that XRv3 re-establishes its proper RPF interface via XRv4, which triggers a prune to CSR5. Notice that MoFRR sequence number is 3, which indicates another change occurred when the link came back up.

```

RP/0/0/CPU0:XRv3#show mrib ipv4 route 232.4.1.0 | begin 232

```

To test MoFRR on XE, we will add a new link between CSR6 and CSR7, while concurrently shutting down the link between XRv3 and CSR7. This gives CSR6 two options for its original P(S,G), and still leaves XRv3 with two options as well. In order for ECMP to work from CSR6 to CSR1, the IS-IS cost of this new link must be 20. Because CSR7 and XRv3 no longer have direct reachability, we have additional path diversity. The path from CSR6 to XRv4 is totally independent of links and nodes via CSR7 and XRv3, which is ideal for HA design. The updated diagram is shown below.

The interface configurations are basic and are not shown, but we will verify the ECMP behavior as I just described. CSR6 has two paths via XRv3 and CSR7, and XRv3 has two paths via XRv4 and CSR5.

```
R6#show ip cef 213.1.1.1
213.1.1.1/32
  nexthop 213.6.7.7 GigabitEthernet2.567 label 7005
  nexthop 213.6.13.13 GigabitEthernet2.563 label 93005

RP/0/0/CPU0:XRv3#show cef ipv4 213.1.1.1 | include via
  via 213.13.14.14, GigabitEthernet0/0/0/0.534, 7 dependencies, weight 0,
class 0 [flags 0x0]
  via 213.5.13.5, GigabitEthernet0/0/0/0.553, 10 dependencies, weight 0,
class 0 [flags 0x0]
```

In this way, we can have MoFRR enabled both at the edge and core routers for additional redundancy. In a purely planar network, this wouldn't be necessary, since the two planes would be "enough" redundancy for the vast majority of cases. I demonstrate it here because it is possible; there is nothing that says MoFRR is limited to a certain type or quantity of nodes. The configuration on XE is very similar to XR, except we will enable the "sticky" option. This ensures that the primary RPF doesn't change even if a better one shows up later. This leads to better stability in the network, and unlike with XRv3, we would not prune stable links to choose a link that just came back up. This is also supported in XR and the option is "non-revertive", which is a little more descriptive. XE MoFRR can only accept an extended ACL, so we will identify the specific tunnel endpoint of CSR1, along with all SSM groups for variety.

```
! CSR1
ip multicast rpf mofrr ACL_MOFRR sticky
ip access-list extended ACL_MOFRR
 permit ip host 213.1.1.1 232.0.0.0 0.255.255.255
```

To verify it, we can look at the P(S,G) entry for the multicast tunnel. The output is comparable to XR. We can see RIB-based MoFRR (different than flow-based MoFRR described earlier) is enabled and the secondary RPF information is made very clear. CSR6 selects XRv3 as the primary RPF due to having a low IP address. Otherwise, nothing is different.

```
R6#show ip mroute 232.4.1.0 | begin \
(213.1.1.1, 232.4.1.0), 01:19:06/stopped, flags: sTIZ

  Outgoing interface list:
    MVRP MC, Forward/Sparse, 01:01:26/00:01:33
```

We verify that CSR7 received the P(S,G) join for this group and adds CSR6 to its OIL. XRv3 is still running MoFRR and has added both XRv4 and CSR5 as RPF interfaces, which means both of them should have the entry, too.

```
R7#show ip mroute 232.4.1.0 213.1.1.1 | begin \

Outgoing Interface List  
  GigabitEthernet0/0/0/0.563 Flags: F NS, Up: 00:11:08
```

We quickly verify CSR5 and XRv4 as well. CSR5's output is very basic and not exciting, but now XRv4 will be very busy. It now has three interfaces in its OIL for this group having received P(S,G) joins from CSR5, CSR7, and XRv3. There is only one receiver yet the traffic is being replicated three times, which is highly inefficient.

```
R5#show ip mroute 232.4.1.0 213.1.1.1 | begin \

GigabitEthernet0/0/0/0.554 Flags: NS EG, Up:00:16:59
GigabitEthernet0/0/0/0.574 Flags: NS EG, Up:00:09:15

```

There is nothing new on XRv3, since the duplicated packets arriving from CSR5 are dropped due to RPF failure. 180 packets have arrived, but only 90 are transmitted. XRv3 still forwards traffic to CSR6, which is imported because CSR6 has selected XRv3 as the primary RPF neighbor.

```

RP/0/0/CPU0:XRv3#show mfib ipv4 route 232.4.1.0 213.1.1.1 | begin 232
(213.1.1.1,232.4.1.0), Flags: MoFE MoFS

GigabitEthernet0/0/0/0.553 Flags: A2, Up:00:17:59
GigabitEthernet0/0/0/0.563 Flags: NS EG, Up:00:17:59

```

CSR5 and CSR7 are very straightforward and their outputs are not shown, since they receive a single flow of traffic and replicate it once downstream. CSR6 has interesting output as we expected to see several RPF failures for this P(S,G). The reason the forwarding packets are higher is because I did not clear the counters before this test, but it isn't necessary to see the difference.

```

R6#show ip mroute 232.4.1.0 213.1.1.1 count | begin Forwarding
Forwarding Counts: Pkt Count/Pkts per second/Avg Pkt Size/Kilobits per second

```

Using EPC, we will conduct a quick verification to see two packets arriving at approximately the same time from XRv3 and CSR7, but only one being forwarded to the customer. In this case, the first packet that arrived was from XRv3 and was immediately forwarded to the customer. The backup flow from CSR7 came a short time later and was discarded. I show the MAC addresses for CSR7 and XRv3 for confirmation.

```

To quickly test the sticky feature, we will shutdown the link to XRv3 on CSR6. CSR6 immediately switches to CSR7 as the primary RPF interface, and since there are no alternate paths, the secondary RPF does not exist.

```

R6#show ip mroute 232.4.1.0 213.1.1.1 | begin \
(213.1.1.1, 232.4.1.0), 01:39:16/stopped, flags: sTIZ
Incoming interface: GigabitEthernet2.567, RPF nbr 213.6.7.7, RIB based
MoFRR
Secondary RPF interface: Null, Secondary RPF nbr 0.0.0.0
Outgoing interface list:
MVRF MC, Forward/Sparse, 01:21:36/00:02:47

```

Of paramount importance is CSR6's ability to continue receiving multicast traffic. Checking the packet counters, we can see the forwarded packets continue to increase with no new RPF drops. Because there isn't a second path, there isn't a backup flow to discard.

```

R6#show ip mroute 232.4.1.0 213.1.1.1 count | begin Group
Group: 232.4.1.0, Source count: 1, Packets forwarded: 1808, Packets received:
2541
Source: 213.1.1.1/32, Forwarding: 1808/1/142/1, Other: 2541/733/0

R6#show ip mroute 232.4.1.0 213.1.1.1 count | begin Group

```

```
Group: 232.4.1.0, Source count: 1, Packets forwarded: 1818, Packets received: 2551
```

```
Source: 213.1.1.1/32, Forwarding: 1818/1/142/1, Other: 2551/733/0
```

We will bring the link to XRv3 back up and see how CSR6 reacts. Ideally, CSR6 should continue using CSR7 as the primary RPF which will reduce P-PIM control-plane churn in the network core. When ECMP is in play, it may not matter which path is chosen, so constantly changing may be undesirable. As expected, XRv3 is now the secondary RPF path. When performing an unrelated RPF lookup for 213.1.1.1, we see that XRv3 is still shown, but for this particular MoFRR P(S,G) this default RPF mechanism does not take effect, thanks to the “sticky” option.

```
R6#show ip mroute 232.4.1.0 213.1.1.1 | begin \  
(213.1.1.1, 232.4.1.0), 01:42:25/stopped, flags: sTIZ  
Incoming interface: GigabitEthernet2.567, RPF nbr 213.6.7.7, RIB based  
MoFRR  
Secondary RPF interface: GigabitEthernet2.563, Secondary RPF nbr  
213.6.13.13  
Outgoing interface list:  
MVRP MC, Forward/Sparse, 01:24:45/00:02:37
```

```
R6#show ip rpf 213.1.1.1  
RPF information for ? (213.1.1.1)  
RPF interface: GigabitEthernet2.563  
RPF neighbor: ? (213.6.13.13)  
RPF route/mask: 213.1.1.1/32  
RPF type: unicast (isis 213)  
Doing distance-preferred lookups across tables  
RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

Checking the packet counters, CSR6 is still receiving traffic, but is now incurring RPF failures as well, this time discarding traffic from XRv3.

```
R6#show ip mroute 232.4.1.0 213.1.1.1 count | begin Group  
Group: 232.4.1.0, Source count: 1, Packets forwarded: 2058, Packets received: 2937  
Source: 213.1.1.1/32, Forwarding: 2058/1/142/1, Other: 2937/879/0
```

```
R6#show ip mroute 232.4.1.0 213.1.1.1 count | begin Group  
Group: 232.4.1.0, Source count: 1, Packets forwarded: 2068, Packets received: 2957  
Source: 213.1.1.1/32, Forwarding: 2068/1/142/1, Other: 2957/889/0
```

We can prove this further with EPC again. This time, the packets from CSR7 and XRv3 arrived at exactly the same time, but the one from CSR7 was forwarded to the customer.

Additional Reading – Reference configurations “mvpn-mofrr”

29.3 Protecting mLDP LSPs with Fast Re-Route (FRR)

This section details how to provide FRR for mLDP traffic. For testing, we will use the same alternative MVPN network used in the MoFRR section which adds an additional link between CSR6 and CSR7 for redundancy. The base configuration is MVPN profile 1, which uses a MP2MP default tree, statically configured, with PIM C-multicast signaling.

Since mLDP does not have any inherent ability to be protected by TE (unlike P2MP RSVP-TE), it relies on existing TE-FRR mechanisms. Specifically, we can provide link protection only for mLDP LSM traffic in the network core using a combination of existing technologies. As examined in the TE section, we can use NHOP tunnels for link protection coupled with primary one-hop tunnels to reach each next-hop. The primary tunnels use auto-route announce and FRR, and the NHOP backup tunnels can protect these tunnels. mLDP can be configured to use these primary one-hop TE tunnels for recursive forwarding which are inherently protected by NHOP backups. This protects every link in the topology if configured everywhere. This can be done manually or automatically, but the combination of auto-primary and auto-backup tunnels suits this purpose perfectly. Those topics are covered in detail in the TE section so we configure them quickly on all LSRs in the topology. **Note: The feature does not appear to work well on XR. There is no obvious way to have auto-backups protect auto-primaries that request FRR, nor is there a way to force mLDP traffic into a TE tunnel.** We will limit the test to CSR6 and CSR7 instead.

```

! All XE LSRs
mpls mldp path traffic-eng
mpls ldp discovery targeted-hello accept
mpls traffic-eng auto-tunnel backup nhop-only
mpls traffic-eng auto-tunnel backup tunnel-num min 5000 max 5999
mpls traffic-eng auto-tunnel primary onehop
mpls traffic-eng auto-tunnel primary config mpls ip
mpls traffic-eng auto-tunnel primary tunnel-num min 6000 max 6999

! All XR LSRs
mpls ldp
  address-family ipv4
    discovery targeted-hello accept

```

The configuration isn't exactly straightforward. Enabling auto-backup and auto-primary tunnels is basic, with the exception that because these primary tunnels are one-hop, not PE-PE, we must enable LDP on them as well. This stitches the LSP together end to end. All routers are able to accept targeted sessions to support this, even the XR core routers. I explicitly used different number ranges for the backup and primary tunnels to make verification easier. The "magic" command is "mpls mldp path traffic-eng" on XE which allows the mLDP LSPs to use TE tunnels. A quick check on CSR6 shows us that the tunnels are up; there will be 2 primary tunnels to XRv3 and CSR7, and the backup tunnels routing around those protected links. This magic command also assumes the tunnels are LDP-enabled with autoroute announce configured on them, which is fitting for auto-primary tunnels.

```

R6#show mpls traffic-eng tunnels summary | begin auto
auto-tunnel:
  backup Enabled (2 ), id-range:5000-5999
  onehop Enabled (2 ), id-range:6000-6999
  mesh Disabled (0 ), id-range:64336-65335

```

To verify this further, we can look at the RSVP RESV messages to see the tunnels originating on CSR6. We can clearly see the direction each tunnel is going. The backup tunnels are highlighted in yellow with the primary tunnels in green.

```

R6#show ip rsvp reservation filter session-type 7 sender 213.6.6.6

```

Destination	Tun Sender	TunID	LSPID	Next Hop	I/F	Fi	Serv	BPS
213.7.7.7	213.6.6.6	5000	1	213.6.13.13	Gi2.563	SE	LOAD	0
213.7.7.7	213.6.6.6	6001	8053	213.6.7.7	Gi2.567	SE	LOAD	0
213.13.13.13	213.6.6.6	5001	1	213.6.7.7	Gi2.567	SE	LOAD	0
213.13.13.13	213.6.6.6	6000	928	213.6.13.13	Gi2.563	SE	LOAD	0

We can determine which primary tunnel is protected by which backup tunnel by checking the FRR database. Unlike previous examples, the FRR database on the PLR has no in-label since the PLR is the tunnel head. Tunnel6000 goes to XRv3 and is backed up by Tunnel5001 which also terminates there. We

can tell this is an NHOP tunnel as a result; we confirm this by looking at the RSVP RESV messages above to see the same tunnel tail-end. The same is true about the relationship between Tunnel6001 and Tunnel5000.

```
R6#show mpls traffic-eng fast-reroute database
P2P Headend FRR information:
Protected tunnel      In-label Out intf/label    FRR intf/label    Status
-----
Tunnel6000           Tun hd   Gi2.563:implicit  Tu5001:implicit-  ready
Tunnel6001           Tun hd   Gi2.567:implicit  Tu5000:implicit-  ready
```

Now that we have verified FRR was enabled on the primary tunnels, we can verify that autoroute announce was as well. We can see each tunnel with autoroute announce enabled with its specified tail-end.

```
R6#show mpls traffic-eng autoroute
MPLS TE autorouting enabled
  destination 0000.0000.0007.00, area isis level-2, has 1 tunnels
    Tunnel6001 (load balancing metric 0, nexthop 213.7.7.7)
      (flags: Announce)
  destination 0000.0000.0013.00, area isis level-2, has 1 tunnels
    Tunnel6000 (load balancing metric 0, nexthop 213.13.13.13)
      (flags: Announce)
```

Next, we will verify LDP is enabled on the tunnel and has established targeted sessions. This will allow the LDP label exchange to occur between the head and tail ends, which is important for tunnel stitching and described in the TE section. The reason CSR7's entry says active/passive is because CSR7 has also established a session to CSR6, but XRv3 has not established one to CSR6. The "xmit/recv" is what really matters for label exchange.

```
R6#show mpls ldp discovery | begin Targeted Hello
Targeted Hellos:
  213.6.6.6 -> 213.13.13.13 (ldp): active, xmit/recv
    LDP Id: 213.13.13.13:0
  213.6.6.6 -> 213.7.7.7 (ldp): active/passive, xmit/recv
    LDP Id: 213.7.7.7:0
```

This implies CSR6 can learn the labels towards any node beyond these primary tunnels, such as XRv14. We confirm this by checking the LDP bindings and ultimately, the FIB. These labels are stacked before the TE label (which is implicit-null on the primary tunnels) when sending traffic outbound. This is just a basic unicast check and isn't terribly relevant to mLDP.

```
R6#show mpls ldp bindings 213.14.14.14 32
lib entry: 213.14.14.14/32, rev 15
local binding: label: 6002
```

```
remote binding: lsr: 213.13.13.13:0, label: 93000
remote binding: lsr: 213.7.7.7:0, label: 7000
```

```
R6#show ip cef 213.14.14.14
213.14.14.14/32
  nexthop 213.7.7.7 Tunnel6001 label 7000
  nexthop 213.13.13.13 Tunnel6000 label 93000
```

Of greater importance is mLDP. We verify that CSR6 has joined the MP2MP default MDT, which is the result of having sent a label mapping message upstream. CSR6 informs XRv3 that it should receive traffic using label 6012, and XRv3 responds with an upstream mapping of 93009 which is used to send traffic towards the root. The next-hop interface is a TE tunnel which is not possible unless the router is explicitly told to consider TE tunnels as paths for mLDP (configured earlier).

```
R6#show mpls mldp database opaque_type mdt 213:213 0
LSM ID : 1 (RNR LSM ID: 2)   Type: MP2MP   Uptime : 01:20:04
  FEC Root      : 213.14.14.14
  Opaque decoded : [mdt 213:213 0]
  Opaque length  : 11 bytes
  Opaque value   : 02 000B 0002130000021300000000

  Upstream client(s) :
    213.13.13.13:0   [Active]
      Expires        : Never          Path Set ID   : 1
      Out Label (U)   : 93009          Interface    : Tunnel6000*
      Local Label (D) : 6012           Next Hop      : 213.13.13.13
  Replication client(s):
    MDT (VRF MC)
      Uptime          : 01:20:04       Path Set ID   : 2
      Interface       : Lspvif0
```

A quick OAM check verifies that all of the other XE PE routers have configured this properly as well. XRv2 is not running TE with mLDP but can still communicate; we also check the PIM neighbors inside the VPN to prove that the C-PIM signaling works.

```

R6#show ip pim vrf MC neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime/Expires	Ver	DR Prio/Mode
213.7.7.7	Lspvif0	00:21:09/00:01:18	v2	1 / S P G
213.5.5.5	Lspvif0	00:21:09/00:01:44	v2	1 / S P G
213.1.1.1	Lspvif0	00:21:09/00:01:15	v2	1 / S P G
213.8.8.8	Lspvif0	00:21:09/00:01:43	v2	1 / S P G
213.12.12.12	Lspvif0	01:14:37/00:01:38	v2	1 / DR P G

At this point, all links are protected by NHOP tunnels using TE-FRR (assuming we configure auto-primary and auto-backup everywhere, which we didn't). Actually verifying this feature in the data-plane is difficult in this compressed topology, so it is skipped.

Additional Reading – Reference configurations “mvpn-mldp-frr”

29.4 MVPN Extranet

Extranets are defined as networks that have been extended outside of an intranet to provide reachability to external organizations. This could be a business partnership of sorts. According to senior engineers in Cisco, extranets are much more common in enterprise MPLS networks than in SP ones, but the concepts are the same in all environments. Building extranets for unicast connectivity with MPLS L3VPN is simple and is controlled entirely by the RT import/export policies. There are some additional considerations for multicast traffic. Specifically, an MVPN extranet exists when sources are in one VPN and receivers are in another VPN. Some draft RFCs (draft-rosen-l3vpn-mvpn-extranet-03) regarding MVPN extranet refer to these as “red” (sources) and “blue” (receivers) VPNs for simplicity. Those terms are used here also. The network diagram is shown below and is very similar to the previous MVPN examples except that the VPNs have been split in half.

The top half of the network (XRV2, CSR5, and CSR1) are in VPN “N”, meaning North. The bottom half (CSR6, CSR7, CSR8) are in VRF “S” for South. XRV1, CSR9, CSR4, and CSR3 are all requesting the same IPv4 and IPv6 SSM groups with sources spread across both VRFs. This configuration is described in detail later. The groups in use are as follows:

IPv4 SSM with North source: (10.5.10.10, 232.0.0.7)
 IPv4 SSM with South source: (10.2.7.2, 232.0.0.5)
 IPv6 SSM with North source: (2001:10:5:10::10, FF33::2)
 IPv6 SSM with South source: (2001:10:2:7::2, FF33::1)

29.4.1 PIM/GRE

Multicast extranets are achievable using the classic Draft-Rosen family of MDTs. However, newer MVPN profiles can take advantage of BGP-AD to simplify the extranet mechanisms, so this would be similar to profile 3. The draft specified earlier uses terms “red” and “blue” to specify the VPNs in which the sources and receivers lie, respectively. For our first test, CSR10 is the source and CSR6/CSR8 are the extranet receivers for (10.5.10.10, 232.0.0.7). Therefore, VRF N is the “red” VPN and VRF S is the “blue” VPN for this test. The colors of red and blue will swap as we test connectivity in multiple directions for multiple protocols, which is why the VRF names are not tied to colors. Before actually doing any extranet connectivity, we will verify that intranet multicast works within VRF N. XRv11 and CSR9 are both requesting traffic for the aforementioned flow, so they should be able to receive intranet multicast. We won’t verify every component of MVPN profile 3 again, but we will begin by checking the C-MRIB on all PEs. They all claim that a data MDT is in use, which means there should be an associated BGP Type-3 S-PMSI route for the C(S,G). The XE boxes show the ‘Y’ and ‘y’ flag to indicate reception from and transmission to a data MDT, respectively. We can also see the PMSI to C(S,G) binding.

```
R5#show ip mroute vrf N 232.0.0.7 10.5.10.10 verbose | begin \

```

```
RP/0/0/CPU0:XRv2#show pim vrf N mdt cache
Core Source      Cust (Source, Group)                                Core Data      Expires
```

213.5.5.5 (10.5.10.10, 232.0.0.7) 232.4.5.0 never

Checking the BGP MVPN information, we see that CSR5 has originated the Type-3 route to describe the availability of an S-PMSI. As long as the other PEs are importing RT:213:5, they will see this S-PMSI availability. Tunnel-type 3 means this is a PIM-SSM GRE, the root is 213.5.5.5, and the core group is 232.4.5.0. This is how others know about the data MDT when BGP-AD is used.

```

When CSR10 starts sending traffic, we can see the packet counters increasing on all three PEs, indicating that traffic is being sent. The XRv only shows packets out, but it is working.

```

To implement the “red method” as defined by the draft, the blue PEs must import the RT’s for the red multicast sources and BGP-AD routes. The draft specifically states you must use a new RT for this, called the “violet” RT. This is a good practice because only a few VPN routes behind a red PE would be multicast sources, so it makes sense not to have all the blue PEs with receivers import all red RTs. On CSR5, we will solve this in two steps. First, an export-map is applied to CSR5 for IPv4 that matches 10.5.10.0/24 and adds a RT:213:500. CSR10’s loopback, 10.10.10.10/32, is not a multicast source and only has the basic blue RT:213:5.

```
! CSR5
ip prefix-list PL_EXTRANET_SOURCES seq 5 permit 10.5.10.0/24

route-map RM_EXTRANET_EXPORT permit 10
 match ip address prefix-list PL_EXTRANET_SOURCES
 set extcommunity rt 213:500 additive

vrf definition N
 address-family ipv4
  export map RM_EXTRANET_EXPORT
```

Assuming CSR8 imports this RT (configuration is applied for VRF S but not shown), we will have one-way unicast connectivity from CSR8 to CSR5. This is OK because we only need this routing information for RPF; we are not attempting to establish bidirectional unicast connectivity.

```
R8#show bgp vpnv4 unicast vrf S 10.5.10.0/24

      rx pathid: 0, tx pathid: 0x0
```

The problem is that the BGP-AD routes did not get this “violet” RT applied, so CSR8 does not know to import it. We can check XRv2, the RR, to confirm that the route only carries the blue RT:213:5.

```
RP/0/0/CPU0:XRv2#show bgp ipv4 mvpn rd 213:5 [1][213.5.5.5]/40 | include
Exten
      Extended community: RT:213:5
```

```
R8#show bgp ipv4 mvpn vrf S route-type 1 213.5.5.5
```

```
% Network not in table
```

CSR8 still has a semi-valid C(S,G) entry, but there is no big 'Y' to indicate reception from S-PMSI. This is going to lead to problems since the entry has a valid RPF interface but is not using the proper delivery mechanism. CSR8 does not report seeing any multicast traffic arriving for this C(S,G). Its MDT cache only has an entry for the south-intranet VPN flow.

```
R8#show ip mroute vrf S 232.0.0.7 10.5.10.10 count | begin ^Group
Group: 232.0.0.7, Source count: 1, Packets forwarded: 0, Packets received: 0
Source: 10.5.10.10/32, Forwarding: 0/0/0/0, Other: 0/0/0
```

```
R8#show ip pim vrf S mdt receive
Joined MDT-data [group/mdt number : source] uptime/expires for VRF: S
[232.4.7.0 : 213.7.7.7] 14:27:57/stopped
```

To fix this, we configure CSR5 to add the violet RT to its outgoing IPv4 MVPN routes. We can be indiscriminate with the route-map because if an extranet receiver wants multicast from a source behind CSR5, it needs to import the violet RT, so it need not be route/prefix specific.

```
! CSR5
route-map RM_MVPN_EXTRANET_RT permit 10
set extcommunity rt 213:500 additive

router bgp 213
address-family ipv4
neighbor 213.12.12.12 route-map RM_MVPN_EXTRANET_RT out
```

Next, we verify that CSR8 imports the BGP-AD routes from CSR5 and updates its C-MRIB entry via the MDT cache. Checking the packet counters, we can see traffic is flow successful.

```

As always, a quick EPC alleviates any doubt we have about forwarding. CSR8 shows GRE multicast arriving from CSR5's MDT source towards the data MDT group 232.4.5.0. CsR8 decapsulates it and forwards the ICMP multicast for (10.5.10.10, 232.0.0.7) towards the customer. The difference in size is exactly 24 (GRE header) and the timestamps are the same.

Let's try to bend the rules by importing the non-violet RT on CSR6. That is, we will import RT:215:5 and not the violet target of RT:213:500. This will give CSR6 reachability to 10.10.10.10/32, which isn't really relevant, but it's sloppy. The draft clearly states: *"If the route matching S is a blue route (i.e., carries the blue RT but not the violet RT), then a Join is sent over the blue default PMSI. However, if the route matching S is a violet route (i.e., carries the violet RT), a Join is sent over the red default PMSI."* This would imply that an RPF route with only RT:213:5 would have its PIM join sent via the blue VPN. The keyword is "default MDT", which we are not using yet. We will test I-PMSI later. Once CSR6 imports RT213:5, everything literally just works. This RT captures both the unicast route to the source, 10.5.10.0/24, and the BGP-AD S-PMSI route for this C(S,G) in question. All of the same verifications we

did for CSR8 are shown below on CSR6 to confirm proper operation. This mechanism would not require the route-maps on CSR5 to add RT:213:500 to multiple prefixes.

To add complexity, we will remove this C(S,G) from being candidate for data MDT optimization. We do this by removing it from the IPv4 ACL on CSR5 so that it can no longer originate the Type-3 route. Because our ACL is only one line long, removing that one line turns the ACL into a “permit ip any any”. Instead, I will put a “deny ip any any” at the top. The BGP debugs clearly show this S-PMSI advertisement being withdrawn.

```
R5#show access-lists ACL_DATA_MDT
Extended IP access list ACL_DATA_MDT
    5 deny ip any any (3 matches)
    10 permit ip any host 232.0.0.7

```

Another spot check on those same routers shows the MDT cache missing an entry for (10.5.10.10, 232.0.0.7). This is expected since that MDT cache information was gleaned from the Type-3 route that was just withdrawn. CSR8 still has its intranet SSM data MDT which is not being examined right now.

```

```
R5#show ip pim vrf N mdt send
```

```
[no output]
```

Because we did not modify any RT policies, CSR6 is still importing RT:213:5 and CSR8 is still importing RT:213:500, which means both the BGP-AD and unicast extranet sources are inside VRF S (blue VPN). Looking at the I-PMSI BGP-AD routes, we can clearly see the default MDT groups are different. VRF S uses 232.255.0.2 while VRF N uses 232.255.0.1. There is no communication between VPNs over the default MDT, which means no PIM neighbors, etc. The draft clearly states: *"If MI-PMSIs are being used, the blue VRFs must immediately join the P-tunnels specified in the red I-PMSI A-D routes.* This is not happening. Despite CSR8 having imported CSR5's I-PMSI route, it did not join that MDT. I believe this could work with other MVPN profiles (like mLDP), but not GRE. We can immediately see that, when S-PMSI is not used, the complexity of MVPN extranet increases significantly.

There are two solutions for this which have been supported by Cisco routers since 12.2S.

- a. **One option is to configure the source VRF on the receiver PEs, which is known as receive side chaining (RSC).** This allows the “red” sources to have traffic follow the red default MDT all the way to the egress PE, because the egress PE is actually in that VPN now. This will allow the extranet receivers to join the red default MDT. This is best used when the flows are high bandwidth and/or there are few receivers. It is my personal favorite option.
- b. **The second option is to configure the receiver VRF on the source PEs, which is source side chaining (SSC).** This allows the ingress PE to perform ingress replication so that the red multicast traffic is sent as both red and blue. This means that the receiver PEs don’t need to add more VRF configurations. This is best used when the flows are low bandwidth (extra replication) or there are many receivers where RSC scales poorly, as everything egress PE would need to join the red default MDT.

First, I will use the RSC solution. It’s somewhat similar to the “red method” defined in the draft as we are modifying the blue VPN to receive multicast differently. This is quite configuration intensive compared to the S-PMSI solution and requires a lot of verification. The configuration modifications on CSR8 are shown below. We define the “red” VRF containing sources on the receiver PE, which is blue. It imports the routes from CSR5 using the violet RT. The configuration guide says that RT export should also be configured on this additional VRF, but it is not necessary. Another unnecessary step in the guide is importing the red sources into VRF S directly; since VRF S is explicitly using VRF N for RPF, there is no reason to import those routes. We use group-based VRF selection so that VRF S (blue) knows the look in VRF N (red) for sources.

```
! CSR8
vrf definition N
 rd 213:88
 route-target import 213:500
 address-family ipv4
  mdt auto-discovery pim
  mdt default 232.255.0.1

ip multicast-routing vrf N distributed
ip pim vrf N ssm default

ip access-list standard ACL_N_GROUPS
 permit 232.0.0.7

ip multicast vrf S rpf select vrf N group-list ACL_N_GROUPS
```

One interesting thing to note is that we have a unidirectional PIM neighbor over the red default MDT. CSR8 has imported CSR5's RTs but not vice versa, so the PIM hellos only go one way. This isn't terribly relevant, but an interesting note and a quick way to check if the receiver successfully joined the source's default MDT.

```
R5#show ip pim vrf N neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires      Ver   DR

213.12.12.12       Tunnel1          16:41:47/00:01:27  v2    1 / DR B P G
```

```
R8#show ip pim vrf N neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires      Ver   DR
Address
213.5.5.5          Tunnel4          00:06:54/00:01:43  v2    1 / B S P G
```

We can verify the group-based VRF selection policy is configured correctly also.

```
R8#show ip rpf vrf S select
Multicast Group-to-Vrf Mappings
Group(s): 232.0.0.7/32, RPF vrf: N, Acl: ACL_N_GROUPS
```

Next, we step through the three major MRIB entries that build this extranet connectivity. First, we need to verify that the blue PE has joined the red default MDT properly. The 'Z' flag must be set so the router identifies this as a multicast tunnel. The OIL should be directing traffic into the red VRF.

```
R8#show ip mroute 232.255.0.1 213.5.5.5 | begin \
(213.5.5.5, 232.255.0.1), 00:05:30/stopped, flags: sTIZ
Incoming interface: GigabitEthernet2.584, RPF nbr 213.8.14.14
Outgoing interface list:
MVRF N, Forward/Sparse, 00:05:30/00:00:29
```

Next, the red VRF indicates that this entry is an "extranet" entry with the big 'E'. This is a proxy mechanism in the control plane that essentially says "the real receivers are in the blue VRF". Notice that the OIL is null since there are no real receivers in the red VPN from the perspective of the blue PE.

```
R8#show ip mroute vrf N 232.0.0.7 10.5.10.10 | begin \
(10.5.10.10, 232.0.0.7), 00:05:51/stopped, flags: sTE
Incoming interface: Tunnel4, RPF nbr 213.5.5.5
Outgoing interface list: Null
Extranet receivers in vrf S:
(10.5.10.10, 232.0.0.7), 00:07:19/00:02:39, OIF count: 1, flags: sTI
```

VRF S, the blue VPN, has a normal C-MRIB entry except for the RPF lookup uses the red VPN. This makes sense since the blue VPN has no unicast reachability to the red sources. This is a little different than the S-PMSI tests earlier where importing the violet RT actually provided one-way unicast reachability.

```
R8#show ip mroute vrf S 232.0.0.7 10.5.10.10 | begin \  
(10.5.10.10, 232.0.0.7), 00:07:31/00:02:27, flags: sTI  
Incoming interface: Tunnel4, RPF nbr 213.5.5.5, using vrf N  
Outgoing interface list:  
GigabitEthernet2.538, Forward/Sparse, 00:07:31/00:02:27
```

```
R8#show ip rpf vrf S 10.5.10.0  
failed, no route exists
```

```
R8#show ip rpf vrf N 10.5.10.0  
RPF information for ? (10.5.10.0)

RPF neighbor: ? (213.5.5.5)  
RPF route/mask: 10.5.10.0/24  
RPF type: unicast (bgp 213)  
Doing distance-preferred lookups across tables  
BGP originator: 213.5.5.5  
RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

Checking the counters on all three MRIB entries shows that traffic is being piped from the global table (red default MDT) into the red VPN, then into the blue VPN. It's expected that the default MDT will have a few more packets since it carries additional control-plane traffic, and potential other data flows. The red and blue VPN counters should be identical or very close.

```
R8#show ip mroute 232.255.0.1 213.5.5.5 count | begin ^Group  
Group: 232.255.0.1, Source count: 1, Packets forwarded: 688, Packets

```

We will quickly re-test this on CSR6 for completeness. The downside of the RSC mechanism is that you must configure it on all receivers, so we have to do twice the work. We will use RT:213:5, the real blue VPN RT, versus the violet RT:213:500. It should work the same way since draft RFC suggesting the use of “violet RT” was written long after this feature was introduced. The snippet for CSR6 is not shown here since it is the same as CSR8’s with the RD changing to 213:66 and the RT-import policy using RT:213:5. Remember that CSR6’s blue VPN (S) is not importing any new RTs. First, we verify the three MRIB entries: red default MDT, red VPN, and blue VPN. This shows the control-plane linkages between them.

```

R6#show ip mroute 232.255.0.1 213.5.5.5 | begin \

```

We will quickly test the same scenario with IPv6. We can re-use the BGP route-map to add the violet RT (RT:213:500) to the IPv6 MVPN AD routes on CSR5. We will create a new route-map with an IPv6 prefix-list to match the extranet source (2001:10:5:10::/64). We can locally verify the unicast prefix's RT addition, but must check the RR for see the IPv6 MVPN RT addition. Both are correct.

```
R5#show bgp vpnv6 unicast vrf N 2001:10:5:10::/64
```

```
[snip]
```

```

We also configure CSR6 and CSR8 with the RPF selector to allow any source sending to group FF33::2 inside the blue VPN (S) to be RPF-checked using the red VPN (N). Remember that CSR6 is importing RT:213:5 (blue RT) and CSR8 is importing RT:213:500 (violet RT). Both should work as they did for IPv4.

```
! CSR6 and CSR8
ipv6 multicast vrf S rpf select vrf N group-range ACL_N_GROUPS_IPV6
ipv6 access-list ACL_N_GROUPS_IPV6
permit ipv6 any host FF33::2
```

First, we will verify CSR8's MRIB entries in sequence. Traffic is received from the core on the red VPN and passed to the red proxy VRF. This passes the traffic into the blue VPN for delivery to the customer.

```
R8#show ip mroute 232.255.0.1 213.5.5.5 | begin \
(213.5.5.5, 232.255.0.1), 00:45:48/stopped, flags: sTIZ
Incoming interface: GigabitEthernet2.584, RPF nbr 213.8.14.14
Outgoing interface list:
MVRF N, Forward/Sparse, 00:45:48/00:02:11
```

```
R8#show ipv6 mroute vrf N FF33::2 2001:10:5:10::10 | begin \
(2001:10:5:10::10, FF33::2), 00:10:04/never, flags: sTE
Incoming interface: Tunnel4
RPF nbr: ::FFFF:213.5.5.5
Outgoing interface list: Null
Extranet receivers in vrf S, OIF count 1
```

```
R8#show ipv6 mroute vrf S FF33::2 2001:10:5:10::10 | begin \
(2001:10:5:10::10, FF33::2), 03:38:03/never, flags: sTI
Incoming interface: Tunnel4
RPF nbr: ::FFFF:213.5.5.5, using vrf N
Immediate Outgoing interface list:
GigabitEthernet2.538, Forward, 03:38:03/never
```

Because the blue VPN has no unicast route back to the source, our group-based VRF selection policy can satisfy RPF. This mechanism is very clean since the routes remain within the red (source) VPN.

```
R8#show ipv6 route vrf S 2001:10:5:10::/64
% Route not found
```

```
R8#show ipv6 cef vrf S 2001:10:5:10::10
::/0
no route
```

```
R8#show ipv6 rpf vrf S select
Multicast Group-to-Vrf Mappings
```

Group(s): FF33::2/128, RPF vrf: N, Acl: ACL_N_GROUPS_IPV6

We send traffic from CSR10 and check the packet counters to see traffic being forwarded. EPC verifies that the IPv4 GRE traffic is decapsulated to reveal the IPv6-ICMP multicast inside.

```

```

To prove that the violet RT:213:500 isn't really needed when doing RSC in this way, we will verify CSR6 as well. First, we examine the three MRIB entries. Packets arrive from the core multicast tunnel (big 'Z'), then get passed to the red VPN (N) with extranet receivers (big 'E'), then passed to get blue VPN (S).

```
R6#show ip mroute 232.255.0.1 213.5.5.5 | begin \
(213.5.5.5, 232.255.0.1), 00:54:37/stopped, flags: sTIZ
Incoming interface: GigabitEthernet2.563, RPF nbr 213.6.13.13
Outgoing interface list:
MVRF N, Forward/Sparse, 00:54:37/00:02:22
```

```
R6#show ipv6 mroute vrf N FF33::2 2001:10:5:10::10 | begin \
```

```
(2001:10:5:10::10, FF33::2), 00:16:51/never, flags: sTE

```

Finally, EPC confirms proper operation on CSR6 also. We will use the brief output to verify.

```
R6#show mon cap CAP buffer brief
 1 142    0.498027 213.5.5.5      -> 232.255.0.1    GRE
 2 118    0.498027 2001:::0010      -> FF33:::0002    IPv6-ICMP
```

Next, we will test the SSC extranet delivery option. We will use VRF S as the red VPN where CSR2 is the source and XRv1/CSR9 are the receivers. We already know that if we use S-PMSI, things will “just work” as long as we import the proper RTs on the receiver PE's since the data MDTs aren't VPN-specific. Therefore, we will test using I-PMSI only using SSC. The benefit of this approach is that we only have to configure a new VRF on CSR7 (one ingress PE router). The drawback is that multicast will be replicated for each VPN, wasting bandwidth in the core. CSR7 is currently offering an S-PMSI P-tunnel for (10.2.7.2, 232.0.0.5).

```

  (source, group)                                MDT-data group/num  ref_count
  (10.2.7.2, 232.0.0.5)                          232.4.7.0          1
```

The first thing we do on CSR7 is insert a “deny ip any any” at the top of its IPv4 data MDT ACL. This will ensure only I-PMSI can be used and also allows us to revert back to S-PMSI quickly if needed. A quick verification on CSR7 shows that the S-PMSI advertisement is gone. Again, when S-PMSI is used, extranet becomes easy and “just works” since the default MDTs don't need to pseudo-merge.

```
R7#show bgp ipv4 mvpn vrf S route-type 3 10.2.7.2 222.0.0.5 213.7.7.7
% Network not in table
```

```
R7#show ip pim vrf S mdt send  
[no output]
```

Rather than have XRv2 and CSR1 join the red VPN (red is now S, since red means where the sources are), we will configure CSR7 to join the blue (N) VPN. The receiver also needs to import the remote RTs for each receiver so that BGP-AD can build the default MDT. We will use a “violet” RT so we can avoid any potential BGP-AD issues. CSR7 will export its extranet sources with RT:213:700 and interested receivers in the blue VPN will import this to satisfy RPF. I do not show this basic RT import configuration on XRv2 and CSR1. The proxy VRF N needs to be fully connected with the receivers; importing their RTs allows it to import the BGP-AD routes and exporting allows the opposite to happen on the other end. Failing to do this both ways results in a broken I-PMSI P-tunnel.

```

Before looking at the C-MRIB entries, let’s ensure the BGP-AD Type-1 I-PMSI routes were properly exchanged. CSR7 has the Type-1 routes for XRv12 and CSR1 because it imported RT:213:12 and RT:213:1, respectively. It has two local routes for its own I-PMSI advertisement, one for each MDT. This gets sloppy because we are essentially introducing the red MDT into the blue VPN, which is not

desirable. Fortunately, BGP picks the locally sourced route versus the imported one. This is exported with the RTs that CSR1 and XRv2 will import, and determines which multicast group to use.

```

If we didn't use a new "violet" RT, we would have issues on CSR1/XRv2. It will learn two different Type-1 I-PMSI routes; as they have different RDs, the RR sends both to the endpoints. One of them is the wrong MDT (red) with RT:213:7, and the other is the right MDT (blue) with RTs allowed within the blue VPN. Below is an error case where CSR1 selects the wrong MDT as bestpath and fails to join the blue MDT properly.

```

By using RT:213:700 for the unicast routes, we can safely import that route to satisfy RPF without importing the bogus BGP-AD route seen above. CSR1 will now only receive, and select, the correct Type-1 BGP and properly bind the I-PMSI to the C-MRIB entries. Manipulating other BGP attributes/filters could also solve it, but that is sloppy and beyond the scope of good L3VPN design.

```

```

Verification for SSC happens in the reverse order than it did for RSC. We first verify traffic entering from VRF S (red), being passed to VRF N (blue), and then being encapsulated for transmission to the core. Checking the red VPN, we see a valid C-MRIB entry that differs slightly from the RSC equivalent. In RSC,

the OIL was null, and we only had extranet receivers. With SSC, the router still have to send multicast traffic down the red default MDT for other potential red clients, so this extranet VPN is an augment to the overall MVPN. The big 'E' signifies this is an extranet entry, with extranet receivers listed below.

```
R7#show ip mroute vrf S 232.0.0.5 10.2.7.2 | begin \((
(10.2.7.2, 232.0.0.5), 00:15:18/00:03:13, flags: sTE
  Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0
  Outgoing interface list:
    Tunnel3, Forward/Sparse, 00:15:18/00:03:13
  Extranet receivers in vrf N:
    (10.2.7.2, 232.0.0.5), 00:08:24/00:03:05, OIF count: 1, flags: sT
```

Once inside the blue VPN, the C-MRIB verifies RPF. The source is connected (0.0.0.0) and the VRF used for RPF lookups is S. With SSC, we did not have to explicitly configure this VRF-RPF lookup policy as we did with RSC, since the unicast routes were exchanged locally on the same PE. The blue VPN directs traffic out of its default MDT; we can see PIM neighbors have formed on this interface with each receiver (blue) PE. This signals the router to process the packet for encapsulation.

```
R7#show ip pim vrf N neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
213.1.1.1         Tunnel1          01:27:46/00:01:39 v2      1 / B S P G
213.12.12.12      Tunnel1          02:18:38/00:01:16 v2      1 / DR B P G
```

```
R7#show ip mroute vrf N 232.0.0.5 10.2.7.2 | begin \((
(10.2.7.2, 232.0.0.5), 00:21:04/00:03:13, flags: sT
  Incoming interface: GigabitEthernet2.527, RPF nbr 0.0.0.0, using vrf S
  Outgoing interface list:
    Tunnel1, Forward/Sparse, 00:21:04/00:03:13
```

Because CSR7 is within the default MDT now for all receivers, it will have multiple P(S,G) entries in the blue default MDT. In this case, receivers exist behind XRv12 and CSR1, but we care more about the traffic being sent from this router, so we check the local P(S,G) entry. Packets being encapsulated by CSR7 are forwarded into core for transport to the blue receivers.

```
R7#show ip mroute 232.255.0.1 213.7.7.7 | begin \((
(213.7.7.7, 232.255.0.1), 00:00:29/00:03:00, flags: sT
  Incoming interface: Loopback0, RPF nbr 0.0.0.0
  Outgoing interface list:
    GigabitEthernet2.574, Forward/Sparse, 00:00:29/00:03:00
    GigabitEthernet2.573, Forward/Sparse, 00:00:29/00:03:00
```

We can begin sending traffic from CSR2 and checking packet counters. We see packets enter VRF S and get forwarded to VRF N. From there, they are sent down the blue MDT towards blue receivers.

```
R7#show ip mroute vrf S 232.0.0.5 10.2.7.2 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 10, Packets received:

Last, we examine using the SSC method with IPv6. We won't intentionally break this network up front by failing to use a "violet RT" since that issue was already demonstrated. The vast majority of the configuration will be on CSR7 again, and the basic things like configuring the default MDT and BGP-AD under the VRF IPv6 AF is not shown. The configuration is identical to IPv4. Adding a new IPv6 prefix-list and route-map to account for the source behind CSR7 is also required, but is not shown because it is very basic. This sets the violet RT:213:700 so routers in the blue VPN (receivers like XRv2 and CSR1) can import the unicast VPNv6 routes for RPF validation, but not the BGP-AD routes related to the red VPN. It's worth verifying that those egress PEs only have a single BGP Type-1 I-PMSI route for the blue VPN. The default MDT for VRF N (the blue VPN in this test) is 232.255.0.1, which is shown below. Notice there is no violet RT attached to these BGP-AD routes.

```
R1#show bgp ipv6 mvpn vrf N route-type 1 213.7.7.7
[snip]

```

Both XRv2 and CSR1 have valid RPF interfaces for these extranet sources, so they send C-PIM joins towards CSR7 over the blue MDT. The output doesn't show which protocol the RPF route was learned, but the admin distance of 200 hints at iBGP (VPNv6). These blue receivers need not have any red configuration on them as the source (CSR7) is performing the replication.

```
R1#show ipv6 mroute vrf N FF33::1 2001:10:2:7::2 | begin \

Performing the MRIB verification on CSR7, we do them in reverse order from RSC. Traffic entering the PE arrives in the red VPN (S) from the LAN first. The traffic is sent down the red MDT (not null, as it was in RSC) and also sent into the extranet VPN, which is blue. The blue C-MRIB sends it to the blue default MDT for encapsulation, and this blue VPN uses the red VPN for RPF verification.

```
R7#show ipv6 mroute vrf S FF33::1 2001:10:2:7::2 | begin \
(2001:10:2:7::2, FF33::1), 01:33:52/00:03:18, flags: sTE

At the remote end, we can see XRv2 and CSR1 accepting and forwarding packets. An EPC capture on CSR1 further proves it by showing the GRE encapsulated MDT tunnel arriving and the raw IPv6-ICMP exiting towards the extranet customer.

Additional Reading – Reference configurations “mvpn-extranet-gre”

29.4.2 mLDP

Extranet services for mLDP is not very different in principle from the PIM/GRE examples. We are still using the concepts of default/data MDTs, along with Type-1 (I-PMSI) and Type-3 (S-PMSI) BGP-AD routes. The base MVPN profile in use this time is profile 9, so C-PIM signaling is still used in the overlay. VRF N covers the top three routers and VRF S covers the bottom three. VRF N uses XRv4 as its mLDP MP2MP root and VRF S uses XRv3. VRF N has a VPN ID of 213:1512 while VRF S had a VPN ID of 213:678. These must match on all routers in a VPN, along with the MP2MP root addresses.

Before getting started with extranet services, we will do very brief checks of the mLDP infrastructure for both VPNs to ensure the basic MP2MP trees are built. As the root for VRF N, XRv4 should have three downstream clients on its MP2MP tree: CSR1, CSR5, and XRv3 (towards XRv2). XRv3 likewise has one downstream (XRv2) and one upstream (XRv4) client. For VRF S, XRv3 has three downstream clients: CSR6, CSR7, and XRv4 (towards CSR8). XRv4 has one upstream client (XRv3) and one downstream client (CSR8). This is a good estimate that things are working properly.

```

RP/0/0/CPU0:XRv4#show mpls mldp database mp2mp brief
LSM ID   Type   Root           Up Down Decoded Opaque Value
0x00004  MP2MP  213.13.13.13   1  1    [mdt 213:678 0]
0x00001  MP2MP  213.14.14.14   0  3    [mdt 213:1512 0]

```

```

RP/0/0/CPU0:XRv3#show mpls mldp database mp2mp brief

```

LSM ID	Type	Root	Up	Down	Decoded Opaque Value
0x00002	MP2MP	213.13.13.13	0	3	[mdt 213:678 0]
0x00001	MP2MP	213.14.14.14	1	1	[mdt 213:1512 0]

Next, we validate C-PIM adjacencies in each overlay. For brevity, we will check CSR1 and CSR8 only. Each of them has a neighborhood with the other two VPN members. Realistically, one would want to verify all PEs in this way as PIM neighbors can be unidirectional.

```
R1#show ip pim vrf N neighbor | begin ^Neighbor
Neighbor          Interface          Uptime/Expires      Ver   DR
Address           Prio/Mode
213.12.12.12      Lspvif0          00:23:09/00:01:23  v2    1 / DR B P G

213.6.6.6         Lspvif0          00:03:17/00:01:24  v2    1 / B S P G
213.7.7.7         Lspvif0          00:03:17/00:01:23  v2    1 / B S P G
```

A quick test of intranet MVPN traffic will verify proper operation before progressing to extranets. This will not be a comprehensive review of mLDP profile 9, however. CSR10 starts sending traffic to group 232.0.0.7. We check the C-MRIB states to see how the routers are forwarding traffic. A data MDT (mLDP P2MP) is in use, which implies the presence of a Type-3 S-PMSI route. This is where XRv stops working; it claims null RPF when clearly that is not true. We don't expect it to work with LSM anyway.

```
R5#show ip mroute vrf N 232.0.0.7 10.5.10.10 verbose | begin \

```

via LmdtN with rpf neighbor 213.5.5.5

We check the MDT data bindings on all routers. XRv2 and CSR1 receive MDT information via the Type-3 S-PMSI route, while CSR5 sends it. The S-PMSI specifies an mLDP P2MP tunnel (type 2) rooted at CSR5.

Sending traffic from CSR10 shows packets being sent into the core by CSR5 and received by CSR1. EPC confirms the MPLS decapsulation and native IP multicast forwarding to CSR9. The difference in 4 bytes represents the popping of the MPLS shim header. A final validation of label 0x3F4 (1012) shows this is the proper local downstream label for CSR1 along that data MDT. The label is highlighted in yellow while the IP headers are in green.

Because S-PMSI is offered for (10.5.10.10, 232.0.0.7), we theorize that importing the RT associated with the BGP-AD and VPNv4 routes from CSR5 will be sufficient to build connectivity to extranets. With GRE, this worked quite easily, since the entire core was PIM-enabled and there was nothing stopping PIM P(S,G) joins for data MDT groups transiting between any PEs. At this point, neither CSR6 nor CSR8 have the red VPN (N) configured locally. VRF N will be our “red VPN” at first, the one with the sources, so we will not verify intranet MVPN on VRF S yet. Instead, we will perform a similar test as we did with GRE. CSR5 will create a “violet” RT for its BGP-AD routes along with any extranet sources. CSR8 will import this “violet” RT as an extranet client. CSR6 will import the raw red RT:213:5 and attempt to draw extranet MVPN services. These imports are happening directly into the blue VPN (S), not a proxy red VPN (N). Fortunately, the entire “violet” RT constructs are identical to the PIM/GRE model and the configurations are not displayed again. We can verify that both the VPNv4 route for 10.5.100/24 and the BGP-AD Type1/3 routes from CSR5 both have the new violet RT:213:500.

```

A quick check of the mLDP database on CSR6 shows that the P2MP tunnel rooted at CSR5 was not built. We can clearly see the Type-3 S-PMSI route has been imported. The issue is that the VPN ID is encoded in the variable-length opaque nested inside the FEC element. The PMSI attributes carry this value, which

is 213:1512. There are no VRFs locally configured that match this VPN ID, so the MVPN construction cannot occur. We must use another method.

We will create the red VPN locally on CSR6 and CSR8. This is the RSC method we used for PIM/GRE, which implies we configure the source VPN on the receiver PE. The VPN ID will be 213:1512 and for cleanliness, we will remove the red and violet RT import statements from VRF S on CSR6 and CSR8, respectively. We will import these into the red VPN (N) only. Between the violet and red RTs, both CSR6 and CSR8 should be part of this mLDP MP2MP tree. We can check for C-PIM neighbors in each router. CSR6 and CSR8 also form neighbors with one another, as expected, but of greatest importance are the neighborships with CSR5.

Examining the C-MRIB entries, we see that traffic arrives into the proxy red VPN (N) and is piped in software to the blue VPN (S). The red entry shows both the big 'Y' and big 'E' entries, indicating traffic was received from an MDT data group and also represents extranet capability. We never saw these two flags together in the PIM/GRE method because the traditional RSC/SSC extranet configuration was not needed when using S-PMSI. Also notice that, so far, it doesn't seem to matter whether we used the violet (CSR8) or red (CSR6) RTs for pulling in these BGP-AD and VPNv4 unicast routes.

*>i [3] [213:66] [10.5.10.10] [232.0.0.7] [213.5.5.5] /22
```

The RPF mechanism for this traffic is identical to how it was for PIM/GRE. CSR6 and CSR8 have group-based RPF selection policies inside VRF S (blue) that specify certain groups can be RPF-checked in VRF N (red). The configuration is identical on CSR6 and CSR8, so only one is shown.

```
R6#show ip rpf vrf S select
Multicast Group-to-Vrf Mappings
Group(s): 232.0.0.7/32, RPF vrf: N, Acl: ACL_N_GROUPS
```

Knowing that the MDT number is 1, we can check their mLDP databases to determine the incoming label for each one. This will be used for the final data-plane verifications as well. CSR8 maps this entry to LSPvif1 while CSR6 selects LSPvif10; in both cases, this matches with the virtual interface assigned to this VPN as shown in the PIM neighbor show commands. CSR8 uses local downstream label 8013 while CSR6 uses 6013. As a sanity check, we also see the root is CSR5 and the type is P2MP, which is correct.

```

```

It is worth mentioning that although these P2MP trees will be used for delivery, both CSR6 and CSR8 are part of the red MP2MP default MDT. Without it, there would be no C-PIM overlay signaling.

```

R6#show mpls mldp database summary | include MP2MP
9      MP2MP  213.13.13.13      [mdt 213:678 0]      1

B      MP2MP  213.14.14.14      [mdt 213:1512 0]      1

```

A quick verification on CSR5 shows nothing unusual; the C-MRIB entry sends traffic down a data MDT (little 'y'). The "verbose" keyword shows us the MDT details that are bound to this C(S,G).

```

R5#show ip mroute vrf N 232.0.0.7 10.5.10.10 verbose | begin \
(10.5.10.10, 232.0.0.7), 00:18:49/00:02:51, flags: sTyp
Incoming interface: GigabitEthernet2.550, RPF nbr 0.0.0.0
MDT TX nr: 1  LSM-ID: 0x7
Outgoing interface list:
  Lspvif0, LSM MDT: 7 (data), Forward/Sparse, 11:47:39/00:02:51, p

```

CSR10 begins sending traffic. CSR5 replicates the traffic to XRv3 and XRv4 using labels 93015 and 94009 respectively. Both of these core routers pass it down the tree to their receivers. Notice that label 1012 is in the replication list for XRv4; the intranet receivers expressing interest in this C(S,G) still receive the traffic flow.

```

R5#show mpls mldp database opaque_type mdt 213:1512 1 | section Replicat

```

Next, we check the C-MRIB counters on CSR6 and CSR8 within both the red and blue VPNs. Traffic counters should be identical between the two if things are working properly. We also show the red VPN counters on CSR1 to prove that intranet connectivity is not broken.

```

Last, we conduct EPC verifications on CSR6 and CSR8 to ensure the proper labels are entering and the ICMP multicast is being decapsulated and sent to the customer. MPLS shim headers are shown in yellow and the IP multicast headers are shown in green. We see that CSR6 receives label 0x177D (6013) and CSR8 receives label 0x1F4D (8013), which is expected.

```
R6#show monitor capture CAP buffer detailed

Next, we will configure CSR5 to stop offering data MDT service for this C(S,G). Using the “deny ip any any” technique in the data MDT ACL, we will force the traffic to use the default MDT. To prove it worked, the two lines below show the before/after results. CSR5 originally originated a Type-3 S-PMSI route for that C(S,G), but now has withdrawn it. CSR5 no longer displays the little ‘y’ flag on its C(S,G) entry and specifically says the MDT in use is the “default”.

```
R5#show bgp ipv4 mvpn vrf N | include \[3\]
*> [3] [213:5] [10.5.10.10] [232.0.0.7] [213.5.5.5]/22
```

!! ACL modification !!

```
R5#show bgp ipv4 mvpn vrf N | include \[3\  
[no output]
```

```
R5#show ip mroute vrf N 232.0.0.7 10.5.10.10 verbose | begin \  
(10.5.10.10, 232.0.0.7), 00:19:29/00:03:11, flags: sTp  
  Incoming interface: GigabitEthernet2.550, RPF nbr 0.0.0.0  
  Outgoing interface list:  
    Lspvif0, LSM MDT: 2 (default), Forward/Sparse, 11:48:18/00:03:11, p
```

CSR6 and CSR8 also lose their data MDT cache information and strip the 'Y' from the C(S,G). Otherwise, the verification is generally the same. The red VPN (N) entries are still marked as 'E' for extranet, and the blue VPN (S) entries still use the red VPN for RPF lookups per the group-based selection policy.

We know that an mLDP default MDT always has MDT ID 0, so we can check the mLDP database to determine the downstream local labels. Also note that there are upstream labels in the MP2MP tree, though we don't care about that for this test. CSR6 uses label 6012 and CSR8 uses label 8011.

```
R6#show mpls mldp database opaque_type mdt 213:1512 0 | section Upstream
Upstream client(s) :
  213.13.13.13:0    [Active]

```

Finally, we confirm proper operation using EPC on CSR6 and CSR8. CSR6 receives label 0x177C (6012) and CSR8 receives label 0x1F4B (8011), which is correct for the default MDT in the red VPN. For brevity, we use the IOS parser to tell us what the payload is for the IP packet.

```

Because we are using LSM (and not raw IP), we can use MPLS OAM to help verify tunnel connectivity. We are using the default red MDT for transport, so we can test the MP2MP tree rooted at XRv4. We see replies from all routers except CSR7, since the 4 shown below are all part of the red VPN in some way. Even when using RSC, CSR6 and CSR8 will respond to these probes.

```
R5#ping mpls mldp mp2mp 213.14.14.14 mdt 213:1512 0

```

```
! reply addr 213.8.14.8
! reply addr 213.1.14.1
```

Next, we will test SSC using VRF S as the red VPN and VRF N as the blue VPN. CSR2 will be the source for (10.2.7.2, 232.0.0.5) with XRv2 and CSR1 as receivers. SSC means that CSR7 will be in both red and blue VPNs. This method is significantly more complex than RSC as CSR7 must import the blue RTs from all interested receivers (RT:213:1 and RT:213:12 in this case), and those receivers must reciprocate. CSR7's red VPN also imports routes from its local blue VPN to stitch the extranet together. This means CSR7's VRF N imports RT:213:7 also. Because the sources are red (S), they need to be advertised in the blue VPN so the egress PEs can satisfy RPF. This means CSR7's blue VPN needs to export an RT that the receivers are importing (can re-use RT:213:1 and RT:213:12) to pass those routes, or potentially use a "violet" RT if desired. In the GRE test, we re-used RT:213:1 and RT:213:12 for the BGP-AD routes and RT:213:700 for the VPNv4 routes, which appeared to work well. Because this method is so much more complicated than RSC, the snippet is shown below. CSR1 and XRv2 also need to import the violet RT:213:700, but that is not shown.

```
! CSR7
vrf definition N
  rd 213:77
  vpn id 213:1512
  route-target export 213:700
  route-target import 213:7
  route-target import 213:12
  route-target import 213:1
  address-family ipv4
    mdt auto-discovery mldp
    mdt default mpls mldp 213.14.14.14
  address-family ipv6
    mdt auto-discovery mldp
    mdt default mpls mldp 213.14.14.14
```

Using RT:213:700 for both BGP-AD and VPNv4 routes was an option I did not consider in earlier tests. The original reason for using the violet RT was because having the remote PEs import multiple I-PMSI routes from the same router allows BGP to decide which tunnel to use (based on best-path). This can have unintentional results as we are not trying to get CSR1/XRv2 to join the red VPN with SSC. Checking CSR1, we only see a single Type-1 I-PMSI route from CSR7 using the violet RT. The root is identified as XRv14 for the mLDP MP2MP (type 7) tree within VPN 213:1512. These fields are highlighted in the PMSI attributes below. We know this is the default MDT since the MD ID is 0 (0x00000000).

```

The default MDT for VRF N is huge now since the RSC configuration is still intact. Nonetheless, we can see CSR7 is a new neighbor from CSR1's and XRv2's perspective, which shows it was recently added. Technically, this is part of the I-PMSI setup, which wasn't really an issue since CSR7 generated its own I-PMSI route with the violet RT:213:700 from the beginning.

```

Normally I don't document my mistakes in detail, but this configuration is broken in many ways. Most of these errors come from trying to use S-PMSI with SSC incorrectly. Looking at CSR7, the issue is clear. Within VRF N, CSR7 selects the locally originated I-PMSI route over the imported one; the best-path has RT:213:700 which allows blue receivers to import it. However, there is only one S-PMSI route, and it is the imported one. VRF N did not create one locally, so this RT is still 213:7. Remote receivers cannot import this per the current design.

The GRE tests did not explicitly test S-PMSI with SSC, so we didn't see this issue earlier. The BGP Type-1 route is already being imported properly, but the Type-3 and VPNv4 routes are not. This explains why we have C-PIM neighbors but not much else. Using the technique from the GRE tests of adding RT:213:700 to the VPNv4/v6 routes will at least correct the RPF problem. I show a portion of the configuration below, since the prefix-lists inside just match the C-Source.

```
! CSR7
```

```
vrf definition S
```

```
  address-family ipv4
```

```
    export map RM_EXTRANET_EXPORT
```

```

```

Within XE/XR, I cannot find a mechanism to selectively match PMSI routes. If I could, some BGP route-maps would be a tempting solution to this problem. Even by setting the RT of the C-source as shown above, this was not transitive to the Type-3 S-PMSI route.

```
R7#show bgp vpnv4 unicast vrf N 10.2.7.0/24 | include Extend
```

```
Extended Community: RT:213:7 RT:213:700
```

```
R7#show bgp ipv4 mvpn vrf N route-type 3 10.2.7.2 232.0.0.5 213.7.7.7 |  
include Extend
```

```
Extended Community: RT:213:7
```

Even if it were transitive, the S-PMSI route still includes the red VPN ID, which is incorrect. Even if we manipulated the RT somehow (which is possible on XRv ... match RD 213:77, set RT 213:700), it would not allow the blue endpoints to build the proper VPN. **The key point is that the VPN membership is determined by more than just the RT; other mLDP FEC elements matter also.** We saw this earlier when we tried to do RSC without configuring the red VPN on the blue PE. mLDP is more strict about VPN membership than GRE.

```
R7#show bgp ipv4 mvpn vrf N route-type 3 10.2.7.2 232.0.0.5 213.7.7.7 |  
include PMSI
```

```
PMSI Attribute: Flags: 0x0, Tunnel type: 2, length 24, label: exp-null,

0001
```

The key to this puzzle is configuring CSR7 to originate its own S-PMSI route. That guarantees that it will have the proper RT and VPN ID values. This is as simple as configuring the data MDTs inside the proper AF (IPv4/v6) under the blue VPN (N) on CSR7. Just like for the Type-1 I-PMSI route, the locally originated route was preferred over the imported one, so it can be advertised to the RR. Notice the correct RT and VPN ID.

Now, we can continue with our standard verification. CSR1 has a populated MDT cache and C-MRIB entry. The mLDP process allocates downstream local label 1012 for this data MDT. The FEC root (CSR7) and tree type (P2MP) are both correct. The big 'Y' shows that data is expected to enter on the data MDT and the MDT information is embedded in the C-MRIB entry.

```

The verification for XRv2 is similar, but since data-plane LSM MVPN does not appear supported, there are some software issues with resolving RPF, I am assuming. I go into some extra detail to verify RPF and unicast routing is correct; we can clearly see the control-plane for unicast VPNv6 is correct, to include a 2-label stack.

Next, we verify the head end where SSC is configured. The sequence of verification is reversed from RSC: first we check the red VPN (S), then the extranet proxy (N), then the core path (mLDP). Be careful of the two different LSM-IDs. 0x7 represents the ID within VRF S, which services the intranet VPN members. LSM-ID 0x8 is within VRF N which is for the extranet members. Remember that SSC replicates traffic for each extranet configured. That is why the OIL for the red VPN (S) entry is not null as it was for RSC.

```
R7#show ip mroute vrf S 232.0.0.5 10.2.7.2 verbose | begin \

```

Below is a summary view of the LSM-IDs and their VPNs. This helps confirm the output seen in the C-MRIB entries. Looking at 0x8, the extranet delivery tree, we see the router is only sending traffic towards XRv4 in terms of LSM. I assume this is because XRv2 has RPF issues and cannot issue the C-PIM (S,G).

```
R7#show mpls mldp database summary | include 7.7.7
7          P2MP      213.7.7.7          [mdt 213:678 1]          3
8          P2MP      213.7.7.7          [mdt 213:1512 1]        2
```

```
R7#show mpls mldp database id 8 | section Replica
Replication client(s):
MDT (VRF N)
  Uptime          : 00:17:02          Path Set ID   : None
  Interface       : Lspvif1
213.14.14.14:0
  Uptime          : 00:17:02          Path Set ID   : None

  Local label (U) : None              Next Hop     : 213.7.14.14
```

When XRv4 receives MPLS packets with label 94016, it forwards them to CSR1 only, as this is a data MDT within an extranet. Label 1012 is what CSR1 sent to XRv4 (in a label-mapping message) to “join” the extranet LSM tree.

```
RP/0/0/CPU0:XRv4#show mpls forwarding labels 94016

Label   Label      or ID           Interface        Next Hop         Switched
-----
94016   1012          MLDP: 0x00007   Gi0/0/0/0.514   213.1.14.1       0
```

For completeness, we will look at the intranet labels also. This is within the red VPN and is not related to extranet. Because there are intranet customers on both sides of the network (CSR6 and CSR8), CSR7 replicates the traffic towards XRv3 and XRv4. The labels used are 93011 and 94015.

```
R7#show mpls mldp database id 7 | section Replica
Replication client(s):
MDT (VRF S)
  Uptime          : 01:20:58          Path Set ID   : None
  Interface       : Lspvif0
213.13.13.13:0
  Uptime          : 01:20:57          Path Set ID   : None
  Out label (D)   : 93011             Interface    : GigabitEthernet2.573*
  Local label (U) : None              Next Hop     : 213.7.13.13
213.14.14.14:0
  Uptime          : 01:20:57          Path Set ID   : None
  Out label (D)   : 94015             Interface    : GigabitEthernet2.574*
  Local label (U) : None              Next Hop     : 213.7.14.14
```

Next, CSR2 begins sending traffic. We expect that CSR1 will be able to receive it properly, as will the existing intranet customers CSR6 and CSR8. First, we verify that CSR7 is seeing identical packet counts on both the red and blue VPN C-MRIB entries.

```
R7#show ip mroute vrf S 232.0.0.5 10.2.7.2 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 28, Packets received:
28
Source: 10.2.7.2/32, Forwarding: 28/1/118/0, Other: 28/0/0
```

```
R7#show ip mroute vrf N 232.0.0.5 10.2.7.2 count | begin ^Group
Group: 232.0.0.5, Source count: 1, Packets forwarded: 28, Packets received:
28
Source: 10.2.7.2/32, Forwarding: 28/1/118/0, Other: 28/0/0
```

An EPC capture on the outgoing interfaces shows the replication occurring. Two MPLS packets are sent towards XRv4 with labels 94015 (red color and VPN) and 94016 (blue color and VPN). One MPLS packet is sent towards XRv3 with label 93011 (yellow color, but is for the red VPN).

```

```

Using EPC, we verify proper extranet connectivity on CSR1. MPLS packets arrive with label 0x3F4 (1012) and are immediately decapsulated and sent towards CSR9 inside the blue VPN (N).

```

```

A quick OAM check on CSR7 shows everyone connected in the S-PMSI for this group. The verification is a little different with SSC since there are technically two P2MP trees as we saw earlier. When testing the extranet tree (blue VPN), only CSR1 responds. When testing the intranet tree (red VPN), CSR6 and CSR8 respond. The trees have the same root and, in this case, the same MDT ID. The major differentiator is the VPN ID. This is the expected and correct behavior.

```

Because the delivery mechanism is identical for IPv6, we will quickly evaluate it. The software plumbing appears to be broken; in all other examples, including the PIM IPv6 examples, the red VPN had extranet entries to connect the LSP to the blue VPN. In this case, it doesn't, but the RPF resolution from our group-based selection process is working. This is based on an RSC model.

```
R6#show ipv6 mroute vrf N  
No mroute entries found.
```

```
R6#show ipv6 mroute vrf S ff33::2 2001:10:5:10::10 | begin \  
(2001:10:5:10::10, FF33::2), 00:11:07/never, flags: sTI  
Incoming interface: Lspvif0  
RPF nbr: ::FFFF:213.5.5.5  
Immediate Outgoing interface list:  
GigabitEthernet2.546, Forward, 00:11:07/never
```

RPF validation appears somewhat correct, except the LSPvif interface enumerations don't match. The data MDT information doesn't appear to have been transported, either.

```
R6#show ipv6 rpf vrf S select

```

There is no point in sending traffic from CSR10 since we know the P2MP trees won't be built. If it were, CSR6 would show a P2MP tree rooted at 213.5.5.5 with the VPN ID 213:1512 inside the opaque. Even a router reload on CSR6 and CSR8 (to potentially fix any order-of-operations issues with the configuration) did not resolve the issue.

```
R6#show mpls mldp database summary

Cnt.
5           P2MP      213.7.7.7      [mdt 213:678 1]      1
1           MP2MP     213.13.13.13   [mdt 213:678 0]      1
3           MP2MP     213.14.14.14   [mdt 213:1512 0]     1
```

However, IPv6 appears to work somewhat with SSC (doesn't actually work, but control-plane looks better). There is no S-PMSI offered for (2001:10:2:7::2, FF33::1) at present, but we can verify the extranet connectivity using the default MDT. CSR7 originates an IPv6 Type-1 I-PMSI route within the blue VPN (N) and advertises it to CSR1. We know this is for the blue VPN since the VPN ID is 213:1512. CSR1 is able to install this and join the default MDT. We can see the C-PIM neighbor with CSR7. We can

also see the tree is MP2MP (type 7) and is rooted at XRv4. Notice the correct “violet” RT:213:700; this is because the route was originated locally from CSR7 inside VRF N.

```

```

Checking the C-MRIB entries on CSR7, we see traffic arriving from VRF S, being forwarded to VRF N (big ‘E’ for extranet), then being encapsulated inside MPLS.

```
R7#show ipv6 mroute vrf S FF33::1 2001:10:2:7::2 | begin \
(2001:10:2:7::2, FF33::1), 02:24:20/00:03:11, flags: sTE
Incoming interface: GigabitEthernet2.527
RPF nbr: 2001:10:2:7::2
Immediate Outgoing interface list:
  Lspvif0, Forward, 02:24:20/00:03:11

Extranet receivers in vrf N, OIF count 1
```

```
R7#show ipv6 mroute vrf N FF33::1 2001:10:2:7::2 | begin \
(2001:10:2:7::2, FF33::1), 00:40:44/00:02:47, flags: sT
Incoming interface: GigabitEthernet2.527
RPF nbr: 2001:10:2:7::2, using vrf S
Immediate Outgoing interface list:
  Lspvif1, Forward, 00:40:44/00:02:47
```

Notice that the two entries have different LSPvif interfaces; the one in VRF S is for red receivers (intranet) and the one in vrf N is for blue receivers (extranet). Two outputs are shown below; the first is for intranet and the second is for extranet. These are the two default MDTs for the red and blue VPNs respectively. We note the upstream labels for each since CSR7 will be replicating traffic for each VPN in this way. Unlike for IPv4, we will later see two packets, not three, since we are using the MP2MP tree.

XRv4 will perform any downstream replication needed as CSR7's only job is to get the traffic to the MP2MP root.

```

CSR1 also reports a valid C(S,G) entry for this flow. Notice there are no 'y' or 'Y' flags as this is using the I-PMSI P-tunnel, which is mLDP MP2MP. Because we know the characteristics of the blue default MDT, we can query the mLDP database to find the incoming local label. That value is 1009.

```
R1#show ipv6 mroute vrf N FF33::1 2001:10:2:7::2 | begin \
(2001:10:2:7::2, FF33::1), 23:15:33/never, flags: sTI

  Totals - Source count: 1, Packet count: 0
```

We already verified the control-plane on CSR7, but EPC clearly shows that CSR7 is only sending traffic upstream to XRv3 along the red default MDT. Three packets, paced one second apart, all have the same label 93010 (0x16B52) and the destination MAC of XRv3.

```
R7#show ip arp 213.7.13.13
```

Protocol	Address	Age (min)	Hardware Addr	Type	Interface

```

Clearing several software processes did not resolve the issue. A reload of CSR7 still did not resolve it. I believe the configuration is correct and all control-plane verifications are accurate.

30. Describe, implement, and troubleshoot MPLS QoS models and related features

The subsections on MPLS QoS all use the same set of diagrams. The diagram changes slightly for cosmetic reasons when demonstrating IOS XR QoS but the general network remains the same. The diagram is universal for the next three sections.

The configurations below include both IOS and IOS-XE configuration files for all 3 MPLS QoS models, plus QPPB.

Additional Reading – Reference configurations “mpls-qos” and “gns3-mpls-qos”

30.1 Uniform

Uniform is a QoS model whereby changes in the SP network are propagated to the customers. Using an MPLS example, if a customer sends traffic into the network as DSCP AF41, the SP will likely mark this as EXP4 for transport. Let's assume that this traffic was remarked to EXP3 in the core, likely due to policing. This value applies only to the topmost shim header as the rest of the label stack is generally not evaluated/seen by an LSR (the exception would be load sharing for non-IP traffic using the bottom label). Therefore, when the penultimate hop tries to remove the topmost label to expose the VPN label (assuming a basic 2-label VPN design) to the egress PE (CSR2), it will not carry this value. The egress PE will be ignorant of any change in the SP network. This is the primary use-case for enabling explicit-null on a PE; it effectively disables PHP to allow those EXP modifications to be maintained. After receiving an explicit-null labeled packet, the egress PE cannot automatically carry this value into an IP TOS mapping since the label stack is stripped when the routing decision is made. This happens before egress QoS in the order of operations; a new placeholder is needed to match the EXP on ingress then set the IPP/DSCP on egress. This is the “qos-group” construct. A brute-force method would be the following applied to the ingress (core-facing) links:

```
! PE routers
class-map match-all CMAP_EXP0
  match qos-group 0
class-map match-all CMAP_EXP1
```

```

    match qos-group 1
[snip]
class-map match-all CMAP_EXP7
    match qos-group 7

policy-map PMAP_IN_FROM_CORE
    class CMAP_EXP0
        set qos-group 0
    class CMAP_EXP1
        set qos-group 1
[snip]
    class CMAP_EXP7
        set qos-group 7

```

While this works, it is configuration intensive and redundant. A more elegant and dynamic mechanism exists; we can simply tell the router to perform a direct copy from EXP to QG. It would have an identical effect as the 8 class-maps above. The drawback of this approach is described later with regards to discard-class-based WRED. Note: The configurations suffixed “gns3” use this semi-dynamic method while the ones with no special suffix are CSR’s using the brute force method. The end result is same, it’s just a matter of configuration elegance and length.

```

! PE routers
policy-map PMAP_IN_FROM_CORE
    class class-default
        set qos-group mpls experimental topmost

```

Let’s pretend that QG numbers 0-7 were used for some other purpose in my network. I demonstrate a simple workaround on CSR2 using the table-map. This is NOT the same logic as the table-map used for QPPB (which is really a route-map). I can still avoid using 8 class maps and maintain some semblance of dynamic configuration while just selecting new values. On CSR2, I map EXP to QG + 50. The table-map is a generic entity just used to map numbers and is not specific to MPLS QoS. Unfortunately, Cisco clearly states in their IOS XE 3S documentation that the “table-map” is supported, but it actually isn’t (it is missing both from global configuration and from MQC constructs). You must use this “brute force” method on the CSR1000v and likely any other IOS XE 3S platform.

```

! PE routers
policy-map PMAP_IN_FROM_CORE
    class class-default
        set qos-group mpls experimental topmost table TM_EXP_TO_QG

table-map TM_EXP_TO_QG
    map from 0 to 50
    map from 1 to 51
[snip]
    map from 7 to 57

```

Going the other way (out to the customer), it would be nice if we could have similar semi-dynamic behavior. We can also configure IPP, DSCP, or EXP to be derived from the qos-group.

```
policy-map PMAP_OUT_TO_CUSTOMER
  class class-default
    set precedence qos-group table TM_QG_TO_IPP

table-map TM_QG_TO_IPP
  map from 50 to 0
  map from 51 to 1
  [snip]
  map from 57 to 7
  default 0
```

The downside to this approach is that we lose some granularity because our egress policy is essentially just copying EXP->IPP now. We aren't doing any queuing or traffic conditioning. If that is desired, you can break out a few individual EXPs (in my examples I use EXP1 and EXP5, using the default for the rest) for custom treatment. Unless, of course, you just want to apply generic shaping to the default class, in which case explicit break-outs would not be required.

An unfortunate lack-of-feature is that discard-class-based WRED cannot be dynamically mapped this way. In the configurations you will see examples of this feature where I statically set the discard-class to a number. It's effectively like IPP based WRED (lower numbers get worse treatment) except it is like the QoS-group; you can set it inbound and perform WRED outbound. If this was supported dynamically you would be able to provide EXP->IPP mapping and WRED with very little configuration.

A quick example of uniform mode: send traffic from CSR6 with DSCP CS2 and expect to see DSCP AF11 on CSR1.

```
R6#ping 12.0.0.1 tos 64 repeat 5
```

We can quickly check CSR2 to see it matching EXP1 on ingress, setting QG1, matching QG1 on egress, and setting DSCP AF11. CSR3 performs the EXP2->EXP1 remarking for all EXP2 transit traffic; this policy is applied to all core interfaces.

```
! CSR3
class-map match-all CMAP_EXP2
  match mpls experimental topmost 2
```

```
policy-map PMAP_REMARK_EXP
  class CMAP_EXP2
    set mpls experimental topmost 1
```

```
R2#show policy-map interface gig2.523 input | section EXP1
  Class-map: CMAP_EXP1 (match-all)
```

```

5 packets, 630 bytes
5 minute offered rate 0000 bps, drop rate 0000 bps
Match: mpls experimental topmost 1
QoS Set
  discard-class 1
    Marker statistics: Disabled
  qos-group 1
    Marker statistics: Disabled

```

```

R2#show policy-map interface gig2.512 output | section QG1
Class-map: CMAP_QG1 (match-all)
  5 packets, 590 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
  Match: qos-group 1
  [snip]
  bandwidth 15% (150000 kbps)
  Exp-weight-constant: 4 (1/16)
  Mean queue depth: 0 packets
  discard-class      Transmitted      Random drop      Tail
drop                Minimum      Maximum      Mark
                    pkts/bytes      pkts/bytes      pkts/bytes
thresh              thresh      prob
16                  0          0/0          0/0          0/0
                    32  1/10
11                  1          5/590        0/0          0/0
                    17  1/7
  [snip]

```

CSR1 should report seeing DSCP AF11 now.

```

R1#show flow monitor FNF_MONITOR_IPV4 cache format table | begin IPV4
IPV4 SRC ADDR      IPV4 DST ADDR      INTF INPUT      IP TOS      pkts
=====
46.0.0.6           12.0.0.1           Gi2.512          0x28          5

```

Math conversion:

DSCP CS2 = 010 000 = 16, left shift x 2 = 64 or 0x40 (0100 0000 for TOS)

DSCP AF11 = 001 010 = 10, left shift x 2 = 40 or 0x28 (0010 1000 for TOS)

30.2 Short pipe

Short pipe is the default mode and requires no special configuration. The word “pipe” indicates that the customer QoS markings are not modified by the SP and are preserved across the VPN. The word “short” indicates that any markings made the provider are NOT used to determine the egress QoS treatment for the customer. Using the same example from above, if the flow is remarked to EXP3 in the core, this value applies to the topmost shim header only and this new marker has no influence on the egress PE’s queuing policy. Thus, PHP can be enabled for this model. The egress queuing on the PE (CSR5) will use

regular IPv4/IPv6 mechanisms. The configuration on CSR5 is very straightforward and I added a simple QoS policy just to illustrate the point. The remarking performed on CSR3 will not affect how CSR5 queues traffic outbound towards the customer. I would imagine this is the most common for service providers as it is the least complex and, since the traffic already arrived at the customer, it doesn't matter as much how you deliver their traffic. It was more important in the SP core to remark the shim headers but at the end of the LSP, it matters less.

A quick example of short-pipe mode: send traffic from CSR6 with DSCP CS2 and expect to see the same value on CSR5.

```
R6#ping 57.0.0.7 tos 64 repeat 5
```

```
R5#show policy-map interface gig2.557 output
[snip]
```

```

      Class-map: class-default (match-any)
        121 packets, 8544 bytes
      [snip]
      default      59/3776      0/0      0/0
52      104  1/10
      cs2          5/590      0/0      0/0
65      104  1/10
      cs6          57/4178     0/0      0/0
91      104  1/10

```

Above, notice that the traffic matches class-default because we did not define any custom actions for IPP2. We can see the counters under the WRED configuration, though. Below, notice that there is no change to the IP TOS byte, as expected, and the PE was NOT able to make queuing/shaping decisions based on SP-modified markings. Only IPP was visible in short-pipe mode.

```

R7#show flow monitor FNF_MONITOR_IPV4 cache format table | begin IPV4
IPV4 SRC ADDR      IPV4 DST ADDR      INTF INPUT          IP TOS              pkts
=====
46.0.0.6           57.0.0.7           Gi2.557              0x40                 5

```

Math conversion:

DSCP CS2 = 010 000 = 16, left shift x 2 = 64 or 0x40 (0100 0000 for TOS)

30.3 Pipe (AKA long pipe)

Long pipe is a combination of the uniform and short pipe modes. It still “pipes” the customer markings through the network, so the customer has no idea that traffic markings were modified along the path. Like uniform mode, the topmost MPLS marking must arrive at the egress PE (CSR4) because the egress QoS treatment will be based on the SP-modified markings. However, these egress policies will NOT remark packets as they are sent to the customer; this is the fundamental difference between uniform

and long pipe. Explicit-null is still required, as are qos-group placeholders. The QoS policies are nearly identical on CSR2 and CSR5, only that CSR5 is not setting new TOS byte values. One other note about this mechanism is that we do not HAVE to match every single value as we did in uniform mode. On CSR4's configuration, notice that I do not have class-maps for EXP2-4 or QG2-4, because I don't need to customize the behavior for those markings. Uniform mode MUST match every single value in order to perform a rewrite on egress.

A quick example of long-pipe mode: send traffic from CSR1 with DSCP CS2 and expect to see the same value on CSR6.

```
R1#ping 46.0.0.6 tos 64 repeat 5
```

Check the PE for matches. CSR4 sees EXP1 coming in as expected, and performs proper outbound actions based on QG1.

```
R4#show policy-map interface gig2.534 input | section EXP1
Class-map: CMAP_EXP1 (match-all)
  5 packets, 630 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
  Match: mpls experimental topmost 1
  QoS Set
    discard-class 1
      Marker statistics: Disabled
    qos-group 1
      Marker statistics: Disabled
```

```
R4#show policy-map int gig2.546 output | section QG1
Class-map: CMAP_QG1 (match-all)
  5 packets, 590 bytes
[snip]
```

	discard-class	Transmitted	Random drop	Tail
drop	Minimum	Maximum	Mark	
thresh	pkts/bytes	pkts/bytes	pkts/bytes	
	thresh	prob		
	0	0/0	0/0	0/0
16	32 1/10			
	1	5/590	0/0	0/0
11	17 1/7			

Above, notice that the traffic matches the specific class for QG1. We can see the counters under the WRED configuration also. Below, notice that there is no change to the IP TOS byte, as expected, yet the PE was able to make queuing/shaping decisions based on SP-modified markings.

```
R6#show flow monitor FNF_MONITOR_IPV4 cache format table | begin IPV4
IPV4 SRC ADDR    IPV4 DST ADDR    INTF INPUT          IP TOS          pkts
```

=====	=====	=====	=====	=====
12.0.0.1	46.0.0.6	Gi2.546	0x40	5

Math conversion:

DSCP CS2 = 010 000 = 16, left shift x2 = 64 or 0x40 (0100 0000 for TOS)

30.4 QoS Policy Propagation through BGP (QPPB)

QoS Policy Propagation through BGP (QGGP) is an interesting feature where the BGP NLRI carries the QoS markings for specific routes in a roundabout way. This can simplify QoS configuration on many devices by encoding it within the prefix via communities. It isn't terribly granular or widely deployed but for simple policies it might be a better option than putting MQC configurations on thousands of network devices. It can be awkward because, in many cases, BGP is just transporting prefixes and is not involved in data plane operations. That is why this feature really only makes sense for IPv4/IPv6 unicast AFI/SAFI.

Notice that only CSR5 and CSR7 are running BGP as the PE-CE protocol; the other CEs just have a static default route for reachability and no other connected routes. CSR7 signals CSR5 to set IPP for any traffic that it sources from specific subnets. This essentially says "When I send traffic FROM this subnet, set this QoS marking on ingress". This is what the table-map does; this not related to the actual "table-map" command in global configuration that we used earlier, this is a route-map applied to BGP using the "table-map" command under an address-family. This could be handy to allow your customers to change their QoS markings per-prefix without the SP becoming involved, which would require some kind of remote signaling not available in MQC. There are a few reasons why wouldn't the customer just do the marking locally in the first place:

1. Customer router is very low end, either in feature set or performance, but does support basic BGP and communities. Classification/marketing can be a CPU intensive process.
2. Customer router is actually a firewall, again with limited feature set.
3. Customer is not network savvy and will accept imprecise QoS in return for minimal complexity
4. Inter-domain route exchange where the source provider can advertise what the QoS treatment should be. This can simplify the ASBR QoS configurations, specifically for Inter-AS MPLS Option A. Other non-MPLS related inter-AS exchanges can benefit as well.

Specifically, this mechanism of QPPB is enabled at the link level with the "bgp-policy source ip-prec-map". Substituting the word "destination" for "source" is also valid but the router uses the destination address for the QPPB lookup. Because QPPB is always processed inbound, the logic would become "When I send traffic TOWARDS this subnet, set this QoS marking on ingress". You can enable both simultaneously; in my example I have all QPPB features enabled at once on the customer facing link.

Once enabling this feature on an interface, a quick verification is recommended. Beware the verbiage; QPPB is an ingress-only feature, so the words "input" and "output" in the show command really mean "source" and "destination" in the configuration, respectively. The show command also confirms the assertion that QPPB is an input feature.

```

! CSR5
interface GigabitEthernet2.557
  bgp-policy source ip-prec-map
  bgp-policy destination ip-prec-map

R5#show ip interface gig2.557 | include BGP
  BGP Policy Mapping is enabled (output ip-prec-map) (input ip-prec-map)
  Input features: BGP Policy Map, QoS Classification, Access List, MCI Check

```

Only a single “table-map” can be applied under a BGP AF at one time. Changing the table-map will overwrite the existing value. Thus, your QPPB route-map should have widely spaced sequence numbers for easy insertions.

CSR7 has five networks advertised into BGP. Two of them want traffic to be marked EXP3 and EXP4 by the PE, while the remaining three have no preference according to the customer. CSR7 sets the communities when it originates the networks into BGP and advertises these to the PE (CSR5). CSR5 receives these communities, checks its table-map for any corresponding matches, and takes action. CSR5 is also configured to provide IPP5 treatment for 7.7.7.5/32 (using a prefix-list match) and IPP6 treatment for 7.7.7.6/32 (matching the BGP AS-path, which CSR7 prepended). This is meant to demonstrate that communities do not have to be signaled from another router and that any arbitrary route-map match statements are valid with a few exceptions; as an example, matching MED does not appear to work, and it is effectively a match-any. In most cases, communities make sense, since the customer can signal QoS through BGP in this way. The prefix 7.7.7.7/32 does not match any table-map clause and thus gets no modification. This is NOT the same as setting IPP0 as a default route-map entry and that would overwrite existing QoS markings.

```

! CSR5
ip bgp-community new-format
ip community-list standard COMMLIST_IPP3 permit 77:3
ip community-list standard COMMLIST_IPP4 permit 77:4
ip as-path access-list 7 permit ^7_.+
ip prefix-list PL_7775 seq 5 permit 7.7.7.5/32

route-map RM_QPPB_FOR_CUSTOMER permit 10
  match community COMMLIST_IPP3
  set ip precedence flash
route-map RM_QPPB_FOR_CUSTOMER permit 20
  match community COMMLIST_IPP4
  set ip precedence flash-override
route-map RM_QPPB_FOR_CUSTOMER permit 30
  match ip address prefix-list PL_7775
  set ip precedence critical
route-map RM_QPPB_FOR_CUSTOMER permit 40
  match as-path 7
  set ip precedence internet

```

```
router bgp 1
 address-family ipv4 vrf A
  table-map RM_QPPB_FOR_CUSTOMER
```

The verifications are shown below. The routing table clearly shows the mapping of each destination prefix on CSR7 to the appropriate QoS value identified in the QPPB table-map.

```
! Signaled by customer community
R5#show ip route vrf A 7.7.7.3 | include Routing_entry|Tag
Routing entry for 7.7.7.3/32
  Tag 7, precedence flash (3), type external

! Signaled by customer community
R5#show ip route vrf A 7.7.7.4 | include Routing_entry|Tag
Routing entry for 7.7.7.4/32
  Tag 7, precedence flash-override (4), type external

! Locally specified
R5#show ip route vrf A 7.7.7.5 | include Routing_entry|Tag
Routing entry for 7.7.7.5/32
  Tag 7, precedence critical (5), type external

! Locally specified
R5#show ip route vrf A 7.7.7.6 | include Routing_entry|Tag
Routing entry for 7.7.7.6/32
  Tag 7, precedence internet (6), type external

! Not specified at all; no treatment yet
R5#show ip route vrf A 7.7.7.7 | include Routing_entry|Tag
Routing entry for 7.7.7.7/32
  Tag 7, type external
```

To test it, we will send unmarked traffic from CSR7 to CSR1 source from all 5 of its addresses using a quick TCL script. Using FNF on CSR1 will allow us to capture the markings.

```
foreach x {
  7.7.7.3
  7.7.7.4
  7.7.7.5
  7.7.7.6
  7.7.7.7
} { ping 12.0.0.1 source $x }
```

Another nice feature of QPPB is that in the order of operations, it occurs before routing (and thus before MPLS imposition), so when the IPP is set by CSR5 on ingress it is automatically copied to EXP just as if we used ingress MQC to classify/mark the traffic. With FNF enabled on CSR3 we can see some of these EXP

markings being carried through. Of course, any SP-remark that occurs will overwrite what was written at imposition, so beware of the order of operations when mixing QPPB with uniform/long-pipe QoS models, or mixing it with MQC ingress classification/markings. Let's compare CSR1's captured IP packets with CSR3's captured MPLS packets.

```
R1#show flow monitor FNF_MONITOR_IPV4 cache format table | begin IPV4
```

IPV4 SRC ADDR	IPV4 DST ADDR	INTF INPUT	IP TOS	pkts
7.7.7.5	12.0.0.1	Gi2.512	0xB8	5
7.7.7.4	12.0.0.1	Gi2.512	0x80	5
7.7.7.7	12.0.0.1	Gi2.512	0x00	5
7.7.7.3	12.0.0.1	Gi2.512	0x60	5
7.7.7.6	12.0.0.1	Gi2.512	0xC0	5

I cannot explain it, but despite telling QPPB to set IPP5 for 7.7.7.5/32, it set DSCP EF (DSCP 46 or TOS 0xB8). This is true on both classic IOS and IOS XE. Perhaps the router assumes that this is a more appropriate value; from an MPLS perspective it makes no difference as EXP only captures the 3 leftmost TOS bits. Let's check CSR3 to see the EXP values in the shim headers. I include "20.." because I want to capture labels going to CSR2 only. The output is not totally authoritative but the correlation between CSR3's MPLS FNF cache and CSR1's IPv4 FNF cache is clear. Without any additional verification, we can safely assume that QPPB is marking traffic correctly.

```
R3#show flow monitor FNF_MPLS_MONITOR cache format table | include 20.. | INTF | =====
```

INTF INPUT	INTF OUTPUT	MPLS LABEL 1	MPLS LABEL 2	pkts
Gi2.535	Gi2.523	3000 / 6	2004 / 6	5
Gi2.535	Gi2.523	3000 / 0	2004 / 0	5
Gi2.535	Gi2.523	3000 / 5	2004 / 5	5
Gi2.535	Gi2.523	3000 / 4	2004 / 4	5
Gi2.535	Gi2.523	3000 / 3	2004 / 3	5

QPPB can also be used to set QoS-group flags for source or destination networks. It works the same way as IPP. The router can set QoS-group on ingress then perform some egress shaping or other mechanism without interrupting your existing MQC ingress classification/markings. This is a less intrusive and more flexible usage of QPPB. It can be enabled using the "ip-qos-map" command instead of "ip-prec-map". The two can be enabled concurrently, and in this example, source-based IPP and QG mapping are enabled together.

```
! CSR5
interface GigabitEthernet2.557
  bgp-policy source ip-prec-map
  bgp-policy source ip-qos-map
  bgp-policy destination ip-prec-map
```

```
bgp-policy destination ip-qos-map
```

```
R5#show ip interface gig2.557 | include BGP
```

```
BGP Policy Mapping is enabled (output ip-qos-map) (input ip-qos-map)
```

```
(output ip-prec-map) (input ip-prec-map)
```

```
Input features: BGP Policy Map, QoS Classification, Access List, MCI Check
```

In this case, we set qos-group 7 for all unmatched traffic in the QPPB route-map just to illustrate its use. CSR5 can now use this on different egress interface encapsulations, MPLS or otherwise. This route-map clause just extends the existing QPPB policy.

```
! CSR5
```

```
route-map RM_QPPB_FOR_CUSTOMER permit 1000
```

```
set ip qos-group 7
```

```
! Default match clause in QPPB route-map
```

```
R5#show ip route vrf A 7.7.7.7 | include Routing_entry|Tag
```

```
Routing entry for 7.7.7.7/32
```

```
Tag 7, qos-group 7, type external
```

Another quick example demonstrates the IPP and QG mapping using the “destination” method. In order for this to work, CSR2 advertises a few test loopbacks into BGP within the customer VRF so that CSR7 has something to which traffic can be destined; I didn’t want to run PE-CE BGP with CSR1. A QPPB route-map entry uses a locally-defined prefix-list to match those subnets (99.99.99.2/32 and 99.99.99.22/32) and sets both an IPP and QG mapping. Another option would be to set communities at CSR2 when the routes were redistributed, match them in the QPPB route-map, and take action. Notice that the new route-map clause comes before the default entry (index 1000 above).

```
! CSR5
```

```
ip prefix-list PL_LOOP99_TESTS seq 5 permit 99.99.99.0/24 le 32
```

```
route-map RM_QPPB_FOR_CUSTOMER permit 200
```

```
match ip address prefix-list PL_LOOP99_TESTS
```

```
set ip precedence network
```

```
set ip qos-group 99
```

Here are the routing entries within the VRF. Since this is a destination learned across the VPN, we must use destination-based QPPB (enabled in the beginning of this section).

```
! Locally specified
```

```
R5#show ip route vrf A 99.99.99.2 | include Routing_entry|bgp
```

```
Routing entry for 99.99.99.2/32
```

```
Known via "bgp 1", distance 200, metric 0, precedence network (7), qos-group 99, type internal
```

```
! Locally specified
```

```
R5#show ip route vrf A 99.99.99.22 | include Routing_entry|bgp
Routing entry for 99.99.99.22/32
  Known via "bgp 1", distance 200, metric 0, precedence network (7), qos-
  group 99, type internal
```

A quick FNF check on CSR3 proves that the IPP7 mapped to EXP7 as imposition. I sent 15 packets per route with TOS 0. Just to prove there is no magic, I also show the label stack per prefix from CSR5 (ingress LSR).

```
R3#show flow monitor FNF_MPLS_MONITOR cache format table | begin INTF
INTF INPUT          INTF OUTPUT      MPLS LABEL 1    MPLS LABEL 2    pkts
=====
Gi2.535             Gi2.523          3000 /7        2000 /7        15
Gi2.535             Gi2.523          3000 /7        2001 /7        15
```

```
R5#show ip cef vrf A 99.99.99.2
99.99.99.2/32
  nexthop 35.0.0.3 GigabitEthernet2.535 label 3000 2000
```

```
R5#show ip cef vrf A 99.99.99.22
99.99.99.22/32
  nexthop 35.0.0.3 GigabitEthernet2.535 label 3000 2001
```

Some Cisco documentation suggests that QPPB is processed before input ACLs and MQC in the order of operations. We will test it quickly in IOS (12.4T) by matching IPP3 traffic entering from the customer, then sourcing traffic from 7.7.7.3/32. So long as QPPB marks the traffic first, we expect to see matches in the MQC and ACL counters. In IOS, we see this is true as the ACL matches the traffic as IPP3 along with MQC.

```
! CSR5
class-map match-all CMAP_IPP3_ORDER_OF_OPS_TEST
  match precedence 3
```

```
policy-map PMAP_ORDER_OF_OPS_TEST
  class CMAP_IPP3_ORDER_OF_OPS_TEST
```

```
interface GigabitEthernet2.557
  ip access-group ACL_IPP3_ORDER_OF_OPS_TEST in
  service-policy input PMAP_ORDER_OF_OPS_TEST
```

```
R7#ping 12.0.0.1 source 7.7.7.3 repeat 15
```

```
Type escape sequence to abort.
Sending 15, 100-byte ICMP Echos to 12.0.0.1, timeout is 2 seconds:
Packet sent with a source address of 7.7.7.3
!!!!!!!!!!!!!!
Success rate is 100 percent (15/15), round-trip min/avg/max = 72/94/108 ms
```

```
R5#show policy-map interface gig2.557 input | include ORDER_OF_OPS|packets
Service-policy input: PMAP_ORDER_OF_OPS_TEST
Class-map: CMAP_IPP3_ORDER_OF_OPS_TEST (match-all)
  15 packets, 1710 bytes
```

```
R5#show access-lists ACL_IPP3_ORDER_OF_OPS_TEST
Extended IP access list ACL_IPP3_ORDER_OF_OPS_TEST
  10 permit ip any any precedence flash (15 matches)
  20 permit ip any any
```

IOS XE's operational flow is different than IOS with respect to QPPB. Specifically, QPPB is now processed after the input ACL but still before MQC. The above output was regular IOS 12.4T, the below output is IOS XE 3.13.2S.

```
R7#ping 12.0.0.1 source 7.7.7.3 repeat 15
```

```
Type escape sequence to abort.
Sending 15, 100-byte ICMP Echos to 12.0.0.1, timeout is 2 seconds:
Packet sent with a source address of 7.7.7.3
!!!!!!!!!!!!!!
Success rate is 100 percent (15/15), round-trip min/avg/max = 72/94/108 ms
```

```
R5#show policy-map interface gig2.557 input | include ORDER_OF_OPS|packets
Service-policy input: PMAP_ORDER_OF_OPS_TEST
Class-map: CMAP_IPP3_ORDER_OF_OPS_TEST (match-all)
  15 packets, 1770 bytes
```

```
R5#show access-lists ACL_IPP3_ORDER_OF_OPS_TEST
Extended IP access list ACL_IPP3_ORDER_OF_OPS_TEST
  10 permit ip any any precedence flash
  20 permit ip any any (15 matches)
```

30.5 QoS specifics on IOS XRv

XRv does not appear to support QoS data-plane operations at all. Although I provide the configurations to mirror what was done above, I cannot test it. I cannot even apply an inbound service-policy without the parser complaining.

```
! Any XRv router
interface GigabitEthernet0/0/0/0.523
 service-policy input PMAP_IN_FROM_CORE
!!% 'NetIO' detected the 'warning' condition 'Netio or a feature DLL
returned:': Invalid argument
```

Outbound policies can be applied but are not actually in effect.

```
RP/0/0/CPU0:XRv1#show run interface gig0/0/0/0.512
```

```

interface GigabitEthernet0/0/0/0.512
[snip]
service-policy output PMAP_SHAPE_TO_CUSTOMER

RP/0/0/CPU0:XRv1#show policy-map interface gig0/0/0/0.512
GigabitEthernet0/0/0/0.512 direction input: Service Policy not installed
GigabitEthernet0/0/0/0.512 direction output: Service Policy not installed

```

Even if it were supported, WRED drop probability doesn't look functional either, as a general comment. Considering XR's WRED configuration is highly granular compared to IOS, I assume this is specific to XRv because the feature is hardware dependent.

```

! Any XRv router
class CMAP_QG1
  set dscp af11
  bandwidth percent 15
  random-detect discard-class 1 11 packets 17 packets probability 7

class class-default
  set precedence 0

!!% Subsystem(8147), Code(5): cerrno 0xafe98a00: Policy-map
PMAP_QUEUE_TO_CUSTOMER class CMAP_QG1 failed: random-detect 'drop
probability' is not supported

```

Nonetheless, we will try to do some testing. The provided configurations are mirrored to the CSRs previously used because I feel they are mostly correct as is. I have replaced the core CSRs with XRv routers. Below is the replacement diagram.

When we try to enable IPP-based QPPB on the interface, XRv rejects it:

```
! Any XRv router
interface GigabitEthernet0/0/0/0.557
  ipv4 bgp policy propagation input ip-precedence source
!!% 'ipv4-ma' detected the 'warning' condition 'Platform doesn't support ip-
prec based QPPB in input direction on this card'
```

XR QPPB appears to only support one direction per type. For example, source-based IPP and destination-based QG is acceptable, but you cannot do both source and destination for IPP or QG concurrently. The QG command is accepted by XRv but, in our case, QG is useless because we cannot apply an MQC policy-map anywhere else. Even if QPPB was actually marking traffic, no follow-on actions could occur (unless there were IOS or IOS XE routers elsewhere in the SP network). I left the command in the configuration for reference.

```
! XRv3
interface GigabitEthernet0/0/0/0.557
[snip]
  ipv4 bgp policy propagation input qos-group source
```

Here is the RPL configuration from XRv3 since it is the most interesting part of this test. It's just like the route-map except more powerful. Like programming functions/methods, you can pass parameters. When you call the RPL, you pass it the actual value. Rather than hardcode the default QG to 7, I pass it in from BGP where the RPL is referenced. I always try to use variety with RPL to master the syntax as it is quite comprehensive.

```

RP/0/0/CPU0:XRv3#show rpl
[snip]
prefix-set PS_LOOP99_TESTS
  99.99.99.2/32,
  99.99.99.22/32
end-set
!
route-policy RPL_QPPB_FOR_CUSTOMER($DEFAULT_QG)
  if community matches-any (77:3) then
    set ip-precedence 3
  elseif community matches-any (77:4) then
    set ip-precedence 4
  elseif destination in (7.7.7.5/32) then
    set ip-precedence 5
  elseif as-path length ge 2 then
    set ip-precedence 6
  elseif destination in PS_LOOP99_TESTS then
    set qos-group 9
    set ip-precedence 7
  else
    set qos-group $DEFAULT_QG
  endif
end-policy

```

Applying the QPPB policy to BGP is almost identical to IOS and IOS XE.

```

RP/0/0/CPU0:XRv3#show run router bgp 1 vrf A address-family ipv4 unicast
router bgp 1
  vrf A
    address-family ipv4 unicast
      table-policy RPL_QPPB_FOR_CUSTOMER(7)
      redistribute connected

```

Despite all the limitations with XRv and QoS, with QPPB we can at least do some control-plane verifications. This can show us if our RPL was configured correctly. In XRv, the QPPB information is not visible from the RIB, but can be seen from the FIB. The quotes around the “A” are because XRv assumes that “A” by itself means “all”, due to ambiguity. Even though the FIB shows IPP values, we cannot enable it at the interface level, as seen above.

```

! Signaled by community
RP/0/0/CPU0:XRv3#show cef vrf "A" ipv4 7.7.7.3/32 | include Prec
  IP Precedence: 3

! Signaled by community

! Locally specified by prefix-set
RP/0/0/CPU0:XRv3#show cef vrf "A" ipv4 99.99.99.2/32 | include QoS
QoS Group: 9, IP Precedence: 7

! Locally specified by prefix-set
RP/0/0/CPU0:XRv3#show cef vrf "A" ipv4 99.99.99.22/32 | include QoS
QoS Group: 9, IP Precedence: 7

```

We know that our uniform and long-pipe QoS models cannot work on XRv since the input MQC policies from the MPLS core cannot be applied. We also cannot configure XRv4 (formerly CSR3) to perform EXP remarking in the core for the same reason. Short-pipe mode does work correctly because when the LSRs perform label swap operations, they don't touch the EXP bits. XRv basically has no mechanism to do anything else with the EXP bits once it copied the IPP into EXP at imposition. A quick test verifies this.

```

R1#ping 57.0.0.7 tos 64 repeat 5

R1#show flow monitor FNF_MONITOR_IPV4 cache format table | begin IPV4
IPV4 SRC ADDR      IPV4 DST ADDR      INTF INPUT          IP TOS              pkts
=====
12.0.0.1           57.0.0.7           Gi2.557              0x40                 5

```

We can reuse our TCL script for CSR7 to test the QPPB marking. Earlier we saw a variety of markings consistent with our QPPB policy. Now, we see TOS 0 for everything. XRv is not marking the traffic despite the FIB being correctly programmed, again because we did not enable the BGP policy feature at the interface level.

```

R1#show flow monitor FNF_MONITOR_IPV4 cache format table | begin IPV4
IPV4 SRC ADDR      IPV4 DST ADDR      INTF INPUT          IP TOS              pkts
=====
7.7.7.5            12.0.0.1           Gi2.512              0x00                 5
7.7.7.6            12.0.0.1           Gi2.512              0x00                 5
7.7.7.7            12.0.0.1           Gi2.512              0x00                 5
7.7.7.3            12.0.0.1           Gi2.512              0x00                 5
7.7.7.4            12.0.0.1           Gi2.512              0x00                 5

```

Netflow is totally unsupported in XRv, so we cannot use it for QoS verification. The command syntax

isn't even available (probably removed due to lack of supported hardware). The XR 5.2.0 documentation clearly states the parser tree begins with the word "flow". Fortunately, the CSRs as CE devices offer some visibility between FNF and EPC.

```
RP/0/0/CPU0:XRv1(config)#flow?
      ^
% Invalid input detected at '^' marker.
```

IOS XR supports QPPB for IPv6 too. I cannot find any documentation that claims IPv6 support for IOS or IOS XE. CSR7 advertises two IPv6 prefixes to XRv13; we will match one (::7:7:7:7/128) by setting the community to give it IPP3 treatment, and we let the other match the default QG setting (::7:7:7:77/128). We don't need to modify RPL because I call the policy from within the IPv6 unicast AFI and can pass in a new value of 6 (not 7) with parameterization. Communities and BGP attributes are not AFI specific so matching non-prefix related things in a QPPB RPL or route-map is preferable.

```
RP/0/0/CPU0:XRv3#show run router bgp 1 vrf A address-family ipv6 unicast
router bgp 1
  vrf A
    address-family ipv6 unicast
      table-policy RPL_QPPB_FOR_CUSTOMER(6)
      redistribute connected
```

```
! Signaled by community
RP/0/0/CPU0:XRv3#show cef vrf "A" ipv6 ::7:7:7:7/128 | utility egrep
'Prec|QoS'
  IP Precedence: 3
```

```
! Not specified; matches default RPL "else" statement
RP/0/0/CPU0:XRv3#show cef vrf "A" ipv6 ::7:7:7:77/128 | utility egrep
'Prec|QoS'
  QoS Group: 6
```

When we try to enable IPP-based QPPB on the interface, XRv also rejects it for IPv6. I just enabled sourced-based QoS group for reference as I did for IPv4.

```
interface GigabitEthernet0/0/0/0.557
  ipv6 bgp policy propagation input ip-precedence source
!!% 'ipv6-ma' detected the 'warning' condition 'Platform doesn't support ip-
prec based QPPB in input direction on this card'
```

30.6 Network Based Application Recognition (NBAR) summary and configurations

Network based application recognition allows MQC to identify applications/protocols directly without having to use other match criteria, such as ports/protocols inside an ACL. It is invoked using the "match protocol" keyword in IOS and IOS XE.

NBAR is not supported on IOS XR. The “match protocol” parser tree only lets you match IP protocols, like TCP and UDP. You can specify a raw IP protocol number also, but this is nowhere near the power of NBAR2 on IOS XE platforms. Given this restriction, NBAR is not evaluated on XR in this test.

The network is simple with CSR8, CSR9, and CSR10 arrayed in a line. NBAR is not specifically an SP technology and is unlikely to be tested, but since XE makes use of many advanced NBAR features, it is discussed. Most of the NBAR configurations will be on CSR9, applied inbound to the link facing CSR8. The diagram is shown below.

A simple and common NBAR deployment is shown by the PMAP_SIMPLE policy. We can identify some protocols based on the built-in NBAR2 protocol pack listing inside a class-map, then perform some action. In this case, I only care about matching packets, not performing QoS treatment, so the policy-map invokes the class and does nothing.

```
! CSR9
class-map match-any CMAP_TTY_MGMT
  match protocol telnet
  match protocol ssh

policy-map PMAP_SIMPLE
  class CMAP_TTY_MGMT
```

Below are a few quick tests where CSR9 is supported to match telnet or SSH traffic arriving from CSR8. CSR8 telnets and SSH'es to CSR10 to test it. The final test is to show that ping traffic does not match.

```
! telnet test
R8#telnet 90.0.0.10
Trying 90.0.0.10 ... Open

R9#show policy-map interface gig2.589 input class CMAP_TTY_MGMT
GigabitEthernet2.589

Service-policy input: PMAP_SIMPLE

Class-map: CMAP_TTY_MGMT (match-any)
  9 packets, 552 bytes
  5 minute offered rate 0000 bps
  Match: protocol telnet
```

```

Match: protocol ssh

R9#clear counter
Clear "show interface" counters on all interfaces [confirm]

! ssh test
R8#ssh -l fakeuser 90.0.0.10
Password:

R9#show policy-map interface gig2.589 input class CMAP_TTY_MGMT
GigabitEthernet2.589

Service-policy input: PMAP_SIMPLE

Class-map: CMAP_TTY_MGMT (match-any)
  82 packets, 4818 bytes
  5 minute offered rate 1000 bps
  Match: protocol telnet
  Match: protocol ssh

R8#ping 90.0.0.10 repeat 15

R9#show policy-map interface gig2.589 input
GigabitEthernet2.589

Service-policy input: PMAP_SIMPLE

Class-map: CMAP_TTY_MGMT (match-any)
  0 packets, 0 bytes
  5 minute offered rate 0000 bps
  Match: protocol telnet
  Match: protocol ssh

Class-map: class-default (match-any)
  15 packets, 1770 bytes
  5 minute offered rate 1000 bps, drop rate 0000 bps
  Match: any

```

Additional Reading – Reference configurations "nbar"

30.6.1 NBAR Custom Protocols

NBAR also allows the user to define custom protocols in a number of ways. I will not be discussing the deprecated "ip nbar port-map method" as it is no longer shown in the context-sensitive help:

```

R9(config)#ip nbar port-map radius udp 1645 1646
%NBAR-6-PORT_MAP_DEPRECATED: Port-map command will be deprecated soon.
    In future it will not be necessary to configure port-map on a Protocol
to create a new

```

Custom protocol onto the same well known port.

1. Simple TCP/UDP port mapping to a custom name. Before NBAR2, some common protocols like Windows RDP and RADIUS were not pre-defined. Using this technique for commonly used protocols is handy, as well as custom applications. PMAP_CUSTOM_RADIUS is an example of using this feature to match the old RADIUS authentication (1645) and accounting (1646) ports. NBAR2 only considers the newer RADIUS ports for classification by default.

```
R9#show ip nbar port-map | include radius
port-map radius                        udp 1813 1812

R9(config)#ip nbar custom UDP_RADIUS_OLD udp 1645 1646

R9#show ip nbar port-map | include RADIUS|radius
port-map UDP_RADIUS_OLD                udp 1645 1646
port-map radius                        udp 1813 1812
```

These are wrapped in the PMAP_CUSTOM_RADIUS policy-map and applied to the interface facing CSR8.

```
! CSR9
class-map match-any CMAP_RADIUS
  match protocol radius
  match protocol UDP_RADIUS_OLD

policy-map PMAP_CUSTOM_RADIUS
  class CMAP_RADIUS
```

On CSR8, we setup a bogus RADIUS server with IP addresses 90.0.0.100. AAA is described in the security chapter, but the commands are in the configuration file. Interestingly, even on this relatively new XE version, the default ports are the old ports.

```
R8(config-radius-server)#address ipv4 90.0.0.100 ?
  acct-port  UDP port for RADIUS accounting server (default is 1646)
  alias      1-8 aliases for this server (max. 8)
  auth-port  UDP port for RADIUS authentication server (default is 1645)
```

Once the server is configured, we will use CSR8 to telnet to itself. CSR8 should then try to reach the RADIUS server for authentication, which appears to be on the LAN behind CSR9. We should see matches under the class-map regardless of which set of ports we use.

```
R8#telnet 89.0.0.8
Trying 89.0.0.8 ... Open

User Access Verification

Username: fakeuser
```

Password:

```
R9#show policy-map interface gig2.589 input class CMAP_RADIUS
GigabitEthernet2.589
```

```
Service-policy input: PMAP_CUSTOM_RADIUS
```

```
Class-map: CMAP_RADIUS (match-any)
  4 packets, 472 bytes
  5 minute offered rate 0000 bps
  Match: protocol radius
  Match: protocol UDP_RADIUS_OLD
```

It works with the old ports, so we know our custom NBAR class is operational. Let's double-check the new ports by using 1812 and 1813 in the RADIUS server configuration (configuration not shown). It also works. The reason we see exactly 4 packets is because retransmit count was set to 3, so that means 3 retries after the first failure.

```
R9#clear counter
Clear "show interface" counters on all interfaces [confirm]
```

```
R8#telnet 89.0.0.8
Trying 89.0.0.8 ... Open
```

User Access Verification

```
Username: fakeuser
Password:
```

```
R9#show policy-map interface gig2.589 input class CMAP_RADIUS
GigabitEthernet2.589
```

```
Service-policy input: PMAP_CUSTOM_RADIUS
```

```
Class-map: CMAP_RADIUS (match-any)
  4 packets, 472 bytes
  5 minute offered rate 0000 bps
  Match: protocol radius
  Match: protocol UDP_RADIUS_OLD
```

A more complicated custom protocol involves measuring byte offsets in the packet to match specific strings in the payload. It is kind of like flexible packet matching (FPM), but is less powerful/easier to use. PMAP_CUSTOM_PAYLOAD demonstrates looking for the string "BEEF" inside a UDP packet using port 55555. CSR8 uses IP SLA (beyond the scope of this test) to generate these packets every 2 seconds towards CSR10. CSR10 will not respond, but it doesn't matter. The IP SLA has been configured to use the string BEEF, or more specifically, 0x0000BEEF since the data-pattern is measured as a 32-bit entity, and I

have only configured 16 bits. This is the packet dump from CSR8 that demonstrates this. Even more confusing is the “phantom” 4 bytes of 0x0010000 (shown in cyan) which is not part of the UDP header (shown in green) nor the payload (shown in yellow) that I specified.

```
! CSR9
IP: s=89.0.0.8 (local), d=90.0.0.10, len 44, local feature
7F1B9765C230: 4500002C 00000000 FF110000 59000008 E.,.....Y...
7F1B9765C240: 5A00000A CEDBD903 001867FC 00010000 Z...N[Y...g|....
7F1B9765C250: 0000BEEF 0000BEEF 0000BEEF ..>o..>o..>o
```

We must tell NBAR to offset 6 bytes into the payload of UDP to see the first occurrence of BEEF. This would generally be used to identify a virus or malicious packet entering the network. I would have normally expected a 2 byte offset, but as seen above, IP SLA is adding some extra detail into the payload.

```
! CSR9
ip nbar custom FIND_BEEF 6 hex BEEF udp 55555

class-map match-any CMAP_FIND_BEEF
  match protocol FIND_BEEF

policy-map PMAP_CUSTOM_PAYLOAD
  class CMAP_FIND_BEEF
```

We can verify the operation using the commands shown below.

```
R9#show policy-map interface gig2.589 input class CMAP_FIND_BEEF
GigabitEthernet2.589

Service-policy input: PMAP_CUSTOM_PAYLOAD

Class-map: CMAP_FIND_BEEF (match-any)
  7 packets, 434 bytes
  5 minute offered rate 0000 bps
  Match: protocol FIND_BEEF
```

Taking this a step further, let’s pretend we are trying to stop a virus with a generally unrecognizable hex string on a specific set of ports. At the same time, we need to ensure we don’t drop legitimate traffic. We can specify the port-range as we have before, but abstract a specific portion (up to 4 bytes) of the hex string for specification in a class-map. This adds some flexibility without having to define tons of custom NBAR protocols.

Specifically, packets with the hex strings ending in 0x####5100, 0x####570A, and 0x####5B0C running on UDP port 55556 are considered suspect. Anything else is acceptable. Because we are fabricating the packets with IP SLA, we need to account for the first 4 “phantom” bytes. We are matching the last 2

bytes of the pattern, which implies we still need to account for a 6 byte offset; the “virus” does not modify the first 2 bytes of the payload pattern. The configuration is very similar except instead of the “hex” keyword we use “variable” to denote that this sub-protocol variable will be defined in the class-map. We can call the variable whatever we want.

```
! CSR9
ip nbar custom STOP_VIRUS 6 variable LAST_2_BYTES 2 udp 55556

class-map match-any CMAP_VIRUS_570A
  match protocol STOP_VIRUS LAST_2_BYTES "0x570A"
class-map match-any CMAP_VIRUS_5100
  match protocol STOP_VIRUS LAST_2_BYTES "0x5100"
class-map match-any CMAP_VIRUS_5B0C
  match protocol STOP_VIRUS LAST_2_BYTES "0x5B0C"

policy-map PMAP_STOP_VIRUS
  class CMAP_VIRUS_5100
  class CMAP_VIRUS_570A
  class CMAP_VIRUS_5B0C
```

To test this, I have 4 IP SLA instances; three viruses and one benign flow (uses 0x6BA4570C, which is fine). We expect PMAP_STOP_VIRUS to match the first three, but not the last one. Normally it makes more sense to configure all of these matches in a single match-any class-map, but I used three separate class-maps just to show the counters without having to start/stop IP SLAs and clear counters. All three run at the same rate, so the packet counters should be nearly equal.

```
R9#show policy-map interface gig2.589 input
GigabitEthernet2.589

Service-policy input: PMAP_STOP_VIRUS

Class-map: CMAP_VIRUS_5100 (match-any)
  12 packets, 744 bytes
  5 minute offered rate 0000 bps
  Match: protocol STOP_VIRUS LAST_2_BYTES "0x5100"

Class-map: CMAP_VIRUS_570A (match-any)
  13 packets, 806 bytes
  5 minute offered rate 0000 bps
  Match: protocol STOP_VIRUS LAST_2_BYTES "0x570A"

Class-map: CMAP_VIRUS_5B0C (match-any)
  12 packets, 744 bytes
  5 minute offered rate 0000 bps
  Match: protocol STOP_VIRUS LAST_2_BYTES "0x5B0C"

Class-map: class-default (match-any)
```

```
12 packets, 744 bytes
5 minute offered rate 0000 bps, drop rate 0000 bps
Match: any
```

30.6.2 NBAR Attributes

Another useful feature of NBAR2 is the ability to apply specific attributes to a protocol (whether it's a built-in or custom protocol). These attributes can be used for monitoring, but also to simplify QoS policies. For example, I can classify SSH, telnet, and RADIUS together in a category of "net-admin", then match this attribute in a class-map. The trade-off for a simplified QoS policy is a potentially expanded NBAR configuration, unless the default attributes for a protocol are already acceptable. Attribute types are as follows:

application-group: Used to group things together based on similar application/use (jabber, flash, gnutella, AOL, etc)

category: First level of categorization (email, chat, gaming, etc)

encrypted: Determine if the flow is encrypted (yes, no, unassigned)

p2p-technology: Determine if the flow is point to point only (yes, no, unassigned)

sub-category: Second level of categorization (auth services, database, etc)

tunnel: Determine if the flow is inside a tunnel (yes, no, unassigned)

The process contains up to three steps as the first one is optional.

1. Define custom attributes if you like. If the built-in classifications are not appropriate, XE lets you create one custom attribute per type. Only application-group, category, and sub-category can be redefined since the other attributes are essentially yes/no questions. In this example, I created a custom application-group for RADIUS just to demonstrate. I like that you can specify the context-sensitive help string, too.

```
! CSR9
ip nbar attribute application-group custom RADIUS_GROUP "Custom group for
RADIUS services"
```

The below command shows that we only have a limit of one custom attribute per type, and that we already created an application-group attribute.

```
R9#show ip nbar attribute-custom

      Name :  application-group
      Help :  Application-group attribute
Custom Groups Limit :  1
Custom Groups Created :  RADIUS_GROUP

      Name :  category
      Help :  Category attribute
```

```
Custom Groups Limit : 1
```

```
Name : sub-category  
Help : Sub-category attribute
```

```
Custom Groups Limit : 1
```

If we try to create more application-group attributes, the router rejects it.

```
R9(config)#ip nbar attribute application-group custom NEW_ONE  
% NBAR Error: Custom groups limit reached for attribute "application-group"
```

2. Next, we create an attribute-map, which is essentially a list of attributes. We can specify as many or as few attributes as we like. This map will be attached to a protocol later on. Since we are attaching this to our RADIUS protocol (both the built-in and the custom one), we will select appropriate categories. See below for the snippet.

```
! CSR9  
ip nbar attribute-map RADIUS_ATT_MAP  
attribute application-group RADIUS_GROUP  
attribute category net-admin  
attribute encrypted encrypted-no  
attribute p2p-technology p2p-tech-no  
attribute sub-category authentication-services  
attribute tunnel tunnel-no
```

If we use the ? symbol under the attribute map when setting the application-group, we can see our help text.

```
R9(config)#ip nbar attribute-map RADIUS_ATT_MAP  
R9(config-attribute-map)#attribute application-group ?  
RADIUS_GROUP Custom group for RADIUS services
```

3. Apply the attribute-map to a protocol using the “attribute-set” command. In this case, we want to affix these attributes to our RADIUS definitions. However, before we do that, let’s verify the existing attributes of the protocols first.

```
R9#show ip nbar protocol-attribute radius  
Protocol Name : radius  
application-group : other  
category : net-admin  
encrypted : encrypted-no  
p2p-technology : p2p-tech-no  
sub-category : authentication-services  
tunnel : tunnel-no
```

```
R9#show ip nbar protocol-attribute UDP_RADIUS_OLD
```

```

        Protocol Name :   UDP_RADIUS_OLD
    application-group :   other
            category :   other
        encrypted :   encrypted-unassigned
    p2p-technology :   p2p-tech-unassigned
        sub-category :   other
            tunnel :   tunnel-unassigned

```

Now, we will overwrite those settings with our new attribute-map. Any unspecified attributes in the map are left alone in the original attribute listing. Notice how our policy basically mirrors what “radius” already had, plus our new custom group. The custom “UDP_RADIUS_OLD” protocol we defined had very generic attributes since the router has no idea what it is.

```

! CSR9
ip nbar attribute-set radius RADIUS_ATT_MAP
ip nbar attribute-set UDP_RADIUS_OLD RADIUS_ATT_MAP

```

```

R9#show ip nbar protocol-attribute radius
    Protocol Name :   radius
    application-group :   RADIUS_GROUP
            category :   net-admin
        encrypted :   encrypted-no
    p2p-technology :   p2p-tech-no
        sub-category :   authentication-services
            tunnel :   tunnel-no

```

```

R9#show ip nbar protocol-attribute UDP_RADIUS_OLD
    Protocol Name :   UDP_RADIUS_OLD
    application-group :   RADIUS_GROUP
            category :   net-admin
        encrypted :   encrypted-no
    p2p-technology :   p2p-tech-no
        sub-category :   authentication-services
            tunnel :   tunnel-no

```

For a given attribute, we can see all registered protocols. For example, here is the list of all protocols that are in application-group RADIUS_GROUP. I also show a truncated version of all of the category net-admin protocols to demonstrate the use. Notice we see our custom UDP_RADIUS_OLD in the list, too.

```

R9#show ip nbar attribute application-group RADIUS_GROUP
    UDP_RADIUS_OLD      User defined Protocol UDP_RADIUS_OLD
    radius              Remote Authentication Dial In User Service protocol

R9#show ip nbar attribute category net-admin
    914c/g              Texas Instruments 914 Terminal
    9pfs                Plan 9 file service
    UDP_RADIUS_OLD      User defined Protocol UDP_RADIUS_OLD

```

```

acap                ACAP
active-directory    Active Directory Traffic
agentx              AgentX
alpes                Alpes
[snip]

```

At this point, we can use the attributes any way we like. I built a basic MQC configuration to test it using the policy-map PMAP_RADIUS_ATTRIBUTES. Specifically, the class-map looks for both the category net-admin AND application-group RADIUS_GROUP. We will telnet from CSR8 to itself to test the RADIUS configuration. At this point, it does not matter which ports our RADIUS configuration on CSR8 is using since either set of ports will match.

```

! CSR9
class-map match-all CMAP_RADIUS_ATTRIBUTES
  match protocol attribute category net-admin
  match protocol attribute application-group RADIUS_GROUP

policy-map PMAP_RADIUS_ATTRIBUTES
  class CMAP_RADIUS_ATTRIBUTES

```

Below are some quick tests to ensure the policy is functional.

```

R8#telnet 89.0.0.8
Trying 89.0.0.8 ... Open

```

```

User Access Verification

```

```

Username: fakeuser
Password:

```

```

R9#show policy-map interface gig2.589
GigabitEthernet2.589

```

```

Service-policy input: PMAP_RADIUS_ATTRIBUTES

Class-map: CMAP_RADIUS_ATTRIBUTES (match-all)
  4 packets, 472 bytes
  5 minute offered rate 0000 bps
  Match: protocol attribute category net-admin
  Match: protocol attribute application-group RADIUS_GROUP

Class-map: class-default (match-any)
  0 packets, 0 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
  Match: any

```

Just like before, we see exactly (4) RADIUS packets enter, except this time we classified them based on

two attributes. Let's telnet from CSR8 to CSR10 and ensure telnet traffic does not match the RADIUS class. Telnet is part of category net-admin but not part of application-group RADIUS_GROUP (we validate this using both lookup mechanisms). This test is just validating basic match-all class-map logic when using NBAR attributes.

```
R9#show ip nbar protocol-attribute telnet | include _category|application
      application-group : other
      category : net-admin

R9#show ip nbar attribute category net-admin | include ^__telnet
telnet                               Telnet - virtual text-oriented terminal over network

R9#show ip nbar attribute application-group RADIUS_GROUP | include telnet
[no output]

R8#telnet 90.0.0.10
Trying 90.0.0.10 ... Open

R9#show policy-map interface gig2.589
GigabitEthernet2.589

Service-policy input: PMAP_RADIUS_ATTRIBUTES

Class-map: CMAP_RADIUS_ATTRIBUTES (match-all)
  0 packets, 0 bytes
  5 minute offered rate 0000 bps
  Match: protocol attribute category net-admin
  Match: protocol attribute application-group RADIUS_GROUP

Class-map: class-default (match-any)
  19 packets, 1144 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
  Match: any
```

30.6.3 NBAR Attributes with HTTP

Our next test will include using NBAR to classify HTTP based on the host/URL information. We can do this in two ways: use the built-in MQC syntax inside the class-map with "match protocol http" or generate a custom NBAR protocol of type HTTP. We will test both. I have enabled HTTP server on CSR10 (user/pass: http/http) and added files to flash called "route.txt" and "cef.txt". The files contain the results of CSR10's RIB and FIB respectively. Let's quickly make sure the HTTP download works before continuing; filtering is used to reduce output for verification.

```
R10#show ip route | redirect flash:route.txt
R10#show ip cef | redirect flash:cef.txt

R8#more http://http:http@90.0.0.10/route.txt | begin Gateway
Gateway of last resort is 90.0.0.9 to network 0.0.0.0
```

```

S*    0.0.0.0/0 [1/0] via 90.0.0.9
      90.0.0.0/8 is variably subnetted, 2 subnets, 2 masks
C      90.0.0.0/24 is directly connected, GigabitEthernet2.590
L      90.0.0.10/32 is directly connected, GigabitEthernet2.590

```

```

R8#more http://http:http@90.0.0.10/cef.txt | include Gigabit
0.0.0.0/0          90.0.0.9          GigabitEthernet2.590
90.0.0.0/24        attached          GigabitEthernet2.590
90.0.0.0/32        receive           GigabitEthernet2.590
90.0.0.9/32        attached          GigabitEthernet2.590
90.0.0.10/32       receive           GigabitEthernet2.590
90.0.0.255/32      receive           GigabitEthernet2.590

```

A key point with the “host” and “url” keywords (example: www.cisco.com/go/coolstuff/page.htm)

-Host: matches the host name only (www.cisco.com)

-URL: matches everything after the host name ([/go/coolstuff/page.htm](http://www.cisco.com/go/coolstuff/page.htm))

We will use the “url” feature with a simple regular expression on CSR9. This will ultimate feed into a policy-map called PMAP_HTTP. Let’s also try it with the NBAR custom protocol method to match the CEF file. The policy-map should meter both individually.

```

! CSR9
class-map match-all CMAP_HTTP
  match protocol http url "*route\.txt*"

ip nbar custom HTTP_CEF_FILE http url *cef\.txt*
class-map match-all CMAP_HTTP_CUSTOM
  match protocol HTTP_CEF_FILE

policy-map PMAP_HTTP
  class CMAP_HTTP

```

In case you didn’t know that the parser expected a regular expression, you can verify with the following show command. It will show all the sub-classification parameters for a given protocol.

```

R9#show ip nbar parameter subclassification http
Protocol      Parameter      Parameter type
-----
http          mime          regexp_url
http          content-encoding  regexp_url
http          location       regexp_url
http          server         regexp_url
http          from           regexp_url
http          referer        regexp_url
http          user-agent     regexp_url
http          host           regexp_url

```

```
http          url          regexp_url
```

Now, we can copy the files and look for matches.

```
R8#copy http://http:http@90.0.0.10/route.txt null:
Accessing http://*:~@90.0.0.10/route.txt...
Loading http://*:~@90.0.0.10/route.txt
866 bytes copied in 0.045 secs (19244 bytes/sec)
```

```
R8#copy http://http:http@90.0.0.10/cef.txt null:
Accessing http://*:~@90.0.0.10/cef.txt...
Loading http://*:~@90.0.0.10/cef.txt
664 bytes copied in 0.045 secs (14756 bytes/sec)
```

```
R9#show policy-map interface gig2.589
GigabitEthernet2.589
```

```
Service-policy input: PMAP_HTTP
```

```
Class-map: CMAP_HTTP (match-all)
  22 packets, 1858 bytes
  5 minute offered rate 0000 bps
  Match: protocol http url "*route\.txt*"
```

```
Class-map: CMAP_HTTP_CUSTOM (match-all)
  22 packets, 1850 bytes
  5 minute offered rate 0000 bps
  Match: protocol HTTP_CEF_FILE
```

```
Class-map: class-default (match-any)
  16 packets, 960 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
  Match: any
```

The reason we see some class-default matches is because the underlying TCP setup/teardown process is not HTTP-specific and would not contain HTTP URL information. If we downloaded a bigger file this would be less significant as we should see about the same number of class-default packets. As always, let's prove it. We should see approximately 8 class-default packets (we saw 16 for two downloads), and many more data packets, when downloading a large file. I can't explain the MQC byte counters, but I estimate it is because NBAR is sampling only certain packets in the flow to conserve CPU/memory resources. Later versions of code allow you to select coarse or fine granularity when sampling; coarse is less accurate but conserves resources.

```
R10#show tech-support | append bootflash:route.txt
```

```
R10#dir bootflash: | include route
 39  -rw-          642828  MON 3 2015 00:14:18 +00:00  route.txt
```

```
R8#copy http://http:http@90.0.0.10/route.txt null:
Accessing http://*:~@90.0.0.10/route.txt...
Loading http://*:~@90.0.0.10/route.txt !!!
642828 bytes copied in 0.448 secs (1434884 bytes/sec)
```

```
R9#show policy-map interface gig2.589
GigabitEthernet2.589
```

```
Service-policy input: PMAP_HTTP
```

```
Class-map: CMAP_HTTP (match-all)
  2792 packets, 162518 bytes
  5 minute offered rate 0000 bps
  Match: protocol http url "*route\.txt*"
```

```
Class-map: class-default (match-any)
  8 packets, 480 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
  Match: any
```

The design reason to use the NBAR option (cef.txt) over the MQC inline option (route.txt) for HTTP matching is NBAR attributes. I've added an attribute-map for the CEF inspection. Because the custom protocol was defined outside of a specific class-map, this protocol can be customized. Of course the FIB has nothing to do with "file-sharing", so the attributes below are for testing only.

```
! CSR9
ip nbar attribute-map HTTP_CEF_ATT_MAP
  attribute category file-sharing
  attribute encrypted encrypted-no
  attribute sub-category file-sharing

ip nbar attribute-set HTTP_CEF_FILE HTTP_CEF_ATT_MAP
```

Notice how some fields, like P2P and tunnel, remain unassigned because my attribute-map did not modify them. Other fields, such as category, sub-category, and encrypted were modified. The first show command shows the map as a stand-alone entity, and the second show command is used to validate that the attribute-set operation worked; that is, that the attribute-map was properly applied to the protocol in question.

```
R9#show ip nbar attribute-map HTTP_CEF_ATT_MAP
  Profile Name : HTTP_CEF_ATT_MAP
    category : file-sharing
    encrypted : encrypted-no
    sub-category : file-sharing
```

```
R9#show ip nbar protocol-attribute HTTP_CEF_FILE
```

```

    Protocol Name : HTTP_CEF_FILE
  application-group : other
    category : file-sharing
    encrypted : encrypted-no
  p2p-technology : p2p-tech-unassigned
    sub-category : file-sharing
    tunnel : tunnel-unassigned

```

Let's double check and ensure NBAR registered these attributes with our protocol using the reverse-lookup mechanism.

```

R9#show ip nbar attribute category file-sharing | include CEF
HTTP_CEF_FILE          User defined Protocol HTTP_CEF_FILE

R9#show ip nbar attribute sub-category file-sharing | include CEF
HTTP_CEF_FILE          User defined Protocol HTTP_CEF_FILE

R9#show ip nbar attribute encrypted encrypted-no | include CEF
HTTP_CEF_FILE          User defined Protocol HTTP_CEF_FILE

```

The policy-map PMAP_HTTP_ATT was created to match this traffic now based on attributes.

```

! CSR9
class-map match-all CMAP_HTTP_ATT
  match protocol attribute category file-sharing

policy-map PMAP_HTTP_ATT
  class CMAP_HTTP_ATT

```

We can see the matches below. Of course, this policy would also match anything else displayed by the “show ip nbar attribute category file-sharing” command, as all of these protocols share this category attribute.

```

R8#copy http://http:http@90.0.0.10/cef.txt null:
Accessing http://*:*@90.0.0.10/cef.txt...
Loading http://*:*@90.0.0.10/cef.txt
664 bytes copied in 0.041 secs (16195 bytes/sec)

R9#show policy-map interface gig2.589
GigabitEthernet2.589

Service-policy input: PMAP_HTTP_ATT

Class-map: CMAP_HTTP_ATT (match-all)
  22 packets, 1850 bytes
    5 minute offered rate 0000 bps
    Match: protocol attribute category file-sharing

```

```

Class-map: class-default (match-any)
  8 packets, 480 bytes
  5 minute offered rate 0000 bps, drop rate 0000 bps
Match: any

```

30.6.4 NBAR Protocol-ID

NBAR can be used to determine a specific “protocol-id” for a given parameter, along with the type. For common layer3/layer4 protocols, the IP protocol number or transport port number are used for the protocol-id, respectively. Here are some examples of layer-3 and layer-4 protocol-IDs. You can use this, along with the NBAR port-map, to determine port/protocol numbers. Some people do not know the IP protocol number for RSVP, for example, as it is only really used for MPLS-TE, call admission control, and a few other topics. TFTP is based on UDP and uses port 69, as shown below.

```

R9#show ip nbar protocol-id rsvp
Protocol Name      id      type
-----
rsvp               46      L3 IANA

R9#show ip nbar protocol-id tftp
Protocol Name      id      type
-----
tftp              69      L4 IANA

```

Some things are not IANA assigned but are still semi-common. Notice that the protocol-id is the same value for TFTP and bittorrent, but the type of protocol is different. I am assuming that “L7 STANDARD” is some commonly agreed-upon numbering scheme for applications not tracked or managed by IANA. I have not found any authoritative documentation on what that means for certain.

```

R9#show ip nbar protocol-id bittorrent

Protocol Name      id      type
-----
bittorrent         69      L7 STANDARD

```

Custom protocols get an internally allocated protocol-id, which are larger numbers.

```

R9#show ip nbar protocol-id FIND_BEEF
Protocol Name      id      type
-----
FIND_BEEF         242     Custom

```

You can specify this ID for tracking/collection purposes when you define a new protocol using the “id” suffix keyword. The relevance of this number for custom protocols is generally limited to Netflow exports because NBAR can be integrated with FNF (shown under the FNF section of this document).

```
R9(config)#ip nbar custom PROTO_ID destination tcp 55557 id 57
```

```
R9#show ip nbar protocol-id PROTO_ID
```

Protocol Name	id	type
PROTO_ID	57	Custom

30.6.5 NBAR Protocol Discovery

NBAR can also be used as a mechanism for protocol discovery. It's like Netflow except less granular, but also very easy and automatic. It can be enabled at the interface level for IPv4, IPv6, or both. We have applied it to the link facing CSR8. I've performed a file download via HTTP, a telnet session to CSR10, and some pings. The main show command by itself prints verbose output, showing several counters per protocol it learns.

```
! CSR9
interface GigabitEthernet2.589
 ip nbar protocol-discovery
```

```
R9#show ip nbar protocol-discovery
```

GigabitEthernet2.589

Last clearing of "show ip nbar protocol-discovery" counters 00:01:31

Protocol	Input	Output
	-----	-----
	Packet Count	Packet Count
	Byte Count	Byte Count
	5min Bit Rate (bps)	5min Bit Rate (bps)
	5min Max Bit Rate (bps)	5min Max Bit Rate (bps)
	-----	-----

	0	0
Total	63	55
	4592	5797
	0	0
	0	1000

We can narrow down this output by selecting only specific rows (packet count, byte count, etc).

```
R9#show ip nbar protocol-discovery stats packet-count
```

```
GigabitEthernet2.589
```

```
Last clearing of "show ip nbar protocol-discovery" counters 00:01:20
```

	Input	Output
	-----	-----
Protocol	Packet Count	Packet Count
-----	-----	-----
telnet	26	25
HTTP_CEF_FILE	22	20
ping	5	5
unknown	10	5
Total	63	55

We can narrow it even further by restricting it to a single protocol as well. When you do this, the “unknown” traffic is always displayed. In this particular case, the unknown traffic is the IP SLA traffic using bogus ports from earlier tests (some were still running).

```
R9#show ip nbar protocol-discovery stats packet-count protocol telnet
```

```
GigabitEthernet2.589
```

Protocol	Packet Count	Packet Count
-----	-----	-----
telnet	26	25
unknown	10	5
Total	63	55

The nice thing about this feature is that it honors your custom protocols at all times. Even without configuring MQC anywhere, you can see if your custom protocols are traversing the network. Earlier we looked at using NBAR to find a certain text string, specifically 0x0000BEEF. If we turn on that IP SLA again, NBAR should be able to see that protocol without MQC. Unfortunately, this feature doesn’t work well with our STOP_VIRUS protocol, because we abstracted the last 2 bytes to the MQC class-map, so

that protocol will essentially match anything on UDP 55556. That is one downside to the MQC abstraction method (with the “variable” keyword); it relies on MQC being configured and applied.

```
R9#show policy-map interface brief

31. Describe, implement, and troubleshoot MPLS TE / QoS mechanisms

31.1 MPLS RSVP-TE (General)

The configurations for all MPLS TE features are contained in the files below (manual TE, FRR, CBTS/PBTS), with the exception of DS-TE and automatic tunnels. Each of those has an alternative architecture since it was not conducive to mix them in a test with the vast majority of existing TE features.

Additional Reading – Reference configurations “te-manual”

31.1.1 TE Topology (TED) construction and RSVP-TE signaling

MPLS traffic engineering is one of MPLS' most powerful features. It allows for completely arbitrary traffic steering from the source to destination based on a variety of attributes, such as available bandwidth, link colors, and other characteristics. OSPF and IS-IS were extended to carry these attributes. Also, RSVP was extended to RSVP-TE to support MPLS-TE, which includes some new objects.

First, we will examine how IS-IS exchanges TE information. The diagram is shown below. The topology is large and densely connected so as to create many routing paths. CSR7, XRv13, and XRv14 are all connected by both an L3VPN and L2VPN so we can demonstrate TE features for both (there isn't much difference, really). Most of the testing will use IS-IS but it isn't significant since both IS-IS and OSPF carry the same information, just in different ways. MPLS-TE attribute information is limited to an IS-IS level or

OSPF area, so the entire topology is IS-IS L2. OSPF will be examined later. Inter-area TE is examined in the Unified MPLS section while Inter-AS TE is examined in the Inter-AS MPLS sections.

Because everything is intra-level, every router can see every link characteristic in the topology. This means that we can fully validate a correct configuration only accessing one router. From the perspective of CSR1, we can check the TE topology and look specifically at the MPLS TE router-ID. This is normally a loopback on each router, and it must be configured under the IGP process. TE must also be enabled for an IS-IS level or OSPF area. In the case of IS-IS, wide metrics must be enabled to carry the TE attributes. A very cursory check of the topology at least shows we have all 11 LSRs running TE under IS-IS. We can see the IS-IS NETs and the TE-ID, which is the loopback0 IPv4 address.

```
! XE routers
router isis 132
metric-style wide
mpls traffic-eng router-id Loopback0
mpls traffic-eng level-2

! XR routers
router isis 132
address-family ipv4 unicast
metric-style wide
mpls traffic-eng router-id Loopback0
mpls traffic-eng level-2
```

```
CSR1#show mpls traffic-eng topology level-2 brief | include TE_Id
IGP Id: 0000.0000.0001.00, MPLS TE Id:1.1.1.1 Router Node (isis level-2)
IGP Id: 0000.0000.0002.00, MPLS TE Id:2.2.2.2 Router Node (isis level-2)
IGP Id: 0000.0000.0003.00, MPLS TE Id:3.3.3.3 Router Node (isis level-2)
IGP Id: 0000.0000.0004.00, MPLS TE Id:4.4.4.4 Router Node (isis level-2)
IGP Id: 0000.0000.0005.00, MPLS TE Id:5.5.5.5 Router Node (isis level-2)
IGP Id: 0000.0000.0006.00, MPLS TE Id:6.6.6.6 Router Node (isis level-2)
```

```
IGP Id: 0000.0000.0008.00, MPLS TE Id:8.8.8.8 Router Node (isis level-2)
IGP Id: 0000.0000.0009.00, MPLS TE Id:9.9.9.9 Router Node (isis level-2)
IGP Id: 0000.0000.0010.00, MPLS TE Id:10.10.10.10 Router Node (isis level-2)
IGP Id: 0000.0000.0011.00, MPLS TE Id:11.11.11.11 Router Node (isis level-2)
IGP Id: 0000.0000.0012.00, MPLS TE Id:12.12.12.12 Router Node (isis level-2)
```

If we forget to set an MPLS TE-ID on a router, this quick check will reveal that. It can be a simple mistake. We remove it under CSR3 as a test; it no longer shows up. CSR3 is now incapable of running MPLS-TE. We will see this in action later when we build TE tunnels.

```
CSR3(config-router)#no mpls traffic-eng router-id
```

```
CSR1#show mpls traffic-eng topology level-2 brief | include TE_Id
IGP Id: 0000.0000.0001.00, MPLS TE Id:1.1.1.1 Router Node (isis level-2)
IGP Id: 0000.0000.0002.00, MPLS TE Id:2.2.2.2 Router Node (isis level-2)
IGP Id: 0000.0000.0004.00, MPLS TE Id:4.4.4.4 Router Node (isis level-2)
IGP Id: 0000.0000.0005.00, MPLS TE Id:5.5.5.5 Router Node (isis level-2)
IGP Id: 0000.0000.0006.00, MPLS TE Id:6.6.6.6 Router Node (isis level-2)
IGP Id: 0000.0000.0008.00, MPLS TE Id:8.8.8.8 Router Node (isis level-2)
IGP Id: 0000.0000.0009.00, MPLS TE Id:9.9.9.9 Router Node (isis level-2)
IGP Id: 0000.0000.0010.00, MPLS TE Id:10.10.10.10 Router Node (isis level-2)
IGP Id: 0000.0000.0011.00, MPLS TE Id:11.11.11.11 Router Node (isis level-2)
IGP Id: 0000.0000.0012.00, MPLS TE Id:12.12.12.12 Router Node (isis level-2)
```

We will repair CSR3 by adding the TE-ID back. If we change the filter to be more generic and look at all of the "nodes" in the topology, we see a new node type at the bottom. The "network" node is the TE representation of an OSPF DR or IS-IS DIS. Every single link in the topology is OSPF/IS-IS point-to-point specifically to bypass the DR/DIS election, except for the link between CSR2-CSR3. This is just for demonstration purposes and has no operational benefit in this network. The point is that DR/DIS pseudonodes count as TE nodes and are included in the TE topology.

```
CSR1#show mpls traffic-eng topology level-2 brief | include ^IGP
IGP Id: 0000.0000.0001.00, MPLS TE Id:1.1.1.1 Router Node (isis level-2)

IGP Id: 0000.0000.0003.01, Network Node (isis level-2)
```

Tracing the entire topology is excellent practice for understanding how TE works, but we can validate a few select links for brevity. Looking at the router node for CSR1, we can see 5 attached links. This is consistent with the topology and it also links the neighbors by IS-IS NET. Provided the NETs are logical and easily understandable, we can see the neighbors are CSR8, CSR4, CSR6, CSR9, and CSR3, which is correct. The links are identified as point-to-point and this is very similar to reading OSPF LSA1s. Each link has specific attributes, including TE and IGP metrics, attribute flags (link colors discussed later), and shared risk link groups (SRLG). These detailed characters are validated in later sections.

```
CSR1#show mpls traffic-eng topology level-2 1.1.1.1 brief
```

```
IGP Id: 0000.0000.0001.00, MPLS TE Id:1.1.1.1 Router Node (isis level-2)

```

Moving on to CSR3, we can see there is a link to CSR1, plus four more to CSR4, CSR9, CSR10, and a pseudonode identified as 0000.0000.0003.01. Notice that the show command references the IS-IS NET and not the loopback address as this is an alternative method of verification. Stepping through the network in this way is the best way to validate that the network has been configured properly.

```
CSR1#show mpls traffic-eng topology level-2 igp-id isis 0000.0000.0003.00 brief
```

```
IGP Id: 0000.0000.0003.00, MPLS TE Id:3.3.3.3 Router Node (isis level-2)

```

```
link[4]: Point-to-Point, Nbr IGP Id: 0000.0000.0010.00, nbr_node_id:18, gen:1847
frag_id: 0, Intf Address: 132.3.10.3, Nbr Intf Address: 132.3.10.10
TE metric: 10, IGP metric: 10, attribute flags: 0x0
SRLGs: None
```

Next, we examine the pseudonode, which is the only one in the topology. The IGP ID is similar to the IS-IS NET of the DIS, minus the area, and with a non-zero N-selector. CSR3 is the DIS and the pseudonode connects to CSR3 and CSR2. This node isn't a real physical router in the graph and does not have any specific MPLS-TE attributes. Just like an OSPF LSA2 or IS-IS DIS LSP, it just connects other routers; all costs are zero.

```
CSR1#show mpls traffic-eng topology level-2 igp-id isis 0000.0000.0003.01 brief
```

```
IGP Id: 0000.0000.0003.01, Network Node (isis level-2)
  link[0]: Broadcast, Nbr IGP Id: 0000.0000.0003.00, nbr_node_id:8, gen:1848
  link[1]: Broadcast, Nbr IGP Id: 0000.0000.0002.00, nbr_node_id:16, gen:1848
```

From this, we can look at CSR2. We will use the IP address format for variety in the show command. CSR2 is connected to the DIS (CSR3), CSR5, CSR9, and CSR10, which is correct per the diagram. This process should be repeated for all nodes in the topology to verify the TE database (TED) is correct.

```
CSR1#show mpls traffic-eng topology level-2 2.2.2.2 brief
```

```
IGP Id: 0000.0000.0002.00, MPLS TE Id:2.2.2.2 Router Node (isis level-2)

[snip]

The parser syntax above is generic for all IGP's that support TE distribution, which makes it the preferred way to look the TED. The information itself is carried differently in different protocols. We can look at the raw information within IS-IS as well with the "verbose" option. From CSR1, we look at CSR8. As attributes of the individual links (the IS-Extended neighbors), all of the TE attributes are carried. The TE metric is only carried if it is modified, which we will see later. For low-level debugging, this is the best way to see the source of the information, especially if the TED information appears incorrect.

```

We can also look at topology information using some TE link-level commands. We can look at TE-IGP neighbors, link attributes, and other things. The commands are verbose and, for the most part, show the same information we've already seen, except with link-level granularity and in a different display format. Below we look at the TE neighbors as seen by IGP as well as the TE link summary. There isn't anything noteworthy about these commands by themselves, but I document them for completeness. Because this command details the IGP neighbor addresses as seen by TE, it might be valuable for explicit-path construction (discussed later).

```

```

The mechanism by which TE tunnels are signaled is RSVP-TE. Segment routing TE (SR-TE) is very new but not in scope for the lab exam, and is not documented in this chapter. There are three key messages used by RSVP to signal TE LSPs.

PATH: Message sent hop-by-hop from source to destination, or in MPLS terms, head to tail. It carries the previous hop (PHOP) so that the tail end knows how to reply along the same path. After RSVP-TE extensions, the PATH message carries new objects:

Label Request Object (LRO): Used to request TE labels along the path, but does not carry the label values directly as this information needs to flow from tail to head (RESV messages).

Explicit Route Object (ERO): This is the output of the path calculation (PCALC) algorithm which essentially tells the PATH messages which way to go. Since RSVP is used for signaling only, it is not expected to have direct visibility into the TED as this is PCALC's duty.

Record Route Object (RRO): Used to record the route taken by the PATH message, giving a "record" of the LSP to downstream nodes. This can be valuable when using loose-hop expansion to prevent signaling loops.

Session Attribute Object (SAO): Carries information about the session, such as the mode of operation (shared explicit, described later), node/bandwidth protection flags, and fast-reroute.

Sender Tspec: Carries bandwidth reservation information as an average rate.

RESV: Message sent hop-by-hop using the PHOPs learned from the PATH message. It is impossible for the RESV messages to follow a different path than the PATH messages. The next-hop (NHOP) is carried inside the RESV messages so that the upstream nodes know the proper direction of the LSP.

Label object: This message primarily carries the label object, which is the actual label value of the TE tunnel. Coupled with the NHOP value, this defines the LSP forwarding plane.

Record Route Object (RRO): Used to record the route taken by the RESV message, giving a "record" of the LSP to upstream nodes. This can be valuable when using loose-hop expansion to see the actual path that was signaled.

PATHERR: An error message to signal something went awry during RSVP signaling. This could be insufficient bandwidth or a link failure, as examples. Upon receipt of a PATHERR message, the headend will recompute the path.

First, we will examine PCALC operation in detail using a very basic TE tunnel from CSR1 to CSR5 [ID 1]. TE tunnel configuration in XE has some awkwardness; the tunnel is not running IP, yet requires an IP address in the form of the TE-ID (unnumbered). The tunnel source is unspecified, but the destination is the remote TE-ID (tail end). I also clear all affinity bits so link coloring is not a factor, and this is discussed later. The PCALC process is also called constrained shortest path first (CSPF), which takes all of the tunnel constraints into consideration, finds the shortest path that meets the constraints, and assembles the hop-by-hop path into an ERO. This gets fed into the RSVP process via the PATH message for

signaling. Before creating the tunnel, we enable debug on CSR1 so we can watch the PCALC process. The "lookup" debug is typically the more valuable one, but we can also check the "spf" debug occasionally for extra detail. The SPF output is extensive but we will analyze it once. The debug is broken into sections for clarity.

```
CSR1#debug mpls traffic-eng path lookup
CSR1#debug mpls traffic-eng path spf
```

```
! CSR1
interface Tunnel1
  description BASIC
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 5.5.5.5
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 dynamic
```

Towards the top of the debug, we see the "constraints" being fed into the algorithm as input. The process performs a lookup within IS-IS level-2 and finds a shortest path (there are many) to XRv11 via CSR9 and CSR10 based on these constraints; right now, there aren't any. The total path-cost is 30, which is based on the TE metrics contained within the TE topology. This metric is copied over from the IGP metric by default, which is 10 for IS-IS. The path lookup process can then begin to find a path from 1.1.1.1 to 5.5.5.5.

```
! CSR1
TE-PCALC-API: 1.1.1.1_1->5.5.5.5_1 {7}: P2P LSP Path Lookup called

  affinity_bits 0x0, affinity_mask 0x0
TE-PCALC-PATH: 1.1.1.1_1->5.5.5.5_1 {7}: Area (isis level-2) Path Lookup
begin
```

The first step of the SPF algorithm is to evaluate the neighbor links. First, the local node address is obviously in the path, so it is immediately move from the tentative (tent) list to the path list. The other 5 links to CSR1's neighbors are added to the tent list for evaluation. After this pass, the output shows the current tent list along with their administrative weights (also known as the TE metric, shown as "aw"), along with the minimum bandwidth and hop count. We can see the tentative list is actually a stack structure, since items added first are at the bottom of the tent list.

```
! CSR1
TE-PCALC-SPF: Begin SPF for tunnel1 to dest 0000.0000.0005.00
TE-PCALC-SPF: Added 0000.0000.0001.00 to tent list (aw 0, min_bw
18446744073709551615, prev_node(NULL))
```

```

TE-PCALC-SPF: Moved 0000.0000.0001.00 to path list
TE-PCALC-SPF: Evaluating link 132.1.8.8
TE-PCALC-SPF: Added 0000.0000.0008.00 to tent list (aw 10, min_bw 100000,
prev_node(0000.0000.0001.00))
TE-PCALC-SPF: Evaluating link 132.1.4.4
TE-PCALC-SPF: Added 0000.0000.0004.00 to tent list (aw 10, min_bw 100000,
prev_node(0000.0000.0001.00))
TE-PCALC-SPF: Evaluating link 132.1.3.3
TE-PCALC-SPF: Added 0000.0000.0003.00 to tent list (aw 10, min_bw 100000,
prev_node(0000.0000.0001.00))
TE-PCALC-SPF: Evaluating link 132.1.6.6
TE-PCALC-SPF: Added 0000.0000.0006.00 to tent list (aw 10, min_bw 100000,
prev_node(0000.0000.0001.00))
TE-PCALC-SPF: Evaluating link 132.1.9.9
TE-PCALC-SPF: Added 0000.0000.0009.00 to tent list (aw 10, min_bw 100000,
prev_node(0000.0000.0001.00))
TE-PCALC-SPF: rrr_pcalc_dump_tentative list:
    0000.0000.0009.00: (aw=10, min_bw=100000, hops=1)
    0000.0000.0006.00: (aw=10, min_bw=100000, hops=1)
    0000.0000.0003.00: (aw=10, min_bw=100000, hops=1)
    0000.0000.0004.00: (aw=10, min_bw=100000, hops=1)
    0000.0000.0008.00: (aw=10, min_bw=100000, hops=1)

```

At this point, all 5 options appear equal, so CSR1 must select one to continue running SPF. It selects the first option (the last one pushed onto the tent stack) and adds it to the path list. It then evaluates all of CSR9's links. Notice that only CSR10, CSR2, and XRv12 are considered tentative candidates and are added to the tent list; other paths are not due to being farther away from the destination. The tent list grows to include these new nodes, and CSR9 has been removed from the tent list (being added to the path list does this).

```

! CSR1
TE-PCALC-SPF: Moved 0000.0000.0009.00 to path list
TE-PCALC-SPF: Evaluating link 132.9.12.12
TE-PCALC-SPF: Added 0000.0000.0012.00 to tent list (aw 20, min_bw 100000,
prev_node(0000.0000.0009.00))
TE-PCALC-SPF: Evaluating link 132.6.9.6
TE-PCALC-SPF: Evaluating link 132.4.9.4
TE-PCALC-SPF: Evaluating link 132.8.9.8
TE-PCALC-SPF: Evaluating link 132.2.9.2
TE-PCALC-SPF: Added 0000.0000.0002.00 to tent list (aw 20, min_bw 100000,
prev_node(0000.0000.0009.00))
TE-PCALC-SPF: Evaluating link 132.3.9.3
TE-PCALC-SPF: Evaluating link 132.1.9.1
TE-PCALC-SPF: Evaluating link 132.9.10.10
TE-PCALC-SPF: Added 0000.0000.0010.00 to tent list (aw 20, min_bw 100000,
prev_node(0000.0000.0009.00))
TE-PCALC-SPF: rrr_pcalc_dump_tentative list:
    0000.0000.0006.00: (aw=10, min_bw=100000, hops=1)

```

```

0000.0000.0003.00: (aw=10, min_bw=100000, hops=1)
0000.0000.0004.00: (aw=10, min_bw=100000, hops=1)
0000.0000.0008.00: (aw=10, min_bw=100000, hops=1)
0000.0000.0010.00: (aw=20, min_bw=100000, hops=2)
0000.0000.0002.00: (aw=20, min_bw=100000, hops=2)
0000.0000.0012.00: (aw=20, min_bw=100000, hops=2)

```

The process continues for the next node in the tent stack, which is CSR6. All of its links are evaluated, but none are added to the tent list as all of them are suboptimal. CSR6 is added to the path list and thus removed from the tent list.

! CSR1

TE-PCALC-SPF: Moved 0000.0000.0006.00 to path list

TE-PCALC-SPF: Evaluating link 132.6.8.8

TE-PCALC-SPF: Evaluating link 132.1.6.1

TE-PCALC-SPF: Evaluating link 132.6.10.10

TE-PCALC-SPF: Evaluating link 132.6.12.12

```

The entire PCALC computation happens locally on CSR1. The output of PCALC is the ERO, which is essentially the path that RSVP should signal. Provided the TED is correct, PCALC can complete. We will flap the tunnel (shut/no shut) with RSVP debugging enabled so we can view the signaling process also. First, CSR1 sees an incoming PROXY_PATH, which is basically a PATH message generated locally on the router from some other process (PCALC, in this case). The key part of this message, at least for now, is the ERO. Other things like the sender Tspec (bandwidth reservation) will be discussed later.

```

CSR1 turns this into a "real" PATH message and sends it to CSR9, which is the next item in the explicit path. Notice the interface address is used since TE is selecting specific links, not just selecting nodes. Notice that the minimum bandwidth towards the bottom is 125 MBps, or 1 Gbps, which is the link speed as seen by RSVP. By looking at "debug ip rsvp dump-messages" we can see all the details of the RSVP signaling.

```

```

CSR5 receives the PATH message and knows that it is the tail end of the LSP (tunnel destination indicates this). Now that the PATH message signaling from head to tail is done, the RESV messages must be sent in the reverse direction. The PHOPs carried in the PATH messages are used to derive next-hops (NHOPs)

for the RESV messages on the way back. This ensures that the proper interfaces are used in the reserve path. The most significant part of the RESV message is the last line, which is the label. PHP is supported with RSVP-TE so the tail-end router typically allocates implicit-null.

```

CSR2 receives this RESV message from CSR5, programs the label into its LFIB for this LSP, and sends another RESV back to CSR9. CSR2 allocates label 2008 for this LSP. Label 3 is implicit-null, which makes sense since CSR2 is the penultimate hop along the TE LSP. Just like LDP, having the next-hop plus label effectively creates a link in the FEC. This makes RSVP a good candidate for MPLS-TE since the RESV message nicely carries both, similar to LDP.

We can also look at a terser version of the RSVP signaling with "debug ip rsvp signalling". Refreshing the tunnel again, we see CSR1 send a PATH message to CSR9 with a PHOP of its local link address facing CSR9. The ERO details are not revealed here, but the basic RSVP message type (PATH, RESV, etc) and critical hop information (PHOP, NHOP, etc), are shown.

```

! CSR1
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Path refresh, Event: none, State: stay
in normal
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Path refresh (msec), config: 30000 curr:
30000 xmit: 30000
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Sending Path message to 132.1.9.9
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: building hop object with src addr:
132.1.9.1

```

CSR9 receives this PATH message, updates the PHOP, and sends it to CSR2. We won't trace the remainder of the path as it is the same at each hop. CSR9 receives a RESV back in from CSR2 and sends it back to CSR1.

```

! CSR9
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Received Path message from 132.1.9.1 (on
GigabitEthernet2.519)
  RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: [rsvp_examine_and_mark_md_events]
Existing PSB MD = Ignore
  RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: [rsvp_examine_and_mark_tspec_events]
Existing PSB TSpec = Ignore
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Incoming Path, No change

```

```

RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Sending Resv message to 132.1.9.1 from
132.1.9.9
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: building hop object with src addr:
132.1.9.9

```

CSR1 receives the RESV and sees no change.

```

! CSR1
RSVP: session 5.5.5.5_1[1.1.1.1] (7): Received Resv message from 132.1.9.9
(on GigabitEthernet2.519)
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: Successfully parsed Resv message from
132.1.9.9 (on GigabitEthernet2.519)
RSVP: 1.1.1.1_5->5.5.5.5_1[Src] {7}: No change in reservation

```

We can verify the tunnel with several show commands also. The primary show command is below and details most of the critical tunnel components. The first line shows the status of the interface. "Path" determines whether PCALC was successful and "Signalling" determines whether the path has been actually set up. A broken RSVP configuration won't affect PCALC, so PCALC can be valid while RSVP signaling is broken. The path options are listed and the one being used is identified as "basis for setup", along with the cost of the path. The next several lines just show configuration details. Next, there is RSVP information, to include the labels being used. There is no incoming label since this is the tunnel head; traffic only exits, never enters. The ERO, RRO, Tspec, and Fspec attributes are shown under the PATH and RESV fields as well.

```

CSR1#show mpls traffic-eng tunnels tunnel 1

```

```

```

You can verify the tunnel signaling by checking RSVP directly as well. We can verify the PATH messages in brief and verbose form. "session-type 7" refers to RSVP-TE tunnels as opposed to regular IPv4 RSVP. This original flavor of RSVP is not commonly used since the Integrated Services (IntServ) QoS model is unpopular. The tunnel head has no PHOP or incoming interface, but all other routers will. The detailed output is similar and shows in incoming and outgoing ERO (before and after the local address is removed), along with other traffic parameters, such as bandwidth and fast-reroute. The detailed output is also very similar to the "dump-messages" debugging in terms of format.

```

Likewise, we can do the same for the RESV messages. This time, there is a NHOP and outgoing interface, but there won't be at the tail end. We can also see the label value of 9013 which we saw in the RSVP dump-messages and the MPLS-TE show commands.

```

The same commands are valid on any router in the LSP. Moving to CSR9, we will issue the same commands. Since CSR9 has no concept of "tunnel 1", as an interface, we can specify that we want to see all tunnels for which CSR9 is a "midpoint". Other role options include "head" and "tail". We could specify the "tunnel ID" of 1, and Cisco's implementation populates this ID based on the tunnel interface number. We can see the local label sent to CSR1 is 9013 and the downstream (outbound) label is 2008 received from CSR2. A quick look at the LFIB clearly shows a swap operation. The [5] represents the LSP ID, which is the "Tun_Instance" in the detailed output. The "1" just before this LSP IP in the LFIB represents the tunnel ID.

```
CSR9#show mpls traffic-eng tunnels role middle
```

P2P TUNNELS/LSPs:

LSP Tunnel BASIC is signalled, connection is up

InLabel : GigabitEthernet2.519, 9013

Prev Hop : 132.1.9.1

OutLabel : GigabitEthernet2.529, 2008

Next Hop : 132.2.9.2

RSVP Signalling Info:

Explicit Route: 132.2.9.2 132.2.5.5 5.5.5.5

Record Route: NONE

Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

RSVP Resv Info:

Record Route: NONE

Fspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

CSR9#show mpls forwarding-table labels 9013

Local	Outgoing	Prefix	Bytes Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched	interface	
9013	2008	1.1.1.1 1 [5]	0	Gi2.529	132.2.9.2

As a midpoint, CSR9 has both PHOPs and NHOPs in the RSVP signaling chain. Traffic arrives from CSR1 and is switched towards CSR2. Notice that the destination and sender addresses are the same in both outputs, since the LSP is unidirectional. The output will be similar on all midpoints in the LSP, so we will skip CSR10. CSR1 is the PHOP (upstream) and CSR2 is the NHOP (downstream).

CSR9#show ip rsvp sender filter session-type 7 tunnel-id 1

Destination	Tun Sender	TunID	LSPID	Prev Hop	I/F	BPS
5.5.5.5	1.1.1.1	1	5	132.1.9.1	Gi2.519	0

CSR9#show ip rsvp reservation filter session-type 7 tunnel-id 1

Destination	Tun Sender	TunID	LSPID	Next Hop	I/F	Fi	Serv	BPS
5.5.5.5	1.1.1.1	1	5	132.2.9.2	Gi2.529	SE	LOAD	0

On the tail end, the outputs are different. We can reference the tunnel by ID as well, or use "role tail", etc. Notice that the local label is implicit-null but there is no out label; this is the opposite of what we saw at the headend. This makes sense because the TE LSP ends at CSR5. Additionally, the RESV message has no NHOP or outgoing interface since this is the terminating point of the LSP, as mentioned earlier.

CSR5#show mpls traffic-eng tunnels source-id 1

P2P TUNNELS/LSPs:

LSP Tunnel BASIC is signalled, connection is up

```

To detail an example of a valid PCALC but failed RSVP signalling, I will configure an ACL on all of CSR5's interfaces to block IP protocol 46, which is RSVP. If RSVP cannot receive PATH messages, the LSP signalling cannot complete.

```

! CSR5
ip access-list extended DENY_RSVP
  deny  46 any any
  permit ip any any

interface GigabitEthernet2.525
  ip access-group DENY_RSVP in

interface GigabitEthernet2.550
  ip access-group DENY_RSVP in

interface GigabitEthernet2.551
  ip access-group DENY_RSVP in

```

Because RSVP PATH messages sent to CSR5 are discarded, there is no RSVP PATHERR signaling since CSR1 keeps originating PATH messages. PCALC sees no issue with the network at all, though. In this case, it would not make sense to troubleshoot the TED or anything related to IGP as the issue is likely data-plane/RSVP related; we know this because the “path is valid. There are several other issues that can cause TE failures but most are related to specific constraints and will be examined later.

```

```

31.1.2 TE attributes

This section continues from the last with a functional topology (test ACLs removed). We will begin adding tunnels with various attributes to see how they are used. We can use MPLS OAM (detailed in a separate section) to verify the tunnels are functional in the data-plane also. The first and most straightforward tunnel attribute is the TE metric. This is a "second metric" that we assign to each link. The TE metric is commonly used for creating two topologies in a network; IGP metrics can be used for data flows while TE metrics can define a separate topology for voice flows, as an example. If it is not specified, it is copied from the IGP metric. Like any metric, it can be asymmetric, and is evaluated by the local node. A new tunnel [ID 2] will create an LSP to XRv11 but we want to force it through CSR6. Knowing that all other link costs are equal, we can lower the TE metric on CSR1 facing CSR6 to achieve this. We do not need to do it in the other direction, technically, since we don't expect return traffic to take the same path. This means the path will be lower cost than the other 2-hop paths through CSR3 or CSR9.

```

! CSR1
interface GigabitEthernet2.516
 mpls traffic-eng administrative-weight 5

```

We can verify this change is present in the TED. After all, all TE-aware nodes need to be aware of this change. Checking CSR6 also, we see that its local TE metric did not change, so we have introduced some asymmetry into the network.

```

CSR1#show mpls traffic-eng topology level-2 1.1.1.1 brief

```

Once the tunnel comes up, we can see the ERO specifies CSR6 as the next hop. The path weight is 25 which implies the TE metric of 5 was used (5+10+10 for total path). Recall that this ERO was the output of the PCALC operation and the input for the initial RSVP PATH message. The tunnel configuration specifies that the TE metric should be used explicitly, but this is the default. You can also specify IGP, but this is rare.

```

! CSR1

```

A similar example on XRv11 can be used to steer traffic to CSR8 away from XRv12. We increase the TE metric on the XRv11-XRv12 link so that it is less preferred. We make the configuration change then

check the TE topology. For variety, we will verify it from XRv12's perspective as all routers in the IS-IS level have this updated information.

```
! XRv11
mpls traffic-eng
 interface GigabitEthernet0/0/0/0.512

Another TE attribute is affinity. This is often called link coloring. It is a 4 byte hexadecimal number where each of the 32 bit positions represents a "color". This approach allows for 32 different colors (some routers, like XR, support 256 using extended link attributes) and any combinations of colors is valid. In this topology, 4 colors are used with the following binary and hexadecimal strings. This information is also depicted on the main diagram for quick reference.

Red: 0001 or 0x1

Green: 0010 or 0x2

Blue: 0100 or 0x4

Orange: 1000 or 0x8

Individual links are colored (can be asymmetric like TE metric) administratively and this can be used as a constraint for a given TE LSP. The red path might be high bandwidth, the green path might low latency, and the blue path might be scavenger traffic, as an example. Some links may be both low latency and high bandwidth, and would be colored both red and green. A tunnel uses the affinity mask to select which colors it cares about in terms of constraints. The default affinity and affinity mask on XE and XR is 0x00000000 and 0x0000FFFF, respectively. MPLS-TE made things confusing by reversing the bitwise logic used in ACLs for TE affinity. With ACLs, a value of 0 in the mask means "I care about it" while 1 means "I ignore it". The logic is reversed with affinity masks, so a value of 1 means it is honored. The default values, therefore, mean that the lower-order 16 bits MUST be zero by default. In our earlier examples, we specifically had to set the mask to 0x0 which says "I don't care about any affinity bits". If we fail to clear these affinity bits in a "colored" network, no tunnels will come up. Looking at the PCALC debugs along with TE logging, this becomes clear. RSVP doesn't even get an ERO and no signaling takes place since PCALC cannot find any suitable path that meets the tunnel constraints. The affinity mask is shown as 0xFFFF which is also visible via the TE show commands [ID 3].

```
! CSR1
interface Tunnel3
 ip unnumbered Loopback0
 tunnel mode mpls traffic-eng
```

```

tunnel destination 11.11.11.11
tunnel mpls traffic-eng path-option 10 dynamic

```

We will specifically configure this tunnel to traverse green links. This assumes we have an end-to-end green path, and we have a few. To accomplish this, we can specify the green affinity bit (0x2) and modify

the mask to only account for that bit (0x2). We see that the tunnel comes up and has selected the path CSR3 > CSR2 > CSR10 > XRv11, which contains only green links. Notice that the links traversed by this tunnel are all green, but not only green; multi-colored links can also be used. The affinity mask simply chose not to test for the presence or absence of the other colors, so PCALC does not care. The cost of this path was 40, but we know the lower cost (unconstrained) path was 25. This is what makes TE so powerful; routing decisions can become arbitrary yet dynamic.

```

We can do the opposite as well by instructing the tunnel to take any path that is NOT green [ID 4]. We still need to evaluate the same bit, so the mask does not change as we are only evaluating against the green color. The difference is that we clear the bit in the affinity so as to say "This bit must be zero, and I care about it". CSR1 selects a path that avoids all green paths, traversing CSR6 > XRv12 > XRv11.

```
! CSR1
interface Tunnel4
  description NOT GREEN
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng

```

The opposite logic is invalid; you cannot set something in a tunnel's affinity then say you don't care about it in the mask. The configuration doesn't make sense and is rejected by the parser. If you don't care about it, set the affinity bit and mask bit to zero.

```
CSR1(config-if)#tunnel mpls traffic-eng affinity 0x2 mask 0x0
% Bits cannot be set in affinity (0x2) if unset in mask (0x0)
```

The logical AND operation is valid when combining colors. From CSR3 to CSR10, we can create a path which requires all transit links be green, blue, and orange at the same time [ID 5]. There isn't a one-line mechanism to do Boolean OR logic, though, as you would normally use separate path-options for this, which is evaluated in more complex examples later. The more aggressive the constraints, the less likely the tunnel is to form. In this case, there is only one path with all three colors and it traverses CSR2. The sum of 0x2, 0x4, and 0x8 is 0xE (14 in decimal) or 1110 in binary. We specify this as the affinity and the bits we care about (mask).

```
! CSR3
interface Tunnel5

```

A small adjustment of the affinity mask changes the logic significantly and breaks the tunnel. We can specify the tunnel must traverse links that are blue, green, and orange, but also NOT red. This is accomplished by setting the mask to 0xF or 1111 in binary, which forces PCALC to examine the last 4 bits of the link colors. There is no path from CSR3 to CSR10 that meets the constraints since the CSR2-CSR10 is colored red. We told the affinity mask to care about all four of our colors, but did not instruct the tunnel to use red links.

```
! CSR3
interface Tunnel6
```

```

description GREEN BLUE ORANGE TOGETHER, BUT NOT RED
ip unnumbered Loopback0

(no path)

```

We will repeat a similar set of tests with XR. The affinity configuration in XR is much simpler and more flexible than XE. You can assign strings of text to affinity values and enumerate these strings on an interface; XR can add them together to determine the link attributes, which is a simple, human-readable operation. XRv12 uses this mechanism, plus some legacy syntax. Attribute values (generally a single bit or color) is mapped to a string, and then those strings are assigned to interfaces. The manner in which bits are assigned to strings can vary between the classic hex syntax of specifying bit positions, where 0 is the least significant bit (0x1). You can also use the legacy syntax by specifying the hexadecimal value directly at the link level.

```

! XRv12
mpls traffic-eng
interface GigabitEthernet0/0/0/0.502
  attribute-names RED ORANGE

interface GigabitEthernet0/0/0/0.512
  attribute-names BLUE ORANGE

interface GigabitEthernet0/0/0/0.562
  attribute-flags 0xc

interface GigabitEthernet0/0/0/0.592
  attribute-names RED

affinity-map RED bit-position 0
affinity-map BLUE 0x4
affinity-map GREEN bit-position 1
affinity-map ORANGE 0x8

```

From XRv12, we will create a tunnel to CSR1 that requires an orange path [ID 3]. We will verify this tunnel by checking the outgoing ERO, which is used as input to the RSVP process within PATH messages. We can validate the path using OAM. The "include-strict" option selects a set of colors that must exist on a link, but no others may. If this command were used in this tunnel, it would mean only use orange links

that contain no other colors. Colorless links would also be rejected using strict inclusion. This would be identical to an IOS affinity mask of 0xFFFFFFFF since all bits are being evaluated.

```
! XRv12
interface tunnel-te3
  description ORANGE
  ipv4 unnumbered Loopback0
  logging events all

! 4 132.1.4.1 10 ms
```

We can also invert the logic by select a path that is NOT orange also [ID 4]. We can reference the tunnel by name also, provided we include quotes if the name has spaces. The outgoing ERO is shown at the bottom. MPLS traceroute verifies connectivity and the TE labels. The number in parenthesis is the bit-position from right to left regarding this color. The third bit position is 1000 in binary, or 8. The syntax in XR makes this very straightforward.

```

We can combine affinities by enumerating multiple strings. From XRv12, we build a path to CSR5 that is both red and orange. The output shows the bitmap 0x9 which is red (0x1) plus orange (0x8). This simplifies the logic for the operation and improves readability over the IOS configuration. we can see the path traverses CSR10 > CSR2 > CSR5, which is the only available path meeting the affinity constraints.

```

Likewise, we can specify affinities we specifically want to exclude in conjunction with those we want to include. We instruct XRv12 to build a path to CSR5 that is red and orange, but not blue [ID 6]. The configuration is very similar to the previous tunnel except with the added blue exclusion. No such path exists, and PCALC is not able to find a path that meets the affinity constraints. The tunnel information shows the affinity names, along with their values, both for inclusion and exclusion.

```

TE tunnels can also request bandwidth. This is a control-plane reservation carried in the RSVP signaling and accounted for by both RSVP and the TED. We configure a TE tunnel from CSR1 to XRv11 requesting 20 Mbps of bandwidth [ID 7]. This is a constraint that gets fed into PCALC, and then to RSVP for signaling. Looking at the RSVP dumps, we can see the PROXY PATH (output from PCALC) contains a request for 2.5 MBps (big B for bytes), which is 20 Mbps. All of the other RSVP PATH attributes are present also, such as the SAO, ERO, and sender Tspec.

When signaling is complete, the head end receives the final RSVP RESV message containing the TE label for the next-hop and the flowspec record showing the reservation was successful. Note: Shared Explicit (SE) is used to ensure make-before-break (MBB). This is contained in the PATH message as a flag shown above. When an LSR needs to reroute an LSP, the new LSP is built before the old one is torn down. SE prevents double-booking of bandwidth on links during this process.

We can verify this bandwidth reservation several ways. The reservations are made outbound; because the LSP is unidirectional, CSR1 needs to send 20 Mbps of data, so the reservation is applied to that outgoing interface. The PATH message carries the initial bandwidth request and the RESV confirms it.

```
CSR1#show ip rsvp sender filter session-type 7 tunnel-id 7

```

For additional verification, we can check the TED to ensure the bandwidth reservation is accounted for. All nodes must be aware of this allocated bandwidth so that when new tunnels are created, the local PCALC process has a complete and updated view of the topology. CSR6 shows that 20 Mbps are allocated on its interface towards CSR10. This is also present in the IS-IS database with CSR6's LSP (verbose information). The higher number priorities are less important, and the default priority is 7 (lower priority). This is examined next.

```

RSVP now reports a total of 60 Mbps reserved on the link between CSR1 and CSR6. The prioritization of flows happens within the PCALC process as RSVP is just used to signal them. When we check the TED on CSR1 relating to the CSR6-facing link, we can see that 20 Mbps is reserved at priority 7 and 40 Mbps is reserved at priority 4. The remaining reservable bandwidth is the remaining sum of bandwidths across all priorities. If a priority 4 flow requests 40 Mbps, then that 40 Mbps is not available for priority 4 or worse. Higher priorities can preempt (based on the hold priority, which is the second number) but lower ones cannot.

```

CSR1#show ip rsvp interface

```

Adding a third tunnel, we configure a reservation for 90 Mbps at the highest priority following similar constraints as the previous tunnel [ID 9]. Tunnels 7 and 8 are preempted since only 10 Mbps of remaining reservable bandwidth is available at all priorities, and both of them are request more than that. Tunnel7 had no affinity constraints so it recalculated to select a alternate lowest-cost path that provided the bandwidth (CSR3). Tunnel8 was constrained by affinity so it selected a higher-cost path (CSR8) to meet its bandwidth requirement. Tunnel9, as the highest priority, is what caused the tunnels to recalculate. Just because bandwidth is no longer available for lower priority flows does not mean those tunnels will fail forever; they just cannot compete for the bandwidth on those links.

```
! CSR1
interface Tunnel9
  description BLUE PRIORITY BW REQ (BEST)
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11

11.11.11.11 (Strict IPv4 Prefix, 8 bytes, /32)

RSVP is now tracking different bandwidth reservations on different interfaces based on the new path calculations. Again, this is the result of the 90 Mbps reservation at the higher priority causing the existing TE tunnels to recalculate.

CSR1#show ip rsvp interface

interface	rsvp	allocated	i/f max	flow max	sub max	VRF
Gi2	ena	0	750M	750M	0	
Gi2.513	ena	20M	100M	100M	0	
Gi2.514	ena	0	100M	100M	0	
Gi2.516	ena	90M	100M	100M	0	
Gi2.518	ena	40M	100M	100M	0	
Gi2.519	ena	0	100M	100M	0	

We won't show all of the link bandwidth updates, but checking CSR1's interface to CSR6, we see that only 10 Mbps is available for all priorities as the 90 Mbps reservation was the highest priority.

CSR1#show mpls traffic-eng topology level-2 1.1.1.1 | begin 0006

bw[7]:	0	10000	0

During the initial pre-emption, the LSPs may issue log messages that show PCALC's inability to meet the requirements. These messages are often transient, but could lead to short-term outages when TE-FRR is not in use.

```
! CSR1
%MPLS_TE-5-TUN: Tun8: LSP path change nil for 8_35, path verification failed
%MPLS_TE-5-LSP: LSP 1.1.1.1 8_37: No path to destination, 0000.0000.0011.00
(bw or affinity)
```

You cannot configure a tunnel to have a higher setup priority over the hold priority. If a tunnel is setup at a certain priority, the tunnel's ability to sustain that priority should be at least as good as the setup. You can, however, give a tunnel better hold priority so ensure that when it is setup, it is less likely to be pre-empted.

```
CSR1(config-if)#tunnel mpls traffic-eng priority 4 5
% Setup priority (4) may not be higher than hold priority (5)
```

Since the configuration is almost identical in XR, we will configure one test for brevity. A tunnel is built to CSR8 [ID 7] requesting 45 Mbps following the path with the lowest IGP metric (TE metric is the default). No IGP metrics have been modified, but this means that any TE metric modifications will not be considered. XRv12 makes the reservation on the interface towards CSR6 when the LSP is signaled.

```
! XRv12
interface tunnel-te7
 description BASIC BW REQ
 ipv4 unnumbered Loopback0
 logging events all
 priority 5 3
 signalled-bandwidth 45000
 destination 1.1.1.1
 path-selection metric igp
 affinity ignore
```

```
path-option 10 dynamic
```

```
RP/0/0/CPU0:XRv12#show rsvp sender session-type lsp-p2p destination 1.1.1.1
detail | begin Outgoing
```

```
Explicit Route (Outgoing):
```

```
Strict, 132.6.12.6/32
Strict, 132.1.6.1/32
Strict, 1.1.1.1/32
```

Checking the TED, we use XRv12 to check CSR6's link to CSR1, confirming the bandwidth reservation. Notice that despite having a setup priority of 5, the hold priority was higher at 3, so if other LSRs want to preempt this path, they have to do so against a priority 3 flow as this is already established. For priority 3 and below, 55 Mbps is remaining, but higher priority flows can use the full 100 Mbps.

Despite having all these fancy TE attributes for dynamic calculations, we can arbitrarily steer traffic through a network using a predefined explicit path. This is essentially a hand-made ERO that gets fed into PCALC for sanity checking, but is ultimately delivered to RSVP with minimal changes. This is generally useful for testing purposes, loose-hop expansion, or link/node exclusion. From CSR1, we create a path to XRv11 that follows the path CSR3 > CSR2 > CSR10 > XRv11 [ID 10]. We can specify this using link addresses or TE IDs; link addresses are more strict, while TE IDs allow any link to be chosen if there are parallel links between nodes. The path below uses the most strict method, which is unnecessary in this topology as there are no sets of parallel links. Technically, you don't need to specify the remote TE ID as the last entry, but it is good practice and makes the code self-documenting.

```
! CSR1
ip explicit-path name PATH_1_3_2_10_11 enable
  next-address 132.1.3.3
  next-address 132.3.9.9
  next-address 132.2.9.2
  next-address 132.2.10.10
  next-address 132.10.11.11

interface Tunnel10
  description EXPLICIT PATH STRICT
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name PATH_1_3_2_10_11
```

Notice that this pre-defined path is almost identical to the ERO delivered from PCALC to RSVP. As shown in the debug below, PCALC is just verifying that the path makes sense. The CSPF algorithm is still invoked to ensure other constraints (affinity, bandwidth, etc) are accounted for, but that isn't the focus now. Using affinity with explicit paths is possible but doesn't make much sense unless loose-hop path expansion or link/node exclusion is in effect.

```

```

An alternative approach is to specify the TE IDs. This is simpler to read and understand, but is a little less strict in cases where there are parallel links between nodes. Given the current topology, the result is identical, since there are no parallel links between any pair of nodes. We can also use a numerical ID (not preferred) to identify paths versus names. Below is an example of using path IDs versus names, but this is similar to using numbered ACLs or named ones; it is generally considered a legacy mechanism. The ERO in the PATH message gets expanded to the link values via PCALC. MPLS traceroute confirms the path is the same as it was in the link-specific path. Notice that this explicit path does not specify the last node; this technically works as long as the path specifies the penultimate hop and the tunnel destination is correct, but is more difficult to read/understand/troubleshoot.

```

```

We can become even more explicit by using the "verbatim" option. This completely bypasses the PCALC sanity check as the explicit-path is turned into an ERO exactly as written. PCALC receives the explicit-path but the topology check is skipped. This can be used for Inter-AS/Inter-area TE, as well as TE over IGP's that don't support TE extensions. For example, you can do MPLS TE over RIP or EIGRP using verbatim paths since the destination address of each PATH message has been identified. Following the same path, we create a new tunnel [ID 12] with verbatim option. We will recycle the explicit path from tunnel 10. OAM confirms the operation. This feature is examined in great detail in the for Inter-AS/Inter-area TE sections of this book. Since the entire TE topology is within a single IGP flooding domain, detailing this feature here is not interesting nor useful.

```

Explicit paths can also use loose hop expansion. We can specify a path that must traverse CSR6, but the intermediate hops can be anything (provided other constraints are met). A path from CSR1 to XRv11 that meets the aforementioned requirements is shown below [ID 13].

```
! CSR1
ip explicit-path name PATH_1_6_11_LOOSE enable
  next-address loose 6.6.6.6

interface Tunnel13
  description EXPLICIT PATH LOOSE
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name PATH_1_6_2_11_LOOSE
```

The signaling for loose paths is different than normal paths. Because PCALC on CSR1 was told to use an explicit path, it finds a path to CSR6 and creates an ERO for it. CSR1's ERO is very short as it only expands to include CSR6. The PCALC debug is shown below.

```
CSR1#show ip rsvp sender detail filter session-type 7 tunnel-id 13 | section
outgoing
```

```
ERO: (outgoing)
  132.1.6.6 (Strict IPv4 Prefix, 8 bytes, /32)

Debugging RSVP messaging on CSR6, the RSVP PATH message arrives with an ERO destined for CSR6. CSR6 needs to signal the remainder of the LSP, but it cannot make an ERO since it has no basis for determining the path; every other router in the path will determine the path dynamically upon receiving the path message. The outgoing PATH has no ERO.

As a result of this, CSR1 has no idea what the actual path is from a control-plane perspective. After CSR6, the actual LSP path is not known to the head-end. We can use the RRO object in the tunnel to record the route in the RESV messages.

```
CSR1#show mpls traffic-eng tunnels tunnel 13 | section RSVP_Signalling

! CSR1
interface Tunnel13
 tunnel mpls traffic-eng record-route
```

Clearing the tunnel (shut/no shut) allows the path to be signaled again. Looking at CSR6 RSVP signaling, we can see the RRO being built. The RRO is included in the PATH message to record the PHOPs, which isn't as relevant as the RRO in the RESV message to carry the NHOPs. This information is now available on the headend, even with loose explicit-paths. If this feature seems confusing, it is a result of the artificial setup. This is typically used for Inter-AS/Inter-area TE as it has little purpose within a TE domain. The feature is examined in deeper detail in those appropriate sections.

Explicit paths on XR are very similar to XE, so for brevity we examine one example using TE IDs in a strict path [ID 11]. In XR, you must specify the last-hop in explicit paths.

```
! XRv11
explicit-path name PATH_11_5_2_3_4_1
  index 10 next-address strict ipv4 unicast 5.5.5.5
  index 20 next-address strict ipv4 unicast 2.2.2.2
  index 30 next-address strict ipv4 unicast 3.3.3.3
  index 40 next-address strict ipv4 unicast 4.4.4.4
  index 50 next-address strict ipv4 unicast 1.1.1.1

interface tunnel-te11
  description EXPLICIT PATH STRICT TE ID
  ipv4 unnumbered Loopback0
  logging events all
  destination 1.1.1.1
  affinity ignore
  path-option 10 explicit name PATH_11_5_2_3_4_1
```

You can verify the ERO using the "dst-port" option and specifying the tunnel ID also. The ERO is a per-link expansion of the TE IDs were specified in the explicit path. This implies that PCALC was involved to evaluate those TE IDs into the appropriate link addresses.

```
RP/0/0/CPU0:XRv11#show rsvp sender session-type lsp-p2p dst-port 11 detail |
begin Outgoing
  Explicit Route (Outgoing):

    Strict, 132.2.5.2/32
    Strict, 132.2.3.2/32
    Strict, 132.2.3.3/32
```

```
Strict, 132.3.4.4/32
Strict, 132.1.4.1/32
Strict, 1.1.1.1/32
```

Bandwidth can be automatically adjusted for a TE tunnel based on measured traffic also. This can help optimize bandwidth usage to ensure that tunnels are requesting the bandwidth they actually require, versus making reservations that remain under-utilized. The feature samples that average data rate through the tunnel and periodically adjusts the signaled-bandwidth to the largest sample since the last adjustment. Globally, we can enable the feature and define the interval between the samples (5 minute default). On a per-tunnel basis, we can define the interval between adjustments (24 hour default), min/max bandwidth reservations as upper and lower bounds (unlimited by default), and a threshold that signals how much different the sample must be in order to make a change (10% by default). **As a best practice, the timers should follow this logic: load-interval < global sampling frequency < tunnel adjustment frequency.** This way, the load-interval can change sufficiently between samples, and the tunnel adjustments will run less frequently than the sampler. If a tunnel is down when the global sample time hits, the sampler is ignored. Below is an example of auto-bandwidth. Every minute, the global process samples the bandwidth on all tunnels. The bandwidth is adjusted every 5 minutes based on the traffic going through it. Technically, we don't have to specify an initial bandwidth, but we do using 5 Mbps. We specify a lower bound of 2 Mbps and upper bound of 10 Mbps also [ID 14]. This ensures that the tunnel is not grossly over or underutilized.

```
! CSR1
mpls traffic-eng auto-bw timers frequency 60

interface Tunnel14
  description AUTO BW TIMERS
  ip unnumbered Loopback0
  load-interval 30
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng priority 7 7
  tunnel mpls traffic-eng bandwidth 5000
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 dynamic
  tunnel mpls traffic-eng auto-bw frequency 300 max-bw 10000 min-bw 2000
```

The tunnel comes up immediately and we can see 5 Mbps has been reserved. We can check the TE tunnel details to see the auto-bw information. The (300/96) represents the configured adjustment timer over the remaining time until the next evaluation. It counts down to zero. The zero following this field is the last measured bandwidth, which is also zero at present. The samples collected represents how many samples, based on the global interval have occurred. One was skipped since the tunnel was down during the initial configuration.

```

```

```
auto-bw: (300/96) 0 Bandwidth Requested: 5000
```

```
Samples Missed 1: Samples Collected 3
```

After the timer hits zero, the adjustment happens. Since we don't have any traffic going through the tunnel, we expect the lower-bound measurement of 2 Mbps to be signaled. We see a log message stating that the tunnel has been "reoptimized", which is what happens periodically with TE tunnels anyway, but this was initiated by the auto-bw process. The LSP ID has changed from 1 to 2, and RSVP is now reporting 2 Mbps reserved on the outgoing interface. The tunnel details also show the change. This can introduce churn into the topology as the TED information is re-flooded.

```

We can also perform adjustments based on consecutive threshold crossings based on the global interval. This can react more quickly to changing conditions since we don't have to wait for all the samples, we can say that if we are consistently incorrect, we can make an adjustment sooner. XE does not appear to support "underflow", which means we cannot react by reducing bandwidth. The timer mechanism can still react to underflow conditions, but not the event-driven threshold feature [ID 15]. If the bandwidth is more than 5% greater than the current signaled bandwidth 3 times in a row (sampled by the global frequency), then the overflow adjustment occurs.

```

Another option includes the ability to simply monitor bandwidth on the tunnel, but take no action. The output looks similar except there are no adjustments ever being made. The tunnel can still request bandwidth but it cannot be adjusted. The output specifically says "collected" and not "requested" since the latter never changes. We don't specify the max-bw since it isn't relevant, and the maximum value is applied for this field.

```

```

The auto-bandwidth feature is very similar in XR. We will configure a TE tunnel from XRv11 to CSR8 requesting 7 Mbps of bandwidth initially, with a min/max of 2.5/9.5 Mbps [ID 14]. The adjustment "application" is every 5 minutes where the global timer takes samples once every minute (IOS measures this in seconds while XR uses minutes). The tunnel will adjust bandwidth when the difference is at least 15% different and 10 kbps different to avoid constant churn. As an unrelated feature, the path-option is

limited to a specific IS-IS process and level, which can be useful when constraining TE tunnels to a single TE topology (could be useful if, for example, XRv11 were an ABR or L1L2 router).

```
! XRv11
mpls traffic-eng
  auto-bw collect frequency 1

interface tunnel-te14
  description AUTO BW TIMERS
  ipv4 unnumbered Loopback0
  load-interval 30
  auto-bw
    bw-limit min 2500 max 9500
    adjustment-threshold 15 min 10
    application 5
    logging events all
    signalled-bandwidth 7000
    destination 8.8.8.8
    affinity ignore
    path-option 10 dynamic isis 132 level 2
```

When the tunnel comes up, we can see the auto-bandwidth details. This is very similar to the XE output. XR also has an auto-bandwidth brief command that shows each tunnel as a row, along with the relevant bandwidth information.

```
RP/0/0/CPU0:XRv11#show mpls traffic-eng tunnels 14 | begin Auto-bw
Auto-bw: enabled
  No BW Applied
  Bandwidth Min/Max: 2500-9500 kbps
  Application Frequency: 5 min   Jitter: 0s   Time Left: 3m 40s
  Collection Frequency: 1 min
  Samples Collected: 2   Next: 35s
  Highest BW: 0 kbps   Underflow BW: 0 kbps
  Adjustment Threshold: 15%   10 kbps
  Overflow Detection disabled
  Underflow Detection disabled
[snip]
```

```
RP/0/0/CPU0:XRv11#show mpls traffic-eng tunnels auto-bw brief
```

Tunnel Name	LSP ID	Last appl BW (kbps)	Requested BW (kbps)	Signalled BW (kbps)	Highest BW (kbps)	Application Time Left
tunnel-te14	2	-	7000	7000	0	3m 18s

After five minutes, we can see the tunnel has been reoptimized to 2.5 Mbps. Since there is no traffic in the tunnel, the minimum bandwidth of 2.5 Mbps is applied. The LSP history also shows that the previous

LSP ID was 2, the new one is 3, since the LSP was "reoptimized" by the auto-bandwidth process. The brief output shows similar output in summary form.

```

Tunnel Name	LSP ID	Last appl BW (kbps)	Requested BW (kbps)	Signalled BW (kbps)	Highest BW (kbps)	Application Time Left
tunnel-te14	3	2500	2500	2500	0	21s

Next, we will look at using flow thresholds on XRv11 [ID 15]. XR also supports the underflow option which allows over-subscribed tunnels to be reduced again, where XE only supports overflow (other direction). This tunnel requests 10 Mbps of bandwidth and is constrained to the range of 8-20 Mbps. If there is a 5% increase in bandwidth that is at least 256 kbps of a change, and this occurs in three samples, the tunnel can react to the overflow condition and request more bandwidth. If there is a 10% reduction in bandwidth that is at least 128 kbps of a change, and this occurs two times, the tunnel can react to the underflow condition and request less bandwidth. Both are considered reoptimizations and resignal the LSP. The application is defaulted to 1440 minutes (24 hours) so without the flow thresholds, it would take a long time for the tunnel to reoptimize using default timers.

```
! XRv11
```

```
interface tunnel-te15
```

```
description AUTO BW FLOW THRESHOLDS
```

```

ipv4 unnumbered Loopback0
load-interval 30
auto-bw
  bw-limit min 8000 max 20000
  overflow threshold 5 min 256 limit 3
  underflow threshold 10 min 128 limit 2
logging events all
signalled-bandwidth 10000
destination 3.3.3.3
affinity ignore
path-option 10 dynamic

```

The tunnel comes up as expected (output not shown). We see a log message showing the underflow condition as there is no traffic in the tunnel after about 2 minutes. The global sample interval is 1 minute, so after two under-threshold conditions, the underflow event is triggered. The new signaled-bandwidth is the minimum, 8 Mbps, per the configuration. The brief output also shows tunnel-te14, which is shutdown, and has LSP ID 0 since the tunnel is not up. This tunnel was shutdown after the last test for clarity.

```

! XRv11

Last, we will examine bandwidth monitoring on XR for TE tunnels. We create a tunnel to CSR1 only for collecting bandwidth statistics [ID 16]. The tunnel requests 512 kbps of bandwidth and this value can never change since we are only monitoring BW on this tunnel. The "Highest BW" field represents the highest sample of bandwidth seen. The underflow bandwidth is the difference between the highest measured bandwidth and current bandwidth.

```

```

RP/0/0/CPU0:XRv11#show mpls traffic-eng tunnels auto-bw brief

Tunnel Name	LSP ID	Last appl BW (kbps)	Requested BW (kbps)	Signalled BW (kbps)	Highest BW (kbps)	Application Time Left
tunnel-te14	0	2500	7000	7000	0	1m 26s
tunnel-te15	0	8000	10000	10000	0	23h 55m 21s

Many of these features can be combined to create some very sophisticated TE tunnels using multiple path-options. Individual path options have can separate LSP attributes for maximum flexibility. On CSR1, we configure a tunnel to CSR5 to follow these requirements, in sequence:

1. Red path, 40 Mbps reservation at priority 5
2. Any color but must avoid CSR9, 105 Mbps reservation
3. Blue path, 20 Mbps reservation, must transit XRv12, should record the route taken, and the path can never be changed
4. Any path as a last resort, and should monitor the bandwidth used for future plans

We create several LSP attribute classes to account for these options. Many of these options can be configured directly on the tunnel, which apply to all path-options. Applying an LSP attribute class to a path-option overrides whichever options are specified at the tunnel interface level. For example, affinity is cleared on the tunnel, so options 2 and 4 don't need to specify affinity since ignoring it is the tunnel default. These requirements use a combination of explicit and dynamic paths to meet the transit routing constraints for some options. One restriction is that all bandwidth requests for all path-options must have the same priority, so 5 is used for all options and is defined in the tunnel for inheritance [ID 17].

We can enable debugging on CSR1 to look at the PCALC lookup process. PCALC is invoked for each path-option in sequence. The first option tries to find a red path from CSR1 to CSR5, but there are none. This option fails due to affinity which the log message reveals. The combination of syslog and debug messages is always ideal for troubleshooting.

```

! CSR1, path-option 1

```

The second option inherits the "ignored" affinity attribute but is requesting more bandwidth than is available. PCALC returns success since there is a path, but the bandwidth admission control mechanism rejects this as a viable path.

```

```

The third option chooses a blue path with 20 Mbps of bandwidth that transits XRv12. Since the PATH message terminates on XRv12, a lot of path control is lost after that point. This is another semi-awkward usage of loose-hop expansion within an TE domain. We see that CSR10 is in the path despite not being a blue link, which demonstrates the danger of using loose-hop inclusion. Nonetheless, this is a valid path-option.

```

We can verify the tunnel is functional by checking the tunnel details and using OAM for traceroute. The RRO seems to be missing the CSR10-XRv12 hop as well. Notice that all of the other path-options are

listed, by option 3 is used for “setup”. This implies that options 1 and 2 were untenable while option 100 was not evaluated yet.

```

We will demonstrate a complicated TE tunnel on XR also [ID 17]. The XR options are surprisingly limited as the only significant things we can do are specify the affinity and bandwidth. Options like bandwidth priority and record-route are global to the tunnel, not the LSP attributes per path-option. In this example, XRv12 follows similar rules as CSR1 except builds a tunnel to CSR4, minus the loose next-hop.

```
! XRv12
explicit-path name EP_NO_R9
  index 1 exclude-address ipv4 unicast 9.9.9.9

interface tunnel-te17
  description COMPLEX
  ipv4 unnumbered Loopback0
  logging events all
  destination 4.4.4.4
```

```

record-route
affinity ignore
path-option 1 dynamic attribute-set LSP_ATT_RED40
path-option 2 explicit name EP_NO_R9 attribute-set LSP_ATT_NO_R9
path-option 100 dynamic lockdown attribute-set LSP_ATT_ORANGE20

mpls traffic-eng
attribute-set path-option LSP_ATT_NO_R9
signalled-bandwidth 105000 class-type 0
no affinity ignore

attribute-set path-option LSP_ATT_RED40
signalled-bandwidth 40000 class-type 0
affinity include RED

attribute-set path-option LSP_ATT_ORANGE20
signalled-bandwidth 20000 class-type 0
affinity include ORANGE

```

Because there is a red path with 40 Mbps available, that first option is valid. The tunnel is up and operational and the backup path-options are also listed; only details for the active path options are expanded as shown below. The RSVP signaling information is included in the "detail" output for the tunnel, and this is where we can see the RESV RRO. The path goes from CSR9 to CSR3 to CSR4, which are all red links as expected. We also quickly confirm the 40 Mbps reservation is properly allocated by RSVP.

```

31.1.3 Directing traffic into TE tunnels and tunnel stitching

So far, we have not transferred any real traffic inside of our TE tunnels other than OAM tests. Without TE, the routers typically use LDP for transport label bindings based on the BGP next-hops, PW destinations, or other destinations reachable through IGP. The entire purpose of TE is to modify this IGP-based behavior. For these examples, we will use CSR1 and XRv11 as endpoints and direct traffic between these PEs into TE tunnels using various methods. First, we see that they currently use LDP labels. CSR1 has a VPNv4 route (and label) for XRv13 within the VPN. Based on the IGP route to XRv11's loopback, we see three possible LDP labels that can be used.

Although somewhat unrelated to this exact task, it can be confusing to know which ECMP path will be taken for VPN traffic from CSR7 to XRv13. The VPN CEF table points to CSR9 while the global table between BGP next-hops points to CSR3. The latter is actually correct; since the transport label lookup happens in the global table, the global FIB is consulted. We confirm this with a traceroute inside the VPN.

```

```

The first and most straightforward way to get this flow into the tunnel is using static routes. We no longer want to use LDP labels for the topmost label, which means we have to learn the route to the BGP next-hop via a TE tunnel. The router knows that it should use the TE label when the routing converges in this way. We configure a basic tunnel that can take any path not transiting CSR9. We also configure a static route to direct all traffic to XRv11's loopback into the TE tunnel. This method includes ALL IPv4 traffic between the two, including existing BGP sessions, pings, etc. If the tunnel is down for whatever reason, regular routing rules apply. This isn't a special case but a default behavior of the static route. If the specified outgoing interface is down, the static route is removed from the RIB unless marked with

the “permanent” option. The route with the next lowest AD out of a functional interface is used, so IGP routes + LDP labels can be a fallback for failed or shutdown TE tunnels.

```
! CSR1
interface Tunnel18
  description STEER WITH STATIC
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name EP_NO_R9

ip route 11.11.11.11 255.255.255.255 Tunnel18
```

We verify that the tunnel is up (path is CSR6 > CSR10 > XRv11) and that the static route was installed successfully.

```
CSR1#show mpls traffic-eng tunnels tunnel 18 | section RSVP_Path
  RSVP Path Info:
    My Address: 132.1.6.1
    Explicit Route: 132.1.6.6 132.6.10.10 132.10.11.11 11.11.11.11
    Record Route: NONE
    Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

CSR1#show ip route 11.11.11.11

  Known via "static", distance 1, metric 0 (connected)
  Routing Descriptor Blocks:
    * directly connected, via Tunnel18
      Route metric is 0, traffic share count is 1
```

Next, we can find the new outgoing label by checking the RSVP RESV details for this specific tunnel. Using traceroute inside the VPN on CSR7, we can see that the traffic is now being transported inside the TE tunnel. Even outside the VPN from CSR1's global table, the traffic is inside the tunnel, as mentioned earlier.

```
CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 18 |

```

The return traffic from XRv11 is taking an LDP path since there isn't a corresponding TE tunnel configured on XRv11. We will quickly verify this statement below. The route is learned via IGP and does not point to a TE tunnel. The router has LDP labels for both paths and selects CSR10's label of 10007 per the FIB. We verify it via several show commands and traceroute.

```

Last, we verify the outgoing label via the RSVP RESV details and test the path through traceroute. As we will see in the MVPN and per-VRF TE sections, this approach can be problematic for multicast transport due to RPF inconsistencies. Because TE tunnels cannot run PIM (doesn't make sense), RPF is now broken because potential MDT endpoints.

```

```

Another option is using "auto-route". There are two main flavors: announce and destination. Destination is only supported on IOS and XE platforms and is almost identical to the static routing approach except is more dynamic. It automatically programs a static route for the tunnel destination out of the tunnel upon which it was configured [ID 19]. This can increase scalability because static routes don't need to be manually added. Changing the tunnel destination will automatically update the static route, also. Using an identical tunnel we just did, we will apply auto-route destination to achieve the same effect. Regarding MVPN RPF, this introduces the same issues as static routing (discussed in detail in other sections).

```
! CSR1
interface Tunnel19
  description STEER WITH AUTOROUTE DESTINATION
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
```

```
tunnel mpls traffic-eng path-option 10 explicit name EP_NO_R9
```

We can verify the path by checking the RSVP PATH message's outgoing ERO. We also have an automatic static route for the tunnel's destination, which works well for PE-PE tunnels.

```
CSR1#show ip rsvp sender detail filter session-type 7 tunnel-id 19 | section outgoing
```

ERO: (outgoing)

```
132.1.6.6 (Strict IPv4 Prefix, 8 bytes, /32)

As mentioned earlier, auto-route destination is not supported in XRv 5.3.0, and this is probably XRv specific.

```
! XRv11
interface tunnel-te88
  autoroute destination
!!% The requested operation is not supported: This feature is not supported
in this release.
```

The other option for auto-route creates an IGP route through the TE tunnel. This seems highly suspect since link-state protocols do not advertise routes per se, they advertise topology information. Routers collect this information, and assuming everyone has the same view, can guarantee loop-free paths through the topological graph. This feature does not make any changes to the underlying OSPF LSDB or IS-IS LSPDB, but simply announces the destination to the head-end router as being reachable through the tunnel. Even though it looks like an IGP route, the TE label is used since the outgoing interface is a TE tunnel. The cost of the route learned via the TE tunnel is the same as the shortest IGP path between the endpoints. We test this using the same type of tunnel as before [ID 20].

```
! CSR1
interface Tunnel20
  description STEER WITH AUTOROUTE ANNOUNCE
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name EP_NO_R9
```

We can verify the tunnel is up very quickly by checking the outgoing label. Seeing that it is 6011, we assume the path transits CSR6. When we check the RIB, we see the route is IS-IS but recurses out of the TE tunnel. In the context of label lookups, this isn't an IGP + LDP binding, even though the route is IGP-installed. Only the RSVP label is used in this particular example.

```

```

A quick look at CSR1's IS-IS LSP shows no direct link to XRv11, indicating the IS-IS LSPDB did not change. However, when we check the IS-IS topology, the protocol is aware that reachability to XRv11 is achieved through a new best path, which is the TE tunnel. IS-IS does track all the TE tunnels, since it carries all of the TE attributes. The two processes (TE and IS-IS/OSPF) communicate closely within software.

A minor adjustment to this feature allows us to change the IGP metric for this auto-route. We can specify an absolute value instead of the IS-IS calculated one, which is based on the non-TE best path. It was 30 before, but we can change the auto-route to be 31, as an example. Now, the best-path is no longer through the TE tunnel but is via the ordinary paths. This can be used for advanced failover scenarios. For example, if the regular path IGP metric is 30 or less, that will be preferred. If the IGP cost is too high (greater than 30), we decide we want to use the TE tunnel and apply bandwidth reservations to compensate for the less optimal routing paths.

```
! CSR1
interface Tunnel20
 tunnel mpls traffic-eng autoroute metric absolute 31

    Tunnel20 (load balancing metric 0, nexthop 11.11.11.11, absolute
metric 31)
      (flags: Announce)
```

We can also use a relative modifier to scale the metric up or down. In this case, the IGP-computed metric can be scaled up or down within a range of +/- 10. This is mostly useful for when there are multiple TE tunnels going to the same destination, both using autoroute, and one should be preferred over the other. Another tunnel [ID 21] has been added to prove this point, and the original tunnel has

the absolute metric removed. This new tunnel has a lower IGP metric by 1, and is thus preferred. This is another dimension to flexibility in TE in addition to the path-options within a given tunnel. This provides prioritization between tunnels as well.

```
! CSR1

```

We can also see the paths side-by-side as tracked by the auto-route feature. This can help with troubleshooting when trying to determine which tunnel should be used.

```
CSR1#show mpls traffic-eng autoroute 11.11.11.11
MPLS TE autorouting enabled
  destination 0000.0000.0011.00, area isis level-2, has 2 tunnels
    Tunnel20      (load balancing metric 0, nexthop 11.11.11.11)
                  (flags: Announce)
    Tunnel21      (load balancing metric 0, nexthop 11.11.11.11, relative
metric -1)
                  (flags: Announce)
```

We will quickly test autoroute announce with metric manipulations on XR as well [ID 20, 21]. First, we create a single tunnel using the same constraints as earlier with an exact metric of 28. We check the RSVP PATH message's outgoing ERO to see the path; CSR5 is the next-hop. The LFIB reveals the TE label as 5012 and we can verify that the remote prefix 1.1.1.1/32 is using this label.

```
! XRv11

```

Another method is policy routing. This is generally the least desirable option, but can give additional flexibility as to what traffic goes into the TE tunnel. PBR does not work for VPN traffic and can only be used within a single routing instance, so for L3VPN, this is not an option. For global MPLS transport, such as 6PE, this can work. We use CSR4 as a test client briefly by forcing traffic to 11.11.11.11 to CSR1, and also disabling LDP on the interface to CSR1. This allows the traffic to XRv11 to be raw IP so CSR1 can steer it into the TE tunnel with PBR. CSR1 has a normal tunnel configuration with nothing fancy since the PBR is applied separately [ID 22]. Access-list based forwarding (ABF) is the XR equivalent and is not supported for this use.

```
! CSR4
interface GigabitEthernet2.514
 no mpls ldp igp autoconfig

ip route 11.11.11.11 255.255.255.255 132.1.4.1

! CSR1
interface Tunnel22
 description STEER WITH PBR

```

We quick verify the tunnel path and label. The next-hop is CSR6 using label 6010.

```
CSR1#show mpls traffic-eng tunnels tunnel 22 | section Label|RSVP_Path
InLabel   : -
OutLabel  : GigabitEthernet2.516, 6010
RSVP Path Info:
My Address: 132.1.6.1
```

```
Explicit Route: 132.1.6.6 132.6.10.10 132.10.11.11 11.11.11.11
Record Route: NONE
Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits
```

When CSR4 sends traffic towards XRv11, no label is applied since LDP is disabled on that interface and the route is static (which counts as an IGP route from the perspective of using LDP labels). Using traceroute, we can confirm this traffic is entering the tunnel. The PBR counters on CSR1 should increment every time a packet enters the tunnel via PBR.

```

```

Another option for steering traffic into the tunnel is using the CEF forwarding adjacency. Earlier, we saw that the auto-route options did not make any underlying changes to the IGP link-state topology, but rather changed the local routing table. In contrast, this alternative technique does actually create a

point-to-point link between the tunnel head and tail as part of the IGP topology. In order for this to work, the TE tunnel must be bidirectionally configured with forwarding-adjacency. We can also directly adjust the IGP metric on these interfaces to ensure there are no unintended routing issues; this feature is seen by all nodes in the OSPF area or IS-IS level, so set the cost appropriately. The hold-time value causes the tunnel to wait 10 seconds before informing the network of a down event. This ensures that brief tunnel flaps do not reflood OSPF/IS-IS topology information.

```
! CSR1
interface Tunnel24
  description STEER WITH FORWARDING ADJ
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11

  Metric Type: TE (default)
  AutoRoute: disabled LockDown: disabled Loadshare: 0 [0] bw-based
  Forwarding adjacency: holdtime 10000 ms
  auto-bw: disabled
```

With the tunnel up, we can begin the detailed verification process. CSR1 accounts for this tunnel as a forwarding-adjacency and has a special show command for it.

```

CSR1#show mpls traffic-eng forwarding-adjacency 11.11.11.11
destination 0000.0000.0011.00, area isis level-2, has 1 tunnels
Tunnel24 (load balancing metric 0, nexthop 11.11.11.11)
(flags: Forward-Adjacency holdtime 10000)

```

Checking the IS-IS database, we can see a new link to XRv11 was installed. There isn't an IS-IS neighbor (no hello packets, etc), but the link exists in the topology. The metric of this P2P link is 25 as configured on the tunnel interface.

```

CSR1#show isis database level-2 CSR1.00-00 detail | include IS-Extend
Metric: 10          IS-Extended CSR4.00
Metric: 10          IS-Extended CSR6.00

CSR9	L2	Gi2.519	132.1.9.9	UP	26	00

Some additional, but less useful, IS-IS show commands are below. We can see the TE tunnels and topology information in summary form as viewed by IS-IS.

```

CSR1#show isis mpls traffic-eng tunnel | begin Forward
Forwarding-adjacencies

```

System Id	Tunnel Name	BW	Metric	Nexthop	Metric	Type
XRv11.00	Tunnel24	0		11.11.11.11	25	L2

```

CSR1#show isis topology level-2 00.0000.0000.0011.00

```

Tag 132:

IS-IS 0 level-2 path to XRv11

System Id	Metric	Next-Hop	Interface	SNPA
XRv11	25	XRv11	Tu24	*MPLS TE-Tunnel

Most importantly, we verify that the tunnel endpoint is reachable through the TE tunnel. If the metric was defaulted to 10, then many other endpoints would be reachable through the tunnel also. For example, 10.10.10.10/32 would have a metric of 20 via this new TE tunnel and three other LDP paths, causing some awkward traffic patterns.

```

CSR1#show ip route 11.11.11.11
Routing entry for 11.11.11.11/32
  Known via "isis", distance 115, metric 25, type level-2
  Redistributing via isis 132
  Last update from 11.11.11.11 on Tunnel24, 00:14:54 ago
  Routing Descriptor Blocks:

      Route metric is 25, traffic share count is 1

```

The verification on XR is very similar, with most of the commands being identical. The TE process is aware of the forwarding-adjacency as an announcement mechanism and IS-IS sees it as a topology link. The other show commands are included for completeness also.

```

Because the feature must be configured bidirectionally, we should verify it works both ways. XRV11's tunnel to CSR1 goes CSR5 > CSR2 > CSR3 > CSR1. I am not certain why this suboptimal path was chosen, but it might have been due to network instability or the 100kbps CSR1000v bandwidth limit that caused certain IGP adjacencies to be down at the moment this was configured. In any event, note that the tunnels don't have to follow the same path bidirectionally, just that any valid LSP exists. We trace the labels hop-by-hop, then verify with traceroute within the VPN.

Not all TE tunnels need to "home run" all the way from PE to PE. Tunnels can exist from PE-PE, PE-P, P-P, and P-PE if necessary. We can create more hierarchical TE architectures in this way, much like using H-VPLS with U-PE and N-PE pseudowires. In PE-PE and P-PE tunnels, all transport signaling is done by RSVP as the tunnel provides a new LSP; LDP is not necessary at all in this case. When doing PE-P or P-P options, we need some other mechanism to binds labels for the remote PE IP prefix. The tunnels don't terminate at the final destination, so the transport labels need to be allocated in other ways. In other words, we still need to resolve that FEC since the TE-tunnel does not go end-to-end. In the example below, a pair of TE tunnels are created. One goes from CSR1 to XRv12, and the other goes from XRv12 to XRv11. The ultimate goal is to get traffic from CSR to XRv11 using these two tunnels, "stitching" them together. The first tunnel takes an explicit path through CSR8 and CSR6, while the second takes any red path that is also not blue [ID 23].

```

! CSR1
ip explicit-path name PATH_1_8_6_12 enable
  next-address 8.8.8.8
  next-address 6.6.6.6
  next-address 12.12.12.12

interface Tunnel23
  description PE-P
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 12.12.12.12
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name PATH_1_8_6_12
```

```

! XRv12
interface tunnel-te23
  description P-PE
  ipv4 unnumbered Loopback0
  logging events all
  destination 11.11.11.11
  affinity include RED
  affinity exclude BLUE
  path-option 10 dynamic

```

We quickly verify the tunnel paths are correct and within constraints, and then use OAM to verify the data-plane [ID 23]. On XRv12, we should specify that we want to see the head-end of tunnel 23, since we used the same tunnel ID for both and XRv12 is the head for one and the tail for the other. XRv12 shows being both a head and tail within this "extended" LSP.

```

```

TUNNEL NAME	DESTINATION	STATUS	STATE
tunnel-te23	11.11.11.11	up	up
PE-P	12.12.12.12	up	up

Each LSP appears to be fully functional. We will configure a static route to XRv11 on CSR1 so we can send VPN traffic into the tunnel. Auto-route destination would not be appropriate here, since the destination of CSR1's tunnel (XRv12) is not the address to which we are sending traffic (XRv11). Auto-route announce technically could work on CSR1, but we will use a static route for simplicity. We can use auto-route announce (or destination) on XRv12 for the second leg without causing any complexities. We quickly verify that each router is directing traffic to XRv11 out of the appropriate TE tunnel.

```
! CSR1
ip route 11.11.11.11 255.255.255.255 Tunnel23

! XRv12
interface tunnel-te23
  autoroute announce

    Route metric is 10
  No advertising protos.
```

When we traceroute from CSR1 to XRv11 to verify the path, we that CSR6 is performing PHP of the TE label as expected, and the traffic is raw IP on the hop to XRv12. This works for traffic in the core since we can route IP or MPLS. As such, there is no breakage in the BGP sessions, etc. We see that this breaks the VPN service between CSR7 and XRv13.

```
CSR1#traceroute 11.11.11.11 source loopback0
Type escape sequence to abort.
Tracing the route to 11.11.11.11

Packet sent with a source address of 7.7.7.7
.....
Success rate is 0 percent (0/5)

```

Because CSR6 is performing PHP of the TE label, and the next label is the VPN label, this is being exposed to XRv12 when it was allocated by XRv11. We confirm this with MPLS packet debugging on XRv12; it receives a packet from CSR6 but cannot route it since there isn't an LFIB entry for label 91011, which is the VPN label allocated by XRv11 for XRv13's loopback.

```

CSR1#show bgp vpnv4 unicast vrf TE labels | include 13\.

```

To solve this problem, we need to introduce another label into the stack. At imposition, CSR1 is currently accounting for a transport label to XRv12 and a VPN label for the final destination. There is no label representing the remote PE anywhere in the stack. Without this label, XRv12 will not know how to forward traffic along the second leg of the LSP. The solution is to enable LDP on the TE tunnel, which is basically telling the software to originate a targeted session to the tunnel destination. Rather than manually configure the destination to reciprocate, we can configure XRv12 to accept targeted sessions and respond accordingly. We can verify the LDP neighbors are up on both sides. CSR1 initiates the session and is considered active (TCP client), and XRv12 receives the session request and is considered passive (TCP server).

```

With an LDP session established between CSR1 and XRv12, labels can be exchanged. CSR1 is already routing to 11.11.11.11/32 out of the TE tunnel, which means the TE label is imposed. We also learn label 92003, which is XRv12's local LDP label for XRv11's loopback. If packets arrive on any of XRv12's LDP enabled interfaces with this label, XRv12 will be able to route the packet according to its LFIB. We confirm that CSR1 imposes this label above the VPN label in its FIB, and confirm that XRv12 can route MPLS packets with label 92003 out of the proper TE tunnel (the second leg). On ingress, XRv12 "swaps" this LDP local label for the TE label learned from CSR10 via RSVP. I say "swaps" because the LFIB shows a pop followed by a push, which is effectively a swap.

```

CSR1#show mpls ldp bindings 11.11.11.11 32 neighbor 12.12.12.12

```

We can run our traceroute tests again from the global and VPN tables to ensure the tunnel stitching was successful. The global table does not reveal any IP-only hops, and the VPN traffic has a fully MPLS-enabled path for transport. The TE label is topmost to steer traffic as needed, the LDP label is used at the stitch point to direct traffic towards the remote PE, and the VPN label remains unchanged at the bottom to represent the final destination. The second leg of the tunnel did not require tLDP since the tunnel terminates on the final PE.

```

We also don't have to fully stitch tunnels together. Another design option would be to tunnel traffic to XRv12, then let XRv12 use the dynamic LDP path to deliver it to XRv12. We still need LDP on the PE-P tunnel for the reasons outlined above, but stitching TE tunnels together is not a requirement. We can use a combination of LDP and RSVP for the PE-to-PE transport. We can test this by shutting down tunnel 23 on XRv12 (not shown). Now, XRv12 learns the route via IGP out of a non-TE interface, so an ordinary LDP label can be used. Since XRv12 is the penultimate hop, it can pop label 92003 in ingress rather than swap it, as shown in the LFIB.

The LSP is shorter by one hop, but the logic is the same. We verify the path in the global and VPN tables, noting that the initial TE and LDP labels are identical as before until XRv12 is introduced. CSR1 isn't aware of any changes in the path since the path from XRv12 to XRv11 was always beyond CSR1's purview.

31.2 TE Fast-ReRoute (FRR) and rapid provisioning

MPLS-TE is an excellent option for FRR. Other options, such as IP LFA, are much newer and not as widely supported. IP FRR is discussed in a dedicated sections.

31.2.1 Link (NHOP), Node (NNHOP), and Path protection – Manual

Using MPLS TE for fast reroute (FRR) is a very common way to achieve HA in MPLS networks. If a link or node within the path of a TE tunnel fails, a pre-sigaled backup path is available and traffic can be routed into the backup tunnel as soon as the failure is detected. TE FRR introduces some new terminology as well.

PLR: The point of local repair is the head-end of the backup path. When a failure is detected, it routes packets into the backup tunnel. This is much faster than signaling back to the original TE LSP headend to recalculate since the FRR occurs locally at the point of failure.

MP: The merge point is the tail-end of the backup path. When traffic arrives at the MP, it is routed along the normal TE path again, merging the traffic back on the original path. The PLR and MP work in concept to ensure that TE nodes upstream and downstream from the failure are minimally affected while FRR is active.

There are three main types of protection offered, in order from least to most desirable.

Path protection: Pre-signals a backup path from head to tail on a per path-option basis to be used in case of a failure anywhere along the path. Easy to configure and automatically protects all hops in the path without having to use PLRs. It is slowest to converge and scales the worst, and is not supported on XRv.

NHOP protection: Next-hop protection (link protection) protects the path to the next-hop by routing around failed links. This may scale better than NNHOP protection if many LSPs transit an LSR but have many different NNHOPs.

NNHOP protection: Next-next-hop protection (node protection) protects the path to the hop after the next-hop by routing around failed nodes. This offers better protection than NHOP but may not scale.

RFC 4090 details two ways of achieving FRR in the data-plane.

1. **N:1 or many-to-one or facility backup.** The PLR pushes a new FRR label (wraps the existing MPLS packet) as part of a new TE tunnel. The MP advertises a null label (implicit or explicit), effectively allowing it to see the original TE label so that the traffic can be merged easily since the incoming label would be the same as the main path. Many LSPs can be tunneled in the FRR tunnel in this way, providing more scalability at the low cost of 4 bytes extra encapsulation.

2. **1:1 or one-to-one or detour backup.** The PLR swaps the top label rather than pushes a new one. The MP advertises a normal label so the penultimate hop performs a label swap. This means that the label arriving at the MP will be different than the main path, and also different for each LSP. This scales poorly and isn't even supported in Cisco platforms.

We will configure a basic TE tunnel on CSR1 towards CSR8. CSR1 has two path options; the first is an explicit path through the network, the second is a secondary dynamic option requiring a green path and 2 Mbps. The tunnel uses auto-route destination to steer traffic into it, and also requests FRR protection.

```
! CSR1
mpls traffic-eng lsp attributes LSP_ATT_GREEN
  affinity 0x2 mask 0x2
  bandwidth 2000

ip explicit-path name PATH_1_3_10_6_8 enable
  next-address 3.3.3.3
  next-address 2.2.2.2
  next-address 10.10.10.10
  next-address 6.6.6.6
  next-address 8.8.8.8

interface Tunnel30
  description BASIC TE FRR
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 8.8.8.8
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name PATH_1_3_10_6_8
  tunnel mpls traffic-eng path-option 20 dynamic attributes LSP_ATT_GREEN
  tunnel mpls traffic-eng fast-reroute
```

Debugging RSVP message dumps on CSR3, we can see this FRR request inside the RSVP PATH message from CSR1. The outgoing path and incoming RESV are not shown, but the final RESV sent to CSR1 contains an RRO with additional detail; it includes the labels at each hop in the TE tunnel. It also records where the backup tunnels are in the network, and right now there aren't any. Each entry says there is "no local protection" so FRR isn't completely configured yet.

```

Before continuing, we can verify the TE tunnel is at least operational using MPLS OAM in the core and traceroute in the VPN. This shows us that auto-route is working properly and that there are no data-plane filters that might block traffic. It also allows us to verify the exact label values used to confirm it matches what the RESV RRO contained. The labels 3012, 10011, 6011, and implicit-null are shown in the RRO above.

```

```

First we will look at NHOP protection. Let's assume that the link between CSR3 and CSR10 is known to be unreliable [ID 30]. We know our tunnel transits this link but want to be able to route around it quickly if/when it fails. We configure CSR3 to be our PLR and CSR10 to be our MP; a new tunnel is created from CSR3 to CSR10 that specifically avoids this link using explicit-path excluding the link addresses. We can configure the tunnel however we like, including bandwidth reservations and affinity. The tunnel also requires colors green, blue, and orange. We also specify the outgoing interface through which the original tunnel (the one we are backing up) is transiting. This tells RSVP that RESV messages arriving on that interface can use Tunnel 30 as a facility backup if FRR is requested.

```

! CSR3
ip explicit-path name PATH_AVOID_CSR3_CSR10 enable
  exclude-address 132.3.10.3
  exclude-address 132.3.10.10

interface Tunnel30
  description REPAIR PATH (PLR)
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 10.10.10.10
  tunnel mpls traffic-eng affinity 0xE mask 0xE
  tunnel mpls traffic-eng path-option 10 explicit name PATH_AVOID_CSR3_CSR10

interface GigabitEthernet2.530
  mpls traffic-eng backup-path Tunnel30

```

We quickly verify that the backup tunnel comes up and doesn't traverse the link directly to CSR10. The tunnel routes through CSR2 to reach CSR10 and avoids the protected link.

```

CSR3#show mpls traffic-eng tunnels tunnel 30 | section Status|RSVP_Path
Status:
  Admin: up          Oper: up      Path: valid      Signalling: connected
  path option 10, type explicit PATH_AVOID_CSR3_CSR10 (Basis for Setup,
path weight 20)

RSVP Path Info:
  My Address: 132.2.3.3
  Explicit Route: 132.2.3.2 132.2.10.10 10.10.10.10
  Record Route: NONE
  Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

```

We check the RESV details on the tunnel head again and see that NHOP protection is now available to protect 3.3.3.3/32's "next-hop". This protects the link from CSR3 to CSR10 using a backup tunnel that avoids that link. We can see the flag is different for this hop (0x21 versus 0x20) compared to the ones that offer no protection. Notice that the output says "avail" but not "in use".

```

CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 30
Reservation:
  Tun Dest: 8.8.8.8 Tun ID: 30 Ext Tun ID: 1.1.1.1

```

On the PLR, we can verify the FRR configuration by checking the FRR database, which tracks the LSPs to be backed up along with the available FRR tunnels. Specifying the incoming label 3011, we can see how this specific LSP is being backed up. The summary view shows the incoming label, along with the ordinary LSP's outgoing interface and label. It also includes the FRR tunnel; because this entry is "ready" and not "active", we know FRR is not currently in effect.

```

CSR3#show mpls traffic-eng fast-reroute database labels 3011
[snip]
P2P LSP midpoint frr information:
LSP identifier          In-label Out intf/label    FRR intf/label    Status
-----
1.1.1.1 30 [19]        3011      Gi2.530:10010      Tu30:10010        ready

```

The final step in the configuration is configuring some kind of mechanism to detect a failed link. We can do this using RSVP hellos. Without a mechanism like this, RSVP will not be able to tell when the link fails, and will not be able to converge around it. The logic is identical to IGPs which necessitate some kind of active discovery mechanism when using TE-FRR. Enabling the command globally allows FRR to use the hellos, and it also needs to be enabled at the link level. We tune to timers to 5 second hellos with a neighbor being declared dead after 4 are missed, for a total of 20 seconds dead detection time.

```

! CSR3 and CSR10
ip rsvp signalling hello

interface GigabitEthernet2.530
  ip rsvp signalling hello
  ip rsvp signalling hello refresh interval 5000
  ip rsvp signalling hello refresh misses 4

```

Verifying on CSR3, we can see that RSVP hellos are enabled for FRR. CSR10 won't produce much output for the show commands because it is the "passive" side of the link. CSR3 is the tunnel head and has FRR bound to RSVP hellos as a client. The output even describes the difference between active and passive. The detailed output mostly shows various counters related to the session.

```

Debugging RSVP dumps, we can see the hellos being exchanged back and forth. The ordinary RSVP hello debugging does not yield any output. At this point we can assume everything is working properly. Different colors are used to identify the different hello messages (checksums will match).

To test FRR, we will temporarily remove the backup path-option from the main LSP. This will give us more time to analyze traffic inside the FRR tunnel. When an LSP fails and FRR kicks in, the RSVP PATHERR message is sent back towards the head-end, causing a recalculation using the next path-option in sequence. Once we remove the alternative path-option, there is no other choice, so traffic is stuck in the FRR tunnel for some time. It is good design to have alternate path options for this reason when FRR is in use.

! CSR1

```
interface Tunnel30
no tunnel mpls traffic-eng path-option 20 dynamic attributes LSP_ATT_GREEN
```

To break the link, we will change the encapsulation on CSR10 to an incorrect VLAN. Shutting down the interface triggers a graceful shutdown, allowing IGP and RSVP to converge immediately, which is not a good way to test FRR. First, we will enable RSVP signaling debugs on CSR1 and CSR3 so we can watch the error event propagation. We also start a ping with a 1 second timeout on CSR7 (within the VPN) to XRv14. We expect to see about 20 dropped packets since we know it takes RSVP 20 seconds to determine there was a failure (also depends on IGP timers).

! CSR10

```
interface GigabitEthernet2.530
encapsulation dot1Q 999
```

After ~20 seconds, CSR3 determines there is a failure and sends an RSVP PATHERR message back to CSR1. CSR3 no longer has any RSVP neighbors. CSR3 should have locally repaired the tunnel.

! CSR3

```

```

The labels have changed slightly from before since I was bringing the tunnel up and down for testing, but the output is clearly different. The FRR database shows this tunnel is "active". The label is still the ordinary TE label to CSR10. The new label pushed is 2010, so label 10012 is tunneled inside label 2010 across CSR2.

```
CSR3#show mpls traffic-eng fast-reroute database labels 3010 detail
FRR Database Summary:
  Protected interfaces      : 1
  Protected LSPs/Sub-LSPs  : 1

```

```
CSR3#show mpls traffic-eng tunnels tunnel 30 | include Label
InLabel   : -
OutLabel  : GigabitEthernet2.523, 2010
```

CSR1 receives this RSVP PATHERR message, which is a notification that the tunnel has been locally repaired. This is a good notification, but also informs CSR1 to recalculate a new path. The goal of TE-FRR is not to redirect traffic long-term, but to allow the PLR-to-head signaling to take place, and continue passing traffic during that short time. In this case, the head-end tunnel times out after several minutes, allowing us to view the process. CSR1 claims the tunnel is pending a reroute, but the tunnel remains up since it was locally repaired. The RSVP RESV details also show that NHOP protection is available, but is also "in use". The flags have changed again to indicate this.

```

```

On CSR7, we can see 18 dropped packets (275 - 257), which is approximately correct given the 20 second RSVP dead-peer detection time. Traffic is now using the FRR tunnel since CSR1 cannot recalculate a new path, given that we removed the backup path option. We can also confirm the imposition of the third label (FRR) on the PLR (CSR3), which tunnels traffic across the backup path to the MP (CSR10). The label arriving on CSR10 is the normal TE label, which means the backup tunnel can be used for many LSPs (facility backup).

Using RSVP hellos is very uncommon since BFD has been introduced. Like many other protocols, the TE-FRR process can be a BFD client, obviating the need to run a new dead peer detection mechanism. We will enable this on all XE-to-XE links in the topology; XRv does not support BFD, and XR in general does not support RSVP slow hellos. The configuration is almost identical to the RSVP hellos except we add the word "bfd" to the end. This cannot coexist with the legacy RSVP hellos, which must be removed first on CSR3 and CSR10 before configuring this (not shown). Checking CSR3, we can see that BFD for FRR is now enabled instead of RSVP hellos.

```
! All XE MPLS routers
ip rsvp signalling hello bfd

interface GigabitEthernet2.XXX
 ip rsvp signalling hello bfd

CSR3#show ip rsvp hello
Hello:
  RSVP Hello for Fast-Reroute/Reroute: Disabled
  Statistics: Disabled
  BFD for Fast-Reroute/Reroute: Enabled
  RSVP Hello for Graceful Restart: Disabled
```

BFD TE-FRR neighbors won't show up until a TE tunnel runs through it. As described in the BFD section, there is no neighbor discovery, but higher-level processes (TE-FRR) can notify BFD when they need fast fall-over. The signaling of the original LSP requesting FRR builds this. In this case, the main LSP is shutdown on CSR1 but the FRR tunnel is up. On the PLR (CSR3), we can see the details of the BFD neighbor with respect to TE-FRR now. This is a host-downstream neighbor as it is the NHOP of the backup TE tunnel.

```
CSR3#show ip rsvp hello bfd nbr detail

NeighAddr	LD/RD	RH/RS	State	Int
132.2.3.2	4100/4097	Up	Up	
Gi2.523				

Bringing up the original LSP adds two new TE-FRR clients to BFD, the PHOP (CSR1) and NHOP (CSR10), to use RSVP terminology. The RSVP details show the PHOP as a passive neighbor and the NHOP as an active neighbor. The NHOP neighbor is protected by FRR which is indicated by the value "1"; the output above has a zero since the backup tunnel is not protected by FRR.

```

We quickly check the RSVP RESV details on CSR1 to ensure the tunnel still has FRR and that enabling BFD did not break any RSVP signaling configuration. The PLR shows the backup tunnel as ready and shows the in/out labels for the original LSP from CSR1.

```
CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 30 |

1.1.1.1 30 [112]	3013	Gi2.530:10014	Tu30:10014	ready

Starting a ping from CSR7 and breaking the link again by changing encapsulation, we see the failover is about 1 second as BFD requires 900 ms for dead peer detections based on current configuration. The PLR marks this LSP as being actively protected, and the PLR's LFIB shows a label swap followed by a push. Not only did the traffic get re-routed faster, we removed another set of packets (RSVP hellos) from the network, saving some bandwidth and router resources.

```

```

We can also configure NNHOP protection, also called node protection. Rather than protect a link between two routers, we can avoid a node entirely. We will configure CSR9 with an FRR tunnel that avoids CSR6 completely, protecting the PLR's next-next-hop using any link colors. The destination of the tunnel should be the next-hop after the protected node, which is CSR8, the actual tail end. CSR8 is technically the MP also in this case. We can see this NNHOP backup tunnel goes through CSR9 to CSR8 after the tunnel is signaled.

```
! CSR10
ip explicit-path name PATH_AVOID_CSR6 enable
  exclude-address 6.6.6.6

interface Tunnel30
  description REPAIR PATH NNHOP (PLR)
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 8.8.8.8
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name PATH_AVOID_CSR6

interface GigabitEthernet2.560
  mpls traffic-eng backup-path Tunnel30
```

```
CSR10#show mpls traffic-eng tunnels tunnel 30 | section RSVP_Path
RSVP Path Info:
  My Address: 132.9.10.10
  Explicit Route: 132.9.10.9 132.8.9.8 8.8.8.8
  Record Route: NONE
  Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits
```

Checking CSR1, we can see that CSR10 is offering NNHOP (node protection) in connection with CSR3 offering NHOP (link) protection. Each individual hop in the TE LSP can offer different protection. We see that the NNHOP protection is available, but not in use, and the flags are different than the rest (0x29). In an ideal network, every single hop would have some kind of FRR protection.

```
CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 30 |
begin RRO
RRO:
  3.3.3.3/32, Flags:0x21 (Local Prot Avail/to NHOP, Node-id)

```

The RESV RRO shows label 10010 arriving to CSR10 along the LSP, so we can check the FRR database against this inbound label. Along the normal LSP, this inbound label is swapped to 6015 which is also present in the RESV RRO. When NNHOP protection is in use, we no longer need to preserve the NHOP label since CSR6 won't be seeing this traffic at all. Instead, we can swap label 10010 for label 9011, which is the FRR label in for the backup tunnel. Technically, this isn't a label swap operation, it is pushing implicit-null and then 9011, as we will see later. The router is probably smart enough to do a swap for efficiency reasons in this special case as the LFIB suggests.

```
CSR10#show mpls traffic-eng fast-reroute database labels 10010 detail
[snip]
P2P LSPs:
  Tun ID: 30, LSP ID: 137, Source: 1.1.1.1
  Destination: 8.8.8.8
  State       : ready
  InLabel     : 10010
  OutLabel    : Gi2.560:6015
  FRR OutLabel : Tu30:implicit-null

CSR10#show mpls traffic-eng tunnels tunnel 30 | include Label
  InLabel  : -
  OutLabel : GigabitEthernet2.590, 9011
```

Changing the encapsulation on CSR6 so the link to CSR10 fails, we see the PLR in action. Traffic is redirected into the tunnel and the LFIB reflects this. The FRR database is updated and a RESV message is sent to CSR1 notifying it that NNHOP protection is now activated on CSR10.

```

We confirm connectivity through this new path within the VPN. Notice there aren't 3 labels anymore since we don't need to tunnel traffic to the next-hop, thus preserving the original TE label. We can swap it to the FRR label since we are essentially taking a new path. Technically, we "pushed" the NNHOP's label to reach the tail-end, but since it was the same router, no additional label was needed. The next-next-hop label was 3, which means the tail-end and MP are the same router.

```

We can also have multiple FRR backup tunnels in use at the same time protecting the same LSP. Assuming the CSR3-CSR10 link fails at the same time CSR6 fails, both the NHOP and NNHOP backups can

be in use concurrently (link breaks not shown). We can verify this on each PLR by checking the FRR database and seeing both entries as "active". We can also verify within the VPN using traceroute; we see the NHOP protection across CSR2 and the NNHOP across CSR9 concurrently. I highlight the LSP information also (Tunnel ID 30, LSP ID 164) to prove it is the same TE tunnel.

A certain node may offer both NHOP and NNHOP protection concurrently. A router can provide multiple backup tunnels on a given interface as well. On CSR3, we will configure NNHOP protection (in addition to the NHOP protect) using a new tunnel [ID 31]. This will prefer a green path to the NNHOP, which is CSR6. We quickly verify the tunnel path; interestingly, it traverses CSR1, which looks like a loop, but technically is not since this is a different LSP. The path continues through CSR9 to merge onto CSR6.

```

```

We can check the FRR database to see that the original tunnel is now being backed up by the new NNNHOP tunnel and not the original NHOP tunnel at CSR3. TE tunnels requesting FRR will always prefer NNNHOP over NHOP when it is available (there are other comparison criteria which are evaluated in detail later). We confirm this protection on CSR1; notice that NNNHOP protection is available at both CSR3 and CSR10 now.

```

Notice that the outgoing label in the FRR database is the NNNHOP label of 6010. Normally, CSR10 would have performed the swap from 10013 to 6010, but assuming CSR10 fails, CSR3 will perform this swap from 3020 to 6010, and then push the FRR label of 1015.

```

1.1.1.1 30 [212]	3020	Gi2.530:10013	Tu31:6010	ready

We quickly test this new NNHOP protection by changing the encapsulation on CSR10's link to CSR3. Rather than avoiding that link, CSR3 will now avoid CSR10 entirely, making CSR6 the MP and using CSR6's local label for the original LSP for merging. The FRR database marks this entry as active since FRR is in effect.

We can also set a special flag in the RSVP PATH message to signal that node protection should be preferred over link protection. Because IOS XE and XR both automatically prefer NNHOP over NHOP, this option doesn't do much, but may help in multi-vendor environments where the explicit flag in the RSVP PATH message is used to select NNHOP. The PATH and RESV messages are shown below. The PATH message shows the "node-protection desired" flag while the RSV message is unchanged, since NNHOP protection is already preferred on CSR3 (PLR).

```

Another special flag can be assigned to request bandwidth protection. This is used as a tie-breaker when there are FRR tunnels with an aggregate bandwidth greater than the aggregate bandwidth offered by the set of FRR tunnels. FRR tunnels will request bandwidth, and backup tunnels can provide it. Reserving bandwidth on backup tunnels can be wasteful/inefficient (it is an option, though). Alternatively, we can specify the backup bandwidth on the repair tunnels. This serves as an admission control mechanism to ensure that, when using facility backups, there isn't an oversubscription of bandwidth inside backup tunnels for primary TE LSPs that require dedicated bandwidth. The bandwidth is not actually reserved in the TED, but it does help balance the FRR flows across various backup paths when a failure occurs. The main tunnel requests 1 Mbps of bandwidth, while the NHOP and NNHOP backups on CSR3 offer 3 Mbps

and 2 Mbps of backup bandwidth, respectively. We can see the PATH message "bandwidth-protection desired" flag set, and the RESV message also indicates that bandwidth protection is enabled for that hop using the NNHOP tunnel.

```

If we configure the main TE LSP to request more bandwidth than the NNHOP tunnel can provide, but the NHOP tunnel can provide it, the NHOP tunnel is preferred since bandwidth-protection was enabled. NNHOP tunnels with no bandwidth are still preferred over NHOP tunnels with explicit bandwidth, even when bandwidth-protection is configured. This is because a backup tunnel with “no” bandwidth is assumed to have unlimited bandwidth. The exact sequence of preferences is detailed more in the DS-TE section.

```

Bandwidth protection takes precedence over node protection when both flags are set concurrently in the PATH message. Even after adding the node-protection flag to the main LSP head-end, the NHOP tunnel is preferred due to the bandwidth-backup request.

Because the vast majority of the TE-FRR configuration and complexities lies with the PLR, we will not be testing this again with XRv as it does not support BFD. However, we will configure dummy tunnels on XRv11 to show the syntax for the features and perform basic control-plane verifications of the RSVP signaling. The head-end LSP is shown below, which requests FRR, along with node protection and bandwidth protection. We also verify the tunnel comes up.

```

TUNNEL NAME	DESTINATION	STATUS	STATE
tunnel-te30	8.8.8.8	up	up

We can check the locally-generated RSVP PATH message to verify the flags: local protection, node protection, and bandwidth protection are all enabled. Because we have built this tunnel over the CSR3-CSR10 link, we have the NHOP and NHHOP tunnel protection there, as well as the NNHOP protection CSR10-CSR6. The RSVP RESV message doesn't show this in XR, so we look at the TE tunnel details instead. Specifically, we can see there is protection available, along with bandwidth protection, at CSR3. The word "node" does not appear, so we assume this is NHOP protection. At CSR10, we have available "node" protection (NNHOP) but no bandwidth protection. The XR outputs are more difficult to interpret than the XE ones inside the RESV message, but the summary information shown near the beginning is succinct and clear.

```

```

Backup tunnel configuration is similar to XE as the backup tunnel itself has no special characteristics and is not shown. Assigning a backup tunnel to a link is shown below.

```

! XRv11
interface tunnel-te31
 description DUMMY BACKUP PATH
 shutdown

mpls traffic-eng
 interface GigabitEthernet0/0/0/0.551
  backup-path tunnel-te 31

```

Link and node protection are the best ways to do TE-FRR. An alternative exists which is a little slower and less scalable, but not nearly as slow as having disparate path-options. This is called path protection, which is configured on a per path-option basis and is used to backup that path-option. In addition to the main path-option, this “protecting” or “backup” path is pre-sigaled. In IOS, backup-paths must be explicit, while the main path can be explicit or dynamic. As soon as the head-end receives the PATHERR message from the network core, it can immediately switch traffic over into the backup tunnel. This is still slower than NHOP/NNHOP protection since local repair is always faster, but it does not require any

configuration changes in the network core. This might be a compromise if different organizations/administrators control P routers versus PE routers. We can create a list of backup path-options to allow multiple choices for a single path-option we want to backup. Only the best option in the list is pre-sigaled. These backup paths cannot use NHOP/NNHOP protection for themselves, since they are backup paths already. For efficiency, we can re-use some older explicit-paths for backup options. There is no reliance on RESV RROs with label recording as the headend performs the rerouting (no concept of PLR).

```
! CSR1
ip explicit-path name EP_1_4_3_10_11 enable
  next-address 4.4.4.4
  next-address 3.3.3.3
  next-address 10.10.10.10
  next-address 11.11.11.11

mpls traffic-eng path-option list name POPT_LIST

```

```
CSR1#show ip rsvp reservation detail filter session-type 7 destination
11.11.11.11 | include Label|LSP_ID
  Tun Sender: 1.1.1.1  LSP ID: 33
  Label: 3022 (outgoing)
  Tun Sender: 1.1.1.1  LSP ID: 34
  Label: 4014 (outgoing)
```

Verifying the tunnel status, we see that the ordinary path-option 10 is used for the tunnel setup. The path protection engine tells us that the primary and backup paths share 1 link and 2 nodes, which is not ideal. Normally you would ensure the two paths were as different as possible so that the failure of a single link/node doesn't break both paths. Path-option 100 was the most desirable backup option and is the "basis for protect".

```
CSR1#show mpls traffic-eng tunnels tunnel 32 | section Status
Status:
  Admin: up      Oper: up      Path: valid      Signalling: connected
  path option 10, type explicit EP_1_4_3_10_11 (Basis for Setup, path
weight 40)
  Path Protection: 1 Common Link(s), 2 Common Node(s)
  path protect option 10, type list name POPT_LIST
  Inuse path-option 100, type explicit (Basis for Protect, path weight
50)
```

For additional detail on the two paths, we can look at the specific protection attributes of the tunnel. We can see that the CSR10-XRv11 connection is the common link, with CSR3 and CSR10 being the common nodes.

```
CSR1#show mpls traffic-eng tunnels tunnel 32 protection
PATH PROTECTION
LSP Head, Tunnel32, Admin: up, Oper: up
Src 1.1.1.1, Dest 11.11.11.11, Instance 34
Fast Reroute Protection: None
Path Protection: 1 Common Link(s), 2 Common Node(s)
Primary lsp path: 132.1.4.4 132.3.4.3
                  132.3.10.10 132.10.11.11
                  11.11.11.11
Protect lsp path: 132.1.3.3 132.3.9.9
                  132.2.9.2 132.2.10.10
                  132.10.11.11 11.11.11.11
```

A quick look on XRv11 shows both tunnels terminating. This helps prove that the backup path is fully signaled in advanced.

```
RP/0/0/CPU0:XRv11#show rsvp reservation destination 11.11.11.11
Destination Add DPort      Source Add SPort Pro   Input IF Sty Serv   Rate Burst
-----
11.11.11.11  32      1.1.1.1  33    0      No  SE  LOAD  3000K  1K
11.11.11.11  32      1.1.1.1  34    0      No  SE  LOAD   0    1K
```

Using autoroute destination for simplicity, traffic from CSR1 to XRv11 now traverses this tunnel. We can test it from inside the VPN, expecting to see label 4014 at the first MPLS hop.

```

```

Assuming CSR4's link to CSR1 fails (not shown), the backup path should route around it. We know this is not a shared link or shared node, so the backup path is still effective according to the protection details we saw earlier. Shortly after shutting down this interface, we send additional VPN traffic to verify the new label 3022 is used along the backup LSP. We can also verify the tunnel status to see the backup path in use. The closer the failure is to the head-end, the less distance the PATHERR has to travel, which means faster convergence. With NHOP/NNHOP FRR, the failure location is irrelevant, which leads to a more consistent FRR behavior.

```

CSR7#traceroute 13.13.13.13 source 7.7.7.7
Type escape sequence to abort.

```

To verify the control-plane in greater details, we can check CSR1's tunnel information. Several log messages indicate that the main path via CSR4 is no longer available and that path-protection is now in use.

```

! CSR1
%MPLS_TE-5-LSP: LSP 1.1.1.1 32_35: No addresses to connect 1.1.1.1 to 4.4.4.4
%MPLS_TE-5-LSP: LSP 1.1.1.1 32_34: DOWN: path verification failed
%MPLS_TE-5-TUN: Tun32: installed LSP nil for 32_34 (popt 10), path
verification failed
%MPLS_TE-5-TUN: Tun32: LSP path change nil for 32_34, path verification
failed
%MPLS_TE-5-TUN: Tun32: installed LSP 32_33 (popt 10) for nil, Path protected
LSP failure
%MPLS_TE-5-TUN: Tun32: LSP path change 32_33 for nil, protected failure

```

The tunnel status and protection details essentially say that the backup LSP is now in use. The tunnel details are a bit redundant, but the message is clear.

```
CSR1#show mpls traffic-eng tunnels tunnel 32 | section Status
Status:
  Admin: up      Oper: up      Path: valid      Signalling: connected
  path protect option 10, type list name POPT_LIST
  Inuse path-option 100, type explicit (Basis for Protect, path weight
50)
  path option 10, type explicit EP_1_4_3_10_11
  Path Protection: Backup lsp in use.
  path protect option 10, type list name POPT_LIST
  Inuse path-option 100, type explicit (Basis for Protect, path weight
50)
```

```
CSR1#show mpls traffic-eng tunnels tunnel 32 protection
PATH PROTECTION
  LSP Head, Tunnel32, Admin: up, Oper: up
  Src 1.1.1.1, Dest 11.11.11.11, Instance 33
  Fast Reroute Protection: None
  Path Protection: Backup lsp in use.
```

RSVP is only tracking one reservation now for the backup LSP. Notice that the LSP ID for the backup path is the same, so the LSP has never been resigned, as expected.

```
CSR1#show ip rsvp reservation
To          From      Pro DPort Sport Next Hop      I/F      Fi Serv BPS
11.11.11.11 1.1.1.1 0    32    33    132.1.3.3    Gi2.513  SE LOAD 3M
```

Bringing CSR4's interface back up will cause the original path-option to recompute and ultimately preempt the backup path. At this point, both the main and backup paths are resigned (new LSP IDs) but no traffic is lost during the transition. The primary LSP is signaled first, then the traffic is moved onto it. Shortly thereafter (probably concurrently), the backup path is torn down and resigned per the "new" path option. Remember that this technique allows multiple path-options to have multiple different backup paths, and the backup paths are only used for a short time until the alternative "primary" path-options are available.

```
CSR1#show ip rsvp reservation
To          From      Pro DPort Sport Next Hop      I/F      Fi Serv BPS
11.11.11.11 1.1.1.1 0    32    42    132.1.4.4    Gi2.514  SE LOAD 0
11.11.11.11 1.1.1.1 0    32    43    132.1.3.3    Gi2.513  SE LOAD 3M
```

The feature is very similar on XR. XR is more flexible with its backup options since the backup can also be dynamic. However, XR does not support backup path-option lists, so only one backup can be specified per path-option. In this example, we re-use an old explicit-path and back it up with any blue path.

```

! XRv1
interface tunnel-te32
  description PATH PROTECTION
  ipv4 unnumbered Loopback0
  logging events all
  destination 1.1.1.1
  affinity ignore
  path-option 10 explicit name PATH_11_5_2_3_4_1 protected-by 100
  path-option 100 dynamic attribute-set ATT_BLUE

mpls traffic-eng
  attribute-set path-option ATT_BLUE
  affinity include 0x4

```

RSVP only shows one LSP, which is incorrect. There is a missing step to actually enable the feature.

```

RP/0/0/CPU0:XRv11#show rsvp reservation destination 1.1.1.1

```

Destination	Add	DPort	Source	Add	SPort	Pro	Input	IF	Sty	Serv	Rate	Burst
1.1.1.1		32	11.11.11.11		2	0	Gi0/0/0/0.551		SE	LOAD	0	1K

To actually activate the feature we need to enable it explicitly. The command to do so is not supported on XRv, but the remaining configuration will be left in place.

```

! XRv11
interface tunnel-te32
  path-protection
!!% The requested operation is not supported: Path-protection is not
supported on this platform

```

There are some additional minor options with respect to MPLS TE also. We can also specify how often the router scans for protected LSPs to "promote". This refers to selecting a better backup path when many are available. The value of 0 disables promotion, and this is the default. We will set the timer to one day (3600 seconds * 24 hours).

```

CSR1#show mpls traffic-eng tunnels brief | include Promotion
Periodic FRR Promotion: Not Running

```

```

! CSR1
mpls traffic-eng fast-reroute timers promotion 86400

```

```

CSR1#show mpls traffic-eng tunnels brief | include Promotion
Periodic FRR Promotion: every 86400 seconds, next in 86395
seconds

```

We can quickly configure this on XRv11 as well, as the syntax is very similar. There does not appear to be a mechanism to verify this configuration, though.

```
! XRv11
mpls traffic-eng
  fast-reroute timers promotion 86400
```

By default, the router does not reoptimize a tunnel when a new link in the TED comes up. This is true for newly-configured links or failed links that return to service. While it seems valuable for existing LSPs to use these new links, this can introduce churn into the network which is why it is disabled. For networks where tunnel optimization is more important than stability/flooding, we can enable this behavior globally. We will use CSR8 and XRv12 to configure these reoptimization features.

```
! CSR8
mpls traffic-eng reoptimize events link-up
```

```
! XRv12
mpls traffic-eng
  reoptimize events link-up
```

There are several reoptimization timers as well. We can delay how long an old tunnel can remain signaled before removing it after reoptimization. This might be valuable to have both tunnels active for a longer period of time in case the newly optimized tunnel fails. This is controlled with the "cleanup" timer. Additionally, we can delay the time before using the newly optimized tunnel. This is the "installation" timer and it should be less than the cleanup timer. In XE, the default cleanup timer is 10 seconds and the default installation timer is 3 seconds. This means that a newly optimized tunnel won't be used for 3 seconds, and 7 seconds later, the old tunnel is torn down. We will adjust the values slightly to 4 and 11 seconds so that the 7-second "dual tunnel" timer difference still exists. Increasing these delays can also ensure that older routers have time to program the new, optimized LSP labels into the LFIB, which may take time. If the traffic switches over to the new path too quickly, packet loss may occur. The defaults in XR are 20 seconds for delay and 20 seconds for installation, so the switchover and teardown happens at about the same time.

```
! CSR8
mpls traffic-eng reoptimize timers delay installation 4
mpls traffic-eng reoptimize timers delay cleanup 11
```

```
! XRv12
mpls traffic-eng
  reoptimize timers delay cleanup 11
  reoptimize timers delay installation 4
```

XR also supports some additional delay options. When a head-end router receives a PATHERR notifying it that FRR has occurred (from the PLR) we can delay how long to wait before reoptimizing. The default is 0 seconds, which makes sense since using FRR for extended periods of time is not optimal. Assuming path-protection was supported on XRv, we can also delay the time before trying to reoptimize a primary

path. This timer is 3 minutes (180 seconds) by default, which is very long, but since the backup path is pre-sigaled and assumed to be good, there isn't a rush. We will set it to 0 to disable it, which would imply the backup path is used forever. Last, we can delay tunnel reoptimization when an affinity failure occurs. If there isn't a path using the proper link colors, we can delay the subsequent attempts to find a path, assuming there are multiple path-options. The command is not hidden, but also does not appear to be documented.

```
! XRv12
mpls traffic-eng
  reoptimize timers delay after-frr 5
  reoptimize timers delay path-protection 0
  reoptimize timers delay after-affinity-failure 15
```

The path-protection reoptimization timer command isn't supported on XRv, but other commands are.

```
! XRv12
mpls traffic-eng
  reoptimize timers delay path-protection 0
!!% The requested operation is not supported: Path-protection is not
supported on this platform
```

Tunnels are automatically reoptimized every hour (3600 seconds) by default. We can also control this timer globally as well. A value of 0 disables periodic reoptimization, which we configure for variety. The command is significantly different on XE and XR.

```
! CSR8
mpls traffic-eng reoptimize timers frequency 0
```

```
! XRv12
mpls traffic-eng
  reoptimize 0
```

We can determine how often TE information is flooded when bandwidth changes on a per-link basis. Flooding this information too frequently can result in excessive overhead and tunnel churn. Infrequent flooding leads to outdated decision-making and bandwidth admission control. In our case, we set some new thresholds so that at 25%, 50%, and 100% of bandwidth thresholds, the TE information is reflooded. Ideally it makes sense to configure this consistently everywhere, but we will limit it to CSR3's link to CSR10 for demonstration. The default triggers for down/up are shown below. The defaults represent a more balanced model than the demonstration below and I would recommend using the default values. Regardless of these thresholds, an LSP that fails to get set up will trigger a reflood. XR has a similar configuration, and we configure this on the XRv11 link facing CSR10 for demonstration purposes.

```
! CSR3
interface GigabitEthernet2.530
```

```
mpls traffic-eng flooding thresholds up 25 50 100
mpls traffic-eng flooding thresholds down 100 50 25
```

```
! XRv11
mpls traffic-eng
interface GigabitEthernet0/0/0/0.501
  flooding thresholds up 25 50 100
  flooding thresholds down 100 50 25
```

```
CSR3#show mpls traffic-eng link-management bandwidth-allocation gig2.513 |
include Threshold
  Up Thresholds:   15 30 45 60 75 80 85 90 95 96 97 98 99 100 (default)
  Down Thresholds: 100 99 98 97 96 95 90 85 80 75 60 45 30 15 (default)
```

```
CSR3#show mpls traffic-eng link-management bandwidth-allocation gig2.530 |
include Threshold
  Up Thresholds:   25 50 100
  Down Thresholds: 100 50 25
```

```
RP/0/0/CPU0:XRv11#show mpls traffic-eng link-management bandwidth-allocation
interface gig0/0/0/0.551 | include Threshold
  Up Thresholds   : 15 30 45 60 75 80 85 90 95 96 97 98 99 100 (default)
  Down Thresholds : 100 99 98 97 96 95 90 85 80 75 60 45 30 15 (default)
```

```
RP/0/0/CPU0:XRv11#show mpls traffic-eng link-management bandwidth-allocation
interface gig0/0/0/0.501 | include Threshold
  Up Thresholds   : 25 50 100
  Down Thresholds : 100 50 25
```

We can also adjust some link-level parameters as well with respect to flooding and bandwidth. On both XE and XR, we can specify how long bandwidth should be held on an interface when a PATH message is sent out of it, while waiting for a RESV to come back in. If the PATH messages are lost, the bandwidth should not remain reserved forever, as the LSP will be invalid. The default is 15 seconds. We can also adjust how frequently link-state information is flooded on each link; this is different than the flooding thresholds which were bandwidth based (event-driven). This is 3 minutes (180 seconds) by default on XR and 60 seconds by default in XE, and we will disable it by using a value of 0. This is not recommend since it relies entirely on the bandwidth threshold process for updated flooding, which by definition is less accurate.

```
! CSR8
mpls traffic-eng link-management timers periodic-flooding 0
mpls traffic-eng link-management timers bandwidth-hold 16

! XRv12
mpls traffic-eng
  link-management timers bandwidth-hold 16

To support uniform and ling-pipe MPLS QoS models (described in another section), we can tell the TE process to allocate explicit-null labels on the tail end.

```
! CSR8
```

```
mpls traffic-eng signalling advertise explicit-null
```

```
! XRv12
```

```
mpls traffic-eng
```

```
signalling advertise explicit-null
```

Using tunnel30 on CSR1, which was the tunnel requesting FRR from CSR1 to CSR8, we observe the result of this command. The RRO clearly shows label 0, which is IPv4 explicit-null, as opposed to label 3, which is implicit-null. However, when we check the LFIB of CSR6, we can see it is still performing PHP.

```
CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 30
```

Reservation:

Tun Dest: 8.8.8.8 Tun ID: 30 Ext Tun ID: 1.1.1.1

! 4 132.6.8.8 23 ms
```

XR is a little more intelligent and automatically assumes that receiving an exp-null label in the RSVP RESV message is a good enough reason to use it. We configure XRv11 to allocate explicit-null labels with a tunnel that traverses XRv12; we will reuse tunnel2 on CSR1.

```
! XRv11
mpls traffic-eng
  signalling advertise explicit-null
```

```
RP/0/0/CPU0:XRv11#show rsvp reservation session-type lsp-p2p dst-port 2
detail | include Label
Labels: Local downstream: 0.
```

```
RP/0/0/CPU0:XRv12#show mpls traffic-eng tunnels role mid detail | include
Label
InLabel: GigabitEthernet0/0/0/0.562, 92010
OutLabel: GigabitEthernet0/0/0/0.512, explicit-null
```

```
RP/0/0/CPU0:XRv12#show mpls forwarding | include Exp
92010 Exp-Null-v4 2 Gi0/0/0/0.512 132.11.12.11 0
```

We can confirm this is operational using MPLS OAM. We cannot test it within the VPN since there isn't a steering mechanism for this tunnel, but seeing explicit-null in the label stack shows it is working correctly.

```

When backing up LSPs with bandwidth-protection, routers will typically try to minimize the number of LSPs pre-empted. Tunnels requesting bandwidth protection take priority over those that don't, so if a backup tunnel has no admission, non-bandwidth-protected LSPs can be pre-empted by those that are. We can alternatively configure the feature to minimize the amount of wasted bandwidth by packing each backup tunnel full with as many LSPs as possible (more efficient). More preemption may occur as a result of this increased backup bandwidth efficiency. We will enable the bandwidth optimization on CSR3.

```
CSR3(config)#mpls traffic-eng fast-reroute backup-prot-preempt ?
optimize-bw Reduce bandwidth wastage (default: minimize LSPs preempted)
```

31.2.2 Automatic tunnels (with OSPF)

This section uses a similar topology as the main TE topology with some minor changes. First, OSPF is used, mostly because it supports a feature for auto-tunnels not supported in IS-IS. It also allows us to test OSPF briefly with TE, although its behavior is generally identical to IS-IS. Additionally, many link colors have been removed for simplicity as they are mutually exclusive with some types of auto-tunnels. The diagram does not specify these uncolored links with "X"; they are simply blank.

Examining basic OSPF TE extensions, we can see there are several new LSAs inside of area 0. Specifically, there are 47 Opaque-Area (LSA-10) LSAs which carry the TE information. These are flooded only within an area, much like LSA1 and LSA2.

```
CSR1#show ip ospf 132 0 database database-summary
```

```
OSPF Router with ID (1.1.1.1) (Process ID 132)
```

```
Area 0 database summary
```

LSA Type	Count	Delete	Maxage
Router	9	0	0
Network	0	0	0
Summary Net	0	0	0
Summary ASBR	0	0	0
Type-7 Ext	0	0	0
Prefixes redistributed in Type-7	0		
Opaque Link	0	0	0
Opaque Area	47	0	0
Subtotal	56	0	0

Looking into the details of CSR1's local-originated LSAs, we see 6 different LSAs. OSPF generates one LSA10 to represent the node itself, which always has the Link ID of 1.0.0.0. The other LSA10s represent each one of CSR1's TE-enabled links, of which there are 5.

```
CSR1#show ip ospf 132 0 database self-originate
```

```
OSPF Router with ID (1.1.1.1) (Process ID 132)
```

```
Router Link States (Area 0)
```

Link ID	ADV Router	Age	Seq#	Checksum	Link count
1.1.1.1	1.1.1.1	303	0x80000005	0x00F0AE	6

```
Type-10 Opaque Link Area Link States (Area 0)
```

Link ID	ADV Router	Age	Seq#	Checksum	Opaque ID
1.0.0.0	1.1.1.1	359	0x80000001	0x0058D1	0
1.0.0.7	1.1.1.1	303	0x80000001	0x005681	7
1.0.0.8	1.1.1.1	322	0x80000001	0x0007C8	8
1.0.0.9	1.1.1.1	345	0x80000001	0x002B91	9
1.0.0.11	1.1.1.1	344	0x80000001	0x00D3DC	11
1.0.0.12	1.1.1.1	347	0x80000001	0x008424	12

To prove that the LSAs are only created for TE-enabled links, we will disable TE tunnels on the link to CSR4 (not shown). CSR1 immediately MAXAGEs the corresponding LSA10 to mark it for deletion. It is flushed seconds later.

```
CSR1#show ip ospf 132 0 database self-originate
```

```
OSPF Router with ID (1.1.1.1) (Process ID 132)
```

```
Router Link States (Area 0)
```

Link ID	ADV Router	Age	Seq#	Checksum	Link count
1.1.1.1	1.1.1.1	853	0x80000005	0x00F0AE	6

```
Type-10 Opaque Link Area Link States (Area 0)
```

Link ID	ADV Router	Age	Seq#	Checksum	Opaque ID
1.0.0.0	1.1.1.1	909	0x80000001	0x0058D1	0
1.0.0.7	1.1.1.1	853	0x80000001	0x005681	7
1.0.0.8	1.1.1.1	3608	0x80000002	0x00B77A	8
1.0.0.9	1.1.1.1	895	0x80000001	0x002B91	9
1.0.0.11	1.1.1.1	894	0x80000001	0x00D3DC	11
1.0.0.12	1.1.1.1	897	0x80000001	0x008424	12

Before continuing, we re-enable the TE configuration on the link to CSR4. The LSA10 with Link ID 1.0.0.0 is very simple, containing only the TE-RID. It does not represent a link, but only the TE node (vertex) itself. One of the remaining five LSAs is examined to show what the link-based variant contains. This shows all expected details, such as everything you'd see in an LSA-1 (link type, local/remote addresses, etc) plus the TE information. It is clearly shown in the output and needs no explanation. Also notice that the bandwidth is measured in Bps (bytes/sec), and 1.25 MBps is equivalent to 1 Gbps.

Like with IS-IS, the link between CSR2 and CSR3 is a broadcast network, which means a DR is elected and a corresponding LSA2 is originated by that DR. This appears slightly different to the TE topology. There aren't any new LSAs, but CSR3's "Link ID" in the LSA shows the DR address, which is CSR3. The TE topology show commands that are protocol-agnostic are still identical to IS-IS in this regard and are not shown again. The TE process can interpret this topology properly since the existing LSA1/LSA2 are still in the OSPF LSDB and available for review.

A quick look on XRv11 shows similar output. Link ID 1.0.0.0 represents the local node, and the other 3 represent XRv11's TE-enabled links. The details of the node and a single LSA are shown below. XR supports the extended administrator group (EAG), which allows for additional affinity extensions. The EAG is an array of 32-bit unsigned integers of length 8, effectively creating 256 possible colors. Like XE, the bandwidth is still measured in Bps (it even says so in the output).

The first type of auto-tunnels we will examine are backup. Much like the NHOP and NNHOP tunnels we configured in previous sections, Cisco has a mechanism to automatically create these backup tunnels based on LSPs flowing through a router. The manual mechanism required a backup tunnel to be

manually configured, then assigned to an interface as a candidate backup. For a large-scale network, these backups would ideally exist to protect every link and/or every node in the SP core. Manually configuring these (even if done by a controller) can be time consuming and make the configuration very long. To test it, we will configure a basic TE tunnel from CSR1 to XRv11. We will use an explicit-path to take a long route intentionally to maximize testing. We verify the tunnel is operational with the RRO inside the RSVP RESV message.

```
! CSR1
ip explicit-path name EP_1_4_3_2_10_12_11 enable
  next-address 4.4.4.4

```

We will enable CSR3 to provide NHOP and NNHOP protection for this LSP. Enabling "auto-tunnel backup" is done in global configuration and applies to any LSP transiting the router. First, we will enable the tunnels without any fancy options. We only need one command for this and will enable debugging to see the result. The debug is very straightforward to read since it shows the exact commands used to build the backup tunnels. We can see that the tunnel enumeration starts at 65436, which is the first number in the default range of 65436 - 65535 (100 tunnels). Logging is disabled for the tunnels and loopback0 is used for the IP address by default. The process automatically removes affinity configurations (which is odd as there are none) and relies on the default affinity of 0x0 / mask 0xFFFF. So far, this is OK, since most of the links are colorless. The explicit-path that is generated for tunnel65436 is supposed to avoid using CSR3's link to CSR2; this is an NHOP tunnel. The process repeats again for tunnel65437, which is identical in every way except is configured to avoid CSR2 by Node-ID; this is an NNHOP tunnel. Auto-tunnel backup will always try to make NHOP and NNHOP tunnels by default for each LSP it protects.

```
! CSR3
mpls traffic-eng auto-tunnel backup

CSR3#debug mpls traffic-eng auto-tunnel backup all

```
CSR3#show ip rsvp sender detail filter session-type 7 tunnel-id 65437 |  
section outgoing  
ERO: (outgoing)  
132.3.10.10 (Strict IPv4 Prefix, 8 bytes, /32)  
10.10.10.10 (Strict IPv4 Prefix, 8 bytes, /32)
```

The protected LSP uses label 3016 when sending traffic to CSR3. Checking the FRR database against this label, we see an entry showing that the NNHOP tunnel is currently available (but not in use) and using label 10014. We can confirm this update in the original RSVP RESV message on the headend. NNHOP is preferred over NHOP when both are available and all other parameters are equal (backup bandwidth, etc). All labels show in the FRR database are present in the RESV RRO of the protected LSP.

```
CSR3#show mpls traffic-eng fast-reroute database labels 3016 detail | begin  
100  
Tun ID: 100, LSP ID: 2, Source: 1.1.1.1  
Destination: 11.11.11.11

Label subobject: Flags 0x1, C-Type 1, Label 10014

[snip]

To quickly test the NNHOP backup tunnel, we will break the link to CSR2 by changing the encapsulation on the link to CSR3 (not shown). The auto-tunnel process is just used for provisioning; everything else is just normal TE-FRR. CSR1 receives a PATHERR message from CSR4 that the tunnel was locally repaired. Because there were no other path-options available, the tunnel cannot presently be reoptimized around the failure, and traffic will remain in the TE-FRR tunnel.

```
! CSR1
%MPLS_TE-5-LSP: LSP 1.1.1.1 100_2: Path Error from 132.3.4.3: Notify: Tunnel
locally repaired (flags 0)
%MPLS_TE-5-LSP: LSP 1.1.1.1 100_3: No addresses to connect 3.3.3.3 to 2.2.2.2
```

We verify that the PLR shows the NNHOP tunnel as active for the protected LSP and now swaps label 3016 for label 10014. Notice that a label push need not occur since the PLR and MP are directly connected; the PLR learned label 10014 from the RESV RRO so from CSR10's perspective, the LFIB has not changed.

```
CSR3#show mpls traffic-eng fast-reroute database labels 3016 detail | begin
100
```

```
Tun ID: 100, LSP ID: 2, Source: 1.1.1.1

Label subobject: Flags 0x1, C-Type 1, Label 10014
[snip]
```

To reduce the number of tunnels required, we can configure the auto-tunnel process to only create NHOP tunnels. These may scale better; if there were many LSPs going from CSR2 to CSR3, but then from CSR3 to many different next-hops, many NNHOP tunnels would be required, when a single NHOP tunnel could at least protect a commonly used link. Debugging shows the auto-tunnel process deleting both tunnels from the configuration, which is followed by several syslog messages to indicate it. Notice that the original NHOP tunnel is then resigaled as a result of the configuration change. Tunnel 65337 is shutdown (NNHOP) and tunnel65436 is signaled (NHOP).

```
! CSR3
mpls traffic-eng auto-tunnel backup nhop-only
```

```
TE_AUTO_TUN: backup CLI command:
no ip explicit-path name __dynamic_tunnel65436
end
```

```
TE_AUTO_TUN: backup CLI command:
no ip explicit-path name __dynamic_tunnel65437
end
```

```
TE_AUTO_TUN: FRR lopri process rcv msg TSPTUN_CREATE_BACKUP, ready=1
TE_AUTO_TUN: Create Auto tunnel
TE_AUTO_TUN: backup CLI command:
interface tunnel65436
no logging event link-status
ip unnumbered Loopback0
tunnel destination 2.2.2.2
tunnel mode mpls traffic-eng
end
```

```
TE_AUTO_TUN: backup CLI command:
interface tunnel65436
no tunnel mpls traffic-eng affinity
end
```

```
TE_AUTO_TUN: CLI command:
ip explicit-path name __dynamic_tunnel65436
index 1 exclude-address 132.2.3.3
```

```
TE_AUTO_TUN: backup CLI command:
interface tunnel65436
tunnel mpls traffic-eng path-option 1 exp name __dynamic_tunnel65436
end
```

```
%MPLS_TE-5-TUN: Tun65436: installed LSP 65436_1 (popt 1) for nil, got 1st
feasible path opt
%MPLS_TE-5-LSP: LSP 3.3.3.3 65437_1: DOWN: signalling shutdown
%MPLS_TE-5-TUN: Tun65437: installed LSP nil for 65437_1 (popt 1), signalling

%MPLS_TE-5-LSP: LSP 3.3.3.3 65436_1: UP
%MPLS_TE-5-TUN: Tun65436: LSP path change 65436_1 for nil, normal
```

Now, we can see that the “Nhop Only” flag has changed to yes in the auto-tunnel backup summary.

```
CSR3#show mpls traffic-eng auto-tunnel backup
State: Enabled
  Auto backup tunnels: 1 (up: 1, down: 0)
  Tunnel ID Range: 65436 - 65535
  Create Nhop Only: Yes
  Check for deletion of unused tunnels every: 3600 Sec
  SRLG: Not configured

Config:
  unnumbered-interface: Loopback0
  Affinity/Mask: 0x0/0xFFFF
```

We check the RSVP RESV RRO on the head-end to see if the labels have changed on the original LSP (it has been signaled a few times). The RRO also shows that NHOP protection is available. The local label for CSR3 is now 3015, so we check the TE-FRR database on CSR3 to ensure there is an entry for it. We can tell this is an NHOP tunnel since the FRR label is the same as the outlabel, which indicates the NHOP label is persistent. The PLR will just push a new label in the path to the MP.

```
CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 100 |
begin RRO
RRO:
  4.4.4.4/32, Flags:0x20 (No Local Protection, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 4016
  3.3.3.3/32, Flags:0x21 (Local Prot Avail/to NHOP, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 3015
  2.2.2.2/32, Flags:0x20 (No Local Protection, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 2015
[snip]
```

```
CSR3#show mpls traffic-eng fast-reroute database labels 3015 detail | begin
100
Tun ID: 100, LSP ID: 14, Source: 1.1.1.1
Destination: 11.11.11.11
State      : ready
InLabel    : 3015
OutLabel   : Gi2.523:2015
```

```
FRR OutLabel : Tu65436:2015
```

To verify the NHOP tunnel path, we verify CSR3's tunnel details. Again, it selects CSR9, who allocates label 9015 for the backup tunnel.

```
CSR3#show mpls traffic-eng tunnels tunnel 65436 | section RSVP Path
  RSVP Path Info:
    My Address: 132.3.9.3
    Explicit Route: 132.3.9.9 132.2.9.2 2.2.2.2
    Record Route: NONE
    Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits
```

```
CSR3#show mpls traffic-eng tunnels tunnel 65436 | include Label
InLabel : -
OutLabel : GigabitEthernet2.539, 9015
```

We simulate a failure again by bringing CSR2's interface down facing CSR3. CSR1 shows the normal log messages to indicate it.

```
! CSR1
%MPLS_TE-5-LSP: LSP 1.1.1.1 100_15: No addresses to connect 3.3.3.3 to
2.2.2.2
%MPLS_TE-5-LSP: LSP 1.1.1.1 100_14: Path Error from 132.3.4.3: Notify: Tunnel
locally repaired (flags 0)
```

We check CSR3's FRR database to see the state is now active with tunnel65436 being used, which is NHOP protection. The LFIB shows a swap from 3015 to 2015, as would normally be done, but then a push of label 9015 which is used to tunnel the LSP to the MP (CSR2).

```
CSR3#show mpls traffic-eng fast-reroute database labels 3015 detail | begin
100

    Label subobject: Flags 0x1, C-Type 1, Label 3015
  2.2.2.2/32, Flags:0x20 (No Local Protection, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 2015

```

The concept of shared risk link group (SRLG) is similar to SRLG seen in the IP FRR environment. We can specify links to "share risk" which tells the auto-tunnel process to not prefer, or totally discredit, these links as candidate paths for FRR. This is also called "fate sharing". For example, let's assume that CSR3's links to CSR9 and CSR2 both use the same physical conduit to carry the cabling. If the link to CSR2 fails due to the conduit being damaged, it is highly likely the link to CSR9 will also fail, so we should not prefer that link if possible. By assigning these groups to the same SRLG, which is carried in the TE extensions inside OSPF Type-10 LSAs or IS-IS LSPs, the auto-tunnel process will consider it. The command to enable SRLG for MPLS-TE is different than the one used for IP FRR.

```

! CSR3
interface GigabitEthernet2.523
  mpls traffic-eng srlg 29

interface GigabitEthernet2.539
  mpls traffic-eng srlg 29

```

After configuring it, we will verify it locally on CSR3 by checking the raw OSPF LSAs and the TE topology. Normally you would go straight to the TE topology instead of the raw IGP information. The last octet of the OSPF LSA10 (7 and 10 in this case) correspond to the frag_id listed in the TED. This eliminates the guesswork when querying the LSDP for TE information.

```

CSR3#show ip ospf 132 0 database opaque-area 1.0.0.7 adv-router 3.3.3.3

SRLGs: 29
```

Next, we need to tell the auto-tunnel process how to interpret the SRLG. We can either demand that the SRLG never be used, which means that if an SRLG path is the only path, no tunnel will be made. We can be more liberal and prefer that SRLG not be used, which essentially creates multiple path-options to fall back to SRLG paths as a last resort. First, we look at the strict option. As soon as we configure this feature, assuming debugging is on, we can see the original NHOP tunnel be torn down and a new one created with a new explicit-path. The tunnel configuration itself is identical, but the explicit-path now contains "exclude-srlg". This options is not available in the normal explicit-path configuration on XE as SRLGs are specific to auto-backup tunnels.

```
! CSR3

```

The tunnel still comes up, but avoids the link to CSR9 (SRLG) while also ignoring the link to CSR2 (NHOP protection). Specifically, the path routes via CSR10 > CSR9 > CSR2 to protect the direct link from CSR3 to CSR2 and remaining compliant with the SRLG policy. Technically, this is a valid NHOP-tunnel, despite transiting the NNHOP router (CSR10) along the way. Notice that the SRLG exclusion method is "forced".

```

Next, we will analyze the other SRLG option, which is to prefer non-SRLG paths. The "force" option only created a single path-option that excluded the link address and SRLG (Boolean AND logic). The "preferred" option uses the same first path-option as the "force" option, which means it first tries to find a path that satisfies both conditions. The second path-option is more relaxed and represents a regular NHOP tunnel with no SRLG restrictions as a fallback mechanism. To make the test more interesting, we will break the links between CSR3 and CSR10, as well as CSR3 and CSR1. This means that CSR3 will likely route back via CSR4 to make the NHOP tunnel to CSR2, creating a microloop. This is the same behavior we would have seen with the force option as well, since the path-option sequence still makes it very unlikely that an SRLG path will be selected, as desired.

```

```

```
Record Route: NONE
Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits
```

We perform the basic checks for verification. CSR1 is aware that NHOP protection is available because the PLR is tracking it in its FRR database. The local label for CSR3 (for the protected path) has changed to 3015 since the LSP was signaled after the last test.

```
CSR1#show ip rsvp reservation detail filter session-type 7 tunnel-id 100 |
begin RRO
```

```
RRO:
  4.4.4.4/32, Flags:0x20 (No Local Protection, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 4016
  3.3.3.3/32, Flags:0x21 (Local Prot Avail/to NHOP, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 3015
  2.2.2.2/32, Flags:0x20 (No Local Protection, Node-id)
    Label subobject: Flags 0x1, C-Type 1, Label 2015
[snip]
```

```
CSR3#show mpls traffic-eng fast-reroute database labels 3015 detail | begin

```

We can enable this feature on CSR10 as well to test additional minor features. CSR10 will be configured to provide NHOP and NNHOP protection using paths that are blue. The tunnel-IDs of the automatically created backup tunnels will be in the range of 1500 and 1505 and tunnels not in use (that is, not bound to an LSP requesting FRR) should be removed after every minute, building in a 10 second buffer before removal.

```
! CSR10
```

```
mpls traffic-eng auto-tunnel backup timers removal unused 50 10
mpls traffic-eng auto-tunnel backup tunnel-num min 1500 max 1505
mpls traffic-eng auto-tunnel backup config affinity 0x4 mask 0x4
```

When using an aggressive scan interval, the parser warns you about router performance. Scanning every 50 seconds to discover unused tunnels, then removing them 10 seconds later, meets the 1-minute

removal requirement. We can verify the basic configuration was accepted as well. Notice that only one tunnel is shown when we expected to see two.

```
CSR10(config)#mpls traffic-eng auto-tunnel backup timers removal unused 50 10
```

AUTO TUNNEL: Note that a scan interval of less than 60 seconds, may result in high CPU utilization.

```
CSR10#show mpls traffic-eng auto-tunnel backup
State: Enabled
  Auto backup tunnels: 1 (up: 1, down: 0)
  Tunnel ID Range: 1500 - 1505
  Create Nhop Only: No
  Check for deletion of unused tunnels every: 50 Sec
  SRLG: Not configured

Config:
  unnumbered-interface: Loopback0
  Affinity/Mask: 0x4/0x4
```

Checking the path of the tunnel, we can see that it takes a relatively long path via CSR5 > XRv11 > XRv12. The tunnel even traverses the NNHOP, which is expected since this is a different LSP than the main one (used for FRR only). Checking the tunnel labels to determine the incoming label on the tunnel transiting CSR10 (midpoint router), we see label 10015, as well as the FRR tunnel. The FRR database confirms that tunnel1500 is protecting the original LSP. The reason the NHOP tunnel did not get created is that the NHOP path transits the NNHOP node, so using NHOP protection makes no sense. The auto-tunnel feature is smart enough to account for this case and will conserve resources.

```
CSR10#show ip rsvp sender detail filter session-type 7 tunnel-id 1501 |

```

```
FRR OutLabel : Tu1501:implicit-null
```

Since XRv does not support BFD, FRR is not going to work well, so we won't test the data plane on this tunnel. Testing the feature briefly on XRv, we will create a tunnel using explicit-paths from XRv11 to CSR1. the tunnel will request FRR and XRv12 will create the auto-tunnels. The configuration in XR is much more limited than XE at the global level. The only affinity option is to ignore-all, there is no option for NHOP-only, and there is only one timer for removal timer (scan time only, unused tunnels are removed immediately). Additional options are available at the link level, such as NHOP-only, SRLG exclusion, and tunnel attribute-sets. For variety, we will build NHOP and NNHOP tunnels to protect the LSPs traversing the XRv12-CSR10 link and CSR10 as a node. We will use the strict SRLG option to help engineer the backup tunnels. SRLGs configured on XR are similar to IP FRR, unlike XE which has different mechanisms between IP and TE FRR.

```
! XRv11
interface tunnel-te100
  description BASIC TE FRR (AUTO BACKUP)
  ipv4 unnumbered Loopback0
  logging events all
  destination 1.1.1.1
  fast-reroute
  affinity ignore
  path-option 10 explicit name EP_11_12_6_10_3_1

! XRv12
mpls traffic-eng
interface GigabitEthernet0/0/0/0.562
  auto-tunnel backup
  exclude srlg
auto-tunnel backup
  timers removal unused 0
  tunnel-id min 1200 max 1210
  affinity ignore

srlg
interface GigabitEthernet0/0/0/0.502
  8 value 100
interface GigabitEthernet0/0/0/0.512
  8 value 100
interface GigabitEthernet0/0/0/0.562
  8 value 100
```

We can verify the configuration was successful by checking the TE topology's view of all SRLGs, as well as basic auto-tunnel show command. XR provides very detailed information where XE provides only a summary. We can also specify the SRLG value, IGP PID with area/level, and other filters. Notice that XRv12 can see the SRLGs we configured earlier since these are carried in the TE topology. Using

consistent SRLG values network-wide is important since they have global significance. Of note, we see that the tunnels are down for some reason.

```

tunnel-te1201	down	NHOP	0	Gi0/0/0/0.562	N/A

Looking into the details of tunnel1200 as an example, we see several auto-tunnel backup parameters, as well as the reason for the tunnel failure. We need to specify the IPv4 unnumbered address somehow, but there wasn't an option under the MPLS-TE stanza. Instead, we use a global command to specify that loopback0 should be used by default, an assumption not made by XR. Finding the problem is easy, as shown below, but knowing the command to fix it can be difficult.

```

Displayed 0 up, 1 down, 0 recovering, 0 recovered heads

! XRv12
ipv4 unnumbered mpls traffic-eng loopback0
```

Now, the tunnels comes up. Tunnel1207 is NNHOP and tunnel1208 is NHOP, both of which are operational and also offer SRLG protection. I've cleared the tunnels several times so their numbers are now 1207 and 1208. The summary view shows that the NNHOP tunnel is protecting one LSP at present. The output also specifies that two of the tunnels are operating in SRLG "strict" mode, which is like "force" mode in XE.

```
RP/0/0/CPU0:XRv12#show mpls traffic-eng auto-tunnel backup
AutoTunnel Backup Configuration:
  Interfaces count: 1
  Unused removal timeout: 0s
  Configured tunnel number range: 1200-1210

Tunnel Name	State	Protection Offered	Prot. Flows*	Protected Interface	Protected Node
tunnel-te1207	up	NNHOP+SRLG	1	Gi0/0/0/0.562	6.6.6.6
tunnel-te1208	up	NHOP+SRLG	0	Gi0/0/0/0.562	N/A

*Prot. Flows = Total Protected LSPs, S2Ls and S2L Sharing Families

Looking into the NNHOP tunnel details, we can see that we have protected the link to CSR6 as well as CSR6 itself as a node. The SRLG dictates we cannot use the direct link to CSR10, which would have been convenient and a shorter path. Instead, we use CSR9 for NNHOP protection. We can see this tunnel is being used since it is protecting an LSP.

RP/0/0/CPU0:XRv12#show mpls traffic-eng tunnels 1207 | begin Auto Backup

Auto Backup:

Protected LSPs: 1

Protected S2L Sharing Families: 0

Protected S2L: 0

Protected i/f: Gi0/0/0/0.562 Protected node: 6.6.6.6

Attribute-set: Not configured

Protection: NNHOP+SRLG (SRLG strict)

Unused removal timeout: not running

Path info (OSPF 132 area 0):

Node hop count: 2

Hop0: 132.9.12.9

Hop1: 132.9.10.10

Hop2: 10.10.10.10

The NHOP tunnel is also up and transiting CSR9, but is not protecting the node 6.6.6.6 (CSR6). NNHOP is preferred over NHOP when both are available and all other things are considered equal. This second tunnel protects an interface (a link) only.

RP/0/0/CPU0:XRv12#show mpls traffic-eng tunnels 1208 | begin Auto Backup

Auto Backup:

Protected LSPs: 0

```
Protected S2L Sharing Families: 0
Protected S2L: 0
Protected i/f: Gi0/0/0/0.562
Attribute-set: Not configured
Protection: NHOP+SRLG (SRLG strict)
Unused removal timeout: not running
```

```
Path info (OSPF 132 area 0):
Node hop count: 2
Hop0: 132.9.12.9
Hop1: 132.6.9.6
Hop2: 6.6.6.6
```

We can quickly validate the backup LSPs using MPLS OAM. Notice the different labels in use, which we verify by checking the tunnel details. These two outputs represent the NNHOP and NHOP tunnels respectively.

```

RP/0/0/CPU0:XRv12#show mpls traffic-eng tunnels 1208 detail | include Label
Outgoing Interface: GigabitEthernet0/0/0/0.592, Outgoing Label: 9020
```

Checking the FRR database confirms that the original tunnel is protected with NNHOP support. We can tell because the NNHOP label 10013 is used (local label on CSR10) and the tunnel ID is 1207. The headend RSVP RESV RRO also shows protection available with the "node" flag, implying NNHOP protection.

```
RP/0/0/CPU0:XRv12#show mpls traffic-eng fast-reroute database

To build only NHOP tunnels, we configure this on a per-interface basis in XR. We will apply this to XRv12 so that the NHOP tunnel is used. Because we did not enable debug earlier, we will do it quickly now to watch XRv12 tear down the existing NNHOP tunnel without touching the NHOP tunnel. The debug essentially verifies NHOP protection and disables NNHOP protection.

te_control[1044]: DBG-AUTOBKP[1]: te_frr_autobackup_need_to_create_nnhop:1701
(Tunnel ID: 100): NNHOP not configured GigabitEthernet0_0_0_0.562
te_control[1044]: DBG-AUTOBKP[1]: te_frr_autobackup_need_to_create_nhop:1622
(Tunnel ID: 100): already nhop protected GigabitEthernet0_0_0_0.562

```

Now, we can see that the NHOP tunnel is protecting the LSP since NNHOP protection is not available. We confirm this by checking the FRR database as well. The head-end also shows that protection is available, but does not specify node protection, so NHOP protection is implied.

```

XE supports primary auto-tunnels as well, which creates a one-hop tunnel to every directly connected peer reachable through a TE-enabled interface. There is no way to ignore affinity for these tunnels, since link-coloring doesn't make sense in conjunction with this feature. That is why I removed most of the link colors from the XE-dense parts of the network. We will enable this feature on CSR8 using a single command and with debugging enabled. Like auto-backup, these tunnel commands are shown clearly in the debug. Unlike auto-backup, the default range of tunnels is 65336 to 65435 to avoid overlap. The tunnels also have logging enabled, so we will see their statuses. Each tunnel is built to the one-hop neighbors using an explicit-path to specify using the interface towards that neighbor (these neighbor addresses are interpreted from the TED). Most importantly, each tunnel requests FRR protection and is configured with autoroute announce. Now, traffic to each peer is routed inside of this one-hop tunnel and is FRR-protected with a single command.

```

```

We can quickly check the auto-primary configuration. The output below seems to indicate we can change the tunnel ID range, enabled LDP on the tunnel (for stitching PE-P and P-P tunnels), and change the unnumbered address. There is no ability to adjust affinities, as described earlier.

```
CSR8#show mpls traffic-eng auto-tunnel primary
```

```
State: Enabled
Auto primary tunnels: 3 (up: 3, down: 0)
Tunnel ID Range: 65336 - 65435
Check for deletion of FRR Active onehop tunnels every:0 Sec

Config:
unnumbered-interface: Loopback0
mpls ip: FALSE
```

We can also verify the important aspects of this feature: autoroute and FRR protection. Autoroute shows 3 different destinations, one per tunnel, as expected. The routing table shows the destinations to each router also reachable through the tunnel.

```
CSR8#show mpls traffic-eng autoroute

```

The RSVP RESV RRO is very short since the tunnel is onehop, and the label is implicit-null, but FRR has been requested. Primary one-hop tunnels, whether automatically or manually configured, always use a null label of sorts.

```
CSR8#show ip rsvp reservation detail filter session-type 7 | section include

  Label subobject: Flags 0x1, C-Type 1, Label 3

```

Despite this seemingly harmless command, the network is very broken. Because of autoroute announce, CSR8 is now routing to all remote destination through a TE tunnel that runs PE-P. VPN traffic will no longer work since the transport label is implicit-null. The VPN label is exposed to P routers way too soon, and the VPN traffic will be dropped. We need a way to learn labels from the tail-end routers (at the other end of the one-hop tunnels) for the LSP endpoint.

```

```

We can solve this problem by enabling LDP on the primary auto-tunnels. We assume the P routers will accept the LDP targeted sessions, and if they don't, we would need to enable that also (not shown). Issuing this command immediately updates all of the tunnels with the "mpls ip" command, as expected. The "mpls ip" flag in the show command also changes to TRUE to indicate it is enabled. Last, we verify the LDP targeted sessions are working properly. In the vast majority of auto-primary deployments, this command would be necessary unless all of the PEs are directly connected.

```

! CSR8

    LDP Id: 9.9.9.9:0

```

Now, traffic flows as expected. We now have LDP label bindings for XRv11's loopback. Technically an "implicit-null" would be on the top of the stack if it were a real label, followed by the LDP label. Tracing to CSR1 wouldn't have required LDP on the tunnel since the auto-tunnel was PE-PE, so only the VPN label is used. The labels below are the LDP-learned labels for 11.11.11.11/32 from CSR6 and CSR9.

```

This feature works well with auto-tunnel backup. Since we already have a bunch of one-hop primary tunnels requesting FRR, we can back them up with NHOP auto-backups. After enabling these, we can see three new tunnels were created to backup each of the existing primary tunnels. Based on the labels received, two of them use CSR9 and one of them uses CSR1 for NHOP protection. Pay close attention to the tunnel IDs; the protected and FRR tunnels appear to be the same at a glance, but the third digit is

different. It is coincidental that the auto-primary and auto-backup interface numbers happen to align as they did. The “protected” tunnels are primary and the FRR interfaces are backup.

```
! CSR8
mpls traffic-eng auto-tunnel backup nhop-only

CSR8#show mpls traffic-eng fast-reroute database
P2P Headend FRR information:

We can also adjust the removal timer for these tunnels. After a link failure, the tunnels can be removed from the configuration if desired. By default, the feature is disabled (tunnels are never removed).

```
! CSR8
mpls traffic-eng auto-tunnel primary timers removal rerouted 3600

CSR8#show mpls traffic-eng auto-tunnel primary
State: Enabled
Auto primary tunnels: 3 (up: 3, down: 0)
Tunnel ID Range: 65336 - 65435
Check for deletion of FRR Active onhop tunnels every:3600 Sec

Config:
unnumbered-interface: Loopback0
mpls ip: TRUE
```

Although not clearly documented nor well-advertised, XR supports this feature as well. It is hidden within the "mesh" confines, but it does work the same way. Since XRv12 already has auto-tunnel backup configured, we will enable the one-hop tunnels there.

```
! XRv12
```

```

mpls traffic-eng
  auto-tunnel mesh
  group 999
    onehop
  tunnel-id min 9990 max 9999

```

Checking the status of these tunnels, we can see that XRv12 created 4 tunnels, one for each next-hop. Only two of them are up, but all four are marked with a % sign to indicate "onehop" tunnels.

```

RP/0/0/CPU0:XRv12#show mpls traffic-eng tunnels brief

```

```

The reason those two tunnels are down is the exact reason why affinity was removed from most of the topology; we cannot adjust the affinity of these tunnels, so there is no colorless path to reach the neighbors if affinity is set. The diagram shows this clearly as PCALC cannot find a valid path.

```

```

Design tip: This technique of auto-backup NHOP-tunnels with auto-primary is best enabled everywhere. In doing this, we can automatically protect all links in the topology. This alleviates the need for individual TE tunnels to request FRR on a per-tunnel basis. Since every link is already protected, and every link has an FRR tunnel across it with autoroute, we can assume that any traffic crossing that link is protected as well. This is difficult to test since there is no PLR-originated PATHERR message back to the head-end (on a non-primary tunnel) to indicate local repair has happened. FRR happens by virtue of the links being protected; even normal LSPs can be protected if other TE tunnels are not used. This is the best way to protect mLDP LSM traffic which is detailed in another section. With autoroute enabled, we can simply enable this feature everywhere (along with tLDP) and have fully connectivity with FRR protection.

Last, we will examine automatic tunnel mesh-groups. This allows remote PEs to automatically build tunnels to one another based on an ACL that specifies all of the destinations. We can apply any

constraints we want, and in this case, the path must not be blue. It is somewhat manual when using an access-list in this way, but can greatly reduce configuration. This solution does not require any additional IGP extensions other than the TE ones already in use. We will build a mesh of TE tunnels between CSR1, CSR8, and XRv11. We will use autoroute destination so we can override any existing primary tunnels on CSR8 that are using autoroute announce. On XRv11, we use autoroute announce because we must, and also we have to specify the TE tunnel default source address in global configuration mode. Only numbered ACLs are supported which makes the configuration for difficult to interpret at a glance.

```
! CSR1 and CSR8
mpls traffic-eng auto-tunnel mesh
mpls traffic-eng auto-tunnel mesh tunnel-num min 5000 max 5099

interface Auto-Template500

Next, we quickly check each PE's FIB to ensure the tunnels are being used for routing. This proves that autoroute can be used with the announce or destination options. Normal static or policy routing would not work since the tunnel IDs are dynamically allocated. Forwarding-adjacency also works, provided the tunnels are configured bidirectionally. On XE and XR, the FIBs never show the TE label, so do not be concerned when the labels are not revealed below.

Rather than test all six tunnels, we will test two to ensure the feature works. From CSR1 to XRv11, we know the tunnel ID is 5000. Checking the outgoing label, we find value 3010. Testing from inside the VPN, we can see that the first label in the stack, on the first hop, is 3010. This implies the auto-mesh LSP is being used for transport as desired.

```
CSR1#show mpls traffic-eng tunnels tunnel 5001 | include Label
InLabel : -
OutLabel : GigabitEthernet2.513, 3010
```

```
CSR7#traceroute 13.13.13.13 source 7.7.7.7
Type escape sequence to abort.
Tracing the route to 13.13.13.13

 5 10.11.13.13 25 msec * 14 msec
```

From XRv11 to CSR8, we perform a similar verification. Tunnel ID 5003 is used to forward traffic to CSR8, which uses label 10018. The first hop of the traceroute inside the VPN uses this value, which proves that the auto-mesh works on XRv also.

```

```

OSPF also supports a fancier way to build auto-mesh tunnels. The XR documentation seems to suggest this is supported on XR, but it isn't. It only works on XE for OSPFv2; there is no support for IS-IS currently. We will use this to automatically build a mesh of tunnels to support the VPLS customers behind CSR1, CSR4, and CSR5. The absence of a static ACL means that all routers have identical configurations. We also use an explicit-path selecting any path that does not traverse CSR9. In general, only XE can include explicit-paths (only makes sense to use exclusion or loose hop inclusion); XR must use dynamic paths.

```

! CSR1, CSR4, and CSR5
mpls traffic-eng auto-tunnel mesh
mpls traffic-eng auto-tunnel mesh tunnel-num min 5000 max 5099

router ospf 132
  mpls traffic-eng mesh-group 501 Loopback0 area 0

ip explicit-path name EP_NO_R9 enable
  exclude-address 9.9.9.9

interface Auto-Template501
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination mesh-group 501
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name EP_NO_R9

```

We can verify the tunnel IDs for each destination on each router for further analysis.

```

1.1.1.1      Tunnel5000
4.4.4.4      Tunnel5001

```

Mesh tunnel interface numbers: min 5000 max 5099

Checking the tunnel briefs for tunnels in the "up" state on CSR4 (for brevity), we can see 2 auto-mesh tunnels in the summary. This represents the tunnels for which the local router is the head-end. Below, we see 4 tunnels total: CSR4 is the head for the first two as the destinations are CSR1 and CSR5. CSR4 is the tail end for the other 2 since the tunnel names contain the hostnames of the corresponding head ends.

```
CSR4#show mpls traffic-eng tunnels up brief
```

Displayed 2 (of 2) heads, 0 (of 0) midpoints, 2 (of 2) tails

This information was dynamically exchanged using a new TLV to carry the mesh-group ID (MG-ID) inside of an opaque-area LSA (Type-10). The Link ID is always 4.0.0.0 and each MG-ID is 8 bytes long. The first 4 bytes represent the actual MG-ID, shown in hex (0x000001F5 = 501). The second 4 bytes represent the router's mesh-group IP address which serves as the tunnel destination for everyone else, also in hex (0x040404 = 4.4.4.4). Looking at CSR4's locally generated MG-ID LSA10, we can see this information carried in the TLV.

```
CSR4#show ip ospf 132 0 database opaque-area 4.0.0.0 adv-router 4.4.4.4
```

```
OSPF Router with ID (4.4.4.4) (Process ID 132)
```

Type-10 Opaque Link Area Link States (Area 0)

LS age: 430
Options: (No TOS-capability, DC)
LS Type: Opaque Area Link
Link State ID: 4.0.0.0
Opaque Type: 4
Opaque ID: 0
Advertising Router: 4.4.4.4
LS Seq Number: 80000001
Checksum: 0x4AC3
Length: 32

Capability Type: Mesh-group
Length: 8
Value:
0000 01F5 0404 0404

If we add another MG-ID to CSR4, perhaps to create an unrelated meshed of tunnels, this single LSA can be extended without having to create an LSA for each MG-ID. We can select a different "destination" interface as well, which doesn't make much sense in this case, but is possible. The original MG-ID still exists, with the addition of MG-ID 502 (0x000001F6) and the IP address from the specified link (0x84030404 = 132.3.4.4). I use yellow for MG-ID 501 and green for MG-ID 502. Each new MG-ID adds 8 bytes of length to the TLV.

0000 01F5 0404 0404 0000 01F6 8403 0404

The reason I suspect XR simply does not support this feature is because it cannot read this new TLV. I was not able to find a way to enable a feature to correct this, nor could I find a way to encode an MG-ID locally into the XR OSPF process. If XR cannot understand the MG-ID TLV, it is highly unlikely that the feature is supported.

Unknown TLV: Type: 3 Length: 16

A more graceful way to view this information is to look at the TE topology in brief form. Looking at CSR1, it can see CSR4's remote MG-IDs. It displays all 8 bytes of the TLV value, both the MG-ID and tunnel destination. CSR1 only cares about MG-ID 501 in this specific case, as MG-ID 502 was just a demonstration. The group/destination pairings are shown in different colors for clarity as they were above.

```
CSR1#show mpls traffic-eng topology 4.4.4.4 brief | include mg
Area mg-id's:
: mg-id 501 4.4.4.4 :: mg-id 502 132.3.4.4 :
```

We will verify that each of the PEs is routing correctly using the mesh tunnels before using MPLS OAM to verify the labels. The tunnel IDs being used for each remote destination appear correct.

```
CSR1#show ip cef 4.4.4.4
4.4.4.4/32
attached to Tunnel15002
```

```
CSR1#show ip cef 5.5.5.5
5.5.5.5/32
```

attached to Tunnel5003

```
CSR4#show ip cef 1.1.1.1
1.1.1.1/32
    attached to Tunnel5000
```

```
CSR4#show ip cef 5.5.5.5
5.5.5.5/32
    attached to Tunnel5001
```

```
CSR5#show ip cef 1.1.1.1
1.1.1.1/32
    attached to Tunnel5000
```

```
CSR5#show ip cef 4.4.4.4
4.4.4.4/32
    attached to Tunnel5001
```

We will test connectivity from CSR1 to CSR5. The outgoing label is 3022, which means CSR3 is the next-hop. MPLS OAM can verify that the tunnel is operation since the L2VPN cannot verify this.

```
CSR1#show mpls traffic-eng tunnels tunnel 5003 | include Label
InLabel   : -
OutLabel  : GigabitEthernet2.513, 3022
```

```
CSR1#traceroute mpls traffic-eng tunnel 5003
Tracing MPLS TE Label Switched Path on Tunnel5003, timeout is 2 seconds
[snip]
```

Type escape sequence to abort.

```
0 132.1.3.1 MRU 1500 [Labels: 3022 Exp: 0]
L 1 132.1.3.3 MRU 1500 [Labels: 2020 Exp: 0] 2 ms
L 2 132.2.3.2 MRU 1500 [Labels: implicit-null Exp: 0] 28 ms
! 3 132.2.5.5 23 ms
```

We can confirm this further in the control-plane using ordinary MPLS show commands. The label stack includes the RSVP-bound label 3022 since the next-hop to the targeted LDP endpoint is reachable via a TE tunnel. Using EPC, we can verify that the L2VPN traffic is using this TE LSP. We send traffic from XRv14 to XRv13, which uses CSR1 as the ingress L2VPN PE, and capture traffic heading to CSR3. Label 3022 (0xBCE) is indeed being used for transport, with label 5011 (0x1393) being used for the PW demultiplexer.

```
CSR1#show l2vpn atom vc destination 5.5.5.5 vcid 71314 detail | include
label_stack
    Output interface: Tu5003, imposed label stack {3022 5011}
```

```
RP/0/0/CPU0:XRv14#ping 10.0.0.13 source 10.0.0.14
```

Type escape sequence to abort.

Sending 5, 100-byte ICMP Echos to 10.0.0.13, timeout is 2 seconds:

!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 1/12/29 ms

CSR1#show monitor capture CAP buffer detail

```
11 144 1.035994 00:0C:29:FB:A3:39 -> 00:0C:29:D7:81:FE MPLS unicast
0000: 000C29D7 81FE000C 29FBA339 81000DB9 ..).....)..9....
0010: 884700BC E0FF0139 31FF0000 0000000C .G.....91.....
0020: 2955663D 000C29BE D8F90800 45000064 )Uf=..).....E..d
0030: 00000000 FF01A77E 0A00000E 0A00000D .....~.....
```

For additional testing, we will perform the same verification from CSR5 to CSR4. We already verified the tunnel ID was 5001 and the CEF was properly programmed. The outgoing label is 2018 which means CSR2 is the next-hop in the path. We can confirm this with MPLS traceroute.

CSR5#show ip rsvp reservation detail filter session-type 7 destination

4.4.4.4 | include Label

Label: 2018 (outgoing)

CSR5#traceroute mpls traffic-eng tunnel 5001

Tracing MPLS TE Label Switched Path on Tunnel5001, timeout is 2 seconds

[snip]

Type escape sequence to abort.

```
0 132.2.5.5 MRU 1500 [Labels: 2018 Exp: 0]
L 1 132.2.5.2 MRU 1500 [Labels: 3020 Exp: 0] 1 ms
L 2 132.2.3.3 MRU 1500 [Labels: implicit-null Exp: 0] 29 ms
! 3 132.3.4.4 21 ms
```

The L2VPN control-plane verification shows the proper label stack as well. When we send traffic from XRv3 to CSR7, we verify the proper label stack on the outgoing packets. Label 2018 (0x7E2) is the topmost, RSVP-allocated label and label 4010 (0xFAA) is the PW label.

CSR5#show mpls l2transport vc destination 4.4.4.4 vcid 71314 detail | include label_stack

Additional Reading – Reference configurations "te-auto"

31.3 CBTS (IOS) and PBTS (XR)

This section is a continuation of the manual TE lab and reuses some of the same tunnels for testing (configurations are consolidated at the beginning of the section). Class and Policy Based Tunnel Selection (CBTS/PBTS) are mechanisms of mapping EXP values to different tunnels in XE and XR, respectively. The feature qualifies as a TE QoS mechanism but is not technically DiffServ-aware TE (DS-TE), which is different. The two are not mutually exclusive as we will see later. We will begin with CBTS. A master tunnel [ID 40] is created that bundles all of the member tunnels. The master determines the steering mechanism (autoroute, etc) but isn't a real TE tunnel. It's just a software interface so the routing process knows how to deliver traffic. The members have their own path-options along with mappings of EXP values. In this example, voice and video (EXP 5 and 4) are mapped to tunnel41 and follow the blue path, which we can pretend is low latency. Tunnel42 encompasses all other EXP values which is what the "default" keyword accomplishes. Notice that the member tunnels do not need a steering mechanism.

```

! CSR1
interface Tunnel40
  description CBTS MASTER
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng exp-bundle master
  tunnel mpls traffic-eng exp-bundle member Tunnel41
  tunnel mpls traffic-eng exp-bundle member Tunnel42

interface Tunnel41
  description CBTS VOICE AND VIDEO
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng affinity 0x4 mask 0x4
  tunnel mpls traffic-eng path-option 10 dynamic
  tunnel mpls traffic-eng exp 4 5

interface Tunnel42
  description CBTS EVERYTHING ELSE
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name EP_1_4_3_10_11

```

```
tunnel mpls traffic-eng exp default
```

When the tunnels come up, we see only two exist, not three, since tunnel 40 is just a "traffic cop" to direct traffic into the proper member tunnels based on EXP.

```
CSR1#show ip rsvp reservation
```

To	From	Pro	DPort	Sport	Next Hop	I/F	Fi	Serv
BPS								
11.11.11.11	1.1.1.1	0	41	1	132.1.6.6	Gi2.516	SE	LOAD 0
11.11.11.11	1.1.1.1	0	42	1	132.1.4.4	Gi2.514	SE	LOAD 0

We can confirm this by checking all of the tunnel statuses. The master tunnel is up, but the output is limited to the member tunnels and their EXP mappings. We can see that the member tunnels look like regular TE tunnels with their EROs going in totally different directions, given independent tunnel constraints. Notice that label 4014 is used for the default traffic and label 6020 is used for voice/video.

```
CSR1#show mpls traffic-eng tunnels tunnel 40 | section Status
```

Status: Master

11.11.11.11

Record Route: NONE

Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

We can also see the EXP mappings per destination. This shows the "configured" versus "actual", which is valuable to determine where traffic actually ends up. The D and NE flags are evaluated later.

```
CSR1#show mpls traffic-eng exp 11.11.11.11
```

Destination: 11.11.11.11

Master: Tunnel40	Status: up				
Members	Status	Conf	Exp	Actual	Exp
Tunnel41	up (Active)	4	5	4	5
Tunnel42	up (Active)	Default		0	1 2 3 6 7

(D) : Destination is different

(NE): Exp values not configured on tunnel

We quickly check the autoroute process. The routing is tied to the master tunnel40, not the members. The routing table also shows this as well. Traffic entering the master tunnel is further classified by EXP into the appropriate member tunnels based on the mappings shown above.

```
CSR1#show mpls traffic-eng autoroute 11.11.11.11
MPLS TE autorouting enabled
destination 11.11.11.11 has 1 tunnels
Tunnel40 (load balancing metric 0, nexthop 11.11.11.11)
(flags: Destination)
```

```
CSR1#show ip route 11.11.11.11

Known via "static", distance 1, metric 0 (connected)
Routing Descriptor Blocks:
* directly connected, via Tunnel40
Route metric is 0, traffic share count is 1
```

A quick test from within the L3VPN shows that the CBTS configuration is working. Traffic at EXP 0 uses label 4014, which is for default traffic. Extended traceroute lets us specify DSCP 40 (CS5), which is voice traffic. This uses label 6020 which is correct.

MPLS OAM can be used to verify this as well, provided we specify the master tunnel as the target. We can easily test different EXP values from within the SP network this way. This time, we will test video (EXP 4) and ensure it uses label 6020. EXP 3 still uses the default tunnel, which is correct. Notice that the OAM returning information shows EXP 0 for the packet that was in tunnel40; I assume this is a cosmetic behavior of the MPLS traceroute, since it categorized the traffic properly.

These member tunnels can be protected by FRR, make bandwidth reservations, and do most other things ordinary TE tunnels can do. We will protect the voice/video tunnel with FRR (with bandwidth protection) and give it 2 Mbps of bandwidth. Even though there aren't any NHOP/NNHOP backup tunnels along the path, the features do work. We can check the RSVP RESV details to see the RRO with labels, along with the bandwidth reservation. Notice that the second tunnel42 does not have a bandwidth reservation nor an RRO, as expected.

```

If we remove the "default" option from tunnel42, the tunnel is considered inactive. It is still a signaled and valid LSP from the perspective of RSVP, but cannot be used for CBTS. We can see that all 8 EXP values now map to the voice/video tunnel. Since there was nothing configured on tunnel42, the router makes no assumptions about what it should transport, and so uses it for nothing. Notice the NE flag on the tunnel42 entry below.

```
! CSR1
interface Tunnel42
 no tunnel mpls traffic-eng exp default

CSR1#show mpls traffic-eng exp 11.11.11.11
Destination: 11.11.11.11
```

Master: Tunnel40	Status: up		
Members	Status	Conf Exp	Actual Exp
Tunnel41	up (Active)	4 5	0 1 2 3 4 5 6 7
Tunnel42	up (Inactive)NE	Unassigned	

(D) : Destination is different

(NE) : Exp values not configured on tunnel

Unfortunately, OAM is not helpful in this situation, as it states there is no label. MPLS OAM actually appears to look at the configured EXP, not the actual EXP. Tracing from the VPN yields the proper results, which is a path via CSR6. Though undesirable from a design perspective, this is in accordance with the output above. The label changed to 6007 since enabling FRR caused the tunnel to be resigaled; label 6007 is shown above in the RSVP RESV RRO.

```
CSR1#traceroute mpls traffic-eng tunnel 40 exp 3
Tracing MPLS TE Label Switched Path on Tunnel40, timeout is 2 seconds
[snip]
```

Type escape sequence to abort.

```
0 0.0.0.0 MRU 0 [No Label]
```

Q 1 *

```
CSR7#traceroute 13.13.13.13 source 7.7.7.7
```

Type escape sequence to abort.

Tracing the route to 13.13.13.13

4 132.11.12.11 [MPLS: Label 91012 Exp 0] 33 msec 33 msec 33 msec
5 10.11.13.13 26 msec * 32 msec
```

Next, we will configure a few explicit values on tunnel42, but not all. The lower priority traffic is forced into tunnel42, and the system automatically placed all remaining EXP values into tunnel42 as well. When a "default" is not specified, the tunnel with the lowest explicit EXP is used for all remaining values. This configuration should give us the expected result, like the original setup, as the "actual EXP" is the same.

! CSR1

```
interface Tunnel42
```

```
tunnel mpls traffic-eng exp 0 1
```

```
CSR1#show mpls traffic-eng exp 11.11.11.11
```

Destination: 11.11.11.11

Master: Tunnel40	Status: up

```

```
Q 1 *
```

We can add new tunnels to the bundle at any time. We will use tunnel43 for network control traffic. We can have up to 8 tunnels, one for each EXP.

```
! CSR1
interface Tunnel43
  description CBTS NET CONTROL
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng affinity 0x0 mask 0x0
  tunnel mpls traffic-eng path-option 10 explicit name EP_NO_R9
  tunnel mpls traffic-eng exp 6 7

interface Tunnel40
  tunnel mpls traffic-eng exp-bundle member Tunnel43
```

There still isn't a default tunnel, so the remaining values are mapped to the tunnel with the lowest explicit EXP. This is still the correct operation.

```
CSR1#show mpls traffic-eng exp 11.11.11.11
Destination: 11.11.11.11
```

```
Master: Tunnel40          Status: up
```

Members	Status	Conf Exp	Actual Exp
Tunnel41	up (Active)	4 5	4 5
Tunnel42	up (Active)	0 1	0 1 2 3
Tunnel43	up (Active)	6 7	6 7

The combinations of tunnel failures, EXP mappings, and routing options are vast and this document does not cover them all. We will evaluate a few, though. If we shut down one tunnel causing the member LSP to fail, the values are moved onto the other tunnels. Shutting down tunnel41 moves EXP4 and EXP5 to tunnel42, which has the lowest configured EXP value.

```
CSR1#show mpls traffic-eng exp 11.11.11.11
Destination: 11.11.11.11
```

Master: Tunnel40		Status: up	
Members	Status	Conf Exp	Actual Exp
Tunnel41	down	4 5	
Tunnel42	up (Active)	0 1	0 1 2 3 4 5
Tunnel43	up (Active)	6 7	6 7

If we shut down tunnel43, the traffic is moved into tunnel41. I assume this is because EXP4 and EXP5 are the "next lowest" values. It would not be appropriate to "promote" lower values like 4 and 5 into a tunnel designed for 6 and 7. However, "demoting" higher values to the next-best tunnel appears to be functional.

```
CSR1#show mpls traffic-eng exp 11.11.11.11
Destination: 11.11.11.11
```

Master: Tunnel40		Status: up	
Members	Status	Conf Exp	Actual Exp
Tunnel41	up (Active)	4 5	4 5 6 7
Tunnel42	up (Active)	0 1	0 1 2 3
Tunnel43	down	6 7	

If we shut down tunnel42, the traffic is moved into tunnel41. This is the "next lowest" EXP and is "more" acceptable than moving it into the tunnel carrying higher EXPs.

```
CSR1#show mpls traffic-eng exp 11.11.11.11
Destination: 11.11.11.11
```

Master: Tunnel40		Status: up	
Members	Status	Conf Exp	Actual Exp
Tunnel41	up (Active)	4 5	0 1 2 3 4 5
Tunnel42	down	0 1	
Tunnel43	up (Active)	6 7	6 7

An error condition exists when a member tunnel has an incorrect tunnel destination, as shown below. Because the tunnel is still a member of a bundle with the correct destination, the tunnel is considered inactive. It is still a valid LSP and RSVP will happily signal the path to the new (incorrect) destination. Traffic will not flow correctly, and the EXP values mapped to that tunnel are moved to a valid bundle member.

```
interface Tunnel43
  description CBTS NET CONTROL
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 12.12.12.12
```

```
CSR1#show ip rsvp reservation
```

To	From	Pro	DPort	Sport	Next Hop	I/F	Fi	Serv
BPS								
11.11.11.11	1.1.1.1	0	41	9	132.1.6.6	Gi2.516	SE	LOAD 2M
11.11.11.11	1.1.1.1	0	42	3	132.1.4.4	Gi2.514	SE	LOAD 0
12.12.12.12	1.1.1.1	0	43	4	132.1.6.6	Gi2.516	SE	LOAD 0

While making the change, we can enable debugging to see CBTS remove the tunnel from the bundle. The show command also shows the D flag since the member has a different destination than the master. EXP 6 and 7 are moved to tunnel41 as the next-best valid option.

```
CSR1#show mpls traffic-eng exp 11.11.11.11
Destination: 11.11.11.11
```

Master: Tunnel40		Status: up						
Members	Status	Conf	Exp	Actual	Exp			
Tunnel41	up (Active)	4	5	4	5	6	7	
Tunnel42	up (Active)	0	1	0	1	2	3	
Tunnel43	up (Inactive)D	6	7					

```
(D) : Destination is different
(NE): Exp values not configured on tunnel
```

```
CSR1#debug mpls traffic-eng exp
TE-HE-BNDL: Member destination changed.. remove from bucket
TE-HE-BNDL: Member tunnel property change. walk update adj bundle
TE-HE-BNDL: Member dest different from bundle dest
```

Like any TE tunnel, routing still determines how traffic is steered into the tunnel head. If change the master to use autoroute announce, then create a non-CBTS tunnel with autoroute announce with a better metric, none of the traffic will enter the CBTS tunnel at all.

```
! CSR1
interface Tunnel40
```

```

tunnel mpls traffic-eng autoroute announce

    Route metric is 29, traffic share count is 1

```

The label for this new tunnel is 3018, which is not CBTS related at all. When we traceroute from inside the VPN, all traffic goes into this tunnel, and CBTS is totally bypassed. We will shut down tunnel44 before continuing so CBTS is active again. The point is that CBTS master tunnel is not magic and competes directly with any other TE tunnels based on the routing convergence.

```

PBTS is similar to CBTS except is supported on XR. CBTS is not supported on XR and PBTS is not supported on XE, so the features are mutually exclusive per platform. PBTS is simpler to configure and understand since there is no need for a tunnel bundle. The first set of tunnels [ID 50 - 52] capture the Network Control, Voice/Video, and everything else. If no default tunnel is available, the tunnel with the lowest EXP value carries the remaining traffic. Each tunnel is totally independent in terms of constraints (affinity, bandwidth, path-selection, etc). You cannot explicitly map EXP 0.

```

! Xrv11
interface tunnel-te50
  description PBTS NET CONTROL
  ipv4 unnumbered Loopback0
  logging events all
  autoroute announce
  destination 1.1.1.1
  policy-class 6 7
  affinity 0x8 mask 0x8
  path-option 10 dynamic

interface tunnel-te51
  description PBTS VOICE AND VIDEO
  ipv4 unnumbered Loopback0
  logging events all
  signalled-bandwidth 5000
  autoroute announce
  destination 1.1.1.1
  policy-class 4 5
  affinity ignore

```

```

path-option 10 explicit name PATH_11_5_2_3_4_1

interface tunnel-te52
description PBTS DEFAULT CLASS
ipv4 unnumbered Loopback0
logging events all
autoroute announce
destination 1.1.1.1
policy-class default
affinity 0x4 mask 0x4
path-option 10 dynamic

```

We will quickly check to see that the tunnels came up successfully. We also validate the PBTS mappings per tunnel.

```

RP/0/0/CPU0:XRv11#show mpls traffic-eng tunnels destination 1.1.1.1 up |
utility egrep '^Name|Admin|Policy'
Name: tunnel-te50 Destination: 1.1.1.1 Ifhandle:0x1080
Admin: up Oper: up Path: valid Signalling: connected
AutoRoute: enabled LockDown: disabled Policy class: 6 7
Name: tunnel-te51 Destination: 1.1.1.1 Ifhandle:0x1180
Admin: up Oper: up Path: valid Signalling: connected
AutoRoute: enabled LockDown: disabled Policy class: 4 5
Name: tunnel-te52 Destination: 1.1.1.1 Ifhandle:0x1280
Admin: up Oper: up Path: valid Signalling: connected
AutoRoute: enabled LockDown: disabled Policy class: default

```

We also check the labels bound to each tunnel for verification purposes. We also verify that autoroute is working correctly, showing all three tunnels.

```

RP/0/0/CPU0:XRv11#show rsvp reservation session-type lsp-p2p destination
1.1.1.1 detail | utility egrep 'Label|TunID'
RESV: IPv4-LSP Session addr: 1.1.1.1. TunID: 50. LSPIId: 2.
Labels: Outgoing downstream: 92010.
RESV: IPv4-LSP Session addr: 1.1.1.1. TunID: 51. LSPIId: 3.
Labels: Outgoing downstream: 5012.
RESV: IPv4-LSP Session addr: 1.1.1.1. TunID: 52. LSPIId: 2.

```

The FIB details specifically detail PBTS parameters also. The distribution won't be 1:3 as it is class based, but the FIB shows all three tunnels, their paths, and their position in the hash list.

```
RP/0/0/CPU0:XRv11#show cef ipv4 1.1.1.1/32 detail | begin Weight
Weight distribution:
slot 0, weight 0, normalized_weight 1, class default
slot 1, weight 0, normalized_weight 1, class 4 5
slot 2, weight 0, normalized_weight 1, class 6 7

PBTS class information:
class 4:  1 paths, offset 1
class 5:  1 paths, offset 1
class 6:  1 paths, offset 2
class 7:  1 paths, offset 2
class default: 1 paths, offset 0

Load distribution: 0 1 2 (refcount 3)

Hash  OK  Interface                Address
0     Y   tunnel-te52                point2point
```

1	Y	tunnel-te51	point2point
2	Y	tunnel-te50	point2point

Because XR does not allow us to specify TOS values in traceroute, and XRv does not support MQC-based QoS at all, it is hard to verify operation without changing the topology to use XE and a CE. As a temporary solution, and because no tunnels currently traverse the link between XRv11 and CSR10, we will disable LDP on that link on CSR10, as well as configure a static route to direct traffic to 1.1.1.1/32 towards XRv11. At the end of the PBTS section, these changes are removed.

```
! CSR10
interface GigabitEthernet2.501
  no mpls ldp igp autoconfig

ip route 1.1.1.1 255.255.255.255 132.10.11.11
```

XRv11 will perform a lookup in its FIB since the traffic is IP, not MPLS. It will then place the traffic into the proper TE tunnel based on the first 3 bits of the TOS byte. Below, we test DSCP CS6, CS5, and CS2. Each of them end up in the proper tunnels as we can confirm by checking the first label along the TE-LSPs.

```

Next, we will shut down the default tunnel52 and verify that the traffic traverses tunnel51. This is the "next lowest" traffic class, so all lower priority traffic uses that in the absence of a default tunnel. Notice that the CEF details make no mention of this behavior, so the user must know that EXP values 0-3 are mapped to tunnel51 in this case using label 5012.

```
RP/0/0/CPU0:XRv11#show cef ipv4 1.1.1.1/32 detail | begin Weight

```

We bring up tunnel52 again and note the new label is 5013. We shut down tunnel50, the "best" tunnel. Traffic is moved into the default tunnel52 as expected, per the FIB. We confirm this by using traceroute to see label 5013 at the front of the LSP. Tunnel51 is still servicing classes 4 and 5, which we confirm with DSCP CS4.

Forwarding-adjacency is also supported for PBTS. So long as there is a single tunnel from the tail to head (CSR1 to XRv11) that is also configured for the feature, all of the PBTS tunnels can rely on it. We can quickly reconfigure XRv11's PBTS tunnels, as well as bring up tunnel24 on CSR1 (not shown), which is enabled for forwarding-adjacency.

```
! XRv11
interface tunnel-te50
  no autoroute announce
  forwarding-adjacency
  holdtime 10000

interface tunnel-te51
  no autoroute announce
  forwarding-adjacency
  holdtime 10000

interface tunnel-te52
  no autoroute announce
  forwarding-adjacency
  holdtime 10000

router isis 132
  interface tunnel-te50
    address-family ipv4 unicast
    metric 25

  interface tunnel-te51
    address-family ipv4 unicast
    metric 25

  interface tunnel-te52
    address-family ipv4 unicast
    metric 25
```

The IS-IS topology shows three separate links to CSR1 from XRv11. The FIB has the same look as before since all of the paths appear "equal" until we start sending traffic.

```
RP/0/0/CPU0:XRv11#show isis topology systemid 0000.0000.0001
IS-IS 132 paths to IPv4 Unicast (Level-2) routers
```

System Id	Metric	Next-Hop	Interface	SNPA
CSR1	25	CSR1	tt52	*PtoP*
CSR1	25	CSR1	tt51	*PtoP*
CSR1	25	CSR1	tt50	*PtoP*

```
RP/0/0/CPU0:XRv11#show cef ipv4 1.1.1.1/32 | include class

                     (IS-IS 132 level-2, IPV4 Unicast)
```

For confirmation, we verify the labels on the tunnels. Then, we perform three traceroutes on CSR10 to verify PBTS works with forwarding-adjacency in a quasi-P2MP environment. with CBTS, this behavior is different since there is a tunnel-bundle and only one link.

```
RP/0/0/CPU0:XRv11#show rsvp reservation session-type lsp-p2p destination

31.4 DiffServ-aware Traffic Engineering (DS-TE)

DiffServ-aware TE grants finer granularity to bandwidth reservations. Multiple bandwidth pools can exist with different amounts of bandwidth to service different traffic types. The pre-standard Cisco version accounted for two pools: global and sub. The global pool is what we have already analyzed, which represents the more general pool of bandwidth. If the bandwidth reservation is unspecified, the global pool is assumed. The sub-pool is typically used for higher priority flows, such as voice, and is accounted for separately from the global pool. The IETF later extended DS-TE to encompass up to 8 different class-types (CT), each of which can have flows within the existing 8 priorities, making 64 possible combinations of TE classes; currently, only 2 of the CTs are used (seen later). As a general comment, routers migrating from pre-standard to standard (IETF) modes can be configured to use both. In this model, the local router floods/advertises pre-standard information, but is capable of processing both pre-standard and IETF information. The network diagram is identical to the TE-manual diagram (affinity on all links), but is shown again for clarity.

31.4.1 Pre-standard Model

The pre-standard version is very straightforward to configure; Cisco only changed two commands to account for DS-TE originally. The "ip rsvp bandwidth" command at the link-level includes a "sub-pool" option to specify available sub-pool bandwidth. To use this sub-pool bandwidth, TE tunnels can specify "sub-pool" as an option within the "tunnel mpls traffic-eng bandwidth" command. The feature does not have to be explicitly enabled on core LSRs and all of the show commands are the same. The pre-standard version behaves like the IETF Russian Dolls Model (RDM) except with only two bandwidth constraints (BC). Because RSVP has not been extended to support the pre-standard version, global pool bandwidth is signaled as "controlled-load" service, whereas sub pool bandwidth is signaled as "guaranteed" service. Those terms are discussed later, but the point is that "pre-standard" is functionally similar to IETF RDM minus the RSVP extensions. We will enable an RSVP global pool size of 100 Mbps and a sub pool size of 20 Mbps on all links in the topology. Only CSR5 and XRV11 are shown for brevity.

```
! CSR5
interface GigabitEthernet2.525
 ip rsvp bandwidth 100000 sub-pool 20000

interface GigabitEthernet2.550
 ip rsvp bandwidth 100000 sub-pool 20000

interface GigabitEthernet2.551
 ip rsvp bandwidth 100000 sub-pool 20000

! XRV11
rsvp
interface GigabitEthernet0/0/0/0.501
 bandwidth 100000 sub-pool 20000

interface GigabitEthernet0/0/0/0.512
```

```
bandwidth 100000 sub-pool 20000
```

```
interface GigabitEthernet0/0/0/0.551
bandwidth 100000 sub-pool 20000
```

As a side note, when configuring pre-standard or IETF RDM DS-TE, it is important to ensure that higher numbered BCs have less or equal bandwidth to the next lower BC. In this case, it doesn't make sense for the sub-pool (BC1) to have more bandwidth than the global pool (BC0).

```
CSR3(config-subif)#ip rsvp bandwidth rdm bc0 10000 bc1 20000
Reservable sub pool (pool1) bandwidth must be less than
or equal to RSVP Reservable Bandwidth.
```

We can verify the configuration was successful in both routers by checking the RSVP interface summary. The RSVP interface details don't reveal anything new, but show the same output in verbose fashion.

```
CSR5#show ip rsvp interface

Next, we will configure a DS-TE tunnel [ID 200] requesting 5 Mbps of sub-pool bandwidth from CSR1 to XRv11. The TE tunnel configuration is identical to other TE tunnels except the bandwidth is identified as "sub-pool". We will re-use existing path-options from previous labs for brevity. When the tunnel configuration is complete, we verify that it is functional and that the bandwidth is identified as "Sub".

```
! CSR1
interface Tunnel200
description PRE-STD DS-TE GLOBAL POOL

  AutoRoute destination: enabled
  auto-bw: disabled
```

Debugging RSVP dump-messages and look at the outgoing PATH message, we can see that this is identified as “guaranteed service” with some generally irrelevant parameters. This is just a mechanism for RSVP to identify/classify the flow differently. Notice that the PATH message length is 252 bytes.

```
! CSR1
Outgoing Path:
  version:1 flags:0000 cksum:E808 ttl:255 reserved:0 length:252
SESSION          type 7 length 16:
  Tun Dest: 11.11.11.11 Tun ID: 200 Ext Tun ID: 1.1.1.1
[snip]
Guaranteed Service break bit=0 service length=8

          Path Jitter (microseconds):12
          Path delay since shaping (microseconds):0
          Path Jitter since shaping (microseconds):12
```

Checking RSVP, we can see that 5 Mbps was reserved. The RSVP interface summary does not show that these 5 Mbps are from the sub-pool, nor does the detailed command.

```
CSR1#show ip rsvp interface
```

interface	rsvp	allocated	i/f max	flow max	sub max	VRF

Curr allocated: 5M bits/sec
Max. allowed (total): 100M bits/sec
Max. allowed (per flow): 100M bits/sec
Max. allowed for LSP tunnels using sub-pools (pool 1): 20M bits/sec
Set aside by policy (total): 0 bits/sec

```

The TED does a better job of differentiating between pools. We can tell these 5 Mbps are used from the sub-pool because it was subtracted from both the sub-pool and global-pool. Global-pool reservations are only subtracted from the global-pool. Similar to TE priorities, bandwidth reserved within more important pools is subtracted from lesser pools, but not vice versa.

```

CSR1#show mpls traffic-eng topology 1.1.1.1
[snip]
  link[1]: Point-to-Point, Nbr IGP Id: 0000.0000.0006.00, nbr_node_id:21,

[snip]

To prove this, we temporarily change the bandwidth from sub-pool to global-pool on tunnel200 and look at the TED again. Now, the 5 Mbps was only subtracted from the global-pool. This proves that sub-pool reservations count against global pool reservations on a link. This makes sense because it ensures global-pool flows do not book more bandwidth than is available when sub-pool flows (more important) are also considered.

```

[snip]

Debugging RSVP dump-messages again, we can see this is just a normal “controlled-load” service with no fancy options. The difference in RSVP PATH message length is 32 bytes (252 bytes for guaranteed service minus 220 bytes for controlled-load service) . Since the "service length" of the sub-pool PATH message is 8, I assume this is a measurement counting 4-byte words. Each of the sub-service fields is a 32-bit (4-byte) unsigned integer as a result.

```

! CSR1
Outgoing Path:
  version:1 flags:0000 cksum:FF75 ttl:255 reserved:0 length:220
SESSION          type 7 length 16:
  Tun Dest:   11.11.11.11  Tun ID: 200  Ext Tun ID: 1.1.1.1
[snip]
Controlled Load Service  break bit=0  service length=0

```

For additional verification, we perform a quick data-plane verification of the LSP. CSR1 is using RSVP-bound label 6016 to send traffic to CSR6. Using traceroute on CSR1, we verify that traffic to 11.11.11.11 is forwarded inside the TE tunnel.

```

CSR1#show ip rsvp reservation detail filter session-type 7 destination
11.11.11.11 | include Label
  Label: 6016 (outgoing)

CSR1#traceroute 11.11.11.11 source 1.1.1.1
Type escape sequence to abort.
Tracing the route to 11.11.11.11

```

```

 2 132.6.10.10 [MPLS: Label 10013 Exp 0] 16 msec 16 msec 25 msec
 3 132.10.11.11 9 msec * 21 msec
```

Before continuing, we change the 5 Mbps reservation back to sub-pool bandwidth. Unlike CBTS, all of the traffic towards XRv11's loopback will use this tunnel. The difference is that bandwidth is reserved differently; a bandwidth reservation on a single tunnel cannot reserve both global-pool and sub-pool bandwidth concurrently. Because of this, the underlying QoS queuing/shaping architecture should match the DS-TE configuration. We will create a quick policy on CSR1 to demonstrate this. The PMAP_SHAPE policy is applied to all 5 of CSR1's MPLS-facing sub-interfaces (application of policy is not shown). The math behind the 26 bytes of overhead is described next.

```
! CSR1
class-map match-all CMAP_VOICE
  match mpls experimental topmost 5

policy-map PMAP_QUEUE
  class CMAP_VOICE
    priority 5000
  class class-default
    queue-limit 16 packets

policy-map PMAP_SHAPE
  class class-default
    shape average 100000000  account user-defined 26
    service-policy PMAP_QUEUE
```

We know that 5 Mbps have been reserved; let's assume this is a layer 2 reservation which accounts for necessary overhead already. Cisco queuing and policing always accounts for layer 2 overhead, and shaping can optionally be configured to do so also. The overhead of packets traversing the network will vary depending on the MPLS label stack, but a safe assumption would be: 14 bytes for Ethernet, 4 bytes of 802.1q, and two 4-byte MPLS shim headers. This is a total of 26 bytes, and we can quickly prove it by using our QoS policy. Sending a single 100-byte packet at DSCP CS5 will show us how Cisco queuing accounts for overhead. The policy-map details show a single 126 byte packet, which verifies the 26 bytes of overhead as expected.

```
CSR7#ping 13.13.13.13 source 7.7.7.7 tos 160 repeat 1
Type escape sequence to abort.
Sending 1, 100-byte ICMP Echos to 13.13.13.13, timeout is 2 seconds:
Packet sent with a source address of 7.7.7.7
!
Success rate is 100 percent (1/1), round-trip min/avg/max = 21/21/21 ms
```

```
CSR1#show policy-map interface gig2.516 | section VOICE
  Class-map: CMAP_VOICE (match-all)
```

```
1 packets, 126 bytes
```

```
5 minute offered rate 0000 bps, drop rate 0000 bps
```

```
Match: mpls experimental topmost 5
```

```
Priority: 5000 kbps, burst bytes 125000, b/w exceed drops: 0
```

The math is not always precise. For example, sending VPN traffic to CSR8 results in only a single MPLS label due to PHP, so the overhead is 4 bytes less for a total of 22 bytes. This isn't terribly significant for DS-TE but it is worth mentioning. The reason for the detailed synchronization between RSVP reservations and QoS schedulers is because RSVP is only a control-plane reservation. DS-TE is useless without appropriate queuing mechanisms at the link-level. Because we stated that the 5 Mbps accounts for layer 2 overhead, the actual user traffic would be slightly less than 5 Mbps.

```
CSR7#ping 14.14.14.14 so 7.7.7.7 tos 160 repeat 1
```

```
Type escape sequence to abort.
```

```
Sending 1, 100-byte ICMP Echos to 14.14.14.14, timeout is 2 seconds:
```

```
Packet sent with a source address of 7.7.7.7
```

```
!
```

```
Success rate is 100 percent (1/1), round-trip min/avg/max = 2/2/2 ms
```

```
CSR1#show policy-map interface gig2.518 | section VOICE
```

```

```

```
1 packets, 122 bytes
```

```
5 minute offered rate 0000 bps, drop rate 0000 bps
```

```
Match: mpls experimental topmost 5
```

```
Priority: 5000 kbps, burst bytes 125000, b/w exceed drops: 0
```

For completeness, we will configure pre-standard DS-TE on XRv11 as well. The only difference from a standard TE-tunnel in XR is that the signalled-bandwidth is identified as sub-pool bandwidth. We can re-use old explicit-paths; later we will test FRR on the link between CSR3 and CSR10, so we want to use that link. Once configured, we verify the tunnel comes up and routes the way the explicit-path specified.

```
! XRv11
```

```

```

Checking XRv11's local TE topology information, we see that 11 Mbps of sub-pool bandwidth was allocated at priority 7 (worst). This was also reduced from the global pool, as expected, which is consistent with the RDM BC-model discussed later. It is interesting to note that XR shows the BC model is RDM, which is somewhat true since the pre-standard version behaves like IETF RDM in many ways.

To test FRR with DS-TE, we will begin by modifying an existing NHOP tunnel on CSR3. This is an NHOP backup tunnel that requires green, blue, and orange colors on a link. The tunnel routes via CSR2 as this is the only option meeting the affinity constraints. The tunnel currently does not specify any backup bandwidth.

```

! CSR3
interface Tunnel130

```

```

description REPAIR PATH NHOP (PLR)
ip unnumbered Loopback0
tunnel mode mpls traffic-eng

    Record Route: NONE
    Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

```

For FRR to be effective within the context of DS-TE, we need tunnels that request FRR on CSR1 and XRv11, along with bandwidth protection. We add two tunnels [ID 210 and 211] to test this. Tunnel210 will request global pool bandwidth while tunnel211 will request sub-pool bandwidth. We can look at the RSVP RESV RRO on both CSR1 and XRv11 to see the tunnels are protected at CSR3, the PLR. First, we configure and verify the CSR1 tunnels. The NHOP backup tunnel currently has "unlimited" bandwidth since no backup-bandwidth is specified. Furthermore, not specifying a bandwidth type, such as global or sub-pool, means that the tunnel can back up a tunnel requesting bandwidth from any pool. We also shut down tunnel200 (not shown) so that it does not interfere with this test.

```

  tunnel mpls traffic-eng fast-reroute bw-protect

```

Since tunnels 210 and 211 are requesting FRR, their RSVP RESV RROs should reflect the available NHOP protection. In the FRR section, we saw that backup tunnels with no "backup-bw" identified were

assumed to have unlimited backup bandwidth. Despite requesting bandwidth protection, the tunnel does not specify any, so the assumption of having "unlimited" bandwidth really means that no bandwidth protection is provided. For this reason, CSR1 sees the PLR as offering local NHOP protection, but no bandwidth protection.

```
CSR1#show ip rsvp reservation detail filter session-type 7 | section

```

Next, we configure the equivalent tunnels on XRv11. The tunnels are virtually identical with different bandwidth reservations in different pools.

```
! XRv11
interface tunnel-te210
  description DS-TE GLOBAL-POOL BW FRR
  ipv4 unnumbered Loopback0
  logging events all
  signalled-bandwidth 11000
  destination 8.8.8.8
  fast-reroute protect bandwidth
  affinity ignore
  path-option 10 explicit name PATH_11_5_2_3_10_6_8

interface tunnel-te211
  description DS-TE SUB-POOL BW FRR
```

```
ipv4 unnumbered Loopback0
logging events all
signalled-bandwidth sub-pool 4000
destination 8.8.8.8
fast-reroute protect bandwidth
affinity ignore
path-option 10 explicit name PATH_11_5_2_3_10_6_8
```

Like the CSR1 DS-TE tunnels, both tunnels are requesting bandwidth protection but it is not available. Local protection is supported at CSR3 for both tunnels, though.

```

```

CSR3 sees all four tunnels in its FRR database as well. Each one is mapped to tunnel30, the NHOP tunnel with unlimited bandwidth servicing "any" pool.

```
CSR3#show mpls traffic-eng fast-reroute database | begin midpoint
```

P2P LSP midpoint frr information:

LSP identifier	In-label	Out	intf/label	FRR intf/label	Status
-----	-----	-----	-----	-----	-----
1.1.1.1 210 [25]	3023	Gi2.530:10023	Tu30:10023	ready	
1.1.1.1 211 [25]	3024	Gi2.530:10024	Tu30:10024	ready	
11.11.11.11 210 [5]	3021	Gi2.530:10021	Tu30:10021	ready	
11.11.11.11 211 [5]	3022	Gi2.530:10022	Tu30:10022	ready	

The backup tunnel details show that "any" pool is assumed, since no pool was specified. Also, the total in-use bandwidth on the tunnel is 27 Mbps, none of which is actually protected. 27 Mbps is the sum of all 4 tunnels requested bandwidth but does not specify global or sub pool.

```
CSR3#show mpls traffic-eng tunnels tunnel 30 backup
REPAIR PATH NHOP (PLR)
  LSP Head, Admin: up, Oper: up
  Tun ID: 30, LSP ID: 24, Source: 3.3.3.3
  Destination: 10.10.10.10
  Fast Reroute Backup Provided:
    Protected i/fs: Gi2.530
    Protected LSPs/Sub-LSPs: 4, Active: 0
    Backup BW: any pool unlimited; inuse: 27000 kbps
  Backup flags: 0x0
```

As a test, we will configure the tunnel to offer 7 Mbps of sub-pool backup bandwidth. This is just enough to backup both tunnel211 interfaces on CSR1 and XRv11. At this point, both tunnel210 interfaces now have no protection at all, since the NHOP tunnel services only sub-pool flows. The FRR tunnel has now specified both the type and quantity of bandwidth, making it much more restrictive/selective in terms of which LSPs it is capable of protecting.

```
! CSR3
interface Tunnel30
  tunnel mpls traffic-eng backup-bw sub-pool 7000
```

We can verify that only the tunnel211 interfaces are backed up on the PLR by checking the FRR database and the tunnel30 backup details. The bandwidth type is sub-pool and the amount is 7 Mbps.

```
CSR3#show mpls traffic-eng fast-reroute database | begin midpoint
P2P LSP midpoint frr information:
LSP identifier      In-label Out intf/label  FRR intf/label  Status

```

```
CSR3#show mpls traffic-eng tunnels tunnel 30 backup
REPAIR PATH NHOP (PLR)
  LSP Head, Admin: up, Oper: up
  Tun ID: 30, LSP ID: 24, Source: 3.3.3.3
```

```

Destination: 10.10.10.10
Fast Reroute Backup Provided:
  Protected i/fs: Gi2.530
  Protected LSPs/Sub-LSPs: 2, Active: 0
  Backup BW: sub-pool; limit: 7000 kbps, inuse: 7000 kbps (BWP inuse: 7000 kbps)
  Backup flags: 0x0

```

On CSR1, we notice that tunnel210 is no longer protected by the NHOP tunnel at all. This is because it is requesting global pool bandwidth and the NHOP tunnel only provides sub-pool bandwidth backup. Tunnel211, however, now has local protection and available bandwidth, since it is requesting sub-pool bandwidth and the backup tunnel has a specific amount of bandwidth available (versus unlimited). Tunnel210 would not be protected even if it wasn't asking for bandwidth-protection simply because the bandwidth pools are mismatched between the head-end and PLR tunnels.

```

```

We can also specify the type of bandwidth being protected without specifying an amount. This will limit to tunnel to protecting only a specific pool, as seen above, but not specifying a bandwidth value. In this example, we adjust the NHOP tunnel to support only global pool but with unlimited bandwidth. Now, the FRR database on the PLR shows protection for tunnel210 interfaces since the global pool NHOP tunnel cannot backup sub pool LSPs. There is no limit on the bandwidth and 20 Mbps are in use (sum of CSR1 and XRv11 tunnel210 global pool bandwidth requests).

```

! CSR3
interface Tunnel30
 tunnel mpls traffic-eng backup-bw global-pool unlimited

```

```

CSR3#show mpls traffic-eng fast-reroute database | begin midpoint
P2P LSP midpoint frr information:

```

    Backup BW: global pool; limit 0 kbps, inuse: 20000 kbps (BWP inuse: 0
kbps)
  Backup flags: 0x1

```

As expected, CSR1's tunnel210 is protected again, but without bandwidth protection. We only specified the type of bandwidth, not the amount, so unlimited bandwidth really means no bandwidth. Tunnel211 currently has no protection at all. This is slightly different from the previous example since the protected LSPs are not claiming to have bandwidth protection.

```

CSR1#show ip rsvp reservation detail filter session-type 7 | section

```

The same is true on XRv11. Tunnel211 now has no protection while tunnel210 has NHOP protection without any backup bandwidth guarantee. The point is that specifying the bandwidth type, and not the amount, can be used to differentiate between tunnels used for backups.

To demonstrate multiple backup tunnel selection, we will configure a pair of basic NNHOP tunnels on CSR3 [ID 31 and 32]. The tunnel logic is recycled from earlier but modified for this test. Tunnel31 will provide 5 Mbps of bandwidth for the sub-pool, which will offer protection for it. Tunnel32 won't specify a bandwidth type, but will offer 25 Mbps of general bandwidth (any pool). Both tunnels avoid CSR10 completely. We need two separate tunnels since CSR1 and XRv11 headends have different NNHOPs. As mentioned earlier, this is why NHOP protection often scales better at the expense of less resiliency.

```
! CSR3
interface Tunnel31
  description REPAIR PATH NNHOP (PLR) FOR CSR1
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
```

```
tunnel mpls traffic-eng backup-bw sub-pool 5000
tunnel mpls traffic-eng affinity 0x0 mask 0x0
tunnel mpls traffic-eng path-option 10 explicit name PATH_AVOID_CSR10
```

```
interface Tunnel32
description REPAIR PATH NNHOP (PLR) FOR XRv11
ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 6.6.6.6
tunnel mpls traffic-eng backup-bw 25000
tunnel mpls traffic-eng affinity 0x0 mask 0x0
tunnel mpls traffic-eng path-option 10 explicit name PATH_AVOID_CSR10
```

We quickly verify the paths used by the tunnels. Tunnel31 routes via CSR2 and CSR5 to reach XRv11 to protect CSR1's LSP. Tunnel32 routes via CSR1 to reach CSR6 to protect XRv11's LSP.

```
CSR3#show ip rsvp sender detail filter session-type 7 tunnel 31 | section
outgoing
```

```
ERO: (outgoing)
132.2.3.2 (Strict IPv4 Prefix, 8 bytes, /32)
132.2.5.5 (Strict IPv4 Prefix, 8 bytes, /32)
132.5.11.11 (Strict IPv4 Prefix, 8 bytes, /32)
11.11.11.11 (Strict IPv4 Prefix, 8 bytes, /32)
```

```
CSR3#show ip rsvp sender detail filter session-type 7 tunnel 32 | section
outgoing
```

```
ERO: (outgoing)
132.1.3.1 (Strict IPv4 Prefix, 8 bytes, /32)
132.1.6.6 (Strict IPv4 Prefix, 8 bytes, /32)
6.6.6.6 (Strict IPv4 Prefix, 8 bytes, /32)
```

When there are multiple competing tunnels, the pool type adds a new dimension to the backup tunnel selection. Below is a chart summarizing the selection process. The chart can be generalized with a few general comments:

1. *NNHOP tunnels are preferred over NHOP tunnels*
2. *A tunnel with limited (specified) bandwidth is preferred over unlimited bandwidth*
3. *Specific pool tunnels (global, sub, or specific BC) are preferred over "any" (unspecified) pool tunnels*

Preference	Tunnel type	Bandwidth type	Bandwidth amount
1 (best)	NNHOP	Specific pool/BC	Limited
2	NNHOP	Any	Limited
3	NNHOP	Specific pool/BC	Unlimited
4	NNHOP	Any	Unlimited
5	NHOP	Specific pool/BC	Limited
6	NHOP	Any	Limited
7	NHOP	Specific pool/BC	Unlimited

8 (worst)	NHOP	Any	Unlimited

The FRR database on CSR3 shows very interesting results. We will analyze each row of the database individually. For clarity, the tunnels and their backup-bandwidths are shown again.

```
! CSR3
interface Tunnel30
 tunnel mpls traffic-eng backup-bw global-pool unlimited

interface Tunnel31
 tunnel mpls traffic-eng backup-bw sub-pool 5000

interface Tunnel32
 tunnel mpls traffic-eng backup-bw 25000
```

First, we see tunnel210 from CSR1. It is protected by the original NHOP tunnel30, which offers unlimited global-pool bandwidth. This is option #7 on the chart above, making it relatively undesirable. This LSP cannot choose tunnel31 since that NNHOP backup tunnel protects only sub-pool traffic (limited quantity), which would be option #1. This type of tunnel is the most desirable choice but also the most restrictive/selective. It also cannot choose tunnel32 because this tunnel goes to an incorrect NNHOP for this LSP, but it would have been a better choice since any limited bandwidth is better than specific unlimited bandwidth.

Second, we see tunnel211 also from CSR1. This uses tunnel31 for backup, which offers NNHOP protection for limited sub-pool bandwidth. This is the best possible option. The LSP could not use tunnel30, since it was requesting sub pool bandwidth while tunnel30 only offered global pool protection.

Third is tunnel210 from XRv11. It is protected by tunnel32, offering NNHOP protection with a limited bandwidth amount in any pool (option #2). The LSP could have potentially used tunnel30 as well, since it was requesting global pool bandwidth, but option #2 is better than option #7.

Fourth is tunnel211 from XRv11. It also uses tunnel32 for protection since it is the only feasible option. Tunnel30 is not a candidate since it only backs up global pool bandwidth but the head-end requests sub-pool bandwidth.

```

1.1.1.1 210 [31]        3020     Gi2.530:10019          Tu30:10019        ready
1.1.1.1 211 [28]        3017     Gi2.530:10017          Tu31:implicit-nu  ready
11.11.11.11 210 [5]     3021     Gi2.530:10021          Tu32:6015         ready
11.11.11.11 211 [5]     3022     Gi2.530:10022          Tu32:6016         ready
```

If we temporarily shut down tunnel32, we notice 2 changes. CSR1's tunnels are not affected at all, since they selected other available backups in the first place. XRv11 tunnel210, which selected tunnel32, now chooses tunnel30. As mentioned earlier, tunnel30 was a candidate for protection but was not selected since it was less desirable. XRv11 tunnel211 now has no feasible backup paths, and thus is unprotected. When every LSR in a network is also a candidate PLR (which is common), there are likely to be many backup tunnels. This selection process is important to determine the sequence in which LSPs are protected by specific FRR tunnels.

```
CSR3#show mpls traffic-eng fast-reroute database | begin midpoint
P2P LSP midpoint frr information:
```

LSP identifier	In-label	Out intf/label	FRR intf/label	Status
1.1.1.1 210 [31]	3020	Gi2.530:10019	Tu30:10019	ready
1.1.1.1 211 [28]	3017	Gi2.530:10017	Tu31:implicit-nu	ready
11.11.11.11 210 [5]	3021	Gi2.530:10021	Tu30:10021	ready

When tunnel32 comes back up, the PLR notifies the head-end that protection is available within the RSVP RESV message without any user intervention. The head-end does not need to resignal the LSP, which is why the LSP IDs remain unchanged, as do the TE labels. The LSP promotion for backup tunnels can be controlled by the FRR timers discussed earlier.

```

31.4.2 IETF Russian Dolls Model (RDM)

The lab is a continuation from the DS-TE pre-standard lab. The Russian Dolls Model (RDM) method is the default IETF DS-TE implementation in Cisco routers. It is defined in RFC 4127 and allows different CTs to share bandwidth on a link. This allows for most efficient bandwidth sharing between different CTs, but still allows for preemption when higher priority classes require bandwidth. The IETF implementation is vendor interoperability and extends the sub-pool concept to multiple CTs, briefly described earlier. To enable IETF DS-TE in RDM mode, only one command is required.

```
! All MPLS XE routers
mpls traffic-eng ds-te mode ietf
```

```
! All MPLS XR routers
mpls traffic-eng
```

```
ds-te mode ietf
```

Although we have not defined any bandwidth constraints (BC), entering this global command changes quite a bit. In XE, all of the existing RSVP bandwidth pools configured at the link level are converted to the IETF RDM format. The global pool is identified as BC0 and the sub-pool is identified as BC1, but otherwise the command is very similar. Because the pre-standard DS-TE implementation is based on RDM, the configuration can be easily converted back and forth by IOS. Either syntax is accepted, and both XE and XR don't care either way. XR does not change the commands from the global/sub pool format by default, so we will leave XRv12 with the legacy global/sub pool commands since they still work. I will update XRv11 for completeness to show the alternative (new) syntax.

```
! CSR1, this happens automatically
interface GigabitEthernet2.516
 ip rsvp bandwidth rdm bc0 100000 bc1 20000
```

```
! XRv11, must be configured manually
rsvp
 interface GigabitEthernet0/0/0/0.501
   bandwidth rdm bc0 100000 bc1 20000
```

```
interface GigabitEthernet0/0/0/0.512
 bandwidth rdm bc0 100000 bc1 20000
```

```
interface GigabitEthernet0/0/0/0.551
 bandwidth rdm bc0 100000 bc1 20000
```

The RSVP commands, like before, are not terribly useful for DS-TE and haven't changed much. RSVP still uses terms like "global" and "sub" pool. The existing tunnel200 is still online and requesting 5 Mbps of sub-pool bandwidth.

```
CSR1#show ip rsvp interface
```

interface	rsvp	allocated	i/f max	flow max	sub max	VRF
Gi2	ena	0	750M	750M	0	
Gi2.513	ena	0	100M	100M	20M	
Gi2.514	ena	0	100M	100M	20M	
Gi2.516	ena	5M	100M	100M	20M	
Gi2.518	ena	0	100M	100M	20M	
Gi2.519	ena	0	100M	100M	20M	

Looking at the MPLS TE show commands for TE-classes, we can see there is new information. A small table is shown which defines 4 default TE-classes out of a possible 64. Only class-types 0 (global) and 1 (sub) are currently defined, but the 8 priority values still exist. XE routers appear capable of carrying up to 8 TE classes at any time, as seen in the TED later. The chart below seems to indicate that higher number TE-classes are more important. For example, TE-class 0 uses global-pool bandwidth (CT 0) and

has a priority of 7, which is the worst. TE-class 5 use sub-pool bandwidth (CT 1) and has a priority of 0, which is the best.

```
CSR1#show mpls traffic-eng ds-te te-class
DS-TE Mode: IETF
```

TE-Class	Class-Type	Priority
* 0	0	7
* 1	1	7
* 4	0	0
* 5	1	0
* - default setting		

Class-Type: 0 = Global-pool, 1 = Sub-pool

The TE tunnel configured earlier is still operational in the new RDM-based DS-TE network. Looking at the TED on CSR1, and specifically looking at the link to CSR6, we can see the output is considerably different. It shows us the RDM model, along with BC0 and BC1 reservable bandwidth quantities. A BC defines how much bandwidth a CT can use. Thus, BC0 is 100 Mbps and is the maximum reservable bandwidth between all TE-classes within CT0. BC1 is 20 Mbps and is the maximum reservable bandwidth for TE-classes using CT1. The bandwidth reservations shown below are confusing at first glance. TE-class 1 represents sub-pool flows that are priority 7. The existing TE tunnel is priority 7, the default, because we never set it. It is also using sub-pool bandwidth (CT1), so we know it is part of TE-class 1. The 5 Mbps reservation is counted against TE-class 1 and all lower classes as well; this behavior is consistent with non-DS-TE as well when only bandwidth prioritization for global-pool resources was considered. TE-class 0 is also priority 7 but represents the global-pool bandwidth, so reducing it by 5 Mbps when a sub-pool flow of the same priority is created is consistent with pre-standard DS-TE as well. TE-classes 4 and 5, despite being CT0 and CT1 respectively, are not affected by this reservation.

```

TE-Class[7]:           0             0
[snip]

```

We also check the ISIS LSP. This differs significantly from the pre-standard version since there isn't a separate accounting of global and sub pools. Instead, the BC-TLV signals that the IETF RDM model is being used. The "global pool" bandwidth represents the bandwidth of BC0, which is the all-encompassing bandwidth value. 100 Mbps are available to BC0 with 20 Mbps of it being available to BC1, as shown in the LSP. For brevity, we examine the link to CSR8. The TE-classes are carried instead of the bandwidth pool types.

```

```

The CT of a TE tunnel is carried inside of the RSVP PATH message as a class type object (CTO). The Cisco pre-standard version could not use this CTO since it required changes to RSVP; it is specified to the IETF BC models. When CSR1 signals this tunnel, the CT is carried along the path so routers know how to allocate bandwidth for it when multiple BC pools exist. The TE-class itself is not explicitly signaled in RSVP, which is why all routers must agree on what the TE-class mappings are. The combination of the CT and the LSP priority (carried in the SAO) make up the TE-class.

```

[snip]

```

To test out how bandwidth is divided when there are multiple priorities, next we configure a new tunnel [ID 201] that uses global-pool bandwidth but is the highest priority. The tunnel will take any green path to XRv11 and reserve 7 Mbps of global-pool bandwidth. This maps to TE-class 4, which is a combination of CT0 and priority 0. Auto-route is not configured since this tunnel is for demonstration only.

```

! CSR1
interface Tunnel201
  description RDM DS-TE GLOBAL POOL (HI PRI)
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 11.11.11.11
  tunnel mpls traffic-eng priority 0 0
  tunnel mpls traffic-eng bandwidth 7000 class-type 0
  tunnel mpls traffic-eng affinity 0x2 mask 0x2
  tunnel mpls traffic-eng path-option 10 dynamic

```

It is interesting to note that a lower-priority CT cannot reduce bandwidth from a higher-priority CT. Even though TE-class 4 is "better" than TE-class 1, it uses bandwidth from BC0 which can never take bandwidth from BC1. TE-class 0 is affected by this 7 Mbps reservation since it is within CT0, just like TE-class 4. TE-class 1 is within CT1 and cannot be affected. In short, when a flow has a lower CT but a higher priority (TE-class 4), higher CTs with lower priorities (TE-class 1) are not affected.

```

[snip]

Building another tunnel to XRv11 [ID 202], we will configure a 1 Mbps CT1 reservation at priority 3. Priority 3 was not specified as a valid TE-class by default. Unfortunately, there are no debug or syslog messages to indicate this is a problem, and the tunnel never comes up. I assume that the TE process has no idea how to signal this bandwidth since it does not fit into a predefined TE-class.

```

! CSR1
interface Tunnel202

Metric Type: TE (default)
AutoRoute: disabled LockDown: disabled Loadshare: 1000 [0] bw-based
auto-bw: disabled

```

We can customize the TE-classes as well; the TE-classes seen earlier were just the defaults. We create a new TE-class 3 that uses CT1 and priority 3. This must be consistent on all MPLS routers within the DS-TE domain. After configuring this new class, we verify it on an XE and an XR router. XE shows non-default entries by omitting the asterisk while XR explicitly states whether a TE-class is a default or configured entry.

```
! All MPLS XE routers
mpls traffic-eng ds-te te-classes
  te-class 3 class-type 1 priority 3
```

```
! All MPLS XR routers
mpls traffic-eng
  ds-te te-classes
    te-class 3 class-type 1 priority 3

te-class 4: class-type 0 priority 0 status default
te-class 5: class-type 1 priority 0 status default
te-class 6: unused
te-class 7: unused
```

With the new TE-class 3 configured, tunnel202 comes up and we can check its bandwidth impacts on the TE topology. The tunnel routes through CSR4 which is the only orange link towards XRv11. Because the reservation was made at TE-class 3, all lower TE-classes that have lesser or equal CTs will be affected (they are within BC1 or less). In this case, the reservation affects all lower priority TE classes for BC0 and BC1. TE-classes 4 and 5 are not affected since they are higher priority; the "cascade" effect of bandwidth reduction only applies when both the CT and priority are less or equal to the level at which the reservation was made. TE-classes 4 and 5 are unaffected, despite TE-class 4 being BC0.

```
CSR1#show mpls traffic-eng topology 1.1.1.1

[snip]
```

RDM tunnels on XR are very similar to XE. Recycling tunnel200, we just change the syntax to the RDM version (which isn't required) for clarity. We can verify the reservation by checking the RSVP details, but again, this doesn't show us BC-level granularity.

```
! XRv11
interface tunnel-te200
  signalled-bandwidth 11000 class-type 0

RP/0/0/CPU0:XRv11#show rsvp interface gig0/0/0/0.551
*: RDM: Default I/F B/W % : 75% [default] (max resv/bc0), 0% [default] (bc1)

INTERFACE: GigabitEthernet0/0/0/0.551 (ifh=0xB00).
  BW (bits/sec): Max=100M. MaxFlow=100M.
                 Allocated=11M (11%).
                 BC0=100M. BC1=20M.
```

The TE topology will show this reservation using almost identical output to XE. The output is shown below for reference; we clearly see 11 Mbps reserved within TE-class 0. This represents BC0 at the lowest priority, which is correct.

```

To test FRR with RDM, we will use tunnels 210 and 211 on CSR1 and XRv11 again. We will update them to the IETF RDM syntax for clarity. All previous tunnels are shutdown for this test.

```

! CSR1
interface Tunnel210
  description DS-TE RDM BC0 BW FRR
  tunnel mpls traffic-eng bandwidth 9000 class-type 0

interface Tunnel211
  description DS-TE RDM BC1 BW FRR
  tunnel mpls traffic-eng bandwidth 3000 class-type 1

! XRv11

```

```

interface tunnel-te210
  description DS-TE RDM BC0 BW FRR
  signalled-bandwidth 11000 class-type 0

interface tunnel-te211
  description DS-TE RDM BC1 BW FRR
  signalled-bandwidth 4000 class-type 1

```

Since pre-standard DS-TE operates just like RDM with only two pools, the FRR behavior is identical. We update the existing backup tunnels on CSR3 to the IETF RDM syntax for clarity.

```

! CSR3
interface Tunnel30
  tunnel mpls traffic-eng backup-bw class-type 0 unlimited

interface Tunnel31
  tunnel mpls traffic-eng backup-bw class-type 1 5000

interface Tunnel32
  tunnel mpls traffic-eng backup-bw 25000

```

The only changes we have made thus far have been cosmetic. There isn't any behavior change with DS-TE and FRR when switching between different modes or BC-models. Verifying each individual tunnel again would be highly redundant, so we will check the FRR database on CSR3 as a shortcut. Again, we see all 4 tunnels receiving some level of protection. The behavior is identical to pre-standard RDM with respect to FRR protection, except the configuration syntax changes. The backup tunnels that each LSP selects are based on the same 3-point selection process we evaluated earlier. The chart shown in the previous chapter holds true for IETF DS-TE using RDM.

```

CSR3#show mpls traffic-eng fast-reroute database | begin midpoint
P2P LSP midpoint frr information:
LSP identifier          In-label Out intf/label    FRR intf/label    Status
-----
1.1.1.1 210 [18]        3005     Gi2.530:10008        Tu30:10008        ready
1.1.1.1 211 [16]        3007     Gi2.530:10024        Tu31:implicit-nu  ready
11.11.11.11 210 [4]     3023     Gi2.530:10015        Tu32:6018         ready
11.11.11.11 211 [4]     3001     Gi2.530:10014        Tu32:6019         ready

```

As a quick test, we shut down tunnel32 again to ensure we get the same result, which also supports the claim that the selection process is consistent between pre-standard and IETF DS-TE implementation.

```

```

We quickly verify the bandwidth reserved on the link to CSR10 for additional verification. We can see the RDM BC model in action; the 7 Mbps reduced from TE-class 1 is also reduced from TE-class 0 based on the bandwidth sharing mechanism of RDM. With MAM, we will see that TE-class 0 would not have been affected by TE-class 1 reservations since CTs are entirely isolated.

31.4.3 IETF Maximum Allocation Model (MAM)

This lab continues from the RDM lab. Maximum Allocation Model (MAM) is defined in RFC 4125 and creates total isolation between the CTs. There is no bandwidth sharing between them which means bandwidth can be wasted when higher priority flows are not using all available bandwidth within a BC. Different priorities across different CTs have no effect on one another. This is essentially a way to map BCn to CTn, where $0 \leq n \leq 7$. Each CT will always receive its bandwidth share. This model is effective when the premium traffic (voice, etc) needs better bandwidth protection and total isolation. Like RDM, this is an IETF model so the logic of CT, BC, and TE-class is the same. When switching from RDM to MAM, XE does not conveniently replace all of the link-level RSVP commands with the MAM commands, so we must do it manually. This is because the RDM and MAM commands are functionally different and both commands can exist on a link concurrently. For clarity, I remove the RDM commands and add the MAM

commands. Although the sum of all BCs can total more than the max-reservable bandwidth, it makes more sense to have them sum to exactly that number. In this case, 80 Mbps are reserved for BC0 and 20 Mbps are reserved for BC1.

```
! All MPLS XE routers
mpls traffic-eng ds-te bc-model mam

! All MPLS XR routers
mpls traffic-eng
  ds-te bc-model mam

! CSR1 (example)
interface GigabitEthernet2.516
  no ip rsvp bandwidth rdm bc0 100000 bc1 20000
  ip rsvp bandwidth mam max-reservable-bw 100000 bc0 80000 bc1 20000

! XRv11 (example)
rsvp
  interface GigabitEthernet0/0/0/0.501
    no bandwidth
    bandwidth mam max-reservable-bw 100000 bc0 80000 bc1 20000
```

Before looking at the TE topology, we check the underlying data structures to see how this changes the ISIS LSP. The format has changed slightly for MAM compared to RDM. The BC model is carried in the BC-TLV which identifies this as MAM, whereas before it showed RDM. The BC values are listed individually as 80 Mbps and 20 Mbps for BC0 and BC1, respectively. The "global pool" bandwidth now represents the max-reservable bandwidth of 100 Mbps, which in our case is the sum of BC0 and BC1. With RDM, BC0 showed 100 Mbps of bandwidth, but MAM completely separates the class-types (and therefore the BCs). Technically, routers could be running different BC-models within a network, but it would be difficult to design a QoS solution if routers interpret BCs differently. We can see that TE-classes 0 and 4, the ones based on BC0 by default, now only claim to have 80 Mbps available for reservations using MAM.

```

```

These configuration changes have no affect on existing TE-classes, TE tunnels, or other IETF-related details. TE-class 3 still exists as we configured it for RDM. Changing the BC model just changes how bandwidth is treated with respect to CTs and LSP priorities. First, we will look at tunnel200 again. The tunnel still routes via CSR6, so CSR1 should see a 5 Mbps reservation on this link against TE-class 1. This class represents BC1 (in MAM, this means CT1) at priority 7 (worst). There are 15 Mbps remaining of BC1 bandwidth (sub-pool), but BC0 is unaffected. With RDM, TE-class 0 would have 75 Mbps remaining since the 5 Mbps would have been counted against all lower BCs as well. In this way, MAM keeps bandwidth allocations between CTs totally separate.

```

Next, we check tunnel201 which routes via CSR3 since it is the best green path to XRv11. On the link to CSR3, CSR1 reserves 7 Mbps for TE-class 4, which uses BC0 at priority 0 (highest). Like RDM, this also does not affect BC1, but does affect lower priority BC0-mapped TE-classes, such as TE-class 0. In this way, MAM still keeps the CTs totally separate but honors the importance of prioritization.

```

Last, we analyze tunnel202's behavior with MAM. It routes via CSR4 since that is the only orange path towards XRv11. TE-class 3 uses BC1 (only maps to CT1 with MAM) and has priority 3. It reserves 1 Mbps of BC1 (sub-pool) bandwidth. Lower priority BC1 classes, such as TE-class 1, have their available bandwidth reduced by 1 Mbps as well. TE-class 0, despite being the "lowest priority" traffic, is totally unaffected by the BC1 reservations as it maps to BC0.

```

TE-Class[5]:	0	20000
TE-Class[6]:	0	0
TE-Class[7]:	0	0

MAM DS-TE on XR is very similar to RDM DS-TE in terms of tunnel configuration. In this case, we have a BC1 reservation of 11 Mbps, which should not affect any lower-priority BC0 TE-classes. We quickly verify the tunnel is up before continuing.

```
! XRv11
interface tunnel-te200
  signalled-bandwidth 11000 class-type 1

RP/0/0/CPU0:XRv11#show mpls traffic-eng tunnels 200 role head | begin Path
info
  Path info (IS-IS 132 level-2):
  Node hop count: 6
  Hop0: 132.5.11.5
  Hop1: 132.2.5.2
  Hop2: 132.2.3.2
  Hop3: 132.2.3.3
  Hop4: 132.3.10.10
  Hop5: 132.6.10.6
  Hop6: 132.6.8.8
  Hop7: 8.8.8.8
```

Since CSR5 is the next-hop, we can look at the TE topology to confirm the MAM behavior on XR. Despite 11 Mbps being reserved for TE-class 1, this does not affect TE-class 0 at all as 80 Mbps are still available. This TE-class 0 value would have been reduced to 69 Mbps with RDM.

```
RP/0/0/CPU0:XRv11#show mpls traffic-eng topology 11.11.11.11 | begin 0005

TE-class[4]:	0	80000
TE-class[5]:	0	20000
TE-class[6]:	0	0
TE-class[7]:	0	0

We quickly test FRR with MAM also. The tunnel configurations are identical as they were for RDM, minus descriptions, but are shown again for clarity. All existing DS-TE tunnels are shut down for the FRR testing.

```
! CSR1
interface Tunnel210
  description DS-TE MAM BC0 BW FRR
  tunnel mpls traffic-eng bandwidth 9000 class-type 0

interface Tunnel211
  description DS-TE MAM BC1 BW FRR
  tunnel mpls traffic-eng bandwidth 3000 class-type 1

! XRv11
interface tunnel-te210
  description DS-TE MAM BC0 BW FRR
  signalled-bandwidth 11000 class-type 0

interface tunnel-te211
  description DS-TE MAM BC1 BW FRR
  signalled-bandwidth 4000 class-type 1
```

The NHOP and NNHOP tunnels on CSR3 are totally unchanged, but shown again for clarity.

```
! CSR3
interface Tunnel30
  tunnel mpls traffic-eng backup-bw class-type 0 unlimited

interface Tunnel31
  tunnel mpls traffic-eng backup-bw class-type 1 5000

interface Tunnel32
  tunnel mpls traffic-eng backup-bw 25000
```

We can verify that all of the tunnels are up and protected by FRR by checking the PLR. This output is identical (except for labels) to the outputs seen for the pre-standard and IETF RDM versions. The selection process of NHOP vs. NNHOP, specified vs. unspecified pools, and limited vs. unlimited bandwidth is identical.

```
CSR3#show mpls traffic-eng fast-reroute database | begin midpoint

```

To verify MAM behavior once more, we check the TE topology towards CSR10. A total of 7 Mbps (3 from CSR1 and 4 from XRv11) are reserved for TE-class 1, which includes BC1. A total of 20 Mbps (9 from CSR1 and 11 from XRv11) are reserved for TE-class 0, which includes BC0. There are 60 Mbps remaining for TE-class 0 with this model since the 7 Mbps against TE-class 1 do not count against TE-class 0, as they would for RDM. RDM would have 73 Mbps remaining for TE-class 0 if that model was in use; this is because all 100 Mbps are available to BC0, so reducing all "better or equal" flows counts as 27 Mbps (seen earlier).

31.4.4 Per-VRF TE techniques

For additional granularity when using MPLS-TE with L3VPN, both XE and XR support TE tunnels on a per-VRF basis. This is particularly useful on a PE that has several L3VPN customers, each with different requirements. It is compatible with all of the previously examined techniques, such as CBTS/PBTS and DS-TE. The network is similar to the BGP RR-group and RT retention lab except that XRv4 has been swapped with CSR6. This introduces an XR router into the core network for testing per-VRF TE. The basic IS-IS configuration is not detailed here.

First, we quickly verify that XRv4 has IS-IS connectivity to all nodes since the configuration is omitted for brevity. The core LSRs are level-2 peers while CSR1, a route-reflector, is a level-1 peer.

```
RP/0/0/CPU0:XRv4#show isis neighbors
```

```
IS-IS 56 neighbors:
```

System Id	Interface	SNPA	State	Holdtime	Type	IETF-NSF
R1	Gi0/0/0/0.514	*PtoP*	Up	24	L1	Capable
R8	Gi0/0/0/0.584	*PtoP*	Up	28	L2	Capable
R5	Gi0/0/0/0.554	*PtoP*	Up	25	L2	Capable

This lab uses primary one-hop TE tunnels between each pair of routers in the core rather than LDP directly on the core interfaces. As a result, we quickly check the TED for the proper TE relationships.

XRv4 sees CSR5 and CSR8 as peer vertices in the TE graph, and vice versa. This is critical since the use of primary tunnels relies on MPLS-TE being functional in the core to signal the primary tunnels.

```

```

LDP is enabled on the primary tunnels since many of them are PE-P or P-P tunnels. Since XR's auto-primary tunnel feature is not as powerful as XE's (difficult to get mLDp traffic into them, etc), we will create 2 manual primary tunnels on XRv4: one to CSR5 and one to CSR8. The debugs in the auto-primary testing conducted earlier revealed that these tunnels consist of next-hop explicit-paths, autoroute announce, and FRR. These tunnels are unrelated to the per-VRF TE technique but is important to achieve basic end-to-end LSP reachability.

```
! XRv4
explicit-path name EP_5
  index 10 next-address strict ipv4 unicast 56.5.14.5
```

```
explicit-path name EP_8
  index 10 next-address strict ipv4 unicast 56.8.14.8
```

```
interface tunnel-te505
  description 1HOP TO CSR5
  ipv4 unnumbered Loopback0
  autoroute announce
  destination 56.0.0.5
  fast-reroute
  path-option 10 explicit name EP_5
```

```
interface tunnel-te508
  description 1HOP TO CSR8
  ipv4 unnumbered Loopback0
  autoroute announce
  destination 56.0.0.8
  fast-reroute
```

```
path-option 10 explicit name EP_8
```

```
mpls ldp
interface tunnel-te505
interface tunnel-te508
```

We quickly verify that these primary tunnels come up. Since LDP is enabled on them, we expect to see tLDP sessions towards CSR5 and CSR8.

```

XRv4 must also be configured to accept tLDP sessions since CSR5 and CSR8 will build auto-primary tunnels to XRv4. This is nothing new; we quickly allow XRv4 to accept these sessions then verify that it is the tail end for a pair of primary tunnels from CSR5 and CSR8.

```

XRv4 has the same logical VPNv4/v6 BGP configuration as CSR6 did (the routers swapped places), so it is not discussed in detail. We quickly verify that all VPNV4/v6 sessions to all RRs are functional. 12 routes are received from each RR, which makes sense since each of the 3 remote PEs contributes 4 routes each.

```
RP/0/0/CPU0:XRv4#show bgp vpnv4 unicast summary | begin ^Neigh
```

We also verify that XRv4 is connected to the L3VPN customer which is now CSR6. We can see both the IPv4/v6 peerings are operational in both RED VPN, with RIPv2 and OSPFv3 functioning properly in the BLUE VPN.

Since the BLUE VPN is using mLDP, which does not appear to work on XRv, we will verify the RED VPN PIM neighbors across the default MDT. Although MVPN is not terribly relevant for per-VRF TE, we need to ensure we don't "break" it with our tunnel configuration. Testing MVPN is a major component of this section since TE can have a significant impact on multicast routing behavior.

```
RP/0/0/CPU0:XRv4#show pim vrf RED neighbor | begin ^Neigh
```

Neighbor Address	Interface	Uptime	Expires	DR pri	Flags

To test the data-plane quickly, we use MPLS OAM (LSP ping) from XRv4 to a few PEs. We follow-up with some VRF-aware pings inside CSR6 to test the L3VPN service. This concludes our basic verification; the VPN-aware unicast and multicast testing will be conducted as TE tunnels are built.

```
RP/0/0/CPU0:XRv4#ping mpls ipv4 56.0.0.9/32 source 56.0.0.14

!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 4/6/15 ms
```

The first per-VRF TE technique is the most straightforward and is configured on CSR5. Under each VRF, we can specify a custom BGP next-hop; this references a loopback interface. For maximum scalability, all VRFs on a single PE use the BGP VPNv4/v6 “update-source” as the LSP endpoint by default. This reduces the size of the RIB, LIB, LFIB, and many other internal data structures. However, this “LSP aggregation” also restricts granularity when different VRFs have different traffic forwarding requirements. Specifying different BGP next-hops per VRF (or per group of VRFs) increases the number of routes in the network (along with their corresponding label bindings), but permits greater granularity. Notice that the loopbacks are PIM-enabled and tagged with a route-tag of 56. PIM is required to support MVPN in this specific design (discussed later) and the route-tag allows these loopbacks to leak from level-2 to level-1, satisfying the XR route-reflector’s best-path requirements. **Always define the loopback interfaces and advertise them into IGP before changing the BGP next-hop under the VRF**; this will prevent traffic blackholes in case PEs learn per-VRF loopbacks before they have corresponding IGP routes to them.

```
! CSR5
interface Loopback100
  description RED TE
  ip address 56.0.0.105 255.255.255.255
  ip pim passive
  isis tag 56

  bgp next-hop ipv4 Loopback100

```

Notice that none of the configuration above explicitly references MPLS-TE. We are simply changing the BGP next-hop which gives the LSP a different endpoint. These changes occur on the tail-end router; since LSPs are unidirectional, we are changing the routing towards a VPN endpoint, not from it. At this point, we will perform several control-plane verifications. First and foremost, we ensure that the loopbacks were properly advertised into IGP and have valid LDP label bindings. Since every core router will also learn these prefixes via IS-IS, they should allocate labels for them also.

```

R5#show isis database R5.00-00 detail level-2 | include [12]05
Metric: 0          IP 56.0.0.105/32

```

Next, we verify that the VRF configuration was correct by checking the VRF details for the RED and BLUE VPNs. This displays the actual IPv4/v6 address used as the BGP next-hop; notice that the IPv6 address is converted to 6VPE next-hop as expected.

```
R5#show vrf detail RED | include ^Address|BGP
Address family ipv4 unicast (Table ID = 0x4):
  BGP next-hop: Loopback100 56.0.0.105
Address family ipv6 unicast (Table ID = 0x1E000001):
  BGP next-hop: Loopback100 (ipv4) ::FFFF:56.0.0.105
Address family ipv4 multicast not active
```

```
R5#show vrf detail BLUE | include ^Address|BGP
Address family ipv4 unicast (Table ID = 0x5):
  BGP next-hop: Loopback200 56.0.0.205
Address family ipv6 unicast (Table ID = 0x1E000002):
  BGP next-hop: Loopback200 (ipv4) ::FFFF:56.0.0.205
Address family ipv4 multicast not active
```

To verify that the VPNv4/v6 next-hops were actually changed, we will verify the route-reflector BGP tables. Since the selective RT retention policies are in effect, not all RRs will have all routes. CSR1 and XRv1 will have RED routes while CSR2 and XRv2 will have BLUE routes. We will check the IPv4 routes on CSR1/CSR2 and the IPv6 routes on XRv1/XRv2. Recall that XR always displays 6VPE next-hops as normal IPv4 addresses without the ::FFFF: prepended.

We will use CSR10 as our tunnel head-end for all testing in this lab. CSR5, CSR9, and XRv4 will be the tunnel tail ends towards which we can test different per-VRF TE techniques. From CSR10's perspective, we can quickly check the different BGP next-hops and the number of routes referencing each next-hop. The number 8 is shown instead of the number 4 because CSR10 receives two copies of each route thanks to having 2 RRs per VPN. We can see that CSR10 has seen the new BGP next-hops. CSR9 and XRv4, at present, are still using their loopback0 addresses for BGP next-hops since we have not modified those yet.

```
R10#show bgp vpnv4 unicast vrf RED nexthops
# Paths    Nexthop Address
Route Distinguisher: 56:100 (default for vrf RED)
      8    56.0.0.9
      4    10.4.10.4 (RED)
      8    56.0.0.14
      8    56.0.0.105
```

```
R10#show bgp vpnv6 unicast vrf BLUE nexthops
# Paths    Nexthop Address
Route Distinguisher: 56:200 (default for vrf BLUE)
      8    ::FFFF:56.0.0.9
      4    FE80::4 (FE80::4) (BLUE)
     10    ::FFFF:56.0.0.14
      8    ::FFFF:56.0.0.205
```

Next, we will configure TE tunnels on CSR10 towards CSR5. We will begin with the BLUE VPN by creating a simple explicit-path. The tunnel destination is always the MPLS TE-ID and is not the new loopback address; the new loopback is used only for routing as we will see later. Notice that absence of autoroute and forwarding-adjacency on the tunnel; these are not appropriate options for per-VRF TE. If we configure "announce" or "forwarding-adjacency", all new loopbacks would be reachable via this TE tunnel which defeats the purpose of per-VRF TE. If we configure "destination", a static route is created towards 56.0.0.5/32, which doesn't capture 56.0.0.205/32 and is therefore ineffective.

```
! CSR10
ip explicit-path name EP_9_7_5 enable
next-address 56.0.0.9
```

```
next-address 56.0.0.7
next-address 56.0.0.5
```

```
interface Tunnel5102
description TO CSR5 BLUE
ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 56.0.0.5
tunnel mpls traffic-eng path-option 10 explicit name EP_9_7_5
```

We verify that the tunnel comes up and use LSP traceroute to verify the path. This proves that the tunnel is functional and it correctly routes through CSR9, CSR7, and CSR5.

```
R10#show mpls traffic-eng tunnels tunnel 5102 | section Status
Status:
  Admin: up      Oper: up      Path: valid      Signalling: connected
  path option 10, type explicit EP_9_7_5 (Basis for Setup, path weight 30)
```

```
R10#traceroute mpls traffic-eng tunnel 5102 source 56.0.0.10
Tracing MPLS TE Label Switched Path on Tunnel5102, timeout is 2 seconds
[snip]
Type escape sequence to abort.
 0 56.9.10.10 MRU 1500 [Labels: 9013 Exp: 0]
L 1 56.9.10.9 MRU 1500 [Labels: 7022 Exp: 0] 9 ms
L 2 56.7.9.7 MRU 1500 [Labels: implicit-null Exp: 0] 3 ms
! 3 56.5.7.5 4 ms
```

We need to steer traffic to 56.0.0.205/32 into the tunnel somehow; the most straightforward method is using a static route. This was discussed in the “traffic steering” part of the TE section. Once configured, we verify the routing using normal IP traceroute. The hops and labels from this output match the LSP traceroute above, so we are confident that traffic to 56.0.0.205/32 is now inside this tunnel.

```
! CSR10
ip route 56.0.0.205 255.255.255.255 Tunnel5102
```

```
R10#traceroute 56.0.0.205 source 56.0.0.10

```

We will quickly trace the LSP from CSR10 to CSR5 to verify the full operation using a VPNv4 route. CSR10’s BGP best-path is from CSR5 and uses VPN label 5031. The VPN next-hop is the per-VRF value of 56.0.0.205 and is reachable via a TE tunnel. This is a result of the static route above; the TE tunnel uses label 9013, so CSR9 imposes {9013 5031} on top of the IPv4 packets from CSR4.

```
R10#show bgp vpnv4 unicast vrf BLUE 200.13.0.0 bestpath

```

Before continuing, we will test multicast between these endpoints to ensure we haven't broken anything. CSR4 will issue an IGMPv3 join towards CSR10 requesting traffic for group 232.200.4.4; XRv3 is the source of this traffic. We verify that CSR10 receives this C(S,G) information and creates the proper C-MRIB state. The RPF neighbor is 56.0.0.205 which is CSR5; this is derived from the VPNv4 next-hop.

```
! CSR4
interface GigabitEthernet2.200
 ip igmp join-group 232.200.4.4 source 200.13.0.1

R10#show ip mroute vrf BLUE 232.200.4.4 200.13.0.1 | begin \
(200.13.0.1, 232.200.4.4), 1w3d/00:02:45, flags: sTI
  Incoming interface: Lspvif0, RPF nbr 56.0.0.205
  Outgoing interface list:
    GigabitEthernet2.200, Forward/Sparse-Dense, 1w3d/00:02:45
```

As expected, CSR10 cannot perform RPF for this endpoint since it has no legitimate multicast route. The static route overrode the IS-IS route and cannot be used for RPF. Interestingly, CSR10 doesn't care. It has a direct PIM neighbor inside the MDT for this peer and can freely exchange PIM messages. CSR5 was smart enough to change its MDT source to 56.0.0.205 for this VRF. The PIM neighbor address and the RPF address identified in the C-MRIB entry are the same, so PIM signaling works fine.

```
R10#show ip pim vrf BLUE neighbor | begin ^Neigh
Neighbor          Interface          Uptime/Expires    Ver   DR
Address                                     Prio/Mode
```

```
56.0.0.205      Lspvif0      1w5d/00:01:40      v2      1 / DR S P G
56.0.0.9        Lspvif0      2w3d/00:01:31      v2      1 / S P G
```

```
R10#show ip rpf 56.0.0.205
failed, no route exists
```

Despite the RPF failure, there are no problems. CSR5 receives a single C(S,G) SSM join from CSR10. CSR10 sees CSR5 as 56.0.0.205 for unicast and multicast connectivity within VRF RED; this consistency simplifies L3VPN operation when using per-VRF TE.

```
R5#show ip mroute vrf BLUE ssm
(200.13.0.1, 232.200.4.4), 00:03:29/00:02:57, flags: sT
Incoming interface: GigabitEthernet2.200, RPF nbr 10.5.13.13
Outgoing interface list:
Lspvif0, Forward/Sparse, 00:03:29/00:02:57
```

Pinging this group from XRv3 (assuming multicast-routing is enabled) yields positive results. When using per-VRF TE over an mLDP-based MVPN solution, there do not appear to be any MVPN concerns. The RPF failure is irrelevant since there was no P(S,G) tree to build. Even if CSR10 needed to join a specific P2MP mLDP tree, mLDP is allowed to use TE tunnels anyway, while PIM cannot. We prove that connectivity works by checking the multicast counters at the ingress (CSR5) and egress (CSR10) PEs. I also use EPC on the egress PE towards the customer to see the multicast being forwarded properly.

```
RP/0/0/CPU0:XRv3#ping vrf BLUE 232.200.4.4 source 200.13.0.1 count 100
```

```

```

Next, we will repeat the process for VPN RED on CSR10 towards CSR5. Because the VPN next-hops are different, VPN RED can use an entirely different TE strategy. We will introduce a basic CBTS policy for VPN RED only; one tunnel will carry EXP 0-4 (low priority) while the other carries EXP 5-7 (high priority).

CBTS with per-VRF TE adds another dimension of granularity since we can separate traffic by VRF and EXP at the same time. CBTS is not discussed in detail here as it has a dedicated section.

```
! CSR10
ip explicit-path name EP_8_14_5 enable
  next-address 56.0.0.8
  next-address 56.0.0.14
  next-address 56.0.0.5

interface Tunnel5101
  description TO CSR5 RED CBTS MASTER
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 56.0.0.5
  tunnel mpls traffic-eng exp-bundle master
  tunnel mpls traffic-eng exp-bundle member Tunnel51017
  tunnel mpls traffic-eng exp-bundle member Tunnel51010

interface Tunnel51010
  description TO CSR5 RED LOW PRI
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 56.0.0.5
  tunnel mpls traffic-eng path-option 10 dynamic
  tunnel mpls traffic-eng exp default

interface Tunnel51017
  description TO CSR5 RED HI PRI
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 56.0.0.5
  tunnel mpls traffic-eng priority 7 7
  tunnel mpls traffic-eng bandwidth 65000
  tunnel mpls traffic-eng path-option 10 explicit name EP_8_14_5
  tunnel mpls traffic-eng exp 5 6 7
```

We quickly verify that the tunnels are up and that the EXP mappings are correct. We can accomplish this with a single command. Recall that the tunnel destination is always the remote TE-ID, not the per-VRF BGP next-hop value.

```
R10#show mpls traffic-eng exp 56.0.0.5
Destination: 56.0.0.5
  Master: Tunnel5101      Status: up
  Members      Status      Conf Exp      Actual Exp
  Tunnel51017  up (Active)  5 6 7        5 6 7
  Tunnel51010  up (Active)  Default      0 1 2 3 4
```

We quickly verify both paths using MPLS traceroute. We specify the master tunnel as the target while using EXP values to verify that CBTS is making the proper selection. We must force exp-null whenever XR is the PHP router, which was discussed in the MPLS OAM section; it isn't terribly relevant for this test. The main point is that the tunnels are following totally different paths.

```
R10#traceroute mpls traffic-eng tunnel 5101 exp 4
Tracing MPLS TE Label Switched Path on Tunnel5101, timeout is 2 seconds

L 2 56.8.14.14 MRU 1500 [Labels: implicit-null/explicit-null Exp: 5/5] 3 ms
! 3 56.5.14.5 5 ms
```

Just like VPN BLUE, a simple static route to 56.0.0.105/32 will direct traffic into the CBTS master tunnel. We use regular IP traceroute with varying DSCP values (0 and 56, or CS7) to test the TOS-to-EXP copy mechanism. We confirm that the MPLS labels match between the LSP and IP traceroutes.

```
! CSR10
ip route 56.0.0.105 255.255.255.255 Tunnel5101

R10#traceroute 56.0.0.105 source 56.0.0.10
Type escape sequence to abort.
Tracing the route to 56.0.0.105
VRF info: (vrf in name/id, vrf out name/id)
 1 56.8.10.8 [MPLS: Label 8018 Exp 0] 7 msec 3 msec 6 msec
 2 56.5.8.5 19 msec 8 msec 11 msec

R10#traceroute ip

DSCP Value [0]: 56
[snip]
VRF info: (vrf in name/id, vrf out name/id)
 1 56.8.10.8 [MPLS: Label 8015 Exp 7] 7 msec 6 msec 5 msec
 2 56.8.14.14 [MPLS: Label 94006 Exp 7] 15 msec 5 msec 5 msec
 3 56.5.14.5 8 msec 11 msec 11 msec
```

For brevity, we will use traceroute from CSR4 to quickly verify connectivity rather than trace the next-hop lookups. Traffic is classified based on their TOS/traffic-class values; we can confirm the topmost label of the VPN traffic matches the labels seen in the traceroutes above. The first traceroute uses IPP0 (label 8018) while the second uses IPP5 (label 8015).

```

 5 10.5.13.13 20 msec 18 msec 14 msec
```

We have introduced a significant issue into the network by configuring this static route in VPN RED. Specifically, we have broken MVPN connectivity between CSR5 and CSR10. PIM notifies us of our folly on CSR10 a few minutes after configuring the static route.

```
! CSR10
%PIM-5-NBRCHG: VRF RED: neighbor 56.0.0.105 DOWN on interface Tunnel3 non DR
```

We will quickly backtrack to check some critical MVPN components. Since BGP IPv4 MDT is used for building P(S,G) trees to form the default MDT, we will start there. Earlier, we saw that CSR5 was smart enough to change the MDT source for mLDP trees. It is likewise smart enough to change the P-source in the GRE-based MDT trees as well. Below, we can see a P(S,G) of (56.0.0.105, 232.0.0.100) learned by CSR10. This happened automatically when we changed the BGP next-hop to 56.0.0.105 under the VRF. The next-hop of this particular prefix is 56.0.0.5, but this is less significant since the P-source is derived from the address in the IPv4 MDT prefix, which is 56.0.0.105.

```
R10#show bgp ipv4 mdt vrf RED 56.0.0.105/32 bestpath
BGP routing table entry for 56:100:56.0.0.105/32 version 18
Paths: (4 available, best #4, table IPv4-MDT-BGP-Table)

  Refresh Epoch 2
```

Local

```
56.0.0.5 from 56.0.0.1 (56.0.0.1)
  Origin incomplete, metric 0, localpref 100, valid, internal, best
  Originator: 56.0.0.5, Cluster list: 56.0.0.1,
  MDT group address: 232.0.0.100
  rx pathid: 0, tx pathid: 0x0
```

We can guess that, like VPN BLUE, the static route has introduced RPF issues into the network. CSR10 is not able to join CSR5's MDT, which means it cannot receive PIM messages from CSR5. That is why the PIM neighbor failed on CSR10 but not on CSR5 (CSR5 is still able to join CSR10's tree without issue). Unlike mLDLP, this is significant because CSR10 cannot issue the P(S,G) join towards CSR5.

```
R10#show ip mroute 232.0.0.100 56.0.0.105 | begin \
(56.0.0.105, 232.0.0.100), 1w5d/stopped, flags: sTIZ
  Incoming interface: Null, RPF nbr 0.0.0.0
  Outgoing interface list:
    MVRP RED, Forward/Sparse-Dense, 1w5d/00:01:52
```

```
R10#show ip rpf 56.0.0.105
  failed, no route exists
```

There are two solutions to this problem: static multicast route or BGP IPv4 multicast. The former is quick and easy, and since the focus of this lab is not MVPN, we will use that method. The latter method is more dynamic and would be more appropriate in large-scale deployments. Note that the IGP command "mpls traffic-eng multicast-intact" does not work with static routes for IS-IS or OSPF; we already have this command enabled to overcome the auto-primary tunnels used for MPLS transport. We can be intelligent when identifying the next-hop for this RPF fixup route by specifying CSR5's original loopback0 address. This recurses to an IGP route that will always be IGP learned, and since "mpls traffic-eng multicast-intact" is configured, its RPF interface will be an Ethernet interface of sorts (never a TE tunnel). This is more effective than specifying a hard next-hop, like CSR9 or CSR7 link addresses, since IGP may change over time. It's a semi-dynamic way to fix RPF with static multicast routes, in a sense.

```
! CSR10
ip mroute 56.0.0.105 255.255.255.255 56.0.0.5
```

```
R10#show ip rpf 56.0.0.105
RPF information for ? (56.0.0.105)
  RPF interface: GigabitEthernet2.570
  RPF neighbor: ? (56.7.10.7)
  RPF route/mask: 56.0.0.105/32
  RPF type: multicast (static)
  Doing distance-preferred lookups across tables
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

CSR10's PIM neighbor with CSR5 immediately reforms after CSR10 builds the P(S,G) tree. The P(S,G) state on CSR10 now references a valid RPF neighbor via the static mroute. CSR10 builds the P(S,G) tree

towards CS5 via CSR7. We won't trace the entire tree; the presence of PIM neighbors is proof that the default MDT has been signaled properly.

```
! CSR10
%PIM-5-NBRCHG: VRF RED: neighbor 56.0.0.105 UP on interface Tunnel3

R10#show ip mroute 232.0.0.100 56.0.0.105 | begin \((
(56.0.0.105, 232.0.0.100), 1w5d/stopped, flags: sTIZ
Incoming interface: GigabitEthernet2.570, RPF nbr 56.7.10.7, Mroute
Outgoing interface list:
MVRF RED, Forward/Sparse-Dense, 1w5d/00:02:32
```

With the MVPN control-plane repaired, we quickly test data traffic. Using a similar group address, we configure another IGMPv3 join on CSR4. This is inside the RED VPN and targets XRv3 again. CSR10 has the proper C(S,G) state and sends the C-PIM join to CSR5 who receives it successfully.

```
! CSR4
interface GigabitEthernet2.100
 ip igmp join-group 232.100.4.4 source 100.13.0.1

R10#show ip mroute vrf RED 232.100.4.4 100.13.0.1 | begin \((

```

The per-VRF TE method demonstrated on CSR5 is by far the most straightforward method. There are always alternatives, and we will demonstrate this on CSR9. The concept is the same; we will adjust BGP next-hops on CSR9 outbound towards the RRs to newly-configured loopbacks. This can be accomplished using an outbound route-map; for even finer granularity, we can achieve per-prefix or per-RT TE using this method. To keep the network configuration consistent, we will configure per-RT TE on CSR9, which is effectively the same as per-VRF TE since each VRF in each VPN uses a common RT format. First, we will create two loopbacks, advertise them into IGP, and construct our per-RT “next-hop-self” route-maps. The route-map should always have a “permit any” as the final entry so that non-TE VRFs can continue to use loopback0 as their VPN endpoint for dynamic LDP LSPs.

```

! CSR9
interface Loopback100
  description RED TE
  ip address 56.0.0.109 255.255.255.255
  ip pim passive
  isis tag 56

interface Loopback200
  description BLUE TE
  ip address 56.0.0.209 255.255.255.255
  ip pim passive
  isis tag 56

router isis 56
  passive-interface Loopback100
  passive-interface Loopback200

ip extcommunity-list expanded EXTCOML_BLUE_RT permit RT:56:2..$
ip extcommunity-list expanded EXTCOML_RED_RT permit RT:56:1..$

route-map RM_VPN_NHOP permit 10
  match extcommunity EXTCOML_RED_RT
  set ip next-hop 56.0.0.109
  set ipv6 next-hop ::FFFF:56.0.0.109
route-map RM_VPN_NHOP permit 20
  match extcommunity EXTCOML_BLUE_RT
  set ip next-hop 56.0.0.209
  set ipv6 next-hop ::FFFF:56.0.0.209
route-map RM_VPN_NHOP permit 1000

```

Before we apply the route-maps to BGP, we will ensure these new loopbacks have been advertised into IGP properly. This preliminary check will prevent blackholed traffic during a migration. Additionally, binding LDP labels to these prefixes is a good idea so that if the TE tunnel fails, a dynamic LDP LSP could be used as a last resort.

```
R9#show isis database R9.00-00 detail level-2 | include [12]09
Metric: 0          IP 56.0.0.109/32
Metric: 0          IP 56.0.0.209/32
```

```

  local binding: label: imp-null
  remote binding: lsr: 56.0.0.10:0, label: 10029
  remote binding: lsr: 56.0.0.7:0, label: 7015
```

```
R9#show mpls ldp bindings 56.0.0.209 32
lib entry: 56.0.0.209/32, rev 33
  local binding: label: imp-null
  remote binding: lsr: 56.0.0.10:0, label: 10030
  remote binding: lsr: 56.0.0.7:0, label: 7016
```

Next, we will apply the route-maps to all VPNv4 and VPNv6 peers. We do not need to create two route-maps since the “set ip next-hop” and “set ipv6 next-hop” commands are complementary and mutually-exclusive. Only one can apply for a given route as this depends on the prefix type being matched. As a side note, peer-groups or peer-policy templates could have shortened this configuration.

```
! CSR9
router bgp 56
  address-family vpnv4
    neighbor 56.0.0.1 route-map RM_VPN_NHOP out
    neighbor 56.0.0.2 route-map RM_VPN_NHOP out
    neighbor 56.0.0.11 route-map RM_VPN_NHOP out
    neighbor 56.0.0.12 route-map RM_VPN_NHOP out

  address-family vpnv6
    neighbor 56.0.0.1 route-map RM_VPN_NHOP out
    neighbor 56.0.0.2 route-map RM_VPN_NHOP out
    neighbor 56.0.0.11 route-map RM_VPN_NHOP out
    neighbor 56.0.0.12 route-map RM_VPN_NHOP out
```

After applying the configuration, I perform a soft clear for VPNv4 and VPNv6 to ensure the changes took effect. Rather than check all 4 RRs for the next-hop change, we will jump straight to CSR10 for a cursory check. CSR10 now sees next-hops 56.0.0.109 and 56.0.0.209 within the RED and BLUE VPNs, respectively. We see 8 routes each, as expected, since there are 4 routes times 2 route-reflectors.

```
R9#clear bgp vpnv4 unicast * soft
```

```
R9#clear bgp vpnv6 unicast * soft
```

```
R10#show bgp vpnv4 unicast vrf RED nexthops

  4  10.4.10.4 (RED)
  8  56.0.0.14
  8  56.0.0.105
```

```
R10#show bgp vpnv4 unicast vrf BLUE nexthops
```

```
# Paths    Nexthop Address
Route Distinguisher: 56:200 (default for vrf BLUE)
  8  56.0.0.209
  4  10.4.10.4 (BLUE)
  8  56.0.0.14
  8  56.0.0.205
```

Because we applied a route-map directly to BGP and did not “inform” the VRF of these next-hop changes, we do not expect any change in the MDT source. That is, the P-source for the MDT in both VPNs should still be 56.0.0.9. Checking the RED VPN, the IPv4 MDT routes all carry P-source 56.0.0.9 which is contained in the prefix.

```
R10#show bgp ipv4 mdt vrf RED | include 56.0.0.9
```

```
*>i 56.0.0.9/32      56.0.0.9      0      100      0 ?
* i      56.0.0.9      0      100      0 ?
* i      56.0.0.9      0      100      0 ?
* i      56.0.0.9      0      100      0 ?
```

This means that a static mroute will not be necessary to build to P(S,G) tree back to CSR9 since CSR10 has a valid RPF route for this prefix already. With respect to GRE-based MVPN, this appears “easier” than the purpose-built method of changing the BGP next-hop under the VRF (method on CSR5).

```
R10#show ip rpf 56.0.0.9
```

```

```

```
R10#show ip mroute 232.0.0.100 56.0.0.9 | begin \((
```

```
(56.0.0.9, 232.0.0.100), 2w4d/stopped, flags: sTIZ
```

```
Incoming interface: GigabitEthernet2.590, RPF nbr 56.9.10.9
```

```
Outgoing interface list:
```

```
MVRF RED, Forward/Sparse-Dense, 2w4d/00:00:17
```

One final check is warranted before continuing. Recall the purpose of the BGP connector attribute from the inter-AS MPLS option B discussion. It is used to ensure that the traffic arriving from the PMSI is coming from the actual ingress PE (and not an ASBR, etc). If the attribute is present, its value must match that of the PIM neighbor. This was value not changed by CSR9 since the route-map was applied directly to BGP; notice the difference between the next-hop and connector attribute values.

```
R10#show bgp vpnv4 unicast vrf RED 100.3.0.0 bestpath
BGP routing table entry for 56:100:100.3.0.0/18, version 389
Paths: (2 available, best #2, table RED)
  Advertised to update-groups:
    2
  Refresh Epoch 2
  100
    56.0.0.109 (via default) from 56.0.0.1 (56.0.0.1)
      Origin incomplete, metric 0, localpref 100, valid, internal, best
      Extended Community: RT:56:103
      Originator: 56.0.0.9, Cluster list: 56.0.0.1
      Connector Attribute: count=1
        type 1 len 12 value 56:100:56.0.0.9
      mpls labels in/out nlabel/9026
      rx pathid: 0, tx pathid: 0x0
```

Because VRF-aware PIM is also unaware of this next-hop change, the MDT source remains loopback0, which is correct. The RPF check for incoming packets from the PMSI should pass since both the connector attribute and PIM neighbor address are 56.0.0.9.

```
R10#show ip pim vrf RED neighbor | begin ^Neigh
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
56.0.0.105        Tunnel3              00:47:28/00:01:30 v2      1 / S P G
56.0.0.14         Tunnel3              1w5d/00:01:43    v2      1 / DR P G
56.0.0.9          Tunnel3              2w4d/00:01:31    v2      1 / S P G
```

We will configure a basic TE tunnel from CSR10 to CSR9 to service VPN RED. The tunnel will avoid the direct path because it isn't very interesting. For brevity, we add the static route now since we already know it is required.

```
! CSR9
ip explicit-path name EP_AVOID_LINK_9_10 enable
  exclude-address 56.9.10.9
  exclude-address 56.9.10.10

interface Tunnel9101
  description TO CSR9 RED
  ip unnumbered Loopback0
```

```

tunnel mode mpls traffic-eng
tunnel destination 56.0.0.9
tunnel mpls traffic-eng path-option 10 explicit name EP_AVOID_LINK_9_10

ip route 56.0.0.109 255.255.255.255 Tunnel9101

```

We quickly confirm the tunnel is up, , reveal the first-hop label, then use IP traceroute to verify. This proves that traffic is being directed into the tunnel properly.

```

R10#show mpls traffic-eng tunnels tunnel 9101 brief | begin TUNNEL
TUNNEL NAME          DESTINATION      UP IF      DOWN IF     STATE/PROT
TO CSR9 RED          56.0.0.9        -          Gi2.570     up/up

R10#show mpls traffic-eng tunnels tunnel 9101 | include Label
InLabel   : -
OutLabel  : GigabitEthernet2.570, 7018

R10#traceroute 56.0.0.109 source 56.0.0.10
Type escape sequence to abort.
Tracing the route to 56.0.0.109
VRF info: (vrf in name/id, vrf out name/id)
 1 56.7.10.7 [MPLS: Label 7018 Exp 0] 8 msec 4 msec 4 msec
 2 56.7.9.9 3 msec 4 msec 3 msec

```

To complete the unicast verification, we perform a traceroute from CSR4 to CSR3. I use IPv6 for variety, but since 6VPE next-hops are IPv4-based, both IPv4 and IPv6 will follow these per-RT tunnels.

```

R4#traceroute vrf RED ipv6
Target IPv6 address: 2100:D103::1
Source address: 2100:D104::1
[snip]
 1 FD00:10:4:10::10 4 msec 4 msec 4 msec
 2 ::FFFF:56.7.10.7 [MPLS: Labels 7018/9033 Exp 0] 15 msec 6 msec 24 msec
 3 FD00:10:3:9::9 [MPLS: Label 9033 Exp 0] 17 msec 17 msec 17 msec
 4 FD00:10:3:9::3 22 msec 25msec 15 msec

```

Next, we will confirm RED MVPN traffic flows correctly. CSR4 joins an SSM group and sends the IGMPv3 join to CSR10. CSR10 passes it to CSR9 and both routers show the correct C(S,G) SSM state below.

```

! CSR4
interface GigabitEthernet2.100
 ip igmp join-group 232.100.4.4 source 100.3.0.1

R10#show ip mroute vrf RED 232.100.4.4 100.3.0.1 | begin \
(100.3.0.1, 232.100.4.4), 1w3d/00:02:03, flags: sTI
Incoming interface: Tunnel3, RPF nbr 56.0.0.9
Outgoing interface list:

```

```
GigabitEthernet2.100, Forward/Sparse-Dense, 1w3d/00:02:03
```

```
R9#show ip mroute vrf RED 232.100.4.4 100.3.0.1 | begin \  
(100.3.0.1, 232.100.4.4), 1w3d/00:02:34, flags: sT  
  Incoming interface: GigabitEthernet2.100, RPF nbr 10.3.9.3  
  Outgoing interface list:  
    Tunnel3, Forward/Sparse, 1w3d/00:02:34
```

CSR3 begins sending traffic from the proper source. Both MVPN endpoints sees tallies for this traffic, and CSR10 uses outbound EPC to verify delivery to CSR4. Everything appears to work well without any RPF fixups needed. Also notice CSR10's RPF lookup inside the VPN references the BGP connector attribute. In summary, the BGP route-map option works well with MVPN profile 0.

```

```

Next, we will repeat the same test for the BLUE VPN, which relies on mLDP MP2MP trees. Recall that mLDP-based MVPN does not impose the BGP connector attribute onto VPN updates. It also does not rely on IPv4 MDT to tell it the P-source; in our setup, it is derived from the BGP next-hop. As such, CSR10 will see a PIM neighbor of 56.0.0.209 rather than 56.0.0.9; we theorize that this will cause issues with

PIM signaling later. To prove it, we will create another TE tunnel to CSR9 and direct traffic towards 56.0.0.209 into the tunnel.

```
! CSR10
ip explicit-path name EP_8_7_9 enable
  next-address 56.0.0.8
  next-address 56.0.0.7
  next-address 56.0.0.9

interface Tunnel9102
  description TO CSR9 BLUE
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 56.0.0.9
  tunnel mpls traffic-eng path-option 10 explicit name EP_8_7_9

ip route 56.0.0.209 255.255.255.255 Tunnel9102
```

This should immediately work for unicast flows; the tunnel comes up and routes traffic without issue. We verify the tunnel is up and reveal the first-hop label, then use IP traceroute as confirmation.

```
R10#show mpls traffic-eng tunnels tunnel 9102 brief | begin TUNNEL
TUNNEL NAME          DESTINATION      UP IF    DOWN IF    STATE/PROT
TO CSR9 BLUE         56.0.0.9        -        Gi2.580    up/up

R10#show ip rsvp reservation detail filter session-type 7 tunnel-id 9102 |
include Label
Label: 8006 (outgoing)

R10#traceroute 56.0.0.209 source 56.0.0.10
Type escape sequence to abort.
Tracing the route to 56.0.0.209
VRF info: (vrf in name/id, vrf out name/id)
 1 56.8.10.8 [MPLS: Label 8006 Exp 0] 7 msec 5 msec 4 msec
 2 56.7.8.7 [MPLS: Label 7021 Exp 0] 3 msec 5 msec 4 msec
 3 56.7.9.9 5 msec 5 msec 6 msec
```

We don't expect any issues with our unicast LSPs inside the VPN, so we verify it quickly. Using IPv4, we verify the path to CSR3 inside VPN BLUE ends up in the tunnel with 8006 as the topmost label.

```
R4#traceroute vrf BLUE 200.3.0.1 source 200.4.0.1
Type escape sequence to abort.
Tracing the route to 200.3.0.1
VRF info: (vrf in name/id, vrf out name/id)
 1 10.4.10.10 6 msec 4 msec 4 msec
 2 56.8.10.8 [MPLS: Labels 8006/9034 Exp 0] 6 msec 5 msec 7 msec
 3 56.7.8.7 [MPLS: Labels 7021/9034 Exp 0] 31 msec 31 msec 31 msec
```

```
4 10.3.9.9 [MPLS: Label 9034 Exp 0] 15 msec 14 msec 16 msec
5 10.3.9.3 20 msec 10 msec 10 msec
```

Next, we will repeat the same MVPN test for the BLUE VPN, which relies on mLDP MP2MP trees. We configure an IGMPv3 join on CSR4 then verify CSR10's reception of the message. Right away we can see a problem; CSR10 thinks 56.0.0.209 is the RPF neighbor as this was derived from the BGP next-hop.

```
! CSR4
interface GigabitEthernet2.200
 ip igmp join-group 232.200.4.4 source 200.3.0.1

R10#show ip mroute vrf BLUE 232.200.4.4 200.3.0.1 | begin \
(200.3.0.1, 232.200.4.4), 1w3d/00:02:03, flags: sTI
  Incoming interface: Lspvif0, RPF nbr 56.0.0.209
  Outgoing interface list:
    GigabitEthernet2.200, Forward/Sparse-Dense, 1w3d/00:02:03
```

CSR9 never receives the join because CSR10 cannot send it. We estimate that the lack of an RPF path to 56.0.0.209 prevents MVPN from functioning properly in this design. This is a similar problem we had with the traditional per-VRF design.

```
R10#show ip rpf 56.0.0.209
  failed, no route exists

R9#show ip mroute vrf BLUE 232.200.4.4 200.3.0.1
  Group 232.200.4.4 not found
```

As a quick workaround, we configure a static mroute on CSR10 so that 56.0.0.209's RPF path is equivalent to that of 56.0.0.9. This fixes the RPF issue.

```
! CSR10
ip mroute 56.0.0.209 255.255.255.255 56.0.0.9

R10#show ip rpf 56.0.0.209
RPF information for ? (56.0.0.209)
  RPF interface: GigabitEthernet2.590
  RPF neighbor: ? (56.9.10.9)
  RPF route/mask: 56.0.0.209/32
  RPF type: multicast (static)
  Doing distance-preferred lookups across tables
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base
```

Despite our best efforts, this does not solve the problem. As mentioned earlier, PIM signaling is broken between CSR10 and CSR9. A fundamental behavior of PIM is that the RPF neighbor and the PIM neighbor must have the same IP address in order for PIM signaling to work. For example, if the PIM neighbor is 56.0.0.9, it would not make sense to send PIM signaling to 56.0.0.209 because RPF says so.

```
R10#show ip pim vrf BLUE neighbor | begin ^Neigh
Neighbor          Interface          Uptime/Expires    Ver    DR
Address
56.0.0.9           Lspvif0          00:01:00/00:01:43 v2      1 / S P G
56.0.0.205         Lspvif0          00:01:00/00:01:43 v2      1 / DR S P G
```

In reality, CSR10 simply does nothing. After watching its debug for a few minutes, we can confirm this behavior. C-PIM joins are being sent to CSR5 since the PIM neighbor and RPF neighbor are both 56.0.0.205, which was automatically coordinated by the per-VRF TE feature. With CSR9, we have a disconnect due to our manual next-hop changes; CSR10's resulting confusion means the tree never gets built. This was not a problem for the RED VPN multicast connectivity with CSR9 since 56.0.0.9 was both the PIM neighbor and RPF neighbor IP address. Thus, **when using the route-map method on XE, certain MVPN profiles (such as mLDP profile 1 currently in use) appear unsupported.** Although this method alleviated the need to configure an mroute in the RED VPN, it is overall the less preferred option.

```
R10#debug ip pim vrf BLUE
PIM debugging is on
```

```
PIM(2): Insert (200.13.0.1,232.200.4.4) join in nbr 56.0.0.205's queue
PIM(2): Building Join/Prune packet for nbr 56.0.0.205
PIM(2): Adding v2 (200.13.0.1/32, 232.200.4.4), S-bit Join
PIM(2): Send v2 join/prune to 56.0.0.205 (Lspvif0)
```

```
PIM(2): Insert (200.13.0.1,232.200.4.4) join in nbr 56.0.0.205's queue
PIM(2): Building Join/Prune packet for nbr 56.0.0.205
PIM(2): Adding v2 (200.13.0.1/32, 232.200.4.4), S-bit Join
PIM(2): Send v2 join/prune to 56.0.0.205 (Lspvif0)
```

Because this static mroute will not solve the problem, I raise the AD to 255 so that it is retained in the configuration but has no effect. We leave multicast broken for the BLUE VPN between CSR9 and CSR10.

```
! CSR10
ip mroute 56.0.0.209 255.255.255.255 56.0.0.9 255
```

Last, we examine the per-VRF TE feature on XRv4. Since LSM does not appear to be fully supported on XRv as a PE (imposition operations appear to work for some profiles), we will focus on the RED VPN. XR does not have an equivalent “bgp next-hop” command anywhere in the parser. As such, we will use a combination of the per-VRF and route-map approaches configured on CSR5 and CSR9. First, we will configure new loopbacks, advertise them into IGP, and verify success. We also verify LDP label bindings for these prefixes as a backup.

```
! XRv4
interface Loopback100
  ipv4 address 56.0.0.114 255.255.255.255
```

```
interface Loopback200

Next, we will stage our RPL constructs. Using parameterization, we can feed IPv4 or IPv6 next-hops to be applied to RED or BLUE routes based on the RTs they carry. Using parameterization in this way is similar to XE using IPv4 and IPv6 next-hop applications in the same route-map clause. This also gives us the additional flexibility of defining different next-hops for IPv4 and IPv6; this is also possible in XE by simply specifying different loopbacks.

```
! XRv4
extcommunity-set rt RT_RED
  ios-regex '56:1..$'
end-set
```

```

extcommunity-set rt RT_BLUE
  ios-regex '56:2..$'
end-set

```

```

route-policy RPL_SET_NHOP($NHRED, $NHBLUE)
  if extcommunity rt matches-any RT_RED then
    set next-hop $NHRED
  elseif extcommunity rt matches-any RT_BLUE then
    set next-hop $NHBLUE
  else
    pass
  endif
end-policy

```

XR gives administrators the flexibility to define per-VRF MDT sources. This is the key to providing MVPN services when the BGP next-hop differs. XE has no equivalent command since it expects you to use the “bgp next-hop” feature, not the manual route-maps. Even though we won’t be testing BLUE MVPN traffic on XRv4, the configuration is shown for completeness. Specifying the MDT source under the global IPv4/v6 processes makes it apply to all VRFs (which is loopback0). This can be overridden on a per-VRF basis using the more specific VRF-aware commands shown below. This is a good approach because other VRFs that are not using per-VRF TE can continue to use a common MDT source.

```

! XRv4
multicast-routing
  address-family ipv4
    mdt source Loopback0
  address-family ipv6
    mdt source Loopback0

vrf RED
  address-family ipv4
    mdt source Loopback100
  interface all enable
  address-family ipv6
    mdt source Loopback100
  interface all enable

vrf BLUE
  address-family ipv4
    mdt source Loopback200
  interface all enable
  address-family ipv6
    mdt source Loopback200
  interface all enable

```

Changing the MDT source and BGP next-hop should happen concurrently, since both must be synchronized in order for unicast and multicast services to work. We quickly apply our BGP policy to minimize any issues; normally both changes would be grouped into a single commit action. Note that 6VPE next-hops in XR are entered as ordinary IPv4 addresses. **It is critical to instruct BGP to enforce outbound changes for iBGP peers**, which is not the default behavior in XR. This is required here since the RRs are all iBGP peers; another use case is unified MPLS on the ABRs between core and aggregation IGPs. Just like in XE, we could have simplified this configuration using neighbor-groups or AF-groups.

```
! XRv4
router bgp 56
  ibgp policy out enforce-modifications
  neighbor 56.0.0.1
    address-family vpnv4 unicast
      route-policy RPL_SET_NHOP(56.0.0.114, 56.0.0.214) out
    address-family vpnv6 unicast
      route-policy RPL_SET_NHOP(56.0.0.114, 56.0.0.214) out

  neighbor 56.0.0.2
    address-family vpnv4 unicast
      route-policy RPL_SET_NHOP(56.0.0.114, 56.0.0.214) out
    address-family vpnv6 unicast

```

We quickly check CSR10 to ensure that it sees these BGP next-hop changes. As this point, we can see that CSR5, CSR9, and XRv4 all use custom next-hops in both VPNs. This is the expected output.

```
R10#show bgp vpnv4 unicast vrf RED nexthops
# Paths      Nexthop Address
Route Distinguisher: 56:100 (default for vrf RED)
      8      56.0.0.109
      4      10.4.10.4 (RED)
      8      56.0.0.114
      8      56.0.0.105
```

```
R10#show bgp vpnv4 unicast vrf BLUE nexthops
```

```

# Paths    Nexthop Address
Route Distinguisher: 56:200 (default for vrf BLUE)
      8    56.0.0.209
      4    10.4.10.4 (BLUE)
      8    56.0.0.214
      8    56.0.0.205

```

Before continuing, we will ensure the MVPN control-plane is correct. CSR10 maintains a PIM neighbor with 56.0.0.114. This is the expected IP address since we changed the MDT source manually. Looking at a VPNv4 route's detailed output, we can see the BGP next-hop and connector attribute both reflect this MDT source. This is an ideal situation; just like CSR5's "bgp next-hop" method, all addressing is consistent which simplifies troubleshooting significantly.

```

R10#show ip pim vrf RED neighbor | begin ^Neigh
Neighbor          Interface          Uptime/Expires    Ver    DR

```

Since we aren't verifying BLUE MVPN traffic, we will configure the BLUE VPN TE tunnel first. We create a basic tunnel with no fancy features and add the required static route.

```

! CSR10
ip explicit-path name EP_7_8_14 enable
  next-address 56.0.0.7
  next-address 56.0.0.8
  next-address 56.0.0.14

interface Tunnel10142
  description TO XRV4 BLUE

```

```

ip unnumbered Loopback0
tunnel mode mpls traffic-eng
tunnel destination 56.0.0.14
tunnel mpls traffic-eng path-option 10 explicit name EP_7_8_14

ip route 56.0.0.214 255.255.255.255 Tunnel10142

```

A quick verification shows that the tunnel is up. With a first hop label of 9032 verified by the global IP traceroute, we verify this is consistent from inside the VPN using IPv6. Everything works as expected. So far, from the perspective of CSR10, everything is the same.

```

R10#show mpls traffic-eng tunnels tunnel 10142 brief | begin TUNNEL
TUNNEL NAME          DESTINATION      UP IF      DOWN IF     STATE/PROT

```

To test MVPN, we quickly add an SSM join to CSR4 as we have done many times before. The source is CSR6, which means the C(S,G) join should be sent towards XRv4 across the RED default MDT. Like CSR5's VPN RED test, we expect that adding the static route will cause RPF issues. Just like with CSR5, the PIM neighbor fails on CSR10 after a few minutes. Note that the failure of the PIM neighbor is not a result of having configured a multicast listener on CSR4; it would have happened no matter what.

```
! CSR4
```

```

interface GigabitEthernet2.100
 ip igmp join-group 232.100.4.4 source 100.6.0.1

R10#show ip mroute vrf RED 232.100.4.4 100.6.0.1 | begin \
(100.6.0.1, 232.100.4.4), 00:40:05/00:02:53, flags: sTI
  Incoming interface: Tunnel3, RPF nbr 56.0.0.114
  Outgoing interface list:
    GigabitEthernet2.100, Forward/Sparse-Dense, 00:40:05/00:02:53

R10#show ip rpf 56.0.0.114
  failed, no route exists

! CSR10
%PIM-5-NBRCHG: VRF RED: neighbor 56.0.0.114 DOWN on interface Tunnel3 DR

```

The easiest fix is adding a static mroute towards XRv4's loopback0, which is an IGP route for which CSR10 has a valid RPF. The PIM neighbor reforms as expected, and XRv4 shows the C(S,G) state from CSR10.

```

! CSR10
ip mroute 56.0.0.114 255.255.255.255 56.0.0.14

%PIM-5-NBRCHG: VRF RED: neighbor 56.0.0.114 UP on interface Tunnel3

R10#show ip rpf 56.0.0.114
RPF information for ? (56.0.0.114)
  RPF interface: GigabitEthernet2.580
  RPF neighbor: ? (56.8.10.8)
  RPF route/mask: 56.0.0.114/32
  RPF type: multicast (static)
  Doing distance-preferred lookups across tables
  RPF topology: ipv4 multicast base, originated from ipv4 unicast base

RP/0/0/CPU0:XRv4#show pim vrf RED topology 232.100.4.4 | begin 232
(100.6.0.1,232.100.4.4)SPT SSM Up: 00:43:40

  mdtRED 00:43:40 fwd Join(00:03:01)

```

As a final verification, CSR6 will begin sending multicast traffic into the network. XRv4 encapsulates this into the P(S,G) representing the RED default MDT, which is (56.0.0.114, 232.0.0.100) in this case. The source of these packets is XRv4's loopback100 as all routes in the core will have valid RPF routes for this. CSR10 also expects traffic from this MDT source since that is the address with which a PIM neighbor was build. The C-multicast counters are increasing and CSR10's outbound EPC proves that the operation was successful.

```

Additional Reading – Reference configurations "per-vrf-te"

32. Describe, implement, and troubleshoot E-LAN and E-TREE (extended to general L2VPN)

32.1 MPLS encapsulated L2VPN

32.1.1 Static configuration

32.1.1.1 E-LINE (VPWS)

Virtual Private Wire Service (VPWS) is a self-explanatory term that is meant to form P2P links between sites. E-LINE or EoMPLS are subsets of VPWS as they do exactly that with Ethernet connections. There is no MAC address learning or tracking as there is with VPLS (E-LAN and E-TREE). Several pseudowires (PWs) are built for examination. Because there are many PW knobs and different syntaxes to configure them, we will examine a few at the same time to start. A customer requires VPWS between CSR10 and XRv4. There should be some redundancy in the network also to account for either CSR5 or CSR6 failing. We will create two PWs: CSR8-CSR5 and CSR8-CSR6. The PW to CSR5 will be considered primary while the one to CSR6 will be considered secondary. The network diagram is shown below.

Because they will generally have the same configuration and capabilities, we can create a PW template (not a PW class) to create some CLI inheritance. These PWs will be signaled via LDP and will have the control-word (CW) enabled, which is discussed in detail later. They are also MPLS encapsulated and should include sequence numbers to prevent out of order packet delivery, which is a function of the CW discussed later. The primary path also selects a TE tunnel as its preferred path, which grants 2 Mbps of bandwidth. The backup PW follows the LDP LSP. Because the configurations are very basic, we can add many advanced features to the initial configurations.

```
! CSR8
interface Tunnel85
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 55.0.0.5
```

```

tunnel mpls traffic-eng priority 7 7
tunnel mpls traffic-eng bandwidth 2000
tunnel mpls traffic-eng path-option 1 dynamic

template type pseudowire TMP_PW_R10_XRV14
encapsulation mpls
sequencing both
control-word include
signaling protocol ldp

interface pseudowire10141
description PRIMARY PW R10-XRV14
source template type pseudowire TMP_PW_R10_XRV14
neighbor 55.0.0.5 10141
preferred-path interface Tunnel85

interface pseudowire10142
description BACKUP PW R10-XRV14
source template type pseudowire TMP_PW_R10_XRV14
neighbor 55.0.0.6 10142

```

We also must define the access circuit (AC). We will use dot1q-tunneling so that we can reuse VLAN 3580 to carry multiple EVCs from the perspective of CSR10. This will help scale the testing as we add more EVC configuration.

```

! CSR8
interface GigabitEthernet2
service instance 3504 ethernet
encapsulation dot1q 3580 second-dot1q 3504
rewrite ingress tag pop 2 symmetric

```

At this point, the PWs are doing nothing and would not come up even if the other end was configured. The PWs must be bound to an L2VPN Xconnect context, which is the new syntax. Both PWs are added and prioritized within the same group; the group is just a string and is not defined anywhere else. Lower priorities are preferred, but backup PWs can still be signaled ahead of time, similar to path-protection with MPLS-TE. The Ethernet service-instance (access circuit or AC) is also bound here.

```

! CSR8
l2vpn xconnect context XC_R10_XRV14
member pseudowire10141 group R10_XRV14 priority 3
member pseudowire10142 group R10_XRV14 priority 6
member GigabitEthernet2 service-instance 3504

```

Before doing anything, we can quickly verify the L2VPN XC context. We expect that the PWs are down, but the summary view can show us the PW/AC bindings before we continue. The AC also shows down

since the EVC is broken. Notice that despite being down, the backup PW shows that its XC state is inactive as it is still in standby mode.

```
R8#show l2vpn service xconnect name XC_R10_XRV14
Legend: St=State      XC St=State in the L2VPN Service      Prio=Priority
          UP=Up        DN=Down          AD=Admin Down      IA=Inactive
          SB=Standby   HS=Hot Standby    RV=Recovering      NH=No Hardware
          m=manually selected
```

Interface	Group	Encapsulation	Prio	St	XC St
VPWS name: XC_R10_XRV14, State: DN					
pw10141	R10_XRV14	55.0.0.5:10141 (MPLS)	3	DN	DN
pw10142	R10_XRV14	55.0.0.6:10142 (MPLS)	6	DN	IA
Gi2		Gi2:3580/3504 (Eth VLAN)	0	UP	DN

There is no point in verifying anything else on CSR8 since the network is broken. On CSR5, we will configure the PW, AC, and bind them in an L2VPN cross-connect. The configuration is very similar to CSR8. There is no TE tunnel here just for brevity.

```
! CSR5
interface pseudowire10141
 encapsulation mpls
 neighbor 55.0.0.8 10141
 sequencing both
 control-word include
 signaling protocol ldp

interface GigabitEthernet2
 service instance 1014 ethernet
 encapsulation dot1q 3554 second-dot1q 1014
 rewrite ingress tag pop 2 symmetric

l2vpn xconnect context XC_XRV14_R10
 member pseudowire10141
 member GigabitEthernet2 service-instance 1014
```

Checking CSR8 again, we can see that PW and AC came fully up. The confirms that the configuration is correct.

```
R8#show l2vpn service xconnect name XC_R10_XRV14 | begin Interface
```

Interface	Group	Encapsulation	Prio	St	XC St
VPWS name: XC_R10_XRV14, State: UP					
pw10141	R10_XRV14	55.0.0.5:10141 (MPLS)	3	UP	UP
pw10142	R10_XRV14	55.0.0.6:10142 (MPLS)	6	DN	IA
Gi2		Gi2:3580/3504 (Eth VLAN)	0	UP	UP

We can enable debugging on both ends to understand the process while the PW is being signaled. Using this single debug is verbose, so take care when sending it to the console.

```
! CSR5 and CSR8
debug mpls l2transport vc event
```

Next, we clear the PW on CSR8. The AToM process receives the command to UNPROVISION the PW with VCID 10141. It does this by shutting down the PW which is shown below. CSR8 then begins the process of withdrawing the label bindings associated with the PW. It does this for the local label 8000 and also notifies the remote end, CSR5, by sending a label withdraw. The C-bit in this context relates to the presence or absent of the control-word, which is discussed more later.

```
R8#clear l2vpn service peer 55.0.0.5 vcid 10141
```

```
! CSR8

```

After the LDP session comes up, the two routers can exchange labels. CSR8 allocates local label 8022 and advertises this to CSR5 via the label mapping message. CSR5 receives this remote label, allocates label 5021, and advertises this to CSR8 using the same message.

```

There are even more pages of less-than-useful debug that I've removed, but towards the end of the session, the two routers exchange status updates which detail the characteristics of the PW. This includes the supported VCCV CCs and CVs, support for CW, CW sequencing, and other key parameters. This completes the PW negotiation.

```

We can quickly check CSR8 to ensure both PWs are operational. We can look at the MPLS VC output to see this as well. The backup PW is still down since CSR6 does not have any PWs configured yet.

```

R8#show l2vpn service xconnect name XC_R10_XRV14 | begin Interface
  Interface          Group          Encapsulation          Prio   St   XC St
  -----          -
VPWS name: XC_R10_XRV14, State: UP
  pw10141            R10_XRV14    55.0.0.5:10141 (MPLS)   3       UP   UP
  pw10142            R10_XRV14    55.0.0.6:10142 (MPLS)   6       DN   IA
  Gi2                Gi2:3580/3504 (Eth VLAN) 0       UP   UP

```

```
R8#show mpls l2transport vc 10141
```

Local intf	Local circuit	Dest address	VC ID	Status
Gi2	Eth VLAN 3580/3504	55.0.0.5	10141	UP

We will quickly configure the PW on CSR6 before continuing so we can verify it. We will use the legacy syntax on CSR6, which involves creating a PW-class and binding it to an xconnect under the EVC stanza. Any new features introduced by Cisco (such as FAT-PW, etc) will not be supported by the legacy syntax, so it is best to use the newer syntax for future growth.

```
! CSR6
pseudowire-class PW_1014
  encapsulation mpls
  control-word

interface GigabitEthernet2
  service instance 3504 ethernet
  encapsulation dot1q 3546 exact
  rewrite ingress tag pop 1 symmetric
  xconnect 55.0.0.8 10142 encapsulation mpls pw-class PW_1014
```

We quickly verify the PW came up. In this case, it is marked as STANDBY since it is not in use, but this is better than DOWN.

```
R8#show l2vpn service xconnect name XC_R10_XRV14 | begin Interface
```

```
R8#show mpls l2transport vc 10142
```

Local intf	Local circuit	Dest address	VC ID	Status
-----	-----	-----	-----	-----
Gi2	Eth VLAN 3580/3504	55.0.0.6	10142	STANDBY

I've cleared the PWs a few more times to look at other debugs that proved less valuable. For this reason, the exact label bindings are different than what we saw earlier as the sessions were resigned. By looking at the details of each VC, we can see the full label stack that is used. The primary circuit uses PW label 5020 from CSR5 and the backup circuit uses PW label 6000 from CSR6. Also note the preferred path (MPLS TE) for the primary PW only. The control-word was negotiated and sequencing is enabled on both primary/backup circuits. The primary PW also shows "default path" is ready, which is the LDP path to be used if the tunnel fails. In the case of the backup PW, the default path is the active (and only) available path. Notice that there is no traffic flowing over the backup PW, only the primary one.

```

Let's find out how those label stacks were built. We can check the MPLS L2VPN bindings which we used for MPLS OAM/VCCV in another section. The local and remote labels per VC are listed here, which match what we saw above. The C-bit represents the CW, which is enabled on both VCs.

```

R8#show mpls l2transport binding 10141
  Destination Address: 55.0.0.5, VC ID: 10141
    Local Label: 8000
      Cbit: 1, VC Type: Ethernet, GroupID: 0
      MTU: 1500, Interface Desc: n/a
      VCCV: CC Type: CW [1], RA [2], TTL [3]
      CV Type: LSPV [2]
    Remote Label: 5020

  VCCV: CC Type: CW [1], RA [2], TTL [3]
  CV Type: LSPV [2]
```

For the transport label, we know the primary PW goes through a TE tunnel, so we can check the outbound label on that tunnel. It shows label 91009, allocated by XRv1, which is correct. The backup PW uses the LDP path via 55.0.0.6/32, which is bound to label 91007. To recap what we saw earlier, the full label stacks are {91009 5020} and {91007 6000} for primary and backup PWs, respectively. The first show command viewing the details of the VC can tell us all of this at once. Remember the LDP label for the backup PW, because we will see this later when testing failover.

```
R8#show mpls traffic-eng tunnels tunnel 85 | include OutLabel
OutLabel : GigabitEthernet2.581, 91009

R8#show mpls ldp bindings 55.0.0.6 32 neighbor 55.0.0.11
lib entry: 55.0.0.6/32, rev 8
remote binding: lsr: 55.0.0.11:0, label: 91007
```

A quick data plane check between XRv4 and CSR10 shows the label stack. XRv4 pings CSR10, and when CSR10 replies, the label stack in use is {91009 5020}. Notice that 0x16381 = 91009 and 0x139C = 5020 and is highlighted in yellow. The CW is shown in green; this is discussed in detail later, but the output shows a 4-byte buffer with some unknown values at present. Be careful not to confuse the CW for an MPLS shim header despite them both being 4 bytes. The IP source/destination addresses are shown in cyan, which shows a flow from 10.10.14.10 to 10.10.14.14.

```
R8#show monitor capture CAP buffer detailed
 6 144 3.027007 00:50:56:A9:FB:1C -> 00:50:56:A9:9C:60 MPLS unicast

0030: 00010000 FF018B6C 0A0A0E0A 0A0A0E0E .....l.....
```

We can quickly perform similar verifications on CSR5, which is the other end of the operational PW. There is no TE tunnel on the path back to CSR8, so the LDP default path is active.

```
R5#show mpls l2transport vc 10141
```

Local intf	Local circuit	Dest address	VC ID	Status
Gi2	Eth VLAN 3554/1014	55.0.0.8	10141	UP

```
R5#show mpls l2transport vc 10141 detail
Local interface: Gi2 up, line protocol up, Eth VLAN 3554/1014 up
Interworking type is Ethernet
Destination address: 55.0.0.8, VC ID: 10141, VC status: up
Output interface: Gi2.551, imposed label stack {91008 8000}
Preferred path: not configured
Default path: active
Next hop: 55.5.11.11
[snip]
```

The VC label bindings are identical to those seen at CSR8 except reversed. CSR5 will use PW label 8000 when sending traffic along VC 10141.

```
R5#show mpls l2transport binding 10141
Destination Address: 55.0.0.8, VC ID: 10141
Local Label: 5020
  Cbit: 1, VC Type: Ethernet, GroupID: 0
  MTU: 1500, Interface Desc: n/a
  VCCV: CC Type: CW [1], RA [2], TTL [3]
  CV Type: LSPV [2]
Remote Label: 8000
  Cbit: 1, VC Type: Ethernet, GroupID: 0
  MTU: 1500, Interface Desc: n/a
  VCCV: CC Type: CW [1], RA [2], TTL [3]
  CV Type: LSPV [2]
```

The transport label is 91008, signaled from XRv1 using LDP. As seen earlier, the entire label stack is {91008 8000}.

```
R5#show mpls ldp bindings 55.0.0.8 32 neighbor 55.0.0.11
lib entry: 55.0.0.8/32, rev 23
remote binding: lsr: 55.0.0.11:0, label: 91008
```

Another useful command involves looking at a summary view of allocated labels and PWs. This shows label 5020 locally allocated for VC 10141.

```
R5#show mpls l2transport pwid | include 10141|Label
```

Label	Peer-Address	VCID	PWID	In-Use	FirstUse	ReusedAt	FreedAt
5020	55.0.0.8	10141	12	Yes	13:42:08	Never	Never

Just like earlier, we verify the data plane by capturing outbound on CSR5. We see 0x16380 = 91008 and 0x1F40 = 8000, which matches the expected label stack. The CW is shown in green, and the IP source and destination addresses are 10.01.014.14 and 10.10.14.10, respectively.

```

0030: 00000000 FF018B6D 0A0A0E0E 0A0A0E0A .....m.....
```

We will begin testing the failover capability of this design. First, we will “break” the TE tunnel. Rather than outright destroy it, we will more elegantly pre-empt it with another TE tunnel. This is a more realistic reason for an already-signaled TE tunnel to fail. A high priority tunnel will request all available bandwidth (150 Mbps) on the link to XRv1. We aren’t using this tunnel for anything else other than to cause Tunnel 85 to fail, so we don’t have to use a steering mechanism.

```
! CSR8
interface Tunnel999
 description TAKE ALL BANDWIDTH
 ip unnumbered Loopback0
 tunnel mode mpls traffic-eng
 tunnel destination 55.0.0.11
 tunnel mpls traffic-eng priority 0 0
 tunnel mpls traffic-eng bandwidth 150000
 tunnel mpls traffic-eng path-option 1 dynamic
```

We see log messages on CSR8 that indicate tunnel ID 85 cannot remain operational as the downstream bandwidth request cannot be fulfilled. The VC now falls back to its default path, as the tunnel cannot be used. The default path moves from “ready” to “active” when the preferred path is unavailable.

```
! CSR8
TE-LM-BW: tunnel 55.0.0.8_8->55.0.0.5_85 {7}: Downstream bw hold request
failed
%LINEPROTO-5-UPDOWN: Line protocol on Interface Tunnel85, changed state to
down
```

```
R8#show mpls l2transport vc 10141 detail | include Pref
Preferred path: Tunnel85, no route
Default path: active
```

CSR8 needs to figure out what transport label to use, and it gets this from LDP via XRv1. The route to the PW endpoint is IGP learned, so we should see an LDP label from XRv1.

```
R8#show mpls ldp bindings 55.0.0.5 32 neighbor 55.0.0.11
 lib entry: 55.0.0.5/32, rev 10
```

```
remote binding: lsr: 55.0.0.11:0, label: 91006
```

Testing the data plane outbound from CSR8 again, we can see the LDP transport label in use, yielding a label stack of {91006 5020}, shown in yellow. Notice that $0x1637E = 91006$ and $0x139C = 5020$. We are still not using the backup PW since the default path of the primary PW is still preferred over the backup PW entirely. The xconnect doesn't care about whether the preferred TE path is up or not so long as the primary PW can remain up.

```
R8#show monitor capture CAP buffer detailed
  2 144      2.143989 00:50:56:A9:FB:1C -> 00:50:56:A9:9C:60 MPLS unicast

0030: 00000000 FF018B6D 0A0A0E0A 0A0A0E0E .....m.....
```

We must force the primary PW down entirely before the backup PW can be used. Rather than do an unrealistic test and shutdown the PW interface, we will perform some LDP label filtering. CSR8 will no longer accept bindings for 55.0.0.5/32 from XRv1, which breaks the FEC entirely, assuming the TE tunnel is not used. The LDP binding database, FIB, and LFIB show no label.

```
! CSR8
mpls ldp neighbor 55.0.0.11 labels accept ACL_FILTER_R5_LABEL
ip access-list standard ACL_FILTER_R5_LABEL

```

Because the layer 2 features on XRv are unsupported in the data-plane, I cannot put its uplinks into a bridge-domain and apply an IP address to a BVI. Instead, I will quickly switch interfaces on XRv14 for testing to use backup PW. This will allow XRv4 to send traffic to CSR10, but I acknowledge that it is sloppy and unrealistic.

```

! XRv4
interface GigabitEthernet0/0/0/0.546
  description LINE TO CSR10 VIA CSR6 (BACKUP)
  no shutdown

interface GigabitEthernet0/0/0/0.1014
  description LINE TO CSR10 VIA CSR6 (PRIMARY)
  shutdown

```

Testing the data plane outbound on CSR8, we can see the LDP label for CSR6's loopback is 91007 (0x1637F) which we saw earlier. The PW label is 0x1770, which is 6000, and is what we saw in the PW verifications earlier as well.

```

```

We can recover the primary PW by making any of its paths available again: the TE tunnel or the LDP path. In this case, we will leave the LDP filter in place and simply shutdown the greedy tunnel 999. Tunnel 85 comes back up, which allows the primary PW to come up. This automatically puts the backup PW into standby mode.

```

We still do not have a default path, but since the preferred path is available, the primary PW can still operate. In a real network, you would likely only observe this case when LDP was not running at all; that is to say, TE would be the primary transport between all PEs.

```
R8#show mpls l2transport vc 10141 detail | include path:
  Preferred path: Tunnel85, active
  Default path:
```

A final control-plane check confirms that the new RSVP-TE label and PW label are used for this VC.

```
R8#show ip rsvp reservation detail filter session-type 7 tunnel-id 85 |
include Label
  Label: 91009 (outgoing)
```

```
R8#show mpls l2transport binding 10141 | include Remote

```

```
R8#show mpls l2transport vc 10141 detail | include label_stack
  Output interface: Tu85, imposed label stack {91009 5021}
```

Removing the LDP filter facing XRv1 brings back the default path, also. This returns the network to its normal state.

```
R8#show mpls l2transport vc 10141 detail | include path:
  Preferred path: Tunnel85, active
  Default path: ready
```

To complete the customer network, we will provision an entirely new PW to connect CSR10 with CSR1. We will configure this manually with no signaling protocol; this removes LDP from the process. This comes with several drawbacks, to include a lack of status updates, along with several features like CW sequencing and PW redundancy. Not using LDP means the local and remote label bindings must also be defined manually per PW. When we try to do this on CSR8 under a PW interface, we cannot set a meaningful local label.

```
R8(config-if)#label ?
<0-0> Local pseudowire label
```

The reason is because you must first identify a range of static labels in the configuration. After making this adjustment, we verify the new range is applied. Then, we can configure a local label in accordance with that range.

```
R8(config)#mpls label range 8000 8999 static 800 899

R8#show mpls label range
Downstream Generic label region: Min/Max label: 8000/8999
```

Range for static labels: Min/Max label: 800/899

```
R8(config-if)#label ?  
<800-899> Local pseudowire label
```

The full configuration on CSR8 is as follows. The CW is enabled by default, and does work with static PWs, but I have disabled it for variety. We should see the Ethernet frames immediately after the PW labels in the packet captures now without the additional 4 bytes added by the CW.

```
! CSR8  
interface pseudowire110  
  description PW R10-R1  
  encapsulation mpls  
  neighbor 55.0.0.4 110  
  control-word exclude  
  signaling protocol none  
  label 810 410  
  pseudowire type 5  
  no status  
  
interface GigabitEthernet2  
  service instance 3510 ethernet  
  encapsulation dot1q 3580 second-dot1q 3510  
  rewrite ingress tag pop 2 symmetric  
  
l2vpn xconnect context XC_R10_R1  
  member pseudowire110  
  member GigabitEthernet2 service-instance 3510
```

We will use the legacy configuration on CSR4 but the concept is the same. We also must specify static MPLS label range on CSR4 (not shown), or else we see the issue below again.

```
R4(cfg-if-ether-vc-xconn)#mpls label ?  
<0-0> Local pseudowire label  
  
! CSR4  
pseudowire-class PW_R10_R1  
  encapsulation mpls  
  protocol none  
  no status  
  
interface GigabitEthernet2  
  service instance 3514 ethernet  
  encapsulation dot1q 3514 exact  
  rewrite ingress tag pop 1 symmetric  
  xconnect 55.0.0.8 110 encapsulation mpls manual pw-class PW_R10_R1  
  mpls label 410 810  
  no mpls control-word
```

The normal control-plane verifications are limited now because the PWs will always show UP unless the target FEC (no route to PW endpoint, no corresponding label, etc) is broken. For variety, we will use the “new” syntax for verification in this section.

```
R4#show l2vpn atom vc vcid 110
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw100007	55.0.0.8	110	p2p	Gi2-SI:3514:3514	UP

```
R8#show l2vpn atom vc vcid 110
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw110	55.0.0.4	110	p2p	XC_R10_R1	UP

We can see the label stacks as well. The PW labels were statically allocated while the transport labels came from LDP. Due to the static nature of manually-configured PWs, the administrator must ensure the local/remote labels are configured correctly on both sides.

```
R4#show l2vpn atom vc vcid 110 detail | include label_stack
Output interface: Gi2.542, imposed label stack {92008 810}
```

```
R8#show l2vpn atom vc vcid 110 detail | include label_stack
Output interface: Gi2.581, imposed label stack {91003 410}
```

We can see the VCCV bindings from the above command also, assuming we don’t use a filter. The legacy command didn’t show VCCV information, but the new command does. We will check it from one side, as this information is “assumed” since it cannot be signaled. It is interesting to note that VCCV says Type-1 CC using the control-word is supported, but it actually isn’t.

```
R4#show l2vpn atom vc vcid 110 detail | section VCCV
VCCV CV type 0x02                                0x02
          LSPV [2]                                LSPV [2]
VCCV CC type 0x07                                0x07
          CW [1], RA [2], TTL [3]                CW [1], RA [2], TTL [3]
```

A quick VCCV operation confirms that the PW is operational. It is valuable to check both directions since LSPs are always unidirectional.

```
R4#ping mpls pseudowire 55.0.0.8 110

We will enable RIPv2 on all three customer routers to ensure XRv4 can communicate with CSR1 across CSR10. Running IGP for customers is the biggest driver for L2VPN as it simplifies their enterprise networking. The L2VPN isn't great because traffic hairpins through CSR10, but it does work. A direct connection from XRv4 to CSR1 would make more sense to create optimal traffic flows. The RIP configuration is not shown because it is very basic and is not the focus of this test.

```

```

When XRv4 sends traffic to CSR1, we capture both in and out on CSR8's interface facing the core. There are four relevant packets to see in this test; the initial request entering and existing CSR8, and the reply doing the same in the opposite direction. First, the initial request arrives on PW 10141 with a single label in the stack (yellow) followed by the CW (green) The output below shows that this label is 8011 (0x1F4B). The packet size is 840 bytes.

```
R8#show l2vpn atom binding 10141 | include Local
```

```
Local Label: 8011
```

```

0030: FF018CC3 0A0A0E0E 0A010A01 08002B32 .....+2
```

Next, the packet is routed to CSR10, then hairpins back into the MPLS core via CSR8 as the PE. Notice the length is the same despite having two labels. This is because the PW between CSR8 and CSR4 is not using the CW, but the PW between CSR5 and CSR8 is. Labels 91003 (0x1637B) and 410 (19A) are pushed onto the stack as expected.

```

Traffic traverses the network, ultimately reaching CSR4 where all labels are removed. CSR1 responds to the ICMP echo, and CSR4 sends the reply back towards CS8. Traffic arrives from CSR4 along PW 110. We see this packet is 4 bytes smaller as it contains only the PW label (XRv1 performs PHP) and there is no CW. The incoming label is 810 (0x32A) which is bound to PW 110, sending traffic to CSR10.

```

Last, we see our largest packet yet. It contains two MPLS labels {91009 5021}, derived from 0x16381 and 0x139D respectively, and represents the primary PW towards XRv4 via CSR5. Remember that the transport label comes from RSVP-TE as the outgoing interface is a TE tunnel. The CW (green) is included as well, which is why the packet is 844 bytes.

```
R8#show l2vpn atom vc vcid 10141 detail | include label_stack
Output interface: Tu85, imposed label stack {91009 5021}
```

32.1.1.2 Advanced PW features (CW, Status, etc)

With basic connectivity achieved, we can now explore additional PW features. This section is a continuation from the section and uses the same three PWs already built. While simple to configure, the control-word (CW) has many critical details to understand. It 32 bit (4 byte) field inserted after the PW label, so it is the same length as an ordinary MPLS shim header. In the previous set of examples, we saw the CW in the EPC captures but did not verify its operation nor purpose. The CW is capable of doing five things:

1. **Pad small packets:** Depending on the media type, padding may be needed to meet the minimum frame size when using different media. If the length field in the CW is nonzero at the egress PE, it knows padding was applied and will remove it. Typically the length field is zero as padding frames is uncommon with Ethernet due to header sizes.
2. **Carry control bits for certain layer 2 protocols:** Mostly relevant for ATM and FR, where techniques like FECN, BECN, DE, EFCI, and CLP are needed. The CW is required for some layer 2 protocols (ATM, FR) and optional for others (Ethernet, PPP).
3. **Preserve the sequence of frames:** Like sequence numbers in TCP, this assigns incremental values to each unit using a 16 bit unsigned counter (1 to 65535). The command "sequencing both" enables it for transmitted and received packets, and it is disabled by default. Static PWs

(without LDP) cannot use this feature. Out of sequence frames are not retransmitted, but are simply dropped. The counter goes from 1 to 65535 and wraps around to 1 again (circular).

4. **Facilitate load sharing:** Cisco routers examine the first 4 bits after the MPLS header to determine the payload. For IPv4, this is 0x4, and IOS will perform load sharing (if the FIB indicates so) based on the source and destination addresses. For Ethernet frames, this first hexadecimal digit could be a 4 also depending on the destination MAC address. This could invalidate load sharing strategies as the router will try to parse an IPv4 source/destination address pair from the Ethernet frame. The same is true for IPv6 except Cisco looks for a 0x6. CWs added to the layer 2 frames will begin with either 0x0 (general data) or 0x1 (OAM). By seeing values that are neither 0x4 nor 0x6, the router assumes the frame is non-IP and performs load-sharing based on the bottom label, which is correct. Coupled with FAT-PW, this technique works well for core routers that are unaware of the MPLS service details.
5. **Facilitate fragmentation/reassembly:** Using Beginning and Ending (B and E) bits, AToM frames can be fragmented and reassembled for transit over MPLS. P routers cannot fragment AToM packets.

CWs that begin with bits 0000 represent ordinary data packets. Those that begin with bits 0001 represent PW-ACH (VCCV) test frames. The MPLS OAM section shows VCCV CWs and they always begin with 0x1; this is just a way to multiplex control traffic onto the same “channel” (FEC) as the data traffic. The data frame seen in captures in the previous chapter starts with 0x0. The remaining 28 bits vary based on what is being encapsulated, but we will focus on Ethernet. The next 12 bits are reserved for future use (RFC 4448) and are typically zero. Encapsulations that require the CW will use these bits for things like fragmentation bits, the length field, and other signaling flags. The last 16 bits of all CWs represent the sequence numbers.

To test the sequence numbers, we send traffic from CSR10 to XRv4 using the primary PW where the CW is already enabled. Sequence numbers are enabled bidirectionally from the previous example. Capturing in both directions on CSR8, we can see the sequence numbers increasing as packets are received and sent. The packets from CSR8 to CSR5 are shown in yellow and the return traffic from CSR5 to CSR8 is shown in cyan. Only the CW is highlighted. The “yellow” flow counts 53, 54, 55 and the “cyan” flow counts 15, 16, 17.

```

It makes sense to use sequencing in both directions, but it can also be configured unidirectionally. In this example, CSR8 sends sequence numbers and CSR5 processes them upon receipt, but this is not enabled in the reverse direction. On CSR8, this specific PW setting overrides the inherited template. The “yellow” CWs show traffic from CSR8 with sequence numbers 10 and 11, while the “cyan” CWs show the return traffic from CSR5 with no sequencing.

```

! CSR8
interface pseudowire10141

```

If the sender and receiver PEs remain unsynchronized for long periods of time, this could cause outages since out-of-order frames are simply dropped. On CSR5 and CSR8, we specify that if 500 packets are seen out of order, the sequence numbers are reset. This is like a “reset” button that allows the PW to recover from an variety of forwarding issues in the core. We won’t try to test this in the data plane as it would be very difficult.

```
! CSR5 and CSR8
interface pseudowire10141
 sequencing resync 500
```

```
R8#show l2vpn atom vc vcid 10141 detail | include Seq
Sequencing: receive disabled, send enabled
Sequencing resync enabled, threshold 500
```

```
R5#show l2vpn atom vc vcid 10141 detail | include Seq
Sequencing: receive enabled, send disabled
Sequencing resync enabled, threshold 500
```

The resync configuration has no effect on CSR8 at present since it is only adding sequence numbers for the benefit of CSR5 and not processing them locally. That is to say, the resync feature on matters when

sequence numbers are actually being processed by the egress LER, so “sequencing transmit” does not count. We will return the PW to its baseline by sequencing in both directions. We can manually clear the sequence numbers using the “clear mpls counters” command.

```
R8#show l2vpn atom vc vcid 10141 detail | include Seq
Sequencing: receive enabled, send enabled
Sequencing resync enabled, threshold 500
```

```
R8#clear mpls counters
Clear "show mpls forwarding-table" counters [confirm]
mpls forward counters cleared
```

```
R5#show l2vpn atom vc vcid 10141 detail | include Seq
Sequencing: receive enabled, send enabled
Sequencing resync enabled, threshold 500
```

```
R5#clear mpls counters
Clear "show mpls forwarding-table" counters [confirm]
mpls forward counters cleared
```

Another important concept is the C-bit, or the control word bit. It is set to 1 if the CW is present on a PW. The PW ID FEC element carried by LDP will carry this value (along with the PW ID and other generic but important fields). For encapsulations that require the CW, such as ATM and FR, the C-bit should always be 1. The mechanics of how the C-bit is negotiated is very detailed, but in summary, if the CW is optional (Ethernet) and the two endpoints disagree on whether the CW should be used or not, the PW will come up with CW disabled. Notice that the primary/backup PWs from CSR8 use the CW, while the manual PW to CSR4 does not. This determines whether or not the CW will appear in the MPLS packets.

```
R8#show l2vpn atom binding 10141 | include Cbit
Cbit: 1,      VC Type: Ethernet,      GroupID: 0
Cbit: 1,      VC Type: Ethernet,      GroupID: 0
```

```
R8#show l2vpn atom binding 10142 | include Cbit
Cbit: 1,      VC Type: Ethernet,      GroupID: 0
Cbit: 1,      VC Type: Ethernet,      GroupID: 0
```

```
R8#show l2vpn atom binding 110 | include Cbit
Cbit: 0,      VC Type: Ethernet,      GroupID: 0
Cbit: 0,      VC Type: Ethernet,      GroupID: 0
```

LDP-based PWs can also use the concept of “status” to exchange information about the link with one another. This includes the status of the local AC where the remote end has no visibility. Status is enabled by default, and we can verify it on the LDP PWs from CSR8. The first line of the output is most important; it shows whether status is enabled locally and supported by the remote end. The state machine codes are straightforward: L/R means local/remote router, r/n means ready or not-ready, u/d means up/down. In this case, both local and remote nodes are ready and up, so status is working.

```
R8#show l2vpn atom vc vcid 10141 detail | section Status TLV
```

```
Status TLV support (local/remote)      : enabled/supported
LDP route watch                        : enabled
Label/status state machine             : established, LruRru
Local dataplane status received        : No fault
BFD dataplane status received          : Not sent
BFD peer monitor status received       : No fault
Status received from access circuit    : No fault
Status sent to access circuit          : No fault
Status received from pseudowire i/f    : No fault
Status sent to network peer            : No fault
Status received from network peer      : No fault
Adjacency status of remote peer        : No fault
Status TLV      enabled                supported
```

We can simulate a fault on CSR5 by shutting down the Ethernet flow point (EFP) on CSR5. This means that, from CSR8's perspective, the remote AC is down. This is a good reason to start using the backup PW to CSR6 and is one reason why status is critical when using backup PWs. The debugs below show this happen in real-time, but they are quite chatty. CSR8 receives the status message of DOWN AC from the remote node and updates its state machine accordingly. The remote node is ready, but down, as indicated by "LruRrd".

```
! CSR8
debug l2vpn atom vc status event
debug l2vpn atom vc status fsm
```

```
AToM[55.0.0.5, 10141]: Received remote peer status
AToM[55.0.0.5, 10141]: . Remote status DOWN AC(rx/tx faults)
AToM[55.0.0.5, 10141]: . Remote status change, DOWN AC(rx/tx faults)
AToM[55.0.0.5, 10141]: .. Check if remote connected
AToM[55.0.0.5, 10141]: ... Remote label is ready
AToM[55.0.0.5, 10141]: ..... S:Evt remote ready in LruRru
AToM[55.0.0.5, 10141]: ..... S:Evt remote down, LruRru->LruRrd
AToM[55.0.0.5, 10141]: ..... S:Act send SSS(DOWN)
AToM[55.0.0.5, 10141]: ..... Remote      : DOWN AC(rx/tx faults)
AToM[55.0.0.5, 10141]: ..... Overall    : DOWN AC(rx/tx faults)
```

CSR8 also sets its own DOWN AC status and sends it to CSR5, probably to ensure the PW goes completely down. This might be a software optimization or requirement to get the backup PW working correctly, but we know the local AC is fine. The state becomes "LrdRrd" as the AC is "down" at both ends.

```
! CSR8
AToM[55.0.0.5, 10141]: ..... Update AC for status change from UP
AToM[55.0.0.5, 10141]: ..... Send AC STATUS(DOWN AC(rx/tx faults))
AToM[55.0.0.5, 10141]: ..... S:Evt ADJ up in LruRrd
```

```

AToM[55.0.0.5, 10141]: ..... S:Act send SSS(DOWN), notify(UP)
AToM[55.0.0.5, 10141]: ..... Remote      : DOWN AC(rx/tx faults)
AToM[55.0.0.5, 10141]: ..... Overall    : DOWN AC(rx/tx faults)

  Status TLV enabled                    : supported

```

```
R8#show l2vpn atom vc vcid 10141
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw10141	55.0.0.5	10141	p2p	XC_R10_XRV14	UP

```
R8#show l2vpn atom vc vcid 10142
```

Interface	Peer ID	VC ID	Service		Status
			Type	Name	
pw10142	55.0.0.6	10142	p2p	XC_R10_XRV14	STANDBY

There are sub-features of “status” also. One of them is the route-watch feature which is enabled by default when status is enabled. This listens for routing events to trigger redundancy changes. The command is sparsely documented so we will research it here.

```

R8#show l2vpn atom vc vcid 10141 detail | include route
  LDP route watch                      : enabled

```

We will disable this on CSR8’s primary PW. Status in general is still enabled, but route-watch is not. The command was made for cross-OS support, but even when demonstrating RIB changes, nothing is different besides the show command. I believe this feature is specifically meant to support the “status redundancy” preferential forwarding treatment available only with ATM ACs.

```

! CSR8
interface pseudowire10141
 no status control-plane route-watch

R8#show l2vpn atom vc vcid 10141 detail | include Status TLV|route
  Status TLV support (local/remote)      : enabled/supported
    LDP route watch                      : disabled
  Status TLV      enabled                  supported

```

Of note are the statuses of the backup PW endpoints. CSR8 reports that it is locally down and communicates this to CSR6. CSR6 acknowledges that it is locally up, but has been placed in STANDBY mode by CSR8. CSR8 “received” notification from the AC that it was in standby, which triggers the appropriate status message to CSR6. The reason CSR8 is down is because the xconnect to which this PW is bound already has a functioning, primary PW.

```

R8#show l2vpn atom vc vcid 10142 detail | section Status TLV
  Status TLV support (local/remote)      : enabled/supported
    LDP route watch                      : enabled
  Label/status state machine              : established, LrdRru
  Local dataplane status received         : No fault
  BFD dataplane status received           : Not sent
  BFD peer monitor status received        : No fault
  Status received from access circuit      : DOWN(standby)
  Status sent to access circuit            : No fault
  Status received from pseudowire i/f     : No fault
  Status sent to network peer              : DOWN(standby)
  Status received from network peer       : No fault
  Adjacency status of remote peer         : No fault
  Status TLV      enabled                  supported

```

```

R6#show l2vpn atom vc vcid 10142 detail | section Status TLV
  Status TLV support (local/remote)      : enabled/supported
    LDP route watch                      : enabled
  Label/status state machine              : established, LruRrd
  Local dataplane status received         : No fault
  BFD dataplane status received           : Not sent
  BFD peer monitor status received        : No fault
  Status received from access circuit      : No fault
  Status sent to access circuit            : DOWN(standby)
  Status received from pseudowire i/f     : No fault
  Status sent to network peer              : No fault
  Status received from network peer       : DOWN(standby)
  Adjacency status of remote peer         : No fault
  Status TLV      enabled                  supported

```

Because status is an LDP TLV, it is not available on manually configured (static) PWs. The state machine is always UP and there is no mechanism for status messaging to be exchanged.

```

R8#show l2vpn atom vc vcid 110 detail | section Status TLV

Status received from pseudowire i/f : No fault
Status sent to network peer : No status
Status received from network peer : Not sent
Adjacency status of remote peer : No fault
Status TLV disabled N/A

```

To ensure certain advanced features are supported on certain platforms (in certain roles), you can check the capabilities. The list is very long and covers all supported layer 2 encapsulations, but I filter based on Ethernet. Notice that, for example, sequence checking isn't supported by either P or PE roles. This may be a hardware limitation of the virtual routers since the parser accepts all sequencing commands and counts the numbers correctly as verified earlier.

```

R4#show l2vpn atom hw-capability interface Gig2 | section Eth
Interface GigabitEthernet2

- Disposition rewrite is supported
- QinQ is supported
- QinQ any is supported

Layer 2 protocol tunneling is commonly used on switches to transport specific layer 2 frames such as PAgP, LACP, VTP, BPDU, CDP, VTP, and others. There are two other options as well: forward and peer. Forward means to pass the traffic onward with no local processing, where tunneling implies some kind of encapsulation/MAC address changes. Peer implies the router will process the traffic locally and not forward it on. On the CSR1000v, only certain protocols are supported for certain actions.

“Tunnel” feature does not appear supported on the CSR1000v for any traffic type.

```
R4(config-if-srv)#l2protocol tunnel stp
l2protocol action not supported
```

```
R4(config-if-srv)#l2protocol tunnel lacp
l2protocol action not supported
```

```
R4(config-if-srv)#l2protocol tunnel pagp
l2protocol action not supported
```

“Forward” and “peer” features are only supported for STP.

```
R4(config-if-srv)#l2protocol forward stp
```

```
R4(config-if-srv)#l2protocol forward lacp
l2protocol action not supported
```

```
R4(config-if-srv)#l2protocol forward pagp
l2protocol action not supported
```

```
R4(config-if-srv)#l2protocol peer stp
```

```
R4(config-if-srv)#l2protocol peer lacp
l2protocol action not supported
```

```
R4(config-if-srv)#l2protocol peer pagp
l2protocol action not supported
```

I assume unspecified protocols, such as VTP, BPDU, and CDP are processed as “peer”. Enabling CDP on CSR2 and CSR7 (not shown) suggests this. CSR2 and CSR7 are CDP neighbors despite CSR2 not being explicitly configured to treat CDP messages as “peer” on the EFP.

```
R7#show cdp neighbors | begin Device
Device ID      Local Intrfce  Holdtme    Capability  Platform  Port ID
R2             Gig 2         151        R I        CSR1000V  Gig 2.527
```

Last, we examine logging. The syntax is very straightforward and we specify whether to log all PW events or just redundancy events. Even though this is part of the “new” syntax, it works for legacy PW configurations also.

```
! All XE PE routers
l2vpn
 logging pseudowire status
 logging redundancy

! XRv3
l2vpn
 logging
  pseudowire
```

If we clear the static PW towards CSR4, we see many syslog messages. Notice there are no LDP messages since LDP is not used for signaling this PW.

```
R8#clear l2vpn service xconnect name XC_R10_R1
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.4 vcid 110, VC state DOWN
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.4 vcid 110, VC state DOWN, PW Err
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.4 vcid 110, VC state DOWN, PW Err
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.4 vcid 110, VC state ADMIN DOWN
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.4 vcid 110, VC state DOWN
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.4 vcid 110, VC state UP
```

To cause a redundancy event, we can shut down the remote EFP bound to the primary PW on CSR5. CSR8 shows the redundancy failover logs.

```
! CSR8
%XCONNECT-5-REDUNDANCY: XC VPWS: Activating secondary member 55.0.0.6:10142
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.5 vcid 10141, VC state DOWN, Rem AC
Err
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.6 vcid 10142, VC state UP
```

Bringing the AC on the primary PW back up activates the primary member again. These logs are very helpful for troubleshooting L2VPN and should be enabled at all times.

```
! CSR8
```

```
%XCONNECT-5-REDUNDANCY: XC VPWS: Activating primary member 55.0.0.5:10141
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.5 vcid 10141, VC state STANDBY
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.6 vcid 10142, VC state STANDBY
%XCONNECT-5-PW_STATUS: MPLS peer 55.0.0.5 vcid 10141, VC state UP
```

32.1.1.3 E-LAN and E-TREE (VPLS)

The Metro Ethernet Forum (MEF) defines MP2MP and P2MP Ethernet services as well. E-LAN provides a traditional LAN service to customers, allowing them to control all aspects of their layer 3 routing protocols between multiple sites. This can be useful for removing routing complexity from customers and allowing them to run non-IP protocols over an SP network, and in this case, an MPLS-based SP network. Virtual Private LAN Service (VPLS) is generally synonymous with E-LAN and is similar to VPWS/E-LINE in many ways. It still relies on the PW construct and all of the associated features, such as CW, status, LDP signaling, etc. However, since there are additional PWs to multiple nodes (not just P2P), there needs to be some kind of “glue” to bond these connections into a single VPLS instance. This is what the virtual forwarding instance (VFI) solves. PWs are identified as “members” of a VFI, and this VFI serves as a single layer 2 interface for the VPLS instance. Then, the VFI is connected to the AC via a bridge-domain, which is similar to integrating routing and bridging (IRB) on the IOS XE/XR platforms.

The goal is to connect CSR1, CSR2, XRv4, and CSR10 together via VPLS. The PEs will be CSR4, CSR6, CSR7, and XRv3. The relevant VFI configurations are shown below; PW configurations are all basic and only serve to achieve basic connectivity between the nodes. Since each PW is independent, their configuration can vary, so long as the encapsulation is the same. I use a mix of new (l2vpn vfi context) and legacy (l2 vfi) configurations to achieve this. I also mix up the manner in which PWs are bound to the VFI, sometimes creating a separate interface PW, sometimes defining it within the VFI context. The AC configuration is not shown as it is identical in logic to VPWS/E-LINE. CSR4 uses the new L2VPN VFI with some in-line PWs, CSR6 uses all “new” syntax, and CSR7 uses strictly legacy syntax. For brevity, I do not show the configurations of each individual PW interface as the interface enumeration reveals the endpoints.

```

  neighbor 55.0.0.6 pw-id 613
  neighbor 55.0.0.7 pw-id 713

```

Strictly speaking, the VPN ID does not matter when doing manually-configured VPLS, but I configure it out of habit. Clearly, this mechanism scales poorly since (N-1) PWs are required for connectivity between all nodes. Before checking specific VPLS parameters, we can check to ensure the VCs are up on all nodes. We will use a brief command on XRv; notice that the AC never comes up. This is a limitation of the XRv data plane, so testing reachability to CSR10 via the E-LAN is not possible. It is beneficial to see the PWs come up in the control-plane so that the VPLS instance can be verified with show commands, at a minimum.

```

R4#show l2vpn atom vc | include LAN
pw46      55.0.0.6      46      vfi      LAN      UP

pw100008 55.0.0.13 713 vfi LAN UP
```

```
RP/0/0/CPU0:XRv3#show l2vpn bridge-domain bd-name LAN brief
```

Legend: pp = Partially Programmed.

Bridge Group:Bridge-Domain Name	ID	State	Num ACs/up	Num PWs/up
LAN:LAN	0	up	1/0	3/3

The bridge-domain is like a VLAN in that it maintains separate CAM entries per bridged instance. In this case, we are using it for VPLS. From CSR4's perspective, there are 4 "ports" on this virtual switch. 3 of them are VPLS PWs and one is the AC, which is an EFP with service ID 3541. The aging time of 300 seconds (5 minutes) begins counting down when a MAC address is learned and resets to 300 each time a new frame is received with the MAC address in question. Notice that, like a normal switch, MAC learning is enabled by default. AED stands for "authoritative edge device" which is used for overlay transport virtualization (OTV), which is discussed later. It has no relevance for MPLS L2VPNs.

```
R4#show bridge-domain
```

```
Bridge-domain 3467 (4 ports in all)
```

```
State: UP Mac learning: Enabled
```

```
Aging-Timer: 300 second(s)
```

```
GigabitEthernet2 service instance 3541
```

```
vfi LAN neighbor 55.0.0.7 47
```

```
vfi LAN neighbor 55.0.0.6 46
```

```
vfi LAN neighbor 55.0.0.13 413
```

AED	MAC address	Policy	Tag	Age	Pseudoport
0	0050.56A9.1AAA	forward	dynamic	279	GigabitEthernet2.EFP3541
0	0050.56A9.862A	forward	dynamic	278	LAN.1004019
1	FFFF.FFFF.FFFF	flood	static	0	OLIST_PTR:0xe808b800
0	0050.56A9.BE8A	forward	dynamic	279	LAN.1004018

To confirm these are the correct MAC addresses, we can check the ARP cache on CSR1 to verify the IP addresses match each destination. The address ending in 1AAA is local to CSR4 and is identified as reachable via the EFP. Addresses BE8A and 862A are for CSR2 and XRv4 respectively, and are reachable over VPLS via the VFI. The pseudoport numbers for each remote peer are not terribly significant and do not appear well documented. CSR10's MAC address does not show up because XRv3 cannot forward L2VPN traffic.

```
R1#show arp vrf LAN
```

Protocol	Address	Age (min)	Hardware Addr	Type	Interface
Internet	10.0.0.1	-	0050.56a9.1aaa	ARPA	GigabitEth2.541
Internet	10.0.0.2	176	0050.56a9.be8a	ARPA	GigabitEth2.541
Internet	10.0.0.14	49	0050.56a9.862a	ARPA	GigabitEth2.541

We can also get a summary view of all the PWs within a VFI along with the MPLS labels used to build the VPLS instance using a single command. Notice that the VFI itself is given a PW interface for internal software management purposes, although we know it isn't actually a PW.

```

R4#show l2vpn service vfi name LAN detail | begin Interface
Interface          Group          Encapsulation          Prio   St   XC St
-----
VPLS name: LAN, State: UP
pw100008
pw100007            core_pw      55.0.0.13:413 (MPLS)    0      UP  UP
                  Local VC label 4010
                  Remote VC label 93009

pw46                core_pw      55.0.0.6:46 (MPLS)     0      UP  UP
                  Local VC label 4013
                  Remote VC label 6007

pw47                core_pw      55.0.0.7:47 (MPLS)     0      UP  UP
                  Local VC label 4012
                  Remote VC label 7033

```

Checking the LFIB, each PW gets its own set of local and remote labels, since the data plane treats these as independent paths. The purpose of the VFI/bridge-domain combination is to add some switch-like intelligence. The MAC address learning happens just like ordinary an switch; unknown unicast flooding occurs first until bridge-domain data structures update their CAM tables. The first entry with local label 410 is from an E-LINE PW to CSR8 which is from the last section. The VPLS-bound PWs do not have outgoing interfaces in the LFIB since received traffic is delivered to an EFP. Label 4010 maps to the XRv3 PW and, not surprisingly, has received no data traffic.

```

R4#show mpls forwarding-table | include l2ckt
410      No Label   l2ckt (1)      302670      Gi2         point2point
4010     No Label   l2ckt (6)      0           none        point2point
4012     No Label   l2ckt (4)      2580        none        point2point
4013     No Label   l2ckt (5)      2072        none        point2point

```

A quick check of the CW and status of the VPLS PWs can help us understand what the actual encapsulations will look like. We can ignore the output with 55.0.0.8 as the target as this is the PW not part of the VPLS instance. Notice that status is enabled for all VPLS PWs but the CW was not negotiated with XRv3. Locally, CSR4 is configured to attempt CW negotiation, but we can assume XRv3 did not offer it. We can correct that later.

```

R4#show l2vpn atom vc detail | include Control|Status_TLV|Destination

```

On CSR1, we will send some IP broadcasts to 255.255.255.255. This translates to a destination MAC address of FFFF.FFFF.FFFF. We see earlier that the bridge-domain (BD) CAM table suggests this traffic should be flooded to all ports in the BD. We expect to see three replicated MPLS packets sent from CSR4 towards the CSR6, CSR7, and XRv3. The first packet is shown below with its MPLS labels in yellow and CW in green. With label stack {92002 6007}, we know this is for CSR6 because the output earlier showed label 6007 along that PW. We will verify this again, along with the LDP label. The original IP source/destination of 10.0.0.1/255.255.255.255 is shown in cyan for completeness.

```

R4#show l2vpn atom vc vcid 413 detail | include label_stack

Output interface: Gi2.542, imposed label stack {92007 93009}

Next, we will ensure VPLS performs unknown unicast flooding, then desists once a MAC address is learned. With a cleared BD CAM, we send traffic from CSR1 to XRv4. Before traffic is sent, CSR4's BD has no entry for XRv4's MAC address.

R4#show bridge-domain 3467 | include 862[Aa]

[no output]

This packet should be replicated along all three PWs initially. Upon receiving return traffic from XRv4, it will learn XRv4's MAC via the proper PW and cease the flooding. The first three packets below all have the same IP header checksum (yellow), which indicates it is the same packet replicated three times. The timestamp is also identical. The pink label stack represents the LSP to CSR6, the green represents the LSP to CSR7, and the cyan represents the LSP to XRv3. The last two packets are traveling along the correct LSP with no more flooding; notice the change in checksum and the increased timestamp. The LSP is fixed using CSR6 which is correct.

We can also verify multicast traffic replication. All multicast, both routed and link-local (LL), is replicated to all PWs in the mesh at all times. This is very inefficient for routed multicast compared to any MVPN profile in conjunction with MPLS L3VPN. The PIM Assert process would occur on the emulated LAN but this does not stop the traffic from flooding over the core network in the first place. Even though IGMP snooping appears to be supported on the bridge-domain, it does not properly track routers (PIM messaging or IGMP queries) or hosts (IGMP joins). It appears to be unsupported in VPLS architectures as the corresponding show commands never show any output. All routers are enabled for OSPFv2 on a broadcast network, while only CSR1 and CSR2 are also PIM routers. The configuration is not shown, but we verify it quickly on all routers using a variety of show commands for variety.

Capturing outbound on CSR4 shows OSPF hellos being replicated along all PWs. We can assume the same thing happens for PIM as well (I verified it, but it is not shown for brevity). The label stack is ignored since we have verified it several times, and the OSPF destination IP address of 224.0.0.5 is highlighted in green. Because this is layer 2 transport, I also highlight the destination MAC of 0100.5e00.0005 in yellow. The BD evaluates this, sees that the I/G bit is set, and floods it.

```

For completeness, we test routed multicast also. With IGMP snooping dysfunctional, we expect it to be flooded just like LL multicast. We use the GLOP group 233.190.239.238 (0xE9BEEFEE) because it stands out nicely in hex and is highlighted in green. The timestamps are identical, and I've highlighted the layer 2 and 3 multicast addresses in yellow. This multicast treatment makes MPLS L3VPN a much better option for multicast transport, especially when there are few listeners and high bandwidth flows. Recall that PIM was not even enabled on XRv4, yet multicast traffic is being flooded to it, adding to the inefficiency of the design.

```

Let's get the CW working between XRv3 and CSR4. CSR4 was expecting to use the CW but XRv3 was not even offering it. We create a PW-class similar to legacy IOS syntax and apply it to the manual PW within the XR bridge-domain. The PW flaps but comes back up with the CW negotiated properly.

```

```

We know that adding the CW can prevent “wrong” load balancing when the first nibble of the destination MAC address is either a 4 or 6, since the P routers will attempt to load share based on the IPv4/v6 information within the tunneled packet. The CW allows the router to use the bottom label as the traffic would be properly classified as non-IP. This introduces a new issue, specifically one related to forwarding polarization. The core problem is that all traffic in a given PW, as part of a VPLS instance, is always following the same core path. The flow-aware transport of pseudowires (FAT-PW) adds another label to the stack. It sits beneath the PW label and above the CW, if present. If the CW is not used, it sits under the PW and before the payload. The TTL of this shim header is always 1 in the unlikely event the PW label is accidentally popped early, which guarantees the frame will not be forwarded. The label values are determined by the router based on a source/destination hash. FAT negotiation requires new LDP TLVs, specifically the “T” and “R” TLVs for transmit and receive, respectively. LDP signaling must be

enabled; static PWs cannot exchange the FAT TLV. This feature is only available with the new syntax under a PW template or interface PW; it is not available under a PW-class or xconnect stanza.

```
! CSR4
interface pseudowire46
  load-balance flow ip src-ip
  load-balance flow-label both
```

```
! CSR6
interface pseudowire46
  load-balance flow ip dst-ip
  load-balance flow-label both
```

```
R4#show l2vpn atom vc vcid 46 detail | include Load|Flow
Load Balance: ECMP
Flow Label      T=1, R=1                      T=1, R=1
```

```
R6#show l2vpn atom vc vcid 46 detail | include Load|Flow
Load Balance: ECMP
Flow Label      T=1, R=1                      T=1, R=1
```

Theoretically, we should be able to see load sharing per flow based on the Ethernet addressing (or possibly the IP addressing, if we specify). Using the local label of the PW, along with exact source/destination addressing, the LFIB should tell us the flow label. Only one PW is currently enabled for FAT, so we need to use the proper local label. We see four different flow labels based on IP addresses and would expect to see this at the bottom of the label stack. Note: If FAT is not enabled, the “Ethernet” option for load balancing does not show up in the show command at all.

Flow label: 123886
```

I've added 1.1.1.1, 1.1.1.2, 1.1.1.3, and 1.1.1.4 to CSR1 to use as source addresses for load sharing. A simple TCL script on CSR1 will allow us to send a single packet in each "flow". One would expect to see the aforementioned labels in the packets.

```
! CSR1
tclsh
foreach x {
1.1.1.1
1.1.1.2
1.1.1.3
1.1.1.4
} { ping vrf LAN 10.0.0.14 repeat 1 source $x }
```

We can see there is another label at the bottom of the label stack, under the PW label and before the CW. After an hour of testing, I was never able to see any of the parser-displayed MPLS labels in the packet captures. Most of the time, I saw label 0x80000 (decimal 524288) which is highlighted in yellow. As with the first packet, sometimes I saw 0x82080 (decimal 532608) but it was dependent upon the load balancing method. I also highlight the source IP from each flow so you can clearly see the packets should have different hashes (green). I would have preferred to at least see the proper labels, even if the core load balancing was suboptimal due to only having 4 flows.

Enabling debug on CSR4 to troubleshoot this, I see several messages early in the PW setup that FAT is not supported by CSR6, which is false. I believe this is during the initiation exchange before the “T” and “R” TLVs have been fully exchanged, but the debugging hints that the feature isn’t supported at all.

```

When the PW is actually made, the “fat” feature appears to be supported and enabled. We will move on past this feature for now. One thing to note is that the “load balance” method seen earlier says ECMP, where the documentation says “flow”. Considered I enabled flow-based load balancing, I cannot explain the discrepancy. This may be attributed to the CSR1000v specifically, but the feature is worth discussing at it solves real-world problems.

```

```

“Routed” VPLS is useful to enable a layer 3 touchpoint on a VPLS PE. This can be use to participate somewhat in the customer routed network. A BDI is equivalent to an SVI or BVI in that it lives transparently in the “bridge-domain”. The BVI number must match the BD number, just as SVIs must match the VLAN IDs they serve on layer 3 switches. On CSR4 and CSR7, we configure BDI interfaces and enable OSPF on them. We add a LAN VRF also so that this routing information doesn’t mingle with the global routing table used in the MPLS core. Only CSR4 is shown for brevity since the configurations are nearly identical on CSR7. Note: BDI interfaces are shutdown by default.

```
! CSR4
interface Loopback3467
 vrf forwarding LAN
 ip address 4.4.4.4 255.255.255.255
 ip ospf 1 area 0

interface BDI3467
 vrf forwarding LAN
 ip address 10.0.0.4 255.255.255.0
 ip ospf priority 0
 ip ospf 1 area 0
 no shutdown
```

From an OSPF perspective, be careful about using multi-access network types over VPLS. Since the multipoint L2VPN network is just a collection of P2P PWs, a sufficient number of links may fail to the point where all nodes do not have direct layer 2 reachability, which is not supported for all NBMA designs. Everyone must have reachability to the DR at all times; consider P2MP network type as an alternative despite some of the flooding inefficiencies it may bring. We won’t test this in detail since basic OSPF NBMA design considerations are beyond the scope of this test. In the current design, both CSR4 and CSR7 are now part of the “broadcast network”. There are 5 total OSPF routers in the VPLS, 3 of which are CEs and 2 of which are PEs. IP connectivity is functional over the network as expected.

```

Success rate is 100 percent (5/5), round-trip min/avg/max = 7/9/13 ms
```

Just like SVIs, the BDI gets a virtual MAC address so that it can participate in IPv4 ARP and IPv6 ND. The BD CAM now shows several new entries. There is a local “to_bdi” entry that consumes locally-destined traffic. We also see 0001E.E5DD.FFBF which we presume is the MAC address of CSR7’s BDI. It is reachable via the same pseudoport as CSR2’s MAC address that we used for testing earlier.

```
R4#show interface bdi3467 | include bia
Hardware is BDI, address is 001e.4977.7cbf (bia 001e.4977.7cbf)

R4#show bridge-domain 3467

```

The BD also has some MAC address customizations. On CSR6, we enable several. First, we will disable MAC address learning, forcing CSR6 to flood all frames out of all PWs since all unicast is now “unknown”

by definition. This could be useful if the BD/VFI constructs are used for dynamically creating a VPWS (E-LINE) service. Since traditional xconnects never retain MAC addresses (no reason to between P2P peers), the router can emulate that behavior using this command. The memory efficiencies of xconnect-based E-LINE can translate into VFI-based E-LINE using this technique. The feature is generally not useful when there are more than 2 endpoints in the L2VPN. The exception would be if the vast majority of traffic was multicast, then it would not matter much.

```
! CSR6
bridge-domain 3467
  no mac learning

R6#show bridge-domain 3467
Bridge-domain 3467 (4 ports in all)
State: UP                               Mac learning: Disabled
Aging-Timer: 300 second(s)
  GigabitEthernet2 service instance 3564

  AED MAC address      Policy Tag      Age   Pseudoport
  1   FFFF.FFFF.FFFF flood  static 0     OLIST_PTR:0xe806b400
```

Next, we re-enable MAC learning on CSR6 to test other features. We enable a 60 second timer to keep the MAC address table smaller, but expect more frequency unknown unicast flooding. We also instruct the BD not to flood traffic from MAC addresses not in the BD CAM table when the limit is reached; the default is to treat it like unknown unicast and flood it. The traffic is dropped instead using this command, which saves bandwidth at the expense of breaking traffic flows. There do not appear to be any specific show-commands to validate these limit/flood minor features. Notice that two MACs are learned via two separate PWs. This represents the CSR4 BDI + CSR1 MAC (grey port), and the CSR7 BDI + CSR2 MAC (green port). Since XRv3 cannot support L2VPN, no MACs from that pseudoport are shown in the BD CAM.

```
! CSR6
bridge-domain 3467
  mac learning
  mac aging-time 60

```

Because the routers are constantly generating traffic (OSPF, PIM, etc), this limit will be exceeded and the router will alarm us.

```

! CSR4
%BDOMAIN-4-MAC_LIMIT_VIOL_SYS_LIMIT: Attempt to learn a new MAC on
GigabitEthernet2 service instance 3541 (bridge-domain 3467) caused system
limit (2) to be exceeded.

```

Some basic OSPF debugging on CSR4 shows us that, since CSR4 didn't learn XRv4's MAC address, it cannot communicate via unicast to complete the OSPF adjacency.

```

! CSR4
OSPF-1 ADJ   BD3467: Cannot see ourself in hello from 10.0.0.14, state INIT
OSPF-1 ADJ   BD3467: Nbr 10.0.0.14: Clean-up dbase exchange
OSPF-1 ADJ   BD3467: Neighbor change event
OSPF-1 ADJ   BD3467: DR/BDR election
OSPF-1 ADJ   BD3467: Elect BDR 10.0.0.2

```

```

OSPF-1 ADJ    BD3467: Elect DR 10.0.0.2
OSPF-1 ADJ    BD3467: DR: 10.0.0.2 (Id)
OSPF-1 ADJ    BD3467:    BDR: 10.0.0.2 (Id)
OSPF-1 ADJ    BD3467: Remember old DR 10.0.0.14 (id)

```

XRv4 doesn't need to do any unicast exchange with CSR4 or CSR7, but it does with CSR1 since it is the BDR. Because CSR1 cannot reply to the messages (CSR4 isn't forwarding them), the neighbor can never form.

```

RP/0/0/CPU0:XRv4#show ospf vrf LAN neighbor | begin State
Neighbor ID      Pri   State                Dead Time   Address      Interface
4.4.4.4          0    2WAY/DROTHER         00:00:37    10.0.0.4

GigabitEthernet0/0/0/0.564
    Neighbor is up for 00:00:42

```

The more-specific configuration on the BD does not fix the issue as the system setting is the aggregate of all MAC addresses learned. The global setting should be set only to conserve memory on a router.

```

! CSR4
bridge-domain 3467
    mac limit maximum addresses 100

```

Changing the value from 2 to 200 alleviates the issue. Reducing the BD maximum to 2 generates a similar log message, except it is BD-scope, not system-scope. Interestingly, the BDI does not appear to count in this context, but only the truly dynamic MACs do. The system is now capable of storing many MAC addresses but this specific BD (and thus, the VPLS instance) cannot.

```

! CSR4
ethernet mac limit maximum addresses 200

bridge-domain 3467
    mac limit maximum addresses 2

```

```

! CSR4
%BDOMAIN-4-MAC_LIMIT_VIOL_BD_LIMIT: Attempt to learn a new MAC on (bridge-
domain 3467) caused configured bridge-domain limit (2) to be exceeded.

```

```

R4#show bridge-domain
Bridge-domain 3467 (5 ports in all)
State: UP                               Mac learning: Enabled
Aging-Timer: 300 second(s)
    BDI3467 (up)
    GigabitEthernet2 service instance 3541
    vfi LAN neighbor 55.0.0.13 413
    vfi LAN neighbor 55.0.0.7 47

    0  0050.56A9.1AAA forward dynamic 295  GigabitEthernet2.EFP3541
    1  FFFF.FFFF.FFFF flood  static  0    OLIST_PTR:0xe80d1800
    0  0050.56A9.BE8A forward dynamic 291  LAN.1004014
    -  001E.4977.7CBF to_bdi static  0    BDI3467

```

Even though the BD is not specifically blocking the MAC flooding when the threshold is reached, the system action is. You would think that exceeding the system threshold would incur the system penalty (block) and exceeding the BD threshold would incur the BD penalty (flood), but it doesn't. The traffic is blocked.

```

RP/0/0/CPU0:XRv4#show ospf vrf LAN neighbor 10.0.0.1 | begin 10.0.0.1
Neighbor 10.0.0.1, interface address 10.0.0.1
    In the area 0 via interface GigabitEthernet0/0/0/0.564
    Neighbor priority is 1, State is DOWN, 4 state changes
    [snip]

```

Removing the system-wide “block” action fixes this. The MAC addresses are still not written to BD CAM but can be flooded to the entire VPLS domain (treated as unknown unicast).

```

! CSR4
no ethernet mac limit action flooding disable

RP/0/0/CPU0:XRv4#show ospf vrf LAN neighbor 10.0.0.1 | begin 10.0.0.1
Neighbor 10.0.0.1, interface address 10.0.0.1
    In the area 0 via interface GigabitEthernet0/0/0/0.564
    Neighbor priority is 1, State is FULL, 10 state changes
    [snip]

```

Adding the action to the BD breaks it again. We theorize that the “more strict” MAC threshold action is preferred when the system and BD policies differ.

```

! CSR4
bridge-domain 3467
    mac limit action flooding disable

RP/0/0/CPU0:XRv4#show ospf vrf LAN neighbor 10.0.0.1 | begin 10.0.0.1

```

In the area 0 via interface GigabitEthernet0/0/0/0.564
Neighbor priority is 1, **State is EXSTART**, 3 state changes

Before continuing, we remove the BD-level adjustments from CSR4 for clarity.

```
! CSR4
bridge-domain 3467
  no mac limit action flooding disable
  no mac limit maximum addresses 2
```

Last, we will examine E-TREE. This is still a VPLS-based technology, but as defined earlier, it is not a complete LAN. CE devices are split into two categories: root and leaf. Roots can talk to all nodes, and leaves can only talk to roots. This is identical to how a switch with “protected” ports or private VLANs would operate. Nodes behind promiscuous or non-protected ports are roots, while nodes within secondary VLANs or protected ports are leaves. It is also similar to a Cisco ME switch with UNI ports where the UNI ports are leaves and the NNI ports are roots. The configuration for this involves NOT configuring a full PW mesh as we did for E-LAN. Simply skip configuring PWs between leaves and all tenets of static VPLS configuration remain the same. Like E-LAN, we will use a variety of L2VPN protocol-based CLI, legacy configuration, interface PW, and inline members. I also demonstrate that each PW can be different with respect to variables like status, CW, FAT-PW, sequencing, etc. The encapsulation must be the same, and the PW must not be statically configured.

```

We will enable EIGRP as the customer IGP over the E-TREE. Rather than test connectivity individually, we can just look at the IGP neighbors and see that the leaves only form neighbors with the roots, while the roots are fully meshed. Just like protected switchports, PVLANS, or UNI-to-UNI ports, there is no possibility of leaves communicating over the E-TREE directly via layer 2.

All normal rules apply with respect to layer 2 connectivity just as they would in any NBMA network; specifically, since Ethernet is used for transport, it looks like a PVLAN network. Assuming we wanted to violate the E-TREE design and enable connectivity between the spokes, there are several workarounds. None of these are VPLS related but can be valuable to overcome NBMA complexities when full reachability is required. The first option is to enable local-proxy-ARP on the root nodes. This allows them to proxy-ARP for hosts in the same subnet, which is even more extreme (and rarely used) than ordinary proxy-ARP. We can enable this on CSR10; when XRv4 ARPs for CSR2's MAC address, CSR10 will reply. The same is true in the other direction. This does not enable direct broadcast/multicast communication, so EIGRP multicast discovery doesn't start working.

```
! CSR10
interface GigabitEthernet2.508
 ip local-proxy-arp
```

```
RP/0/0/CPU0:XRv4#show arp vrf TREE | begin Address
Address      Age      Hardware Addr  State   Type   Interface
10.0.0.1     00:09:58  0050.56a9.1aaa Dynamic ARPA   Gigabi0/0/0/0.554
10.0.0.2     00:00:10  0050.56a9.f961 Dynamic ARPA   Gigabi0/0/0/0.554
10.0.0.10    02:10:03  0050.56a9.f961 Dynamic ARPA   Gigabi0/0/0/0.554
10.0.0.14    -         0050.56a9.862a Interface ARPA   Gigabi0/0/0/0.554
```

This means CSR10 is in the transit path, essentially hairpinning traffic using a suboptimal path. Because CSR2's MAC address was never communicated over the PW between CSR8 and CSR5 in the E-TREE, the BD CAM on CSR5 never learns it.

```

```

We can avoid the ARP process altogether by statically configuring ARP entries on the spokes routers to use a root's MAC address. This may speed up communication since local-proxy-ARP resolution does not occur, and also may be necessary if the root node cannot enable local-proxy-ARP for security reasons. We could use multiple hubs to form some weak load sharing, but I select CSR1 for hairpinning this time. There is still no change to the leaf BD CAM as this technique is very similar to the first. Both CSR2 and XRv4 map one another's IOP addresses to CSR1's MAC address, placing CSR1 in the transit path.

```

Additional Reading – Reference configurations "l2vpn-static"

32.1.1.4 Multisegment PW (MS-PW) switching

PW switching is a way to terminate PWs on a common node and have that router bridge the two PWs together. In this way, the PW is "stitched" to provide layer-2 transport end to end. This is typically used in Inter-AS environments (specifically, option B) or when there are disparate MPLS networks. I used a single AS for this test to demonstrate the feature. As we will see, you can chain as many PW switching routers in the path as you like, and I demonstrate using up to 2 PW switching routers. A new network was needed with a larger MPLS core to make this more interesting, and since XRv doesn't support L2VPN, the core is all CSR1000v. I used IS-IS L1 and L2 to add some complexity, as well as MPLS-TE. Rather than do a basic P2P example, I use static VPLS so that we can create many PWs for a combination of direct, single-switched, and double-switched paths.

With 4 PEs in the VPLS instance there are 6 (derived from $(n(n-1))/2$) total PWs. The PWs are configured as follows:

- CSR3 to CSR6 = direct
- CSR3 to CSR4 = double stitched via CSR1 and CSR2, 3 total PWs
- CSR3 to CSR9 = single stitched via CSR2, 2 total PWs
- CSR6 to CSR9 = direct
- CSR6 to CSR4 = single stitched via CSR7 (legacy configuration), 2 total PWs
- CSR4 to CSR9 = direct

For the basic configuration, I extensively use templates to speed up configuration. The VPLS configuration is very basic and uses the new L2VPN method only since that is not the focus here. The VFI contains three member PWs which are shown below. This is a member of a BD which also contains the EFP associated with the CE device. These basic BD, EFP, and L2VPN VFI configurations are not shown.

```
! All core LSRs
l2vpn
 logging pseudowire status
 logging redundancy

template type pseudowire TMP_VPLS
 encapsulation mpls
```

```
control-word include
signaling protocol ldp
```

The direct PWs are very simple. We will examine those three first, remembering that the VFI, BD, and EFP must be configured on each PE as well. The configuration is not shown, but we can verify them quickly. First we examine both ends of the CSR3-CSR6 link, followed by the CSR6-CSR9 and CSR4-CSR9 links. This covers half of the PWs inside of the VPLS instance.

```
R3#show l2vpn atom vc vcid 36 | begin Interface
Interface Peer ID      VC ID      Type      Name      Status

R4#show l2vpn atom vc vcid 49 | begin Interface
Interface Peer ID      VC ID      Type      Name      Status
-----
pw49      17.0.0.9      49      vfi      LAN      UP

R9#show l2vpn atom vc vcid 49 | begin Interface
Interface Peer ID      VC ID      Type      Name      Status
-----
pw49      17.0.0.4      49      vfi      LAN      UP
```

Now, we will configure a single-stitch path. CSR3 to CSR9 should be stitched together by CSR2. The configuration on CSR3 and CSR9 is very basic and is essentially a PW identifying CSR2 as the endpoint. Again, it is assumed these PW interfaces are members of the L2VPN VFI. The point is that the non-stitched PW endpoints (the PEs in this case) don't have anything special in their configurations for MS-PW.

```
! CSR3
interface pseudowire23
 source template type pseudowire TMP_VPLS
```

```

neighbor 17.0.0.2 23

! CSR9
interface pseudowire29
  source template type pseudowire TMP_VPLS
  neighbor 17.0.0.2 29

```

CSR2 needs to terminate both of these sessions, essentially mirroring the configuration and reversing the neighbor address. The magic on CSR2 involves putting both PWs into an L2VPN xconnect pair. Normally, we used xconnects to include one PW and one EFP when doing normal VPWS/E-LINE. In this case, we can pair two PWs, but no more.

```

! CSR2
interface pseudowire23
  source template type pseudowire TMP_VPLS
  neighbor 17.0.0.3 23

interface pseudowire29
  source template type pseudowire TMP_VPLS
  neighbor 17.0.0.9 29

l2vpn xconnect context BRIDGE_PW39
  member pseudowire23
  member pseudowire29

```

At this point, all PWs should be up. Checking from the PW switching router is the fastest way to verify since it can see both ends, but we will check the endpoints for completeness.

```

R2#show l2vpn atom vc service-name BRIDGE_PW39 | begin Interface
Interface Peer ID      VC ID      Type      Name      Status
-----
pw23      17.0.0.3      23         p2p       BRIDGE_PW39  UP
pw29      17.0.0.9      29         p2p       BRIDGE_PW39  UP

```

```

R3#show l2vpn atom vc vcid 23 | begin Interface
Interface Peer ID      VC ID      Type      Name      Status
-----
pw23      17.0.0.2      23         vfi       LAN        UP

```

```

R9#show l2vpn atom vc vcid 29 | begin Interface
Interface Peer ID      VC ID      Type      Name      Status
-----
pw29      17.0.0.2      29         vfi       LAN        UP

```

Next, let's trace the LSP from CSR3 to CSR9 along this switched PW path. To determine the labels, we can look at the VC details for the quick answer. In this case, looking deeper is beneficial since the L2VPN bindings can also tell us the transit PW switching routers, which we cannot see using the VC show

command. The PW label of 2017 was allocated by CSR2, which is technically the end of the LSP. The L2VPN bindings reveals that 17.0.0.2 (CSR2) is the PW switching point and redirects traffic onto VC 29 towards 17.0.0.9 (CSR9). It is also worth noting that VCCV is not supported end to end when using this feature, and the CW cannot be carried end to end, either. We set the C-bit which means the CW is used, but the PW-ACH enhancement of the CW for OAM purposes is not supported.

```
R3#show l2vpn atom vc vcid 23 detail | include label_stack
Output interface: Gi2.513, imposed label_stack {1002 2017}
```

```
R3#show l2vpn atom binding 23
Destination Address: 17.0.0.2, VC ID: 23

Cbit: 1, VC Type: Ethernet, GroupID: 0
MTU: 1500, Interface Desc: n/a
VCCV: CC Type: TTL [3]
CV Type: LSPV [2]
PW Switching Point:
VC ID    Local ID    Remote ID    Description
29       17.0.0.2    17.0.0.9
```

```
R3#show mpls ldp bindings 17.0.0.2 32 neighbor 17.0.0.1
lib entry: 17.0.0.2/32, rev 11
remote binding: lsr: 17.0.0.1:0, label: 1002
```

When CSR1 gets the packet, it swaps the label to explicit-null (added for variety; any null label would work), then forwards the packet with label stack {0 2017} to CSR2. After removing the topmost label, CSR2 essentially performs a label swap from its locally-issued PW label to the one issued by CSR9. In doing so, it copies the EXP bits, decrements TTL, then pushes a new transport label (if necessary) to reach CSR9. This is similar to how Inter-AS Option B works for L3VPN since the VPNv4/v6 label is swapped at the ASBR; in both cases, this is technically a new LSP. For this reason, VCCV Type-1 switching with PW-ACH is not supported end to end. We can verify these labels operations in the control plane first.

```
R1#show mpls forwarding-table label 1002
Local      Outgoing    Prefix          Bytes Label    Outgoing    Next Hop
Label      Label       or Tunnel Id    Switched       interface
1002       explicit-n  17.0.0.2/32     3312           Gi2.512     17.1.2.2
```

The LFIB details indicate that the label is swapped to 9002. We can verify this is the correct PW label by checking the AToM bindings again. Notice that the bindings on the router performing the switching

don't show an intermediate hop, since from its perspective, we have only one router performing PW switching. Later examples detail what happens when the chain is longer.

```
R2#show mpls forwarding-table labels 2017 detail
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id Switched      interface

  Cbit: 1, VC Type: Ethernet, GroupID: 0
  MTU: 1500, Interface Desc: n/a
  VCCV: CC Type: RA [2], TTL [3]
        CV Type: LSPV [2]
```

The LFIB has indicated that there are recursive paths. This means that the LFIB is not preprogrammed with a transport label for its push operation since the RIB says there are ECMP paths via CSR7 and CSR4.

```
R2#show ip route 17.0.0.9
Routing entry for 17.0.0.9/32
  Known via "isis", distance 115, metric 30, type level-1
  Redistributing via isis 17

  Routing Descriptor Blocks:
    17.2.7.7, from 17.0.0.9, 00:08:54 ago, via GigabitEthernet2.527
      Route metric is 30, traffic share count is 1
  * 17.2.4.4, from 17.0.0.9, 00:08:54 ago, via GigabitEthernet2.524
      Route metric is 30, traffic share count is 1
```

Because the packet is non-IP, we use the bottom label to determine ECMP selection. The incoming label and bottom label happen to be the same, which is fine. CSR2 selects CSR7 as the next-hop, so we can check the LDP bindings and FIB to verify the label value of 7007.

```
R2#show mpls forwarding-table exact-route label 2017 bottom-label 2017
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id Switched      interface

nexthop 17.2.4.4 GigabitEthernet2.524 label 4005
nexthop 17.2.7.7 GigabitEthernet2.527 label 7007
```

We perform the same verification for the next singly-attached PW, but this time will verify it with EPC and EXP bit copying. CSR7 uses the legacy configuration but the operation is the same. The endpoint configuration is not shown as those are normal PWs with nothing special.

```
! CSR7
pseudowire-class PW_VPLS
encapsulation mpls
control-word

l2 vfi BRIDGE_PW46 point-to-point
neighbor 17.0.0.6 67 pw-class PW_VPLS
neighbor 17.0.0.4 47 pw-class PW_VPLS
```

We quickly verify that the two PWs are up. From CSR6 to CSR4, we can determine the label stack by checking the AToM bindings and the LDP labels for transport. The command also shows us the PW switching that occurs on CSR7, along with the adjacent PW and LSP endpoint address. The LDP label comes from CSR7, which is attached, so only label 7008 is used for this short PW.

```
R7#show mpls l2transport vc
```

Local intf	Local circuit	Dest address	VC ID	Status
pw100001	17.0.0.6 67	17.0.0.4	47	UP

```

```
R6#show mpls l2transport vc 67 detail | include label_stack
Output interface: Gi2.567, imposed label stack {7008}
```

The LFIB on CSR7 shows a label swap operation occurring when we examine the details. The LFIB says “recursive paths” because there are multiple paths to reach CSR4 per the RIB. Since the traffic is non-IP, the bottom label is used to determine the ECMP forwarding. Since the PW label is the only label, it is used for the LFIB lookup and for ECMP selection.

```

```

We expect to see a label stack of {2012 4008} leaving CSR7 as a result. Capturing in on the link facing CSR6 and out on the link towards CSR2, we can confirm label 7008 (0x1B60) arrives with a CW. The EXP bits are copied (zero), the TTL is reduced from 255 to 254, the PW label is swapped to 4008 (0xFA8), and a new LDP label of 2012 (0x7DC) is pushed. MPLS shim headers are shown in yellow while control-words are shown in green. Shown in cyan is the DSCP CS1 marking; because AToM is not looking deep into the

Ethernet frame, this was not copied to the EXP bits on imposition. Later examples show the 802.1Q CoS being mapped to EXP automatically on imposition when using ATOM.

```

A good summary view of all of the PW labels used for the bridging feature is shown below. Even the new L2VPN commands can still show information about legacy configurations since it's just a parser update.

```
R7#show l2vpn service xconnect all detail | begin Interface
Interface          Group          Encapsulation          Prio  St  XC St
-----
VPWS name: BRIDGE_PW46, State: UP
pw100001           17.0.0.6:67 (MPLS)      0      UP  UP
                    Local VC label 7008
                    Remote VC label 6002
pw-class: PW_VPLS
pw100002           17.0.0.4:47 (MPLS)      0      UP  UP
                    Local VC label 7003
                    Remote VC label 4008
pw-class: PW_VPLS
```

We will quickly test the CoS to EXP mapping feature. CSR5 is configured to mark CoS for all outgoing traffic using CoS 1 for the outer tag and CoS 2 for the inner tag. This will allow us to tell which one the router selects for the MPLS EXP bits.

```
! CSR5
policy-map PMAP_COS
class class-default
set cos 1
set cos-inner 2

interface GigabitEthernet2.556
service-policy output PMAP_COS
```

The label stack has not changed, so we won't validate that again. Label 7008 arrived and label stack (2012 4008) exits towards CSR2. This time, we see a combination of 0x4 and 0x5 in the nibble where EXP

is stored. The positions with 0x5 indicate the S-bit being set which is not related to EXP, so we can assume 0x4 is the only set of EXP markings we see. This evaluates to binary 010x where x is a “don’t care” bit. We can assume this is EXP2, carried over from CoS 2, which was set as the inner CoS. I did not set the DSCP on the IP packet this time since we know it was not effective in transitioning directly to MPLS EXP at imposition; the value of 0 is shown in cyan. All new labels pushed by CSR7 (such as 2012) also contain the same EXP bits as the PW label, which is desirable. This proves that EXP is maintained across MS-PWs.

```

CSR1 consults its LFIB and swaps 1005 to 3002. We can also see this in the L2VPN xconnect service details. Because there are no recursive lookups, the LFIB pre-populates the entire encapsulation, except the TTL=0 in the show command for both shim headers. Not shown in the LFIB is the push operation to add explicit-null, which CSR2 requests.

```

Last time, the PW switching router did not show anything interesting in its AToM PW bindings. Since CSR1 is one of multiple PW switching LSRs, its PW to CSR2 (the next PW in the chain) accounts for all other downstream PWs. Just like CSR3 includes VC 12 and VC 24, CSR1 accounts for VC 24 only. We can also use this to triple-check the outbound PW label of 2006.

```
R1#show l2vpn atom binding 12
  Destination Address: 17.0.0.2, VC ID: 12
  Local Label: 1008
    Cbit: 1,      VC Type: Ethernet,      GroupID: 0

```

```

VCCV: CC Type: TTL [3]
      CV Type: LSPV [2]
Remote Label: 2006
Cbit: 1,      VC Type: Ethernet,      GroupID: 0
MTU: 1500,    Interface Desc: n/a
VCCV: CC Type: TTL [3]
      CV Type: LSPV [2]
PW Switching Point:
VC ID      Local ID      Remote ID      Description
24         17.0.0.2        17.0.0.4

```

CSR2 receives the stack {0 2006} and performs a lookup on the PW label. The label is swapped again to 4009 and explicit-null is not imposed this time. This is the remote PW label learned from CSR4 along VC 24. Notice that for VC 24, CSR2 does not show any PW switching LSRs since this is the last PW in the left-to-right direction.

```

PW Switching Point:
  VC ID   Local ID   Remote ID   Description
  13      17.0.0.1   17.0.0.3

```

CSR4 receives label 4009 which is the PW label it advertised to CSR2. This is the end of the MPLS encapsulation for the traffic as CSR4 removes the PW label and forwards the Ethernet frame to XRv2. When we check the AToM bindings, we see both PW switching LSRs in the return path, as expected. CSR4 would use PW label 2009 to send traffic back towards CSR2.

```

R4#show l2vpn atom binding 24
Destination Address: 17.0.0.2, VC ID: 24
Local Label: 4009
Cbit: 1,      VC Type: Ethernet,      GroupID: 0

VCCV: CC Type: TTL [3]
      CV Type: LSPV [2]
PW Switching Point:
  VC ID   Local ID   Remote ID   Description
  12      17.0.0.2   17.0.0.1
  13      17.0.0.1   17.0.0.3

```

We will quickly test the data plane but with one quick modification. CSR1 will be temporarily configured to remark all traffic entering from CSR3 to EXP4. This will allow us to verify if this remarking will be honored despite the PW label swap.

```

! CSR1
policy-map PMAP_REMARK_EXP4
class class-default
set mpls experimental topmost 4

interface GigabitEthernet2.513
service-policy input PMAP_REMARK_EXP4

```

Next, we will enable EPC on CSR1 and CSR2 to capture left-to-right traffic from CSR3 to CSR4. We expect to see EXP bits copied between swapped PW labels and the TTL decremented at each hop as well. XRv1

will send some traffic for analysis. The EXP bits did not get honored, likely because the exp-null label was remarked but was popped shortly thereafter, not swapped. A new exp-null was pushed and the original EXP values were lost. We see incoming labels {0 1005} and outgoing labels {0 2006} as we expect. The TTL was decremented from 255 to 254 on the PW label. Shim headers are in yellow and control-words are in green.

```
RP/0/0/CPU0:XRv1#ping 10.0.0.12
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.0.0.12, timeout is 2 seconds:

```

I quickly remove LDP explicit-null allocation from CSR1 (not shown) to see if the remarking will be applied to the PW label and thus survive the label swap. This flaps all of the MS-PW sessions, so the actual label values may change, but we won't verify that in detail again. The quick verification is shown below. CSR1 will receive traffic inbound with a single label of 1005, then send {0 2006} out to CSR2.

```
R1#show l2vpn atom vc vcid 13 detail | include local_label
SSO Descriptor: 17.0.0.3/13, local_label: 1005
```

```
R1#show l2vpn atom vc vcid 12 detail | include label_stack
Output interface: Gi2.512, imposed label_stack {0 2006}
```

We retest from XRv11 to XRv12 again and use EPC to capture the packets. My hypothesis held true; removing explicit-null allowed CSR1 to remark the PW label, and these bits persist across the swap. It also guarantees that any new transport labels will have this marking as well. Packets arrive with EXP0 (0x1, S-bit is set) and leave with EXP4. This is 0x8 or binary 1000 in all labels except the bottom, and it's 0x9 in the bottom label which is binary 1001. This is an interesting example because normally explicit-null is meant to sustain SP-core QoS modifications and in this case, it actually did the opposite. Normally, the PW label would have had the proper value from the customer (IP to MPLS imposition) rather than having the topmost exp-null modified on a core router. If we have tested that in the first place, we would have never seen this interesting behavior.

```

```

Last, we will look at some basic troubleshooting of this feature. Most of it applies to ordinary PWs also, but the introduction of IS-IS levels creates additional complexity. Just like ordinary MPLS L3VPN, summarization between PE loopbacks is generally not supported unless you introduce route leaking, unified MPLS (BGP labeled-unicast), or other methods. The L1L2 routers leak all PEs loopbacks back and forth for full reachability. However, not all remote PEs need all remote loopbacks. CSR3, for example, does not need CSR4 or CSR9 loopbacks since it does not have any MPLS services targeting those addresses, yet it has IS-IS IA routes as the L1L2 leaked them from L2 to L1.

```
R3#show ip route 17.0.0.4
```

```

Routing entry for 17.0.0.4/32
  Known via "isis", distance 115, metric 30, type inter area
  Redistributing via isis 17
  Last update from 17.1.3.1 on GigabitEthernet2.513, 10:31:03 ago
  Routing Descriptor Blocks:
    * 17.1.3.1, from 17.0.0.1, 10:31:03 ago, via GigabitEthernet2.513
      Route metric is 30, traffic share count is 1

```

```

R3#show ip route 17.0.0.9
Routing entry for 17.0.0.9/32
  Known via "isis", distance 115, metric 50, type inter area
  Redistributing via isis 17
  Last update from 17.1.3.1 on GigabitEthernet2.513, 10:30:26 ago
  Routing Descriptor Blocks:
    * 17.1.3.1, from 17.0.0.1, 10:30:26 ago, via GigabitEthernet2.513
      Route metric is 50, traffic share count is 1

```

```

R3#show l2vpn atom vc | begin Interface

```

Interface	Peer ID	VC ID	Type	Name	Status
pw13	17.0.0.1	13	vfi	LAN	UP
pw23	17.0.0.2	23	vfi	LAN	UP
pw36	17.0.0.6	36	vfi	LAN	UP

Adding “null” routes for these destinations on CSR3 should have no effect on the VPLS connectivity. The CE behind CSR3 still has full reachability.

```

! CSR3
ip route 17.0.0.4 255.255.255.255 null0
ip route 17.0.0.9 255.255.255.255 null0

```

```

!!!!

Success rate is 100 percent (5/5), round-trip min/avg/max = 1/7/19 ms

We will temporarily modify the prefix-lists on CSR1 and CSR6 to stop leaking 17.0.0.2/32 from L2 into L1. We theorize this will cause a problem on CSR3 for at least one PW. We will enable debugging on CSR3 before we continue.

```
R3#debug l2vpn atom vc event
```

```
! CSR1
```

```
no ip prefix-list PL_REMOTE_PE seq 15 permit 17.0.0.2/32
```

```
! CSR6
```

```
no ip prefix-list PL_REMOTE_PE seq 15 permit 17.0.0.2/32
```

```
R1#clear isis rib redistribution
```

Clearing all local RIB

```
R6#clear isis rib redistribution
```

Clearing all local RIB

```
R3#show ip route 17.0.0.2
```

```
% Subnet not in table
```

Within a few seconds, we see the PW fail on CSR3. The MPLS process is reporting a failure to ATOM that there is a problem with the next-hop. The data-plane error (dp-err) is set as the current status, and a syslog is generated to tell us there was a PW error. In case you miss the debug, you can also see this with a show command. Oddly, the new L2VPN syntax doesn't show it, so you must use the legacy command.

```
! CSR3
```

```

```

We test reachability in the core network and see that it still works. This is because of the attached-bit being set in the IS-IS LSP from the L1L2 routers. However, this is not sufficient for MPLS LDP label binding, which is the real issue. We cannot summarize here unless we have a FEC binding for the IP prefix plus MPLS label. We could introduce labeled-unicast BGP (like unified MPLS), or just leak the route from the L1L2 routers.

```

R3#ping 17.0.0.2 source loopback0

    recursive via 0.0.0.0/0
    nexthop 17.1.3.1 GigabitEthernet2.513

```

The process is very interesting on CSR2. We didn't turn on debugging, but we can use the event-trace to help debug the issue. The first thing we notice is a pair of syslog messages. VC 23 went down due to a PW error, which was signaled by CSR3 since the FEC is broken. CSR2 also forces the other PW down, VC 29, since this indicates an issue with the end-to-end path. As such, you must ensure all PWs are operational or else the PW switching LSRs won't bring up either circuit. This is useful because the up/down status is proxied, in a way, across the entire MS-PW.

```

! CSR2
%XCONNECT-5-PW_STATUS: MPLS peer 17.0.0.3 vcid 23, VC state DOWN, PW Err
%XCONNECT-5-PW_STATUS: MPLS peer 17.0.0.9 vcid 29, VC state DOWN

```

Next, we will examine the event-trace for VC 23. On this PW, the remote side is down due to a FEC issue. We can see this in the state-machine code where the “Local” send is “ready/up” (Lru) while the “Remote” end is “ready/down” (Rrd). Overall, the entire PW is down due to a remote PW fault.

```
R2#show l2vpn atom vc vcid 23 event-trace | begin event_trace
AToM VC event trace:
AToM[17.0.0.3, 23]: ..... Send AC STATUS(DOWN(pw-tx-fault))
AToM[17.0.0.3, 23]: ..... No PW status SP info to report
AToM[17.0.0.3, 23]: ..... Send status update
AToM[17.0.0.3, 23]: ..... Not group switchover capable, cap 0
AToM[17.0.0.3, 23]: ..... Circuit attributes, Send update:

AToM[17.0.0.3, 23]: ..... SYSLOG: VC is DOWN, PW Err
AToM[17.0.0.3, 23]: ..... PW MIB: VC state is: DOWN
AToM[17.0.0.3, 23]: ..... S:Evt ADJ up in LruRrd
AToM[17.0.0.3, 23]: ..... S:Act send SSS(DOWN), notify(UP)
AToM[17.0.0.3, 23]: ..... Remote : DOWN(pw-tx-fault)
AToM[17.0.0.3, 23]: ..... Overall : DOWN(pw-tx-fault)
AToM[17.0.0.3, 23]: ..... [filtered AC]
AToM[17.0.0.3, 23]: ..... Send notify(UP)
AToM[17.0.0.3, 23]: ..... Overall : No fault
AToM[17.0.0.3, 23]: ..... [filtered LDP]
AToM[17.0.0.3, 23]: ... Yes, connected
AToM[17.0.0.3, 23]: .. keeping dataplane up
AToM[17.0.0.3, 23]: .. sync new remote status to standby
```

From the perspective of the other PW, it appears as if the local side is down. VC 29 is treating VC 23 like an AC in this case; since the PWs are switched and one of them is down, it is logically equivalent to the “AC” being down from the perspective of VC 29. We can’t see the state machine codes this time, but we would expect it to indicate that the local side is down and the remote side is up.

```
R2#show l2vpn atom vc vcid 29 event-trace | begin event_trace
AToM VC event trace:
AToM[17.0.0.9, 29]: ..... Local AC : DOWN(pw-tx-fault)
AToM[17.0.0.9, 29]: ..... Overall : DOWN(pw-tx-fault)
AToM[17.0.0.9, 29]: ..... Send LDP for status change from UP
AToM[17.0.0.9, 29]: ..... No PW Status SP info to report to LDP
AToM[17.0.0.9, 29]: ..... Start remote up timer

AToM[17.0.0.9, 29]: .... Ready, label 2010
```

```

AToM[17.0.0.9, 29]: .... Evt local ready, in established
AToM[17.0.0.9, 29]: ..... Local ready and established
AToM HA[17.0.0.9, 29]: ..... Checkpointing not allowed
AToM[17.0.0.9, 29]: .. Check if can activate dataplane
AToM[17.0.0.9, 29]: ... Dataplane already active
AToM[17.0.0.9, 29]: Evt remote up timer expired, in established

```

We can verify the state machines again by checking the PW details. For VC 29, which we have not seen, we confirm that the local side is down (Lrd) and the remote side is up (Rrd). There is no issue with CSR9.

```

R2#show l2vpn atom vc vcid 23 detail | include state_machine
      Label/status state machine           : established, LruRrd

R2#show l2vpn atom vc vcid 29 detail | include state_machine
      Label/status state machine           : established, LrdRru

```

We fix the problem by adding the 17.0.0.2/32 network back into the prefix-lists to propagate across levels and the network becomes operational again.

```

! CSR1
ip prefix-list PL_REMOTE_PE seq 15 permit 17.0.0.2/32

! CSR6
ip prefix-list PL_REMOTE_PE seq 15 permit 17.0.0.2/32

R1#clear isis rib redistribution
Clearing all local RIB

R6#clear isis rib redistribution
Clearing all local RIB

```

With debug still enabled on CSR3, we verify the issue is resolved. The MPLS process immediately tells the AToM process that the data-plane is now operational.

```

! CSR3

3005       1000      17.0.0.2/32    0            Gi2.513    17.1.3.1

```

Syslog messages on CSR2 show that both PWs came up, which implies they are up on both ends. We can quickly check the state machine on CSR2 to confirm.

```

R2#show l2vpn atom vc vcid 23 detail | include state_machine
Label/status state machine           : established, LruRru

R2#show l2vpn atom vc vcid 29 detail | include state_machine
Label/status state machine           : established, LruRru

```

The event-traces will be blank, or nearly so, when there are no faults with the circuits. This makes the event-trace valuable for troubleshooting, sometimes better than debug due to its brevity and ability to filter output by regex.

```

R2#show l2vpn atom vc vcid 23 event-trace | begin event_trace
[no output]

```

```

R2#show l2vpn atom vc vcid 29 event-trace | begin event_trace
AToM VC event trace:
AToM[17.0.0.9, 29]: .. Check if can activate dataplane
AToM[17.0.0.9, 29]: ... Dataplane already active

```

A quick CE to CE ping check verifies an operational switched PW.

```
RP/0/0/CPU0:XRv1#ping 10.0.0.10
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 10.0.0.10, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/11/19 ms
```

Last, we quickly enable sequencing across the MS-PW as this should be supported. Sequence numbers are blindly forwarded through the PW switching LSRs and are not validated there. In fact, we don't even need to enable sequencing on the stitching routers since they do not participate at all.

```
! CSR3
interface pseudowire23
    sequencing both

! CSR9
interface pseudowire29
    sequencing both
```

We verify that sequencing has been enabled and is operational bidirectionally on the endpoints CSR3 and CSR9. We also verify that sequencing is not configured for either PW on the PW switching LSR.

```
R3#show l2vpn atom vc vcid 23 detail | include Seq
Sequencing: receive enabled, send enabled
Sequencing resync disabled
```

```
R9#show l2vpn atom vc vcid 29 detail | in Seq
Sequencing: receive enabled, send enabled
Sequencing resync disabled
```

```
R2#show l2vpn atom vc service-name BRIDGE_PW39 detail | include Dest|Seq
Destination address: 17.0.0.3 VC ID: 23
Sequencing: receive disabled, send disabled
Destination address: 17.0.0.9 VC ID: 29
Sequencing: receive disabled, send disabled
```

Recall that the CW is still negotiated on a PW-by-PW basis, even in MS-PW mode. We need to ensure the CW is supported along the entire MS-PW for sequencing to work. We can quickly check CSR2 since it reports CW status for both local and remote. Since we see the word "on" four times, we can assume it is enabled and supported everywhere.

```
R2#show l2vpn atom vc service-name BRIDGE_PW39 detail | include Dest|Control
Destination address: 17.0.0.3 VC ID: 23
Control word on on
Destination address: 17.0.0.9 VC ID: 29
Control word on on
```

If we disable CW on CSR3 only, the entire MS-PW must reform with CW disabled. This setting must be consistent everywhere, and if a node endpoint does not support it, no segments of the PW can.

```
! CSR3
interface pseudowire23
 control-word exclude

R2#show l2vpn atom vc service-name BRIDGE_PW39 detail | include Dest|Control
Destination address: 17.0.0.3 VC ID: 23
Control word off (configured: enabled) off
Destination address: 17.0.0.9 VC ID: 29
Control word off (configured: enabled) off
```

Before continuing, we enable CW on CSR3 again since we need it for sequencing (just remove the CW exclusion under PW 23 on CSR3). EPC on CSR2 shows the sequence numbers for packets moving in both directions. CSR2 is copying them bidirectionally as expected, which allows the endpoints to process the sequence numbers if configured to do so. Because we capture on both interfaces in both directions, we see that same packet (echo and reply) twice. The CW is highlighted, and the low-order 16 bits (0x0009) represents the sequence numbers. They don't have to be the same in both directions, but can be. The echo request sequence numbers are in yellow and the replies are in green.

```

The configurations for MS-PW are in the next section since the EVC rewrite operations use the same topology.

32.1.1.5 EVC rewrite operations

This section is a continuation from the previous section and uses the same topology. A basic AToM PW has been provisioned between PE routers CSR6 and CSR4, with XRv3 and XRv4 as the CE endpoints. The EFP configuration is not shown below since we will be modifying that constantly for these tests. **Pitfall: Changing encapsulation on an EFP will often remove the EFP from the L2VPN xconnect context, so be sure to re-add it.**

```
! CSR6 (CSR4 is identical with different PW peer IP)
interface pseudowire4600
description REWRITE TESTING
encapsulation mpls
neighbor 17.0.0.6 4600
control-word include
signaling protocol ldp

l2vpn xconnect context XC_REWRITE
```

```
member pseudowire4600
member GigabitEthernet2 service-instance 4600
```

We quickly verify the PW is up. We don't expect to have CE to CE reachability since we haven't configured working EFP encapsulation/decapsulation settings yet. The AC is still operational, which allows the PW to come up.

```
R4#show l2vpn service xconnect name XC_REWRITE | begin Interface
  Interface          Group          Encapsulation          Prio   St   XC St
  -----          -
  VPWS name: XC_REWRITE, State: UP
  pw4600              17.0.0.6:4600 (MPLS)      0      UP   UP
  Gi2                  Gi2:3544 (Eth VLAN)      0      UP   UP

R6#show l2vpn service xconnect name XC_REWRITE | begin Interface
  Interface          Group          Encapsulation          Prio   St   XC St
  -----          -
  VPWS name: XC_REWRITE, State: UP
  pw4600              17.0.0.4:4600 (MPLS)      0      UP   UP
  Gi2                  Gi2:3563/1 (Eth VLAN)    0      UP   UP
```

The most obvious and simple way to do EVC configuration is to use a single 802.1Q tag. This means the CE sends tagged frames to the EFP, which removes the tag on ingress, then forwards the frame into the SP network untagged. When using the "symmetric" keyword, the egress operational automatically becomes pushing the specified encapsulation before sending it out the AC towards the customer. Using only one VLAN tag doesn't account for QinQ, which would be entirely transparent to the EFPs since only the first tag is being evaluated. CSR6 uses the common and easier "symmetric" method, while CSR4 manually pops/pushes the tag on ingress/egress respectively. Both of the configurations are operationally identical.

```
! CSR4
service instance 4600 ethernet
 encapsulation dot1q 3544
 rewrite ingress tag pop 1
 rewrite egress tag push dot1q 3544

! CSR6
service instance 4600 ethernet
 encapsulation dot1q 3563
 rewrite ingress tag pop 1 symmetric
```

The encapsulations on the CE devices are updated to use QinQ so that VLAN ID 46 is transparently passed across.

```
! XRv3
interface GigabitEthernet0/0/0/0.563
```

```
encapsulation dot1q 3563 second-dot1q 46
```

```
! XRv4
interface GigabitEthernet0/0/0/0.544
 encapsulation dot1q 3563 second-dot1q 46
```

Because the EFPs did not touch the inner dot1Q tag of 46, it will exist in the payload bridged over MPLS. A quick outbound EPC on CSR4 confirms this. Following the Ethernet header containing the MAC addresses of XRv4 and XRv3 (destination then source), we see the dot1Q ethertype 0x8100 followed by the VLAN ID 46 (0x2E). The remote end, regardless of which configuration is used, will simply push the outer dot1Q tag while leaving the inner one alone. The benefit of this approach is that the customer can change (or remove) its inner tags at any time and the EFP would not need to be reconfigured.

```
R6#show monitor capture CAP buffer detailed
 0 148      0.000000 00:50:56:A9:DE:0D -> 00:50:56:A9:EA:77 MPLS unicast
0000: 005056A9 EA770050 56A9DE0D 81000DEF .PV..w.PV.....

0030: 45000064 00000000 FF01A77E 0A00000D E..d.....~....
```

Another option is to match the inner tag also. This allows for additional granularity (less transparency) so that the customer can use a single dot1Q outer tag for AC transport, then inner tags to differentiate the service. This is a classic use-case for the EV family of Ethernet services (EVPL, EV-LAN, and EV-TREE) since the inner tag can serve as the service identifier while the outer tag is used for transport, as an example. The example below performs similar logic as the previous example. We extend the configuration to account for VLAN ID 46 as an inner tag on both EFPs. In this case, we actually remove the VLAN ID from the frames by popping both tags, then pushing both back. We could have continued to pop the top tag only, but when you are already matching the inner tag, popping it saves you 4 bytes of encapsulation. We already lost the transparency by matching the inner tag, so popping it doesn't hurt. EPC shows just the IP ethertype 0x800 and no VLAN tag in the transported frame. The size of the packet on the wire is 144 bytes, which is 4 bytes less than the 148 packet observed above.

```
! CSR4
service instance 4600 ethernet
 encapsulation dot1q 3544 second-dot1q 46
 rewrite ingress tag pop 2
 rewrite egress tag push dot1q 3544 second-dot1q 46
```

```
! CSR6
service instance 4600 ethernet
 encapsulation dot1q 3563 second-dot1q 46
 rewrite ingress tag pop 2 symmetric
```

```
R6#show monitor capture CAP buffer detailed

```

You can also match ranges of inner tags to funnel them through a common EFP. However, this adds complexity because now there are certain restrictions. The snippet below attempts to configure CSR6 to place any traffic with an outer tag of 3563 and inner tags of 40 to 50 (inclusive) into an EFP. The issue is that returning traffic will likely need the proper tags pushed back on, but it is now ambiguous as to what the inner tag should be. We cannot push 2 tags on egress anymore using the “symmetric” keyword. Generally you would use this feature with transparency by only popping the topmost (or zero) VLAN tags on both ends, which allows the customer to manage the inner tags (EV family of services).

```

R6(config-if-srv)#encapsulation dot1q 3563 second-dot1q 40 - 50
R6(config-if-srv)#rewrite ingress tag pop 2 symmetric
Rewrite change is not logically valid on ServInst 4600 (Gi2)

```

A similar configuration works on CSR4 only because we are statically pushing tag 46 on egress, even if any other tag came in. CSR4 matches any inner dot1q tag, provided it exists. There is nothing preventing you from popping both tags on ingress, but on egress, pushing “symmetrically” is impossible. This snippet below is syntactically valid but may not actually work since there is asymmetry in the VLAN IDs.

```

R4(config-if-srv)#encapsulation dot1q 3544 second-dot1q any
R4(config-if-srv)#rewrite ingress tag pop 2
R4(config-if-srv)#rewrite egress tag push dot1q 3544 second-dot1q 46

```

For the next test, we will create a hybrid solution. This is not an ideal solution, but it demonstrates the power of the tag rewrite feature. As traffic comes in on CSR6, it will be tagged {3563 46} which will match EFP 4600. CSR6 does absolutely nothing to this tag stack on ingress; it encapsulates the Ethernet frame in MPLS and sends it into the core. CSR4 will receive this traffic and would normally reject it because VLAN 3563 does not match any local EFPs. The outer tag differs at the two sites, so CSR4 can translate this top tag to the value it has locally configured, which is 3544. The inner tag is not touched on egress. This allows CSR4 to deliver traffic to XRv4 with tag stack {3544 46}, which is correct. Returning traffic enters CSR4 and has the topmost tag removed, so only the inner tag of 46 will be transported over MPLS. When CSR6 receives the MPLS packets, it adds the proper outer tag and sends it towards XRv3 with stack {3563 46}.

```

! CSR6
service instance 4600 ethernet
 encapsulation dot1q 3563 second-dot1q 40-50
 rewrite egress tag push dot1q 3563

! CSR4
service instance 4600 ethernet

```

```
encapsulation dot1q 3544 second-dot1q 1-4094
rewrite ingress tag pop 1
rewrite egress tag translate 1-to-1 dot1q 3544
```

We enable bidirectional EPC on CSR6 to view the encapsulation of the VLAN tags. The request and response are about 3ms apart (yellow) according to this capture and have 8 bytes different in length. The MPLS labels are highlighted in green, which we don't care about right now, but since CSR7 performs PHP for returning traffic, inbound PW traffic has only one label. This accounts for 4 of the bytes. The remaining 4 byte difference is highlighted in cyan. The outgoing packet contains tag stack {3563 46} as discussed earlier since CSR6 makes no VLAN tag modifications on ingress. CSR4 rewrites the top tag on egress to deliver the proper tag stack to Xrv4. Inbound traffic on CSR4's EFP pops the top tag on ingress, which means only the inner tag of 46 is present on the return flow. This accounts for the remaining 4 bytes. CSR6 pushes tag 3563 back onto the stack before delivering traffic to Xrv3.

```

```

Alternatively, we could rewrite the tag on ingress on CSR6 to change 3563 to 3544 so CSR4 doesn't have to do it. This might be a good idea if there are multiple routers using outer tag 3544 in the network and this EFP is tied to a multipoint L2VPN service; it is loosely analogous to MVPN extranet source-side chaining (SSC) versus receiver-side chaining (RSC). Each option has its benefits but the selection depends largely on design goals. For additional complexity, we change the inner tag on Xrv4 to 460, which means additional popping or translation is required. We haven't changed the EFP "match" criteria on either router, which is the encapsulation, but we do change the tag handling. On CSR6 ingress, both tags are rewritten from {3563 40-50} to {3544 460}, which means CSR6 did all the work for CSR4. This is sloppy because any inner tag between 40 and 50 is rewritten to 460 no matter what, but technically it does work. CSR4 shouldn't have to do anything on egress now. Returning traffic will be send over MPLS as untagged since CSR4 blindly pops both tags. As such, CSR6 will have to push both tags back onto the stack. These solutions are complex because the EFP matches multiple inner tags yet pushes a static inner tag on egress; this is just to demonstrate the feature.

```
! CSR6
service instance 4600 ethernet
 encapsulation dot1q 3563 second-dot1q 40-50
 rewrite ingress tag translate 2-to-2 dot1q 3544 second-dot1q 460
```

```

rewrite egress tag push dot1q 3563 second-dot1q 46

! CSR4
service instance 4600 ethernet
  encapsulation dot1q 3544 second-dot1q 1-4094
  rewrite ingress tag pop 2

! XRv4
interface GigabitEthernet0/0/0/0.544
  encapsulation dot1q 3544 second-dot1q 460

```

EPC on CSR6 shows the tag stack {3544 460} exiting towards the MPLS core and an untagged frame arriving in reply. The difference in length is 12 bytes: 4 from the lack of a transport MPLS label (green), and 8 from the lack of two dot1q tags (cyan) that were present on the ICMP requests but not the replies (XRv3 to XRv4).

```

```

We can also introduce 802.1ad with EFPs. This is basically QinQ except it represents the standardized version. It uses ethertype 0x88A8 for the outer tag versus the standard dot1Q ethertype of 0x8100. The specification also introduces some basic naming conventions: C-Tag and S-tag represent the customer and service tags, respectively, where the latter is imposed/reviewed by the SP for transit across the core. “Tag 1” and “tag 2” relate to the C-tag and S-tag respectively, which is just an alternative naming convention. In this example, we configure a subtle change on CSR6; it will now rewrite the topmost tag to a dot1ad tag of 3544 versus a dot1q tag with the same value. Because CSR4 was not taking any egress actions in the previous example, we also need it to translate this dot1ad tag back to a dot1q tag (essentially just changing the ethertype from 0x88A8 to 0x8100) while maintaining the proper S-tag, or tag 1.

```

! CSR6
service instance 4600 ethernet
  encapsulation dot1q 3563 second-dot1q 40-50
  rewrite ingress tag translate 2-to-2 dot1ad 3544 dot1q 460
  rewrite egress tag push dot1q 3563 second-dot1q 46

```

```

! CSR4
service instance 4600 ethernet
 encapsulation dot1q 3544 second-dot1q 1-4094
 rewrite ingress tag pop 2
 rewrite egress tag translate 1-to-1 dot1q 3544

```

An EPC capture looks almost identical to the capture above, except the first packet's S-tag (tag 1) has an ethertype of 0x88A8 to indicate 802.1ad. The inner tag is still dot1q (0x8100). Nothing else has changed, and the returning traffic is untagged entirely as it was before.

```

R6#show monitor capture CAP buffer detail
 6 152      1.376039 00:50:56:A9:DE:0D -> 00:50:56:A9:EA:77 MPLS unicast

0030: FF01A77D 0A00000E 0A00000D 00009676 ...}.....v

```

We can continue testing with 802.1ad and introduce some new 802.1Q modifiers also. When frames arrive on CSR6, we can remove double-tagged dot1q frames and replace it with a single dot1ad header if we choose. The remote end (CSR4) can translate this same VLAN tag back to a dot1q header for the customer. In this example, we configure XRv4 to stop doing QinQ and only specify a single tag for the connection to the AC. CSR4 can match this single-tagged traffic using the “exact” keyword, which ensures no double-tagged frames can match CSR4’s EFP on ingress. CSR4 removes this top dot1q tag and continues to send untagged frames over MPLS to CSR6, who expects it and pushes the two required dot1q tags for the XRv3.

```

! CSR6
service instance 4600 ethernet
 encapsulation dot1q 3563 second-dot1q 40-50
 rewrite ingress tag translate 2-to-1 dot1ad 3544
 rewrite egress tag push dot1q 3563 second-dot1q 46

```

```

! CSR4
service instance 4600 ethernet
 encapsulation dot1q 3544 exact
 rewrite ingress tag pop 1
 rewrite egress tag translate 1-to-1 dot1q 3544

```

```

! XRv4
interface GigabitEthernet0/0/0/0.544
 encapsulation dot1q 3544

```

We can verify this behavior using EPC. Now there is a single dot1ad (0x88A8) tag with value 3544 (0xDD8) on the ICMP request frames while the return traffic remains untagged as the ethertype of 0x0800 (IPv4) is highlighted. The difference in length is only 8 now: one MPLS label (green) and one VLAN tag.

```

```

We can specify the payload ethertype from a basic list, and also have different EFPs for different CoS values. Without changing CSR4, we direct CSR6 to only support IPv4 traffic (0x0800). This means our basic ping from XRv3 to XRv4 works for IPv4 only. Other ethertype options include IPv6 (0x86DD), PPPoE discovery (0x8863), PPPoE session (0x8864), or PPPoE all (both 0x8863 and 0x8864).

```
! CSR6
service instance 4600 ethernet

RP/0/0/CPU0:XRv3#ping 2001:10::14
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 2001:10::14, timeout is 2 seconds:
.....
Success rate is 0 percent (0/5)
```

If we add IPv6 (0x86DD) to the list, it works as well. This is how we can separate IPv4 and IPv6 traffic into different EFPs if we choose. Using this example, adding a new EFP to match “pppoe-all” would effectively segregate PPPoE from IPv4/v6 traffic, which might be desirable.

```
! CSR6
```

```

service instance 4600 ethernet
  encapsulation dot1q 3563 second-dot1q 40-50 etype ipv4 , ipv6
  rewrite ingress tag translate 2-to-1 dot1ad 3544
  rewrite egress tag push dot1q 3563 second-dot1q 46

```

```

RP/0/0/CPU0:XRv3#ping 2001:10::14
Type escape sequence to abort.
Sending 5, 100-byte ICMP Echos to 2001:10::14, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/8/19 ms

```

Next, we will specify only CoS 0 traffic can enter this EFP. Everything still works, but this short ping test is a false positive. As soon as we clear the IPv6 ND cache, IPv6 is broken with this new configuration. This would also obviously break any other control traffic that marks its traffic at layer 2. IPv4 ARP is automatically accounted for when 0x0800 (IPv4) is permitted.

```

! CSR6
service instance 4600 ethernet
  encapsulation dot1q 3563 second-dot1q 40-50 cos 0 etype ipv4 , ipv6

.....
Success rate is 0 percent (0/5)

```

Be careful when using the IPv6 ethertype filter and CoS at the same time. Unlike IPv4 ARP, which is a separate ethertype, IPv6 ND relies on IPv6-ICMP and uses CoS 6 (binary 110x) in the Ethernet frame, shown in yellow. This immediately precedes the dot1ad VLAN ID which is 3544 (cyan). IPv6 ND also uses CS7 in the IPv6 header (green), but that isn't relevant here, it's shown for completeness. The first two packets show an IPv6 ND exchange, and have priority values set. The return packet doesn't show the

priority bits because they were popped by the EFP at CSR4 on ingress, but they would have been there had the VLAN tag been allowed into the SP core. The following packets show the ping session with no QoS values set (0 for layer 2 and layer 3 headers). This capture was taken with the “cos” keyword removed from the EFP configuration, because this traffic would have never arrived at the EFP otherwise.

```

A simple solution is to allow CoS 0 and 6, but nothing in between. This would allow low priority traffic, plus relevant control traffic, to utilize this EFP. Alternatively, we could statically configure IPv6 ND peers, but this is sloppy and doesn’t allow for other IPv6 ND communications unrelated to LAN discovery, such as NUD probes, redirects, etc.

```
! CSR6

```

For completeness, the EFP show commands are shown below. They basically give the same information as the running-config, plus some details regarding default values. The summary and stats commands are components of the detailed command, but they all show the same general information. This is one of the rare circumstances where the running-config is the best way to verify EFP state. The only exception is the packet counters shown below, which can be valuable when troubleshooting tag mismatches.

Additional Reading - Reference configurations "l2vpn-mspw-rewrite"

32.1.2 BGP auto-discovery for VPWS/VPLS

This section uses the same basic setup as the static VPLS lab. The static VPWS (E-LINE) configuration is left in place just to show that all of the different PW options can coexist. VPWS autodiscovery is not specifically shown because it is identical to VPLS (E-LAN) with only two endpoints, and for efficiency, would have MAC address learning disabled on the corresponding bridge-domain (BD). The static VPLS (E-

LAN and E-TREE) configuration has been removed as those will be replaced with BGP auto-discovery mechanisms.

32.1.2.1 LDP signaling

LDP signaling is traditionally a Cisco mechanism for signaling BGP-discovered PWs within a VPLS instance. In a sentence, the VPLS endpoints are advertised into BGP, learned by other endpoints within the VPN, and then sessions are created between peers. This procedure relies on route-targets just like L3VPN, but there are some “easy” and automatic enhancements to it. E-LAN is configured on CSR4, CSR6, CSR7, and XRV3 just like last time, except now using LDP for signaling paired with BGP AD. The BD and EFP configurations are not shown again as they are independent of the VPLS configuration; they are identical to the static VPLS examples. CSR4 and CSR6 use the new syntax while CSR7 uses the legacy

syntax. Notice that none of the XE routers specify any RD/RT information, but XRv3 does. This is discussed in detail later.

```
! CSR4 and CSR6

    autodiscovery bgp
    rd auto
    route-target import 55:3467
    route-target export 55:3467
    signaling-protocol ldp
```

We also must configure BGP to exchange these L2VPN routes. XRv1 will be a RR for this AF and all other routers will peer with it. XR uses negative logic in its signaling mechanisms for BGP peers, which can be confusing. Rather than specify the desire to use BGP or LDP signaling, XR requires the administrator to specify which one NOT to use. In this case, we specify that BGP signaling should be disabled, which implies LDP signaling is enabled.

        Signalling bgp disable

```

The first thing we notice is that the BGP sessions will not come up with the XE routers. CSR7, as an example, generates a strange log message alerting us to the problem. The session forms (so we know it isn't a password issue, for example) but as soon as Xrv1 receives a "route", it closes the session.

```

! CSR7
%BGP-5-ADJCHANGE: neighbor 55.0.0.11 Up
%BGP-5-NBR_RESET: Neighbor 55.0.0.11 reset (Peer closed the session)

```

```

bgp[1052]: %ROUTING-BGP-5-ADJCHANGE : neighbor 55.0.0.7 Down - BGP
Notification sent, illegal network (VRF: default) (AS: 55)
```

Debugging on CSR7 and XRv1, unfortunately, does not help much. XRv1 indicates that CSR7 sent a malformed message, but the low-level details prompt additional research.

```
! CSR7

0x00000008, action taken "Reset". Error details: "Error 0x00000008, Field
"MP_REACH_NLRI", Attribute 14 (Flags 0x00, Length 0), Data [60]". NLRI is:
[IPv4 Unicast]
```

This is a strange issue where referencing several Cisco documents and RFCs is required. Section 7 of RFC 6074, "BGP-AD and VPLS-BGP Interoperability," states: *"Both BGP-AD and VPLS-BGP [RFC4761] use the same AFI/SAFI. In order for both BGP-AD and VPLS-BGP to co-exist, the NLRI length must be used as a demultiplexer. The BGP-AD NLRI has an NLRI length of 12 bytes, containing only an 8-byte RD and a 4-byte VSI-ID. VPLS-BGP [RFC4761] uses a 17-byte NLRI length. Therefore, implementations of BGP-AD must ignore NLRI that are greater than 12 bytes."*

RFC 4761 specifies BGP signaling (VPLS-BGP) and RFC 4762 specifies LDP signaling (BGP-AD). The feature naming is confusing since BGP-AD is always used for discovery, while the signaling protocol varies. In either case, the AFI/SAFI is the same despite the very different signaling protocols. The original implementation of Cisco BGP-AD only used one byte for the prefix length, but we must set it to 2 on all XE PEs. This is what XR expects and is not required for BGP sessions between XE peers.

```
! All XE PEs
router bgp 55
 address-family l2vpn vpls
  neighbor 55.0.0.11 prefix-length-size 2
```

Now, we can see the neighbor come up for this specific capability. Nowhere in the capability does it specify LDP or BGP signaling, which is why the previous command was necessary. We also check the RR to ensure all the other sessions are up.

```
R7#show bgp l2vpn vpls all neighbors 55.0.0.11 | include L2VPN
Address family L2VPN Vpls: advertised and received
For address family: L2VPN Vpls

RP/0/0/CPU0:XRv1#show bgp l2vpn vpls neighbors | utility egrep '^BGP|L2VPN'

For Address Family: L2VPN VPLS
BGP neighbor is 55.0.0.13
Address family L2VPN VPLS: advertised and received
For Address Family: L2VPN VPLS
```

Next, we can examine the routes. We will look at CSR6 first. We see the routes have a 96 bit length, which is the result of the RD (64 bit) and the IPv4 address (32) bit. We never configured an RD on any of the XE routers, so it automatically creates an RD as BGP_ASN:VPN_ID. Notice that XR required manual RD configuration; an “auto” feature exists but for consistency, I manually set the RD to be the same as the other VPLS endpoints. The address contained in the prefix header is the BGP next-hop, which is the Loopback0 in this case.

```
R6#show bgp l2vpn vpls all | begin Network
      Network      Next Hop      Metric LocPrf Weight Path
Route Distinguisher: 55:3467
*>i 55:3467:55.0.0.4/96

*>i 55:3467:55.0.0.7/96
      55.0.0.7      0      100      0 ?
*>i 55:3467:55.0.0.13/96
      55.0.0.13      100      0 i
```

Digging into the route from CSR4, we see some familiar components. The RT, for example, is set to 55:3467, which again appears automatic. There is an XE feature called “auto-route-target” which is on by default; it assumes that all VPLS endpoints in the same VPN-ID want to communicate with one another. This is a great assumption for E-LAN but not for E-TREE; we will look at disabling this and

manually defining RT import/export policies for E-TREE designs later. Again, XR needs the RT policies to be manually configured, as shown above. The AGI is the Attachment Group Identifier and is used to group forwarders together for signaling purposes. Essentially it defines endpoints that can be connected via pseudowires; it defines the VPN. The BGP details also show MPLS labels despite us explicitly using LDP. Remember that the exp-null label number is 0, so the label fields are all zeroes in the update, which explains the output.

```
R6#show bgp l2vpn vpls rd 55:3467 55.0.0.4
BGP routing table entry for 55:3467:55.0.0.4/96, version 5

  Refresh Epoch 1
  Local
    55.0.0.4 (metric 30) from 55.0.0.11 (55.0.0.11)
      Origin incomplete, metric 0, localpref 100, valid, internal, best, AGI
version(268435458)
      Extended Community: RT:55:3467 L2VPN AGI:55:3467
      Originator: 55.0.0.4, Cluster list: 55.0.0.11
      mpls labels in/out exp-null/exp-null
      rx pathid: 0, tx pathid: 0x0
```

The AGI is essentially the ASN concatenated with the VPN ID and is used to determine the VC number for the PWs that are dynamically created (constructed just like the RD and RT). **Regardless of the RT import/export policies, the VPN ID (AGI) must match for the VPN to form.** It is an extended community just like the RT and is not “imported” unless the AGI is consistent. Below, we see CSR6 sending an update with AGI 55:999 since I changed its VPN ID to 999 temporarily (not shown). When it tries to import CSR4’s route with AGI:55:3467, it is rejected, much like an L3VPN route with incorrect RTs.

```
! CSR6
BGP(9): (base) 55.0.0.11 send UPDATE (format) 55:999:55.0.0.6/96, next
55.0.0.6, metric 0, path Local, extended community RT:55:999 L2VPN AGI:55:999
BGP(9): 55.0.0.11 rcvd 55:3467:55.0.0.4/96 -- DENIED due to: extended
community not supported;
```

After correcting the error on CSR6, all the routes are imported again. The result of importing these routes instructs the VPLS process to create a PW towards each endpoint. Notice that all of the dynamic PWs have the same VCID, which is the VPN ID. For clarity, the VPN ID and AGI are not the same thing, but the AGI is derived from the VPN ID by default. The RD/RT are also derived from the VPN ID as seen earlier. The RD, RT, and AGI can all be manually adjusted despite this automatic inheritance, which is discussed later.

```
R6#show l2vpn atom vc vcid 3467
```

Interface	Peer ID	VC ID	Service Type	Name	Status
-----	-----	-----	-----	-----	-----

pw100018	55.0.0.4	3467	vfi	LAN	UP
pw100019	55.0.0.7	3467	vfi	LAN	UP
pw100020	55.0.0.13	3467	vfi	LAN	UP

To select a specific PW for analysis, you must specify the destination address followed by the VCID. We can look at the details for the connection to CSR4. We have our usual fields like VC ID, label stack, and signaling protocol, which are important to note. First interesting to notice is the AGI and AII fields. AII is the Attachment Individual Identifier and is meant to identify separate components within an AGI. In this case, the IP addresses are decoded from hex to show the local and remote AIs. Above that is the AGI in hex (XE does not politely decode this for us), which includes 0x37 (55) and 0xD8B (3467). We can see that status and the CW were negotiated as well. Interestingly, VCCV claims that is not capable of using the PW-ACH method (using the CW, even though it was negotiated). We will investigate that later.

There is nothing particularly special about the LDP session. It is just like a normal PW, except it was dynamically discovered using some new BGP extended communities. The discovery mechanism is targeted because once the L2VPN VPLS routes are imported on a PE, the BGP next-hop becomes an endpoint for tLDP.

```

R6#show mpls ldp neighbor 55.0.0.4
  Peer LDP Ident: 55.0.0.4:0; Local LDP Ident 55.0.0.6:0
    TCP connection: 55.0.0.4.646 - 55.0.0.6.16520
    State: Oper; Msgs sent/rcvd: 24/23; Downstream
    Up time: 00:08:10
    LDP discovery sources:
      Targeted Hello 55.0.0.6 -> 55.0.0.4, active, passive
    Addresses bound to peer LDP Ident:
      55.0.0.4      10.35.1.204      55.4.12.4

```

As an aside, the L2VPN RID is derived from the “global MPLS RID” which doesn’t make sense, as there isn’t one. This is according to the IOS XE 3S command reference. I am assuming that it derives its address the same way more RID-aware processes do by checking for the highest loopback address. The BGP prefix itself contains the L2VPN RID, but the BGP next-hop remains the update-source specified in the BGP configuration. We change the L2VPN RID on CSR4 then check the changes on CSR6. The BGP next-hop is unchanged by the prefix itself now reflects the new L2VPN RID. This has no effect on connectivity because, as stated above, the PW is built towards the BGP next-hop, not the L2VPN RID.

```

```

Since there are no PW interfaces or manual xconnects to configure, we appear to have little control over the dynamic PWs. We can apply a template to the PWs to give them certain characteristics. On CSR4, I enable load-balancing without FAT-PW just to demonstrate the template feature.

```
! CSR4
template type pseudowire TMP_LDP_DYNAMIC
  encapsulation mpls
  load-balance flow

l2vpn vfi context LAN
  autodiscovery bgp signaling ldp template TMP_LDP_DYNAMIC
```

Since we know there are three other PWs, we can quickly check each destination to ensure the load balancing feature is enabled. This is basic inheritance from a template and introduce no new technologies.

```
R4#show l2vpn atom vc vcid 3467 detail | include Destination add|Load
  Destination address: 55.0.0.6 VC ID: 3467
  Load Balance: ECMP
  Destination address: 55.0.0.7 VC ID: 3467
  Load Balance: ECMP
  Destination address: 55.0.0.13 VC ID: 3467
  Load Balance: ECMP
```

The VPLS-ID is carried in the BGP update as well, but not as a new community. Configuring a VPLS-ID overwrites the L2VPN AGI parameter, and when this is mismatched, VPNs cannot form. It would have been more convenient if consistent naming conventions were used, but in short, the VPLS-ID and AGI are interchangeable terms. Notice the VPN ID of 3467 (yielding AGI 55:3467) and VPLS-ID 55:12321 (AGI 55:12321). The BGP route will take the VPLS-ID over the VPN ID. In this case, the VPLS instance is broken as CSR4 claims the other routers do not have a matching extended community despite the route-target being the same. The AGI is also an extended community which explains the debug error.

```

Routed VPLS (using BDI interface) is supported for all VPLS types, including static, LDP-signaled, and BGP-signaled. We can quickly verify OSPF neighbors from a few routers to verify this. Always ensure the BDI interface number matches the bridge domain, just like an SVI number must match the VLAN ID. The configuration is shown for CSR4 only as CSR7's BDI is almost identical. We can see that XRv4 is the DR and has full adjacencies to all nodes, while CSR2 is the BDR. CSR1 sees hellos from the BDIs on CSR4 and

CSR7. CSR7, in summary form, shows two full adjacencies (DR and BDR), two 2WAY adjacencies (CSR1 and CSR4), for a total of 4.

Although relevant for all VPLS signaling types, we will briefly examine QoS for VPLS. The MPLS-core related QoS models are covered in detail in a dedicated section, but QoS on the EFPs is slightly different. It is common for VPLS carriers to police multicast and broadcast traffic aggressively, or charge more money for it, since it cannot be intelligently routed. As discussed earlier, it is highly inefficient to transport multicast over VPLS, so carriers can discourage customers from doing so. On CSR6, we will police multicast/broadcast traffic to 16 kbps using a single rate, two-color policer; exceeding traffic is dropped. The aggregate rate of remaining unicast traffic is limited to 48 kbps where exceeding traffic is remarked to EXP0. The EXP2 marking is applied to all conforming unicast traffic. Obviously this policy is sloppy since this will catch signaling multicast traffic like OSPF and PIM, but this is for demonstration only. As a general QoS consideration for VPLS, the 802.1P bits (CoS) are automatically copied into the MPLS EXP bits on all labels at the ingress PE, assuming the customer has marked them.

```

! CSR6
ip access-list extended ACL_BCAST_MCAST
  permit ip any host 255.255.255.255
  permit ip any host 10.0.0.255
  permit ip any 224.0.0.0 15.255.255.255

class-map match-all CMAP_BCAST_MCAST

```

We cannot test broadcast from this node as XR does not support it. Assuming the MQC classification ACL was correct, broadcast traffic would also be policed similarly to multicast traffic.

```
RP/0/0/CPU0:XRv4#ping vrf LAN 255.255.255.255 size 1450 repeat 50 timeout 0
% Ping to Broadcast ipaddress is not supported
```

We will quickly test our unicast policer to ensure it marks traffic accordingly. XRv4 will generate traffic while CSR6 will mark conforming traffic to EXP2 and exceeding traffic to EXP0. The incoming label is 0xFB8 which is 4024 in decimal. We quickly verify this is the correct PW label. In green, I highlight the EXP/S-bit nibble. The left-most 3 bits represent EXP, so a value of 000 is EXP0 and 010 is EXP2. The last bit is always 1 since we are not using FAT-PW and this is the PW label. Thus, EXP0 is represented as 0x1

(0001) and EXP2 is represented as 0x5 (0101). The last byte is TTL and is not highlighted here. We can see the combination of EXP2 and EXP0 given the policer BC/BE values, which we did not explicitly configure. Seeing both values as part of the same flow (and only ms apart) is a good indication that the policer remarking technique is functioning correct.

The configurations for the LDP signaling test are after the next section since both are part of the BGP auto-discovery setup.

32.1.2.2 BGP signaling

This section is a continuation from the last. The BGP signaling feature of VPLS with auto-discovery uses BGP to carry the PW label-related information. This tends to scale better as there are not $N * (N-1) / 2$ LDP sessions being built to support E-LAN. We will use BGP signaling to build an E-TREE between CSR3, CSR8, CSR5, and CSR9. Like the static configurations, CSR8 and CSR3 are roots while CSR5 and CSR9 are leaves. In E-LAN, we allowed the VPN-ID to be copied into the RT field so that everyone would automatically import/export that RT, creating a full mesh of PWs. For E-TREE, that is undesirable, and we require more control over the VPN endpoints. We can disable auto-route-target and perform this process manually, which is identical to L3VPN. The roots will import all RTs and the leaves only import root RTs. I used a separate RT on each node for flexibility and testing, but in real life, only two unique RTs are needed: one root RT and one leaf RT. The VPLS endpoint (VE) configurations are described shortly. The BD and EFP configurations are not shown as they identical to the static VPLS example.

Note: Unlike LDP signaling, BGP signaling is only supported with the new “l2vpn” syntax, so there are no legacy configurations in this model. This feature also does not appear to support CW or FAT-PW, at all. These CW/FAT-PW signaling are bits carried in an extended community (L2VPN INFO) but are always zero. There is no obvious mechanism in XE to modify it.

```

Next, we need to configure BGP similarly for BGP signaling as we did for LDP signaling. This is where the XR AF-groups come into play. We can duplicate the RR configuration except suppress LDP versus BGP for signaling. The XR negative logic is that LDP signaling should be disabled, implying that BGP signaling should be enabled. XE must specifically suppress the LDP signaling to use BGP signaling.

```

We see no BGP “illegal network” errors as we did for LDP, since the prefix-length of 1 is expected for this mechanism of signaling. We can verify connectivity from the RR and ensure the SAFI was negotiated properly.

A quick look at the BGP table on CSR3, a root node, shows four routes. Upon cursory inspection, they look different than the LDP ones. The VE ID is the VPLS endpoint ID and must be configured on each PE. It is like a RID and represents each PE in the VPLS instance. This VE ID is also how you reference these prefixes to look inside them, so there isn’t a dotted-decimal network displayed. The “Blk” represents the block-offset which is discussed shortly.

```

R3#show bgp l2vpn vpls rd 55:3589 | begin Network

```

The route contains some new fields. Notice that exact label values were not exchanged in the traditional L2VPN manner. This makes sense because there are no peer-to-peer sessions between PEs. Since each PW requires a different set of labels, the router must create a mechanism for each PE to automatically and deterministically compute the local/remote labels. Label 9000 shown below is just the start of the peer's label base or label block (LB). The virtual block size (VBS) is 11 from this peer, meaning it can allocate up to 11 local labels to support this VPLS instance. Essentially, this sets a maximum of 11 dynamic PWs. CSR5 is the only router that did not specify a VBS and the default value is the minimum of 10; this is done to conserve local labels for small VPLS deployments.

```

```

BGP signaling introduces quite a bit of math. So far, we have defined the VE-ID, VBS, and LB. The virtual block offset (VBO) is computed by the router according to this formula: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$, where the ROUND function discards the remainder and always rounds down. For this route, $VBO = \text{ROUND}(9/11) * 11 = 0$. When the VBO evaluates to 0, the router automatically uses a value of 1, so in this case, the VBO is actually 1. The VBO is used when a PE needs to allocate multiple different LBs in the form of multiple BGP routes. For now, we will leave the VBO as 1 for each node by ensuring the $\text{VE-ID} < \text{VBS}$ everywhere. The table below gives a quick summary of the routes and the previously defined fields. From the perspective of CSR9, only two PWs are created towards the roots, since it is a leaf in the E-TREE.

So far, we have not seen BGP distribute any discrete labels for any PW on any node, yet somehow the VPLS has formed. This is because upon receiving these BGP VPLS routes, the receiving PE must select a label independently (and deterministically) from everyone else. There is a sanity check that is applied first to ensure the received VBO is within range of the local configuration. Using CSR9, the local VE-ID (on CSR9) is compared against the received VBO and VBO/VBS sum. CSR9 needs to ensure that its VE-ID is in between the received VBO (lower bound) and the received VBO + VBS (upper bound) using the formula $[\text{remote VBO} \leq \text{local VE-ID} < \text{remote VBO} + \text{VBS}]$. In this case, the formula evaluates to true: $1 \leq 9 < 1 + 11$. When there are multiple LBs, this is used as a prefix selection mechanism, discussed later.

```

```

Next, CSR9 needs to select a label from this block. We already know it will be within the range of 3000 – 3010 inclusive, which includes 11 possible choices. The demultiplexer formula is used: $LB + VE-ID - VBO$, where the VE-ID is local to the receiver and the LB / VBO are contained in the received route. In this case, the formula evaluates: $3000 + 9 - 1 = 3008$.

pseudowire100009	55.0.0.3	1	9030	3008	Y

We also notice the local label of 9030 is used on the same PW. We can quickly do the math from CSR3's perspective to ensure that is correct. We can get all the information we need from the first command, but I show the BGP prefix for practice. The sanity check succeeds: $VBO \leq VE-ID < VBS + VBO$, which evaluates as $1 \leq 1 < 1 + 11$. Next, CSR3 selects a label: $LB + VE-ID - VBO$, which evaluates as $9030 + 1 - 1 = 9030$. When the local VE-ID equals the VBO advertised in a route, the first label in the LB is used.

```

Rather than distribute labels within the VPLS instance per PW, BGP allocates a range and allows the receiver to choose that label by following a strict formula. This guarantees that both sides select the same labels so that PWs can form properly. The formula is also deterministic, unlike LDP which will allocate new labels every time the session is cleared. This is more complex to manually verify than LDP but scales better. We will do one more example for practice by tracing the PW signaling between CSR8 and CSR5. CSR5 performs a sanity check on the received route: $VBO \leq VE-ID < VBS + VBO$ evaluates as $1 \leq 5 < 10 + 1$. Then, CSR5 selects a label: $LB + VE-ID - VBO$ evaluates as $8000 + 5 - 1 = 8004$. Remember that when doing these sanity checks and label selections, the VE-ID is the local value, while the VBO, VBS, and LB are the received (remote) values.

```

R5#show l2vpn signaling rib rd 55:3589 detail | begin \.8$

```

Before looking at the actual labels, we will do the math for CSR8 also. We can technically do this on CSR5 since CSR5 is doing the math anyway to determine the local label. CSR5 cannot allocate a local label for the PW until it learns the BGP route as it must know the remote VE-ID. We can use the same output as above and highlighted different focus areas. The logic is reversed: for local label selection, the VE-ID is remote and the VBO, VBS, and LB are local. First, the sanity check is performed: $VBO \leq VE-ID < VBS + VBO$ evaluates as $1 \leq 10 < 10 + 1$. Then, the local label is selected: $LB + VE-ID - VBO$ evaluates as $5000 + 10 - 1 = 5009$.

```

```

We computed the remote label of 8004 and local label of 5009 using a single command to view the L2VPN signaling. We can verify it by checking the VFI status.

```
R5#show l2vpn vfi name TREE
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: TREE, state: up, type: multipoint, signaling: BGP
VPN ID: 3589, VE-ID: 5, VE-SIZE: 10
RD: 55:3589, RT: import 3589:1, import 3589:10, export 3589:14
Bridge-Domain 3589 attachment circuits:
Pseudo-port interface: pseudowire100001
Interface      Peer Address    VE-ID  Local Label  Remote Label  S
pseudowire100003 55.0.0.8       10     5009         8004          Y
pseudowire100002 55.0.0.3       1      5000         3004          Y
```

So far, all VBOs have been 1 since the VE-ID has always been less than the VBS. The VBO calculation has always resulted in zero, which gets automatically rounded to 1 as discussed earlier. On CSR9, we will set the VE-ID to 90 and adjust the VBS to 16. The new block offset should be: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$ evaluates to $\text{ROUND}(90/16) * 16 = 5 * 16 = 80$. A quick look at CSR9 confirms this. Notice that there is also a VBO of 1 in addition to the new VBO of 80. This is how one advertises multiple LBs; the VBO serves as a differentiator for each BGP route.

```

      0.0.0.0      32768 ?
```

Looking at the details of each locally originated route, the only significant difference is the LB. One of them starts at 9020, and one starts at 9036. Since the VBS is 16, 9020 – 9035 was the first available block of 16 contiguous, unallocated labels, and 9036 – 9051 was the next. The two blocks don't have to be contiguous themselves, but coincidentally the blocks are contiguous in this example.

Let's trace the PW label selection between CSR8 and CSR9. We will do all of the calculations from CSR9's perspective. CSR9 needs to identify the remote label to use when sending traffic towards CSR8 inside this VPLS instance; this uses the remote VBO, VBS, and LB, along with the local VE-ID. The sanity check occurs first using formula: $VBO \leq VE-ID < VBS + VBO$ evaluates as $88 \leq 90 < 88 + 11$. The remote VBO of 88 is a new number that has no explanation yet; we will revisit this shortly. Then, CSR9 determines the remote label using formula: $LB + VE-ID - VBO$ evaluates as $8022 + 90 - 88 = 8024$.

```
R9#show l2vpn signaling rib rd 55:3589 detail | begin \.8$
Route 55:3589:10 (epoch:0) from iBGP peer 55.0.0.8

  VE-ID: 90, VBO: 1, VBS: 16 LB: 9036
Forwarder [88000001] VFI TREE

```

We will quickly complete the local label calculation then explain how remote VBO 88 was computed. The sanity check: $VBO \leq VE-ID < VBS + VBO$ evaluates as $1 \leq 10 < 16 + 1$. The label selection: $LB + VE-ID - VBO$ evaluates as $9036 + 10 - 1 = 9045$. We confirm these are the correct labels by checking the VFI members.

To explain the VBO 88, we look back at the BGP output from earlier. I show it again below for reference. Notice that CSR8, without having any new configuration, decided to originate a new route with a new block offset of 88. CSR3 also did this, yet only CSR9 underwent a configuration change.

```

0.0.0.0 32768 ?

```

Before determining why, we can at least figure out where 88 came from. Using the normal VBO formula [VBO = ROUND(VE-ID/VBS) * VBS] on CSR8 and CSR3, we evaluate this as $\text{ROUND}(90/11) * 11 = 8 * 11 = 88$. In this case, the local VBS of 11 was used along with the remote VE-ID of CSR9. If the locally-configured VBS were 10 (default) and not 11, we would have ended up with 80 just as CSR9 did. Because CSR3 has the same VBS value of 11, it computed 88 as well, which shows that the local VE-ID was not used in this calculation. On CSR9, we can look into the route details and see two separate LBs for these. This means that CSR8 has allocated a total of (22) local labels for this VPLS instance. For this reason, the designer must take care when selecting VE-ID and VBS values as they will increase the scale (and LIB size) based on the VBO formula.

Let's assume that, for some reason, CSR8 did not originate this second route. Going back to our math, CSR9 would first perform the sanity check before selecting a label. Assuming the VBO=1 route from CSR8 is used and the VBO=88 route doesn't exist, the formula: $VBO \leq VE-ID < VBS + VBO$ evaluates as $1 \leq 90 < 11 + 1$, which is false. CSR9 has a VE-ID that is too large for the range offered by CSR8. Because CSR8 performs this exact same calculation to identify its local label, it is smart enough to know a new route must be created with a VBO of 88 based on the calculation above. This second route allows CSR8 to compute its local label and CSR9 to compute its remote label. Also notice that the 9000-series label came from the VBO=1 pool of CSR9, while the 8000-series label came from the VBO=88 pool of CSR8. These are just label blocks and there is no artificial coupling between them. The summary outputs below show the remote information for each PW; CSR8 selected a label from the LB 9036 with VBO 1 while CSR9 did the same using LB 8022 with VBO=88.

We saw earlier that CSR3 did the same thing, and because its VBS was 11 just like CSR8, it also computed a VBO of 88. For additional testing and variety, we will update CSR3's VE parameters as well. The VE-ID is set to 300 and the VBS is set to 35.

```

! CSR3
l2vpn vfi context TREE
  autodiscovery bgp signaling bgp
    ve id 300
    ve range 45

```

The new VBO calculation is as follows: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$ evaluates as $\text{ROUND}(300/45) * 45 = 270$. We can now see that many routers are originating three routes with three different VBOs. This is mostly due to the wide variance in VE-ID and VBS configurations across the VPLS PEs. We see that CSR5 originated a route with a new VBO also: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$ evaluates as $\text{ROUND}(300/10) * 10 = 300$. This is done using the local VBS (default) value of 10 along with the remote VE-ID. CSR8 does the same thing: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$ evaluates as $\text{ROUND}(300/11) * 11 = 297$. By dividing by a number, rounding down, then multiplying by that number, we introduce a tiny amount of variance into the result which gives slightly different block sizes, assuming the VBS is different between the nodes. We also see the routes with the block sizes that are about the same as before, but some have been adjusted based on CSR3's VE changes. These new ranges are shown in yellow below. We see that CSR8 and CSR9 still have VBOs of 88 and 80 respectively; this is a result of their local VBS values not changing. CSR3 used to have a block size of 88 when its VBS was 11. With a new VBS of 45, the math needs to be evaluated: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$ evaluates as $\text{ROUND}(90/45) * 45 = 90$. These ranges are shown in green. Fortunately, all of this happens automatically so remembering every detail is less important than understanding the concepts.

```

The routers are smart enough to originate these routes when they determine that they are unable to select labels within the given range based on remote VE-IDs. This is the purpose of the “sanity check”. We will trace two PWs to verify this, starting with the PW from CSR3 to CSR5. We can derive both labels using show commands on CSR3. The sanity check takes place multiple times against all of the VBOs

offered by CSR5. We will evaluate them all. For the first test, we need to reference the output above since they will fail the sanity check. First, the formula $VBO \leq VE-ID < VBS + VBO$ evaluates as $1 \leq 300 < 10 + 1$, which is false. This is why the failed condition does not appear in the output below as it is not valid for PW signaling. The next test is successful: $VBO \leq VE-ID < VBS + VBO$ evaluates as $300 \leq 300 < 10 + 300$, which is true. Now, CSR3 can select a remote label using $LB + VE-ID - VBO$ which evaluates as $5020 + 300 - 300 = 5020$.

```
R3#show l2vpn signaling rib rd 55:3589 detail | begin \.5$
Route 55:3589:5 (epoch:0) from iBGP peer 55.0.0.5
Provisioned (Y) Stale (N)

Forwarder [F7000001] VFI TREE
[snip]
```

CSR3 also has to compute a local label for this PW using the opposite set of information highlighted below. CSR3 has three possible VBOs from CSR3 to use for this: 1, 90, and 270. We can see that VBO 1 was selected since the remote VE-ID is a small number, but we will evaluate the failed conditions for practice. This will clarify why the VBOs of 90 and 270 are not used for label selection. First, the formula $VBO \leq VE-ID < VBS + VBO$ evaluates as $90 \leq 5 < 45 + 90$, which is false. Second, the formula $VBO \leq VE-ID < VBS + VBO$ evaluates as $270 \leq 5 < 45 + 270$, which is also false. Finally, the formula $VBO \leq VE-ID < VBS + VBO$ evaluates as $1 \leq 5 < 45 + 1$, which is true. Now CSR3 can derive its local label for this PW: $LB + VE-ID - VBO$ evaluates as $3076 + 5 - 1 = 3080$. We confirm the label pair of local = 3080 and remote = 5020.

pseudowire100003	55.0.0.5	5	3080	5020	Y

Last, we will trace the signaling from CSR3 to CSR9. We will use CSR3 again for all calculations. We can see that CSR3 is using the VBO=288 route from CSR9 and rejecting the VBO=1 and VBO=80 ones. This is because the sum of CSR9's VBS (which is constant) and those VBO values must be strictly greater than its local VE-ID. This is the second condition of the sanity check, and since $1 + 45$ and $80 + 45$ are both less than 300, the VBO=288 must be used. The passing sanity check is as follows: $VBO \leq VE-ID < VBS + VBO$ evaluates as $288 \leq 300 < 16 + 288$. Now, CSR3 can find the remote label: $LB + VE-ID - VBO$ evaluates as $9052 + 300 - 288 = 9064$.

```
R3#show l2vpn signaling rib rd 55:3589 detail | begin \.9$
Route 55:3589:90 (epoch:0) from iBGP peer 55.0.0.9
Provisioned (Y) Stale (N)

```

CSR3 must also compute a local label. We can use a specific show command (below) to look at this specific PW by specifying the next-hop rather than all PWs in the VFI. This uses the local VE-ID with the remote VBO, VBS, and LB values. Because CSR3 has three routes with varying VBOs (1, 90, 270), it selects the one that satisfies the sanity check. VBO=1 does not work because the sum of the VBS and VBO ($45 + 1$) is less than the VE-ID (90); the VBO is too small. VBO=270 does not work because this value is greater than the VE-ID (90); the VBO is too large. The final VBO value of 90 meets the condition: $VBO \leq VE-ID < VBS + VBO$ evaluates as $90 \leq 90 < 45 + 90$. The label is selected as follows: $LB + VE-ID - VBO$ evaluates as $3121 + 90 - 90 = 3121$. We confirm the label pair of local = 3121 and remote = 9064.

With the signaling validated, we can verify the CE reachability and routing information. Just like the static E-TREE, we expect CSR3 and CSR8, as roots, to have full reachability. Rather than use exhaustive ping tests, we can check the CE IGP (EIGRP) for neighbors. Each root router sees all other nodes in the VPLS instance.

We expect that the spokes can only communicate to the hubs at layer 2. Adjusting IGP parameters, such as split-horizon for EIGRP/RIP, BGP route-reflection rules, and OSPF network types, it is possible to enable spoke-to-spoke communication. We could also adjust how IPv4 ARP and IPv6 ND resolve as seen in previous sections. However, the design of E-TREE was to prevent that in the first place. All leaves should have an identical set of neighbors which is the list of all roots in the E-TREE. CSR2 and XRv4 will

never form EIGRP neighbors with one another unless a PW is provisioned between those two routers. This is controlled by the BGP route-targets as discussed in detail earlier.

32.1.3 Hierarchical VPLS (H-VPLS)

H-VPLS is typically implemented using either MPLS or QinQ in the access network, with MPLS in the core network for both options. MPLS is naturally easier on the CSR1000vs since they are routers. QinQ requires some significant workarounds in a virtual environment by using routers for switches, but it is possible. QinQ can be simpler to configure and manage since there isn't a large IP/MPLS network, but MPLS scales better since QinQ switches still need to store all customer MAC addresses in CAM tables for the S-VLAN. MPLS also offers robust TE and FRR capabilities over QinQ. For router-to-router connections, MAC address learning is not a significant concern, but for data-center interconnect (DCI) applications with large layer 2 domains, the MPLS access networks scale better.

32.1.3.1 MPLS in the Access Network

One option to configure H-VPLS is to use MPLS in the access networks. This technique uses basic PWs from the user-facing PE (UPE) devices to the network-facing PE (NPE) devices. This ties the customers into the MPLS core. The NPEs have PWs between one another, typically a full-mesh, so that traffic arriving from an "access" PW can be transported to any other NPE for delivery to a CE. The "new" syntax makes this very straightforward as we do not have to explicitly disable split-horizon on the NPE-UPE circuits. The new syntax also supports sequencing over VPLS, plus FAT-PW and any other new features added in the future. All configurations in this test use the new syntax. The diagram below shows an MPLS core flanked by two MPLS access networks. The network is broken into IS-IS levels with a common area, which prevents the attached-bit from being set. None of the level-1 domains have a default route, but have the loopbacks of the L1/L2 routers to build PWs. This is done for additional scalability and works well with H-VPLS designs. CSR2, CSR8, CSR4, and CSR5 are the UPE devices which cross-connect EVCs into access PWs. CSR1, CSR6, CSR7, and CSR9 are NPEs that bridge VPLS instances with access PWs. XRv3 and XRv4 are P routers and the remaining devices outside of the SP network are CE devices.

H-VPLS can be very configuration intensive. BGP auto-discovery can be used for NPE pseudowires, but two restrictions apply. First, you must use LDP for signaling, as bridging different PW encapsulations or signaling strategies is not supported. This is true for manual or auto-discovered PWs. Second, you cannot use backup PWs in the access network when using any kind of auto-discovery. Below is an example of the first restriction where the parser does not allow the bridging between a P2P LDP PW and dynamically-discovered VPLS PW, signaled by BGP.

```
R1(config-bdomain)#member vfi VPLS_102
R1(config-bdomain)#member pseudowire 12102
% VFI is using BGP signaling protocol, manual pseudowires are not allowed.
```

In this example, there are two VPNs, referred to as 101 and 102 hereafter. Each CE has a VRF for each for testing purposes, and each UPE has an EVC for each to provide the Ethernet service. VPN 101 has a full mesh of manually configured PWs between all NPEs. CSR8 and CSR5 also have a pair of PWs going to each NPE within their access networks for redundancy; this redundancy forces the core to use manual PWs versus BGP auto-discovery. CSR2 and CSR4 do not have any redundant connections. For brevity, only parts of the configuration are shown, focusing on CSR8 and CSR7. CSR8 is the UPE which controls the redundancy; it has access PWs to two NPEs (CSR7 is primary) and binds these PWs to the EVC using

the L2VPN cross-connect. CSR7 is the NPE which has a full-mesh of network-facing PWs to CSR7, CSR6, and CSR9. These circuits inherit from a template and I enable many additional features for variety. It also terminates the access PW from CSR8; it does not control the redundancy, which means the configuration on CSR1 and CSR7 will be the same, minus circuit enumerations. The VPLS instance and the access PW are bridged in a bridge-domain, allowing layer 2 traffic to flow both ways.

The configuration of the CE devices is not shown. Each CE device sends traffic to the UPE with an inner VLAN tag of 101 or 102 and an outer VLAN tag of whatever metro VLAN was assigned by the provider (varies per site). EIGRP is running inside VPN 101 with OSPF running inside VPN 102. Each VPN has a loopback on the CE device to ensure routing works properly over the L2VPN. The P routers are just MPLS/LDP enabled and have no fancy configuration. We will begin in the core by verifying the PWs are operational. The output shows us all circuits within the L2VPN, even though we know 78101 is an access circuit not strictly part of the VPLS instance. The “detail” keyword shows us the MPLS labels also. Notice that CSR1 shows “standby” for the circuit to CSR8; this is the backup access PW, but CSR1 learned this standby information via status message, not local configuration. We will use a different verification command on every router for variety.

We can also verify that the access PWs have split-horizon automatically disabled. When this feature is enabled (it is by default), traffic entering from one PW cannot exit through another PW; the expectation is that it is manually bridged elsewhere or piped to the AC for delivery. There are no ACs on the NPEs, so traffic entering from the access PW should be allowed to transit the network PWs, and vice versa. What remains disallowed is inter-network PW forwarding, which explains the need for a full-mesh of NPE routers like traditional VPLS requires for E-LAN service. The commands below verify that CSR7 and CSR1 both have split-horizon disabled on their access PWs. Split-horizon remains enabled for all network PWs as expected. CSR1 uses the new show command while CSR7 uses the legacy show command.

R1#show l2vpn vfi name VPLS_101

48.0.0.1	17101	Y

To verify all of the connectivity and signaling is working as expected, we will trace the path from XRv2 to CSR3 within VPN 101. Traffic arrives at CSR8 with dot1q tags {3582 101} as we saw earlier. Both tags are popped by the EVC and the native Ethernet frame is piped to the access PW 78101 using PW label 7004. The transport label is implicit-null since the NPE is one hop away. The full label stack is simply 7004.

R8#show l2vpn atom vc vcid 78101 detail | include label_stack

Output interface: Gi2.578, imposed label stack {7004}

When the MPLS packet arrives at CSR7, the LFIB shows all labels being removed with no obvious next-hop. This is because the PW terminates and is passed into a bridge-domain so the LFIB does not directly perform any label swaps on ingress. We see several MAC addresses learned by the bridge-domain, and identify XRv2 as being present. Normal switching rules apply at this point, and the destination of the Ethernet frame determines the egress PW. This is why the LFIB did not try to route the MPLS packet any further.

Assuming the destination MAC was CSR3 (MAC is below) the packet is routed out of a pseudo-port that is mapped to the PW connected to the NPE towards CSR3. In this case, it is CSR6. I have not been able to find a way to show the pseudo-port to PW mappings, so we will make the assumption without verifying as doing so appears impossible via show commands. The new label stack is {94008 6010} which includes an LDP transport label from XRv4 to reach CSR6's loopback, and the PW label for this circuit.

```
R3#show interfaces gigabitEthernet 2 | include bia

```

Again, we cannot prove that the pseudo-port associated with CSR3's MAC address terminates on CSR4, but we will assume it does and continue. The PW label of 4000 is pushed to reference this circuit on CSR4 and the transport label of 93002 is pushed to reach CSR4's loopback.

```
R6#show l2vpn atom vc vcid 46101 detail | include label_stack
Output interface: Gi2.563, imposed label stack {93002 4000}
```

Like XRv4, XRv3 performs PHP to expose the PW label to CSR4.

```
RP/0/0/CPU0:XRv3#show mpls forwarding labels 93002
Local  Outgoing    Prefix          Outgoing    Next Hop    Bytes
Label  Label        or ID           Interface    Interface    Switched
-----
93002  Pop          48.0.0.4/32     Gi0/0/0/0.543 48.4.13.4    5408591
```

CSR4, as a UPE, has similar output as the NPEs CSR7 and CSR6 when packets arrive along a PW. The difference is that the outgoing interface specifies Gig2, which is correct, as there is an EVC mapped to this PW in the cross-connect process. Label 4000 maps to this cross-connect, and the outgoing dot1q encapsulation is shown as {3534 101} upon receiving the raw Ethernet frame.

```
R4#show mpls forwarding-table labels 4000 detail
Local      Outgoing    Prefix          Bytes Label    Outgoing    Next Hop

Now we will verify the data-plane using EPC. EPC currently does not appear to support EVC monitoring, so we will limit our focus to the NPEs. Assuming the proper labels are imposed as traffic is bridged between different PWs, our control-plane verification shows the MPLS transport functions. Capturing inbound on CSR7 facing CSR8, and outbound on CSR7 facing XRv4, we can see label 7004 (0x1B5C) arriving and labels {94008 6010} (0x16F38, 0x177A) exiting. The FAT-PW label is also inserted beneath the PW label to achieve load-sharing on the network PW only (documented elsewhere) and the control-word is added last in green. The low-order 16 bits of the CW representing sequencing which is enabled on all network PWs, along with FAT-PW. CSR3's MAC is in cyan and is the destination MAC address in the customer frame. CSR3's IP address is in pink and is the destination IP address of 192.168.0.3.

We will also verify our backup PWs are functional on CSR8. To test it, we can shutdown the PW to CSR7 from the perspective of the UPE. Since the PWs are LDP-signaled and status is supported, the backup PW will come online and report this to the backup NPE, which is CSR1 in this case. The backup PW is pre-made and already signaled, so the LSPs should be functional. The PW shows “admin down” on CSR8, which means the PW to CSR1 moves from “standby” to “up”.

```
! CSR8
interface pseudowire78101
shutdown

R8#show l2vpn service xconnect name VPLS_101 | begin Interface
  Interface          Group          Encapsulation          Prio   St   XC   St
  -----          -
  VPWS name: VPLS_101, State: UP
  pw78101           VPLS_101      48.0.0.7:78101 (MPLS)    0      AD   AD

  Last error: Remote peer withdrew label

! CSR1
%XCONNECT-5-PW_STATUS: MPLS peer 48.0.0.8 vcid 18101, VC state UP
```

Checking the control-plane, we see that CSR8 will use PW label 1003 for the backup PW to CSR1. The transport label is implicit-null since CSR8 is the penultimate hop to CSR1 along this LSP.

```
R8#show l2vpn atom binding 18101 | include Remote
  Remote Label: 1003

R8#show mpls ldp bindings 48.0.0.1 32 neighbor 48.0.0.1
  lib entry: 48.0.0.1/32, rev 10
  remote binding: lsr: 48.0.0.1:0, label: imp-null

R8#show l2vpn atom vc vcid 18101 detail | include label_stack
  Output interface: Gi2.518, imposed label stack {1003}
```

CSR1 has CSR3’s MAC address in its BD CAM, and we assume that pseudo-port associated with the MAC address maps to the CSR6 network PW. This imposes labels {94008 6030}. The LDP label is the same one

used by CSR7 earlier to reach CSR6's loopback, which was allocated by XRv4. The PW label is specific to the network PW between CSR1 and CSR6.

```

Output interface: Gi2.514, imposed label stack {94008 6030}
```

XRv4 will pop label 94008 and deliver packets labeled 6030 to CSR6 (not shown again). CSR6 strips the PW label, delivers the frame to the BD CAM, which switches it towards CSR4. This has not changed from the previous example since there was no instability in the remote access MPLS network. A quick check on XRv2 shows that it still has all EIGRP neighbors, which implies connectivity is functional along the backup access PW.

```
RP/0/0/CPU0:XRv2#show eigrp vrf 101 neighbors
IPv4-EIGRP VR(VPLS_101) Neighbors for AS(101) VRF 101

Next, we will configure and test VPN 102. This will provide an E-TREE service and will use BGP auto-discovery with LDP signaling for NPE PWs. CSR6 and CSR9 are roots while CSR1 and CSR7 are leaves; this essentially means CSR1 and CSR7 will not have a PW between them. This implies that all UPEs homed into CSR1 or CSR7 will not be able to communicate with one another. This can be used to scale E-TREE architectures by segmenting groups of nodes, and treating those groups holistically as roots or leaves. In this case, the design will prohibit CSR10 and XRv2 from communicating. PW redundancy on the UPE is not supported with BGP auto-discovery, so there are no backup PWs for VPN 102. The UPE configuration is identical to VPN 101 (minus the backup BW), but the NPEs are more involved. We focus on CSR1 and

CSR9 for brevity. RT:48:1 represents the root RT and RT:48:2 represents the leaf RT. Roots import both RTs, while leaves only import the root RT. The NPE template is not shown again.

```

```

Verifying the VFI configuration and auto-discovered PWs verifies which PWs were built based on the BGP L2VPN VPLS prefixes. We can see the RT import/export policies as well to validate them. CSR1 shows specific import/export RTs, while CSR9 does not specify a direction for RT:48:1, since it is both imported and exported. While we are here, we can also verify that split-horizon is disabled on the access PW, which allows traffic to transit between the NPE-signaled E-TREE and the access circuits to the UPEs.

```

R1#show l2vpn vfi name VPLS_102

Next, we will quickly trace the LSP from CSR2 to CSR5, supporting customers CSR10 and XRv1. CSR2 receives packets in the EFP with dot1q tags {3520 102} and pops both on ingress (shown earlier). This is piped via access PW 12102 to CSR1 using label 1017. We prove all of this with one show command. We also lookup XRv1's MAC address so we know what to reference in the NPE BD CAM tables.

R2#show l2vpn service xconnect name VPLS_102 detail | begin Interface

```

Like CSR1, CSR9 bridges this PW to BD 102. The BD determines the outbound pseudo-port, which we assume maps to the NPE PW towards CSR5. Notice that CSR9 has one more MAC in its BD CAM than CSR1 did; this is because CSR1 does not have the MAC address for XRv2, which is behind a leaf node in the E-TREE. CSR9 pushes label 5006 which is the PW label for the access circuit to the UPE. The transport label is implicit-null since CSR9 is the penultimate hop along this LSP.

```

R9#show bridge-domain 102

R9#show l2vpn atom vc vcid 59102 detail | include label_stack
Output interface: Gi2.559, imposed label stack {5006}

```

CSR5 receives packets labeled with 5006 along VCID 59102 and pipes them to an EFP with dot1q encapsulation {3551 102} via cross-connect. This is all displayed in one show command.

```

R5#show l2vpn service xconnect name VPLS_102 detail | begin Interface
Interface          Group      Encapsulation          Prio  St  XC St
-----
VPWS name: VPLS_102, State: UP
Gi2                 Gi2:3551/102 (Eth VLAN) 0      UP  UP
                    Interworking: ethernet
pw59102             48.0.0.9:59102 (MPLS) 0      UP  UP
                    Local VC label 5006
                    Remote VC label 9023

```

Now we will verify the data-plane by capturing on CSR1 and CSR9. The first set of packets shows traffic entering CSR1 from the UPE with label 1017 (0x3F9) and exiting CSR1 towards the core with labels {94006 9024} (0x16F36, 0x2340). This does not include the FAT-PW label, and the CW isn't terribly important right now. The destination IP address in the VPN is 192.168.0.11. The color scheme is the same as before for consistency.

```

We perform the same capture on CSR9, measuring inbound traffic from the core and outbound traffic towards the UPE, which is CSR5. Label 9024 arrives from the core, CSR9 bridges this to the access PW, and label 5006 (0x138E) is pushed. Nothing else changes except for the MPLS labels as the tunneled Ethernet frame, and higher layer protocols inside it, remain untouched.

```

32.1.3.2 QinQ in the Access Network

The next test uses a smaller network and utilizes dot1q tunneling in the access networks. In real designs, large switched networks would make up the access networks by pushing another dot1q tag (metro or carrier tag) onto the C-VLANs the customer is trying to extend. As such, the devices in the access network do not have to run IP or MPLS at all; they just need to manipulate dot1q tags like switches. In this example, the UPEs are CSR2, CSR4, and CSR5. The NPEs are CSR1, CSR6, and CSR9. The P routers are CSR7 and XRv4. The customer routers are CSR10, CSR3, and CSR8. In order to create this port-based E-LAN service with total VLAN transparency, I created new vSwitches just to connect the CEs to the UPEs. This is because VLAN 101, for example, needs to be on different switches on both ends of the network, so within the scope of vSphere, this means different vSwitches. These new connections connect to Gig3 of the CE and UPE routers. The CEs are not using VRFs this time, and VLANs 101 and 102 are used for testing. Unlike the previous example, this time we offer an entirely transparent service so there is no reference to VLANs 101 or 102 anywhere in the SP network.

The CE configuration is not shown as it is just two dot1q interfaces in VLAN 101 and 102 on each router; no routing protocols exist in the customer network this time. The UPE devices accept all incoming traffic on Gig3 and push the carrier tag on top of the existing tag(s). They also pop it in the reverse direction (egress) so that the customer never sees the S- tag. The UPE bridges the incoming EFP where the tag was pushed to the outgoing EFP which performs no operation, just matches traffic with the proper carrier tag and any inner tag. The NPE (CSR1) pops the carrier tag on ingress (pushes it back on egress), which sustains the original VLAN ID in the tunneled frame. The NPE bridges the EFP and the VFI, consisting of PWs discovered and signaled using BGP for variety. This completes the H-VPLS architecture; the configuration on other NPEs and UPEs is nearly identical, except using different carrier tags and VE-IDs.

```

We will trace the path from CSR10 to CSR3. First, we will record CSR3's MAC address so we know what to look for in the BD CAM tables. Packets arriving from CSR10 with this MAC address on Gig2's EFP 3512 are placed in the BD and sent upstream towards the NPE (CSR1). Packets arrive with tag X where X is any C-VLAN. The EFP pushes tag 3512 for a tag stack of {3512 X} transiting the access network. Imaginary witches in the transit path between the NPE and UPE would switch these frames according to the VLAN 3512 CAM, ignoring the inner tag.

```

R3#show interfaces gig3 | include bia

```

Next, we will verify that CSR1 (NPE) received all the VPLS routes from BGP. We specifically would need to have the prefix from CSR6 at a minimum. Without this, the PWs cannot be built between NPEs which form the core of the VPLS instance.

```

R1#show bgp l2vpn vpls rd 48:100 | begin Network

```

Next, we can see which PWs were automatically created based on these BGP routes. Notice that the concept of split-horizon is moot for this design since there are no NPE-to-UPE PWs. The traffic arrives at the NPE on an EFP, not a PW, so there isn't any bridging of PWs requiring split-horizon to be disabled anymore. The entire access network is layer 2 only which alleviates the complexity of larger IP/MPLS and PW designs. We can also see the remote PW label is 6015, which was computed based on the VE-ID, VBO, and VBS (described in another section). Since we are using auto-route-target, the VPN-ID is used as the RT and is imported/exported by all nodes, creating a full-mesh of PWs fit for providing E-LAN service.

```

R1#show l2vpn vfi name VPLS
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: VPLS, state: up, type: multipoint, signaling: BGP
VPN ID: 100, VE-ID: 1, VE-SIZE: 10
RD: 48:100, RT: 48:100
Bridge-Domain 3512 attachment circuits:
Pseudo-port interface: pseudowire100005
Interface      Peer Address    VE-ID  Local Label  Remote Label  S
pseudowire100007 48.0.0.9        9      1026         9013          Y
pseudowire100006 48.0.0.6        6      1023         6015          Y

```

We can check the VPLS instance to ensure both PWs are up. Specifically, we want to look at the PW with VE-ID 6 to see the label stack and verify the FEC.

```

R1#show l2vpn atom vc service-name VPLS

```

Interface	Peer ID	VC ID	Service Type	Name	Status

```

We verify that CSR1 is actually receiving frames and learns the MAC address of CSR3 via the VPLS instance. The pseudo-port represents one of the PWs within that instance, and we assume this to be towards CSR6. This pseudo-port instructs the router to add MPLS encapsulation to the frame using the labels shown above. Frames received on the EFP have their top tag removed on ingress and only the inner VLAN is preserved end-to-end. The arriving tag stack is {3512 X} but only tag X is encapsulated inside MPLS inside the tunneled Ethernet frame header.

```

```

CSR6 cannot label switch this packet since the LFIB removes all labels. The packet is piped to the BD CAM so a switching decision can be made based on the destination MAC, which is highlighted. The BD CAM table shows this MAC address is accessible via an EFP that sends traffic into another access

network on the other side of the core. A new carrier tag is used simply because the virtualization environment limits, but it could have been the same if the access networks didn't share the same vSwitch. Traffic inside the MPLS packet has tag X and the NPE pushes the carrier tag 3546 before sending it into the access network. The tag stack becomes {3546 X}.

```
R6#show mpls forwarding-table labels 6015

Because we cannot use EPC on the EFPs, we will verify packets being MPLS-encapsulated on CSR1 towards CSR7, and likewise being MPLS-decapsulated on CSR6 from CSR7. We expect to see the tunneled VLAN ID inside the customer traffic, along with the expected label values revealed earlier. The first packet is sent from CSR1 to CSR7, and the second is a packet arriving on CSR6. BGP signaling does not appear to allow us to use FAT-PW or CW, so those components are missing from the capture. This restriction is specified in an extended community that IOS does not let us configure (L2VPN INFO community, which has the CW, sequencing, and FAT-PW bits set to zero unconditionally). Using the same colors as the previous section (labels are yellow, destination MAC is cyan, destination IP is pink), we can verify the packets are following the proper LSP. Packets are sent from CSR1 with labels {7002

6015} (0x1B5A, 0x177F) towards CSR7. CSR6 receives the packet only with label 6015 as expected. The difference with these captures, aside from missing a CW and FAT-PW label, is the presence of the dot1q C-VLAN tag (grey). In this case, it is VLAN 101 (0x65) but since the core is not matching this number anywhere, any VLANs could be used. This is also possible with MPLS in the access network but was not demonstrated last time.

```
R1#show monitor capture CAP buffer dump
```

```

```

Just to prove the transparency is functional, we quickly test another C-VLAN. The forwarding path, carrier tags, and LSPs do not change at all. The only difference is the dot1q C-VLAN tag, shown again in grey. This time, the customer is sending traffic on VLAN 102 (0x66). The other fields are highlighted as well for completeness; they are identical to the packets above.

Additional Reading – Reference configurations "hvpls-qinq"

32.2 IP encapsulated L2VPN

Layer 2 tunneling protocol (L2TP) is another way to offer E-LINE, E-LAN, and E-TREE services when MPLS transport is not available. Like GRE, it is a form of IP encapsulation, but can carry many layer 2 protocols. L2TP, when used with xconnect, uses IP protocol 115 and is referenced in RFC 3931. L2TP can also use UDP encapsulation as seen with VPDN groups, which is beyond the scope of this section. The signaling for L2TP is quite complex and offers many verbose debugs. The network diagram is the same as the MPLS L2VPN tests, except MPLS is disabled everywhere, along with all of its supporting protocols (LDP, BGP, etc). L2TP can only be used in a P2P fashion as all VFI configurations reject all encapsulations other than MPLS. As an alternative to VPLS, we can use Overlay Transport Virtualization (OTV), a Cisco-proprietary protocol (for now) designed for data center interconnects (DCI) to built transparent LANs. Like DMVPN and LISP, it is more customer-oriented, but it is still technically a mechanism of providing E-LAN service, so I consider it in scope for the CCIE SP. Besides, a good service provider is aware of how customer-focused technologies work.

32.2.1 E-LINE with L2TP

Layer 2 tunnel protocol (L2TP) works like a P2P MPLS L2VPN in that it provides transparent layer 2 service across a service provider core. The difference is that it is IP-encapsulated, not requiring MPLS at all. L2TP is a very signaling-intensive protocol with several new messages described below (RFC 3931). Fortunately, the general logic follows a three-way handshake, much like TCP.

Start-Control-Connection-Request (SCCRQ): Initiates a control connection between two L2TP peers. Either router can initiate the session. It carries the L2TP router-ID, hostname, and other details. This is loosely analogous to a TCP SYN.

Start-Control-Connection-Request (SCCRP): Sent in response to a SCCRQ. This is an acknowledgement that the SCCRQ was accepted and setup should continue. This like a TCP SYN ACK.

Start-Control-Connection-Connected (SCCCN): Sent in response to a SCCRP to complete the control session setup. This is like the final TCP ACK. These three messages serve the same function as the TCP three-way handshake.

Stop-Control-Connection-Notification (StopCCN): Sent by either L2TP router that the control connection is being shut down. A result code is carried in the message to explain why. This is like a TCP RST.

Hello packet (HELLO): Control message sent by either L2TP router to serve as a keepalive.

Incoming-Call-Request (ICRQ): Like a SCCRQ, except happens after the session is established. It happens per call, not per session, and is mostly relevant in a dial-up deployment (BBA setup with LAC/LNS). This is also like a TCP SYN.

Incoming-Call-Request (ICRP): Like a SCCRP, except is sent in response to an ICRQ for a particular call. This is sent if the ICRQ parameters are accepted. This is also like a TCP SYN ACK.

Incoming-Call-Connected (ICCN): Like a SCCRCN, except is sent in response to an ICRP for a particular call. This finalizes the L2TP session for the call. This is also like a TCP ACK.

Outgoing-Call-Request (OCRQ): Like an ICRQ, except in the opposite direction. This is specific to calls from a LAC, which is not present in this test. This is also like a TCP SYN.

Outgoing-Call-Request (OCRP): Like an ICRP, except in the opposite direction. This is specific to calls from a LAC, which is not present in this test. This is also like a TCP SYN ACK.

Outgoing-Call-Connected (OCCN): Like an ICCN, except in the opposite direction. This is specific to calls from a LAC, which is not present in this test. This is also like a TCP ACK.

Call-Disconnect-Notify (CDN): Like a StopCCN, except specific for a call within the general L2TP control session. It disconnects the specific session but does not affect L2TP control.

WAN-Error-Notify (WEN): Sent from a LAC to the LNS to indicate an error condition in the WAN. Not present in this test.

Set-Link-Info (SLI): This is used to send updated status reports across between L2TP speakers.

Explicit-Acknowledgement (EXP-ACK): Just acknowledges a message and is typically used with sequencing.

Zero-Length-Body (ZLB): A message received without any attribute-value pairs (AVPs). Serves the same function as the EXP-ACK. The RFC says it can only be used when control channel authentication is disabled, but I see it used all the time, with EXP-ACK never being used.

The normal P2P PW configuration is almost identical to the MPLS AToM section. The most significant change is using L2TPv3 encapsulation versus MPLS, along with some other parameters. The configurations are shown below. We will mirror the setup from earlier where CSR8 has two PWs in primary/backup operation to CSR5 and CSR6 respectively. There is no option for control-word, yet sequencing is available. We can also adjust the tunnel TOS, much like a GRE tunnel, either by reflecting the TOS inside the payload or hard-setting a value (CS1 in this case on the backup tunnel). We will explore these features later. We use the new L2VPN configuration on CSR8 and CSR5, and use the legacy xconnect configuration on CSR6. **Pitfall: L2TP is not supported with EFP/EVC in the CSR1000v. This means we must use a main interface or subinterface, but not a service instance.** Those interfaces don't need any configuration on them other than the encapsulation when using the new L2VPN configuration model (CSR5 and CSR8). When using the legacy model (CSR6), the xconnect goes under the subinterface. We will examine these configurations soon. The network is very similar to before by with some routers

removed since L2TP cannot support E-LAN or E-TREE services. There is no need to have a large network when only P2P connections are being tested.

```

We can verify the L2TP sessions are operational using some basic commands. We can see if the tunnel is up, and to which peer. We can also check the transport information, which shows the IP protocol number and local interface as well. The “tunnel” represents the control channel and all higher level protocols (PPP, xconnect, etc) all rely on this. Between a set of L2TP routers, there is a single tunnel, but multiple “calls” or “sessions”. This is why the SCC and IC messages are different.

```

R8#show l2tp tunnel
L2TP Tunnel Information Total tunnels 2 sessions 2
LocTunID  RemTunID  Remote Name  State  Remote Address  Sessn L2TP Class/
Count VPDN Group
1501687873 1414773374 R6          est    55.0.0.6        1      l2tp_default_cl
2718846397 3521913226 R5          est    55.0.0.5        1      l2tp_default_cl

```

```
R8#show l2tp tunnel transport
L2TP Tunnel Information Total tunnels 2 sessions 2
LocTunID   Type Prot  Local Address  Port  Remote Address  Port
1501687873 IP    115  55.0.0.8      0     55.0.0.6        0
2718846397 IP    115  55.0.0.8      0     55.0.0.5        0
```

We can also check the packets transported by L2TP. The difference between session and tunnel packets is subtle. “Session” packets only counts packets that occur within the given session (or “call”), so clearing the L2TP session or having the PW fail for any reason will reset these counters. “Tunnel” packets continue to increment even after PWs fail, provided the tunnel ID is not deallocated and the control-session doesn’t completely fail. Therefore, the tunnel packets will always be greater than or equal to the session packets since one is a subset of the other. Both commands reference tunnels by their tunnel-ID, which is a 32-bit unsigned number used to represent a connection. This used to be a 16-bit unsigned number in L2TPv2, but was expanded in to 32-bits in L2TPv3. Above, we see that the ID beginning with 150 corresponds to the backup connection to CSR6, while the one beginning with 271 corresponds to the primary connection to CSR5. That is why only one tunnel has packets associated.

```
R8#show l2tp session packets
L2TP Session Information Total tunnels 2 sessions 2
LocID      RemID      TunID      Pkts-In    Pkts-Out   Bytes-In   Bytes-Out
2927100785 1218283557 1501687873 0           0           0           0
3331724010 4005951606 2718846397 105         144         18990       22416
```

```
R8#show l2tp tunnel packets
L2TP Tunnel Information Total tunnels 2 sessions 2
LocTunID   Pkts-In    Pkts-Out   Bytes-In   Bytes-Out
1501687873 0           0           0           0
2718846397 126         186         32068      37198
```

After clearing the session and sending 100 packets through the tunnel, the session counts those, but the tunnel continues to increment from the value it had before the session cleared. The control-channel was reset but remained UP (in software, at least) but the “call” was re-established. This is a minor detail and is not terribly significant, but helps highlight the difference between a “tunnel” and a “session”.

```
R8#show l2tp session packets
L2TP Session Information Total tunnels 2 sessions 2
LocID      RemID      TunID      Pkts-In    Pkts-Out   Bytes-In   Bytes-Out

2718846397 226         288         43868      49546
```

Next, we verify the signaling packet flow. We will clear the backup tunnel then watch CSR6 renegotiate with CSR8. We see that CSR6 sends the initial SCCRP; we can confirm this by checking the tunnel details to ensure the tunnel is “locally” initiated. CSR8 responds with the SCCRP, and CSR6 confirms the session with the SCCN. After the control channel is established, CSR6 originates the call with an ICRQ message on behalf of the xconnect process. Only the “RQ” packets are highlighted during this exchange for brevity, but the debug clearly shows all of the message transactions. Once the session is established, the two routers then exchange status messages using the SLI message.

```
R6#debug l2tp packet brief
```

```
L2TP tnl 08213:4ED2CB86: Tx -> SCCRP loc 4ED2CB86 rem 00000000

Now, we will validate the detailed L2TP information. Using the tunnel ID beginning with 271, we can look deeper into this PW. First, we see the tunnel was “remotely” initiated in green, which makes sense since CSR6 claims to have initiated it. In a peer-to-peer setup like this, it doesn’t matter who really initiates the tunnel or not. Next, basic information about the tunnel endpoints, including IP addresses and hostnames, is displayed. The counters appear incorrect since, having cleared the tunnel, the top set of counters should be less than the bottom set, much like the “session” and “tunnel” packets seen earlier. Both of these fields represent the “tunnel” counters (yellow). The Ns, Nr, RWS, and congestion-control features are examined later (cyan). The next several lines deal with out of order packet drops, and the last line tells us we are not running authentication (pink). This is specific to the tunnel, not the session, which we look at later.

```

Control message authentication is disabled
```

The simplest way to begin adding complexity is to define an L2TP-class. This is a custom construct that is used to control advanced L2TP signaling parameters. This is not the same as a PW-template or PW-class as those contain general PW settings, such as the encapsulation type and neighbor address. The L2TP-class modifies the L2TP control-plane behavior. There are two ways to secure L2TP: L2TP control-channel authentication and L2TPv3 control message hashing. The first one is older and was carried over from L2TPv2 for interoperability with older versions. It behaves like the Challenge Handshake Authentication Protocol (CHAP) commonly used in PPP. The second is newer and uses the entire message in the hash, which is more secure. You can configure both at the same time as well. On CSR8, we will begin by enabling CHAP-style authentication in an L2TP-class and applying it to the backup PW towards CSR6. Note: In order to apply the L2TP-class, you must remove the signaling protocol and re-add it, which tears down the PW.

```
! CSR8
l2tp-class L2TP_CLASS_BACKUP
  authentication
  password L2TP_PASS

interface pseudowire10142
  no signaling protocol l2tpv3
  signaling protocol l2tpv3 L2TP_CLASS_BACKUP
```

We can verify the class configuration as well. This shows all the defaults within the specific class, too.

```
R8#show l2tp class | section BACKUP
class [L2TP_CLASS_BACKUP]
  is a statically configured class
  configuration:
    l2tp-class L2TP_CLASS_BACKUP
      authentication
      digest check
      hello 60
      password L2TP_PASS
      receive-window 1024
      retransmit retries 15
      retransmit timeout max 8
      retransmit timeout min 1
      retransmit initial retries 2
      retransmit initial timeout max 8
      retransmit initial timeout min 1
      timeout setup 300
```

As expected, our tunnel to CSR6 is down due to authentication issues as CSR6 has not been configured for authentication yet. The L2TP debugs are almost unreadable because they are so chatty. Sorting through them, we see a hint at the problem. The challenge was failed so the session cannot establish.

```
R8#show l2tp tunnel
```

```
%No active L2TP tunnels
```

```
R8#debug l2tp event
```

```
L2TP tnl 081F1:2B5DAEAF: Shutting down tunnel
```

```
L2TP tnl 081F1:2B5DAEAF: With 1 app
```

```
L2TP tnl 081F1:2B5DAEAF: Result Code
```

```
L2TP tnl 081F1:2B5DAEAF: Requester is not authorized to establish a  
control channel
```

```
L2TP tnl 081F1:2B5DAEAF: Error Code
```

```
L2TP tnl 081F1:2B5DAEAF: No error
```

```
L2TP tnl 081F1:2B5DAEAF: Vendor Error
```

```
L2TP tnl 081F1:2B5DAEAF: None
```

```
L2TP tnl 081F1:2B5DAEAF: Optional Message
```

```
L2TP tnl 081F1:2B5DAEAF: "process challenge failed "
```

On CSR6, we will correct the issue by creating an L2TP-class and applying it within the PW-class. We have to completely remove the xconnect from the subinterface before changing the signaling mechanism, but this is a simple step and is not shown. We intentionally configure the wrong password to see if the debug message reveals the mismatch.

```
! CSR6
```

```
l2tp-class L2TP_ADVANCED
```

```
authentication
```

```
password L2TP_PASS_WRONG
```

```
pseudowire-class PW_1014
```

```
protocol l2tpv3 L2TP_ADVANCED
```

As expected, debugging on CSR6 reveals that the tunnel still cannot come up. This time, the message is different and says the authentication is mismatched, versus having the “challenge” process totally fail.

```
R6#debug l2tp event
```

```
L2TP tnl 08138:F7AA6808:
```

```
L2TP tnl 08138:F7AA6808: Shutting down tunnel
```

```
L2TP tnl 08138:F7AA6808: Result Code
```

```
L2TP tnl 08138:F7AA6808: General error - refer to error code
```

```
L2TP tnl 08138:F7AA6808: Error Code
```

```
L2TP tnl 08138:F7AA6808: Vendor specific
```

```
L2TP tnl 08138:F7AA6808: Vendor Error
```

```
L2TP tnl 08138:F7AA6808: Authentication failed
```

```
L2TP tnl 08138:F7AA6808: Optional Message
```

```
L2TP tnl 08138:F7AA6808: "Tunnel auth failed for mismatch"
```

We quickly correct the password on CSR6 (not shown) and the PW immediately comes up. Unlike CHAP, we actually didn't create local usernames or a AAA server to authenticate the peer; L2TP will compare the hash from the shared secret and use that by itself, which is part of the reason why this is the "old" method. The hostnames could have been specified in the L2TP-class but, like PPP, will use the router hostname by default.

```
R6#debug l2tp event
L2TP tnl 0818E:09F70EBD: FSM-CC ev Sock-Ready
L2TP tnl 0818E:09F70EBD: FSM-CC Wt-Sock->Wt-SCCRP
L2TP tnl 0818E:09F70EBD: FSM-CC do Tx-SCCRQ
L2TP tnl 0818E:09F70EBD: FSM-CC ev Rx-SCCRP
L2TP tnl 0818E:09F70EBD: FSM-CC Wt-SCCRP->Proc-SCCRP
L2TP tnl 0818E:09F70EBD: FSM-CC do Rx-SCCRP
L2TP tnl 0818E:09F70EBD: Tunnel Authentication success
```

When we verify the details for this new tunnel, we see some interesting output/ CSR8 reports that the peer never had an authentication failure, and that authentication is not configured. Both of these claims are false; I assume that this status output only changes when the newer control-message hashing feature is enabled.

```
R8#show l2tp tunnel state | include R6
2400039996 2929395307 R8 R6 est 00:27:09
```

```
R8#show l2tp tunnel all id 2400039996 | include authen
Total peer authentication failures 0
Control message authentication is disabled
```

Next, we configure the "new" method of authentication on CSR8 and CSR5. The word "digest" houses many features, but when the "secret" option is used, this enables authentication and integrity checking. Again, I configure the password incorrectly on purpose on CSR5.

```
! CSR8
l2tp-class L2TP_CLASS_PRIMARY
digest secret 0 L2TP_DIGEST hash SHA1

interface pseudowire10141
signaling protocol l2tpv3 L2TP_CLASS_PRIMARY

! CSR5
interface pseudowire10141
signaling protocol l2tpv3 L2TP_ADVANCED

l2tp-class L2TP_ADVANCED
digest secret 0 L2TP_DIGEST_WRONG hash SHA1
```

As expected, the tunnel does not form due to the authentication mismatch. Like the control-channel authentication, the debug states this clearly.

```
! CSR5
L2TP tnl 10282:5CF2880D: Shutting down tunnel
L2TP tnl 10282:5CF2880D: Result Code
L2TP tnl 10282:5CF2880D: General error - refer to error code
L2TP tnl 10282:5CF2880D: Error Code
L2TP tnl 10282:5CF2880D: No error
L2TP tnl 10282:5CF2880D: Vendor Error
L2TP tnl 10282:5CF2880D: None
L2TP tnl 10282:5CF2880D: Optional Message
L2TP tnl 10282:5CF2880D: "SCCRQ authen failed"
L2TP tnl 10282:5CF2880D: ERROR: Validate message digest, received digest
mismatch with local
```

Once we correct the password on CSR5, we see the tunnel form immediately. Each control message is displayed in hex and should be followed by a message stating the digest was correct.

```
! CSR5
L2TP tnl 08325:116B1827: Control Message
C8 03 00 55 11 6B 18 27 00 03 00 05 80 08 00 00
00 00 00 10 80 1B 00 09 00 0C 01 00 00 00 00 00
00 00 00 00 00 00 00 00 00 00 00 00 00 00 00 80
0A 00 09 00 03 A1 8E 57 BE 80 0A 00 09 00 04 77
9B 9C 15 00 08 00 09 00 08 00 01 00 0A 00 09 00
72 00 00 00 00
L2TP tnl 08325:116B1827: Message digest match performed, passed.
```

Now, we can see CSR8 reporting authentication being enabled. The output here only updates when relating to the newer digest authentication and not the CHAP-style mechanism as we theorized earlier. You can also configure multiple digest secrets to perform password rollover.

```
R8#show l2tp tunnel state | include R5
4135688314 292231207 R8 R5 est 00:02:31

R8#show l2tp tunnel all id 4135688314 | include authen
Total peer authentication failures 0
Control message authentication is enabled with 1 digest secrets
Last control message authenticated with first digest secret
```

On CSR5, we will add a wrong password back in, but we will remove the right password so the wrong password is the “first” one. Now there are two passwords available. The session stays up because one is correct, but CSR5’s show command output differs from CSR8’s. CSR5 says there are two possible digests and the last message was authenticated using the second. Ideally, removing the “first” one, following a

password rollover, is a time-sensitive task. Cisco supports a maximum of 2 secrets for both IOS and XR, and the expectation is that L2TP would only have 2 passwords during the manual password rollover period.

```
! CSR5
l2tp-class L2TP_ADVANCED
  digest secret 0 L2TP_DIGEST_WRONG hash SHA1
  digest secret 0 L2TP_DIGEST hash SHA1

R5#show l2tp tunnel state | include R8
292231207 4135688314 R5 R8 est 00:05:02

R5#show l2tp tunnel all id 292231207 | include authen
Total peer authentication failures 0
Control message authentication is enabled with 2 digest secrets
Last control message authenticated with second digest secret
```

One last feature of the digest is disabling the digest check. It is enabled by default, and can only be disabled if digest authentication is disabled. Assuming CSR6 is an old router with poor performance, we can disable this feature to save some CPU cycles at the cost of security and message integrity. Other than verifying the L2TP-class, I have not found a way to verify that this is operational.

```
! CSR6
l2tp-class L2TP_ADVANCED
  no digest check

R6#show l2tp class | section ADVANCED
class [L2TP_ADVANCED]
  is a statically configured class
  configuration:
    l2tp-class L2TP_ADVANCED
      authentication
      no digest check
      hello 60
      [snip]
```

The HELLO mechanism is very simple and is similar to other protocols. The default hello timer is 60 seconds and we can see the packets exchanged using L2TP packet debugging. The difference is that L2TP receives a hello and replies with an acknowledgement (ZLB in our case). Peers must not expect hello messages according to a time interval, so there isn't a "dead time" concept. I think the parser just prints the ZLB before the hello, but the two happen at the same time. Notice the "loc" and "rem" fields represent the tunnel IDs in hex. We adjust the timer to 20 seconds on CSR6 only; the timers do not have to match. This will flap the session. This debug does not show received ZLB's since no processing is done on them.

```

```

Next, we will examine L2TP sequencing. With AToM, this information was carried inside the control-word, which is a 4-byte field appended to the end of the MPLS label stack. L2TP handles it differently with a pair of numbers. The Ns and Nr fields represent sequence numbers: Ns is the number of the local message being sent and Nr is the expected number of the next packet being received.

```
! CSR5 and CSR8
```

```
interface pseudowire10141
sequencing both
```

We can verify the configuration was successful by checking the details of the session. The output is verbose but we only care about the sequencing part for now. To specify a session, we must provide the tunnel ID and the session ID, in that order. Alternatively, we can use the PW ID of 10141 which is simpler. We see that sequencing is enabled on CSR5 and CSR8. CSR5 is expecting to receive sequence number 16 (Nr), while CSR8 is using that number for the next packet to send (Ns). This one-way traffic is likely due to the RIP updates being sent by CSR10, since XRv4 is only passively listening.

```
R5#show l2tp session
```

```
L2TP Session Information Total tunnels 1 sessions 1
```

LocID	RemID	TunID	Username, Intf/ Vcid, Circuit	State	Last Chg	Uniq ID

```

XRv4 sends 100 pings to CSR10, who replies to them all. Just like with AToM sequencing, the numbers increase as expected. If packets were dropped due to being out of order, Ns/Nr would reveal it.

```
RP/0/0/CPU0:XRv4#ping vrf LINE 10.10.14.10 count 100
Type escape sequence to abort.
Sending 100, 100-byte ICMP Echos to 10.10.14.10, timeout is 2 seconds:

```

The receive window size (RWS) indicates how many control packets can be queued for processing; smaller numbers are better for networks that cannot handle large bursts of traffic while large numbers allow more sessions (calls) to be processed faster. The default varies by platform, but is 1024 in the CSR1000v as the command shows this value as the “Remote RWS”. This value also does not need to match on both ends of the tunnel, so we configure 2048 on CSR5 while the peer uses the default value. As with all L2TP signaling changes in the L2TP-class, this will reset the session. Notice that we can also reference tunnels by “name”, which is the hostname. We specify the remote and local tunnel names versus the 32-bit unsigned integer tunnel IDs.

```
! CSR5
l2tp-class L2TP_ADVANCED
receive-window 2048
```

```
R5#show l2tp tunnel all remote-name R8 R5 | include RWS
Local RWS 2048, Remote RWS 1024
```

Another interesting component of L2TP sessions (calls) is interworking. With EVC an AToM, we could manipulate the VLAN tags with great flexibility. Without EVC, we can’t do much at all, which means interworking between disparate layer 2 technologies is important. The session type is “VLAN”; since the AC is running dot1q, the VLAN tags are carried across the PW. This is different than interworking for “Ethernet” which does not include the VLAN tags. The output below shows the session QinQ tag stack

{3554 1014}. This behaves a lot like VLAN interworking, but technically interworking is not configured. The detailed output does not make mention of interworking at all.

```
R5#show l2tp session interworking
L2TP Session Information Total tunnels 1 sessions 1
LocID      TunID      Peer-address      Type IWrk Username, Intf/
                                      Vcid, Circuit
3487589522 621690661 55.0.0.8          VLAN -           10141, Gi2.1014:3554/1014
```

```
R5#show l2tp session all vcid 10141 | section Ethernet Vlan
Session Layer 2 circuit, type is Ethernet Vlan, name is
GigabitEthernet2.1014:3554/1014
  Session vcid is 10141
  Circuit state is UP
    Local circuit state is UP
    Remote circuit state is UP
```

XRv4 will send small packets to CSR10 so we can keep the capture short. The VLAN tag stack of packets going from XRv4 to CSR10 (10.10.14.14 to 10.10.14.10 in yellow) is {3554 1014} in green as expected. The reply traffic is highlighted with the same colors and shows tag stack {3580 3504}. These are the correct VLAN encapsulations for each AC. L2TP is smart enough to remove those received tags before delivering the traffic to the forwarding process, which pushes the proper local AC tags on egress. With EFPs, we would normally have to explicitly pop or push the correct tags bidirectionally.

```
RP/0/0/CPU0:XRv4#ping vrf LINE 10.10.14.10 size 64
Type escape sequence to abort.
Sending 5, 64-byte ICMP Echos to 10.10.14.10, timeout is 2 seconds:
!!!!
Success rate is 100 percent (5/5), round-trip min/avg/max = 1/4/9 ms
```

```

Carrying VLAN tags was the default transport type to be negotiated, but there isn't a good reason to include VLAN tags in the tunnel. The interworking type must match between sites, but we can configure "Ethernet" interworking on all L2VPN contexts and PW classes to save 4-8 bytes of encapsulation. This configuration, like sequencing, is a session parameter, not a tunnel parameter, as this has nothing to do with the L2TP signaling.

```

! CSR5 and CSR8
l2vpn xconnect context XC_XRV14_R10
interworking ethernet

! CSR6
pseudowire-class PW_1014
interworking ethernet

```

Checking CSR5, the type is still VLAN, but interworking for Ethernet is now enabled.

```

Remote circuit state is UP

```

The packet capture is the same as before, except with 8 bytes less overhead in each packet. Notice there are no dot1q tags present anywhere in the payload. The IP addresses are highlighted again, and the Ethertype for IP (0x0800) is all that remains. Interworking effectively removed the VLAN tags from the tunneled Ethernet frame as both L2TP endpoints agreed that this forwarding mechanism was supported.

Other minor IP header options exist also, much like those found in a GRE tunnel configuration. Examples include TTL, TOS, and DF-bit handling. We can configure L2TP to reflect the tunneled TOS values into the L2TP header, or hardcode it to a specific value, where setting to 0 (clearing it completely) is the default behavior. The TTL represents the tunnel TTL which can be useful for limiting the “length” of a tunnel. The DF-bit prevents fragmentation of the post-encapsulated tunnel traffic in the network core. Fragmentation is generally undesirable and forcing the L2TP endpoints to fragment traffic will decrease performance significantly. These parameters do not need to match in either direction. CSR8 sets the TTL for all outgoing packets to 8 for both circuits, and sets the DF-bit. For CSR5, the TOS is reflected, and for CSR6 it is hard-coded to CS3. The remote L2TP routers use TTL 16 in the reverse direction, and CSR5 is the only router not setting the DF-bit. The QoS settings are matched both ways per PW.

```

! CSR8
template type pseudowire TMP_L2TP_PW
ip ttl 8
ip dfbit set

interface pseudowire10141
description PW TO CSR8
ip tos reflect

interface pseudowire10142
ip tos value 96

! CSR5
interface pseudowire10141
ip ttl 16
ip tos reflect

! CSR6
pseudowire-class PW_1014

```

```

ip dfbit set
ip tos value 96
ip ttl 16

```

Sending small packets from CSR10 to XRv4, we set the DSCP to CS1. This is reflected in the L2TP header as show below in yellow. The TTL arriving is 7 (green), where CSR8 initially set it to 8 and XRv1 decremented it. The TTL on the return packet is 0x10, which is 16 in decimal, as CSR5 is configured to use this value. Lastly, the DF-bit is set on traffic coming from CSR8 (0100 in binary) while it is cleared on packets coming from CSR5. Memorizing the exact position of the DF-bit in the IP header is unnecessary but I illustrate it here to prove that the configuration worked. The source/destination IP addresses inside the VPN are shown in pink.

We will shut down the PW on CSR5 so that the failover circuit to CSR6 is activated (not shown). We also switch over XRv4 to use this circuit by shuffling the IP addresses between interfaces (L2 bridging isn't supported, so it's an artificiality of the test). Capturing bidirectionally on CSR6, we see slightly different behavior in some places. Most notably, the L2TP header DSCP is now CS3 (hard coded) versus CS1 (original customer value). This is because the configuration specified a fixed value and is not reflecting TOS from the inner header to the outer header. The DF-bit is set in both directions, as configured (cyan). The asymmetrical TTL behavior is identical to before as the configurations on CSR5 and CSR6 are identical here.

Regarding status, you can configure CSR8 to show both the primary and secondary links up at the same time. This allows the head router, CSR8, to advertise UP status to CSR6 so that both tunnels can show up. The xconnect process ensures only the primary one forwards traffic. Normally, CSR6 shows the link as down due to the status signaling, even though the L2TP tunnel is up.

```

R6#show l2vpn service xconnect all | begin Interface
  Interface          Group          Encapsulation          Prio  St  XC  St
  -----          -
VPWS name: Gi2.3546-3546, State: DN
  Gi2.3546           left           Gi2.3546:3546(Eth VLAN)  0      UP  DN
  pw100002           right          55.0.0.8:10142(L2TP)    0      DN  DN

```

We will make the change on CSR8 so that it views the topology as dual-homed.

```

! CSR8
template type pseudowire TMP_L2TP_PW
  encapsulation l2tpv3
  status peer topology dual-homed

```

Now, CSR6 sees the link as UP and relies on the customer redundancy protocol.

```

R6#show l2vpn service xconnect all | begin Interface
  Interface          Group          Encapsulation          Prio  St  XC  St
  -----          -
VPWS name: Gi2.3546-3546, State: UP
  Gi2.3546           left           Gi2.3546:3546(Eth VLAN)  0      UP  UP
  pw100002           right          55.0.0.8:10142(L2TP)    0      UP  UP

```

CSR8 still treats this like a backup link, but allows CSR6 to remain online. The assumption is that there is some kind of redundancy protocol at the remote end; in our case, we are just changing interfaces for testing, but this is a valid configuration. The same holds true for AToM but is demonstrated here.

```
R8#show l2vpn service xconnect name XC_XRV14_R10 | begin Interface
```

Interface	Group	Encapsulation	Prio	St	XC	St
-----	-----	-----	----	--	-----	-----
VPWS name: XC_XRV14_R10, State: UP						
Gi2.3504		Gi2.3504:3580/3504 (Eth VLAN)	0	UP	UP	
pw10141	R10_XRV14	55.0.0.5:10141 (L2TP)	3	UP	UP	
pw10142	R10_XRV14	55.0.0.6:10142 (L2TP)	6	SB	IA	

Next, we will examine a static L2TP PW configuration. Just like with AToM, we can manually configure a PW between two sites but it requires the administrator to specify some low-level details. For AToM, this included local and remote PW labels. Here, it includes local and remote session IDs. The idea is the same as these IDs are normally negotiated when L2TP signaling is used. Additionally, we define local and remote “cookies”. These are additional guarantees that a packet along L2TP session is destined for the proper node. When packets are sent from one router to another, the remote session ID and remote cookie are included in the header. Below, I selected values easy to read in hex, making the EPC easier to comprehend. The session IDs are 0x4444 and 0x8888 for CSR4 and CSR8, respectively. The cookies are 0x8C8C and 0x4C4C for CSR8 and CSR4, respectively. I used untagged interfaces (dedicated) ports for this as static L2TP is not documented to work with VLAN mode. Interworking of any kind is also unsupported. CSR8 uses the new L2VPN CLI commands while CSR4 uses the legacy xconnect configuration.

```
! CSR8
interface pseudowire110
  description PW R10-R1
  encapsulation l2tpv3
  neighbor 55.0.0.4 110
  signaling protocol none
  ip local interface Loopback0
  l2tp id 34952 17476
  l2tp cookie local 4 35980
  l2tp cookie remote 4 19532

interface GigabitEthernet3
  description PW TO CSR1

l2vpn xconnect context XC_R10_R1
  member pseudowire110
  member GigabitEthernet3

! CSR4
pseudowire-class PW_L2TP_STATIC
  encapsulation l2tpv3
```

```

protocol none
ip local interface Loopback0

interface GigabitEthernet3
description PW TO CSR10

```

A quick checking of the interworking shows that it is disabled, but the session type is ETH and not VLAN. When shown on CSR8, the difference is clear, as the other circuits are of type VLAN but are using Ethernet interworking to strip dot1q tags from tunneled Ethernet frames, as discussed earlier. The type is shown as ETH because a dedicated physical interface is used for this test.

```

R8#show l2tp session interworking
L2TP Session Information Total tunnels 2 sessions 3
LocID      TunID      Peer-address  Type IWrk Username, Intf/
          Vcid, Circuit
1428121045 1008940922 55.0.0.6      VLAN ETH  10142, Gi2.3504:3580/3504
4015951127 1455401177 55.0.0.5      VLAN ETH  10141, Gi2.3504:3580/3504
34952      n/a        55.0.0.4      ETH -     110, Gi3

```

We can also check the session details. Specifically, we will look at the cookie and cached encapsulation information. We can see the 4-byte cookie values in hex, which is what we expect to see in the packet captures as well. The IP header encapsulation is shown below, which includes the remote session ID and remote cookie. Immediately following the remote cookie would be the payload; in this case, the beginning of the destination MAC address in the tunneled Ethernet frame. This can be very helpful for manually verifying captured packets via EPC.

```

R8#show l2tp session all vcid 110 | section cookie|cache
Session cookie information:
  local cookie, size 4 bytes, value 00 00 8c 8c
  remote cookie, size 4 bytes, value 00 00 4c 4c

```

```

FS cached header information:
  encaps size = 28 bytes
  45000014 00000000 ff734d6b 37000008
  37000004 00004444 00004c4c

```

As expected, we see no L2TP signaling packets of any kind. Since CSR4 has only one static PW, it has never participated in L2TP signaling, so all control counters are zero. This might be confusing or a false negative when troubleshooting L2TP if you don't understand how static PWs operate.

```

R4#show l2tp counters tunnel
Global L2TP tunnel control message statistics:

Capturing bidirectionally on CSR4, we can see packets entering CSR4 with its local session ID and cookie values (0x4444 and 0x4C4C). When CSR4 sends traffic to CSR8, it uses the remotely configured session ID and cookie values (0x8888 and 0x8C8C). If any of these parameters do not match, the L2TP process discards the packets upon receipt. Just like PW labels, these unique values serve as demultiplexers so the egress PE knows how to map the packet to the proper customer/service. These session ID and cookie fields are shown in yellow. Notice that the traffic was sent with DSCP CS2, yet it was not copied into the L2TP header. This is because TOS reflection was not configured (it could have been) and the default action is to use DSCP 0 (green).

Recall that we have RIPv2 running across these P2P circuits, so CSR1 should have reachability to XRv4 and vice versa. Traffic hairpins through CSR10, but connectivity is achievable. For brevity, we will test it in one direction.

Last, we will quickly look at L2TP on XRv. We know L2VPN isn't going to work, but we expect the control-plane to converge as it did for MPLS-encapsulated PWs. The configuration itself is very straightforward, using the same general concepts as XE. CSR6 creates a dummy AC and PW to peer with XRv3.

! XRv3

Unfortunately, due to a Cisco bug, the session never establishes, even if the control tunnel does. L2TP event debugging on XRv3 reveals an issue with the ICRP message (incoming-call-reply) missing some AVPs. The bug **CSCus72718** clearly states: *“L2TPv3 session between 2 devices is stuck at pending state, wiccn and wicrp respectively. Following error might be observed in the [debug] logs of older release: Missing AVPs in ICRP Cisco Core AVP Pseudo Wire Type missing.*

```

```

I assume the ‘W’ before the ICCN and ICRP messages in the bug log stand for “waiting”. We can verify this by checking CSR6. Sure enough, we see exactly that message, which leads me to believe this is bug related and will not work on the current version of software. The bug specifically cites version 15.4(1)T2.2, which is an IOS issue, not an IOS-XR or XRv-specific issue. The version currently in use is shown below (newer), but this bug is recent and still open. The details of the L2TP session show a functioning control channel and a partially-built session.

```
R6#show version | include 15\.4

```

The show commands and outputs on XRv are almost identical. Some basic outputs are shown below. The tunnel is up, but the session is stuck. Notice that XRv3 is waiting on the ICRP (incoming-call-reply). This means that XRv3 sent the initial ICRQ (incoming-call-request) and thus initiated the session. It is waiting for the “SYN ACK” while CSR6 is waiting for the final “ACK”, to use TCP terms. We can prove it by checking the details and seeing the session is locally initiated.

Additional Reading – Reference configurations "l2vpn-l2tp"

32.2.2 E-LAN and E-TREE using OTV

Overlay Transport Virtualization (OTV) is a MP2MP L2VPN technology that is typically used as a “layer 2 stretch” for DCI (data center interconnection) designs. Unlike MPLS L2VPNs, this is a customer-side protocol, and cannot be enabled on a router with any MPLS features enabled. Like DMVPN, it is not a SP technology directly, but could be used by an SP if the CPE is SP owned/managed. OTV introduces many improvements over VPLS, including simplified OAM/provisioning, better handling of BUM traffic, and no requirement for MPLS transport. It is currently Cisco-proprietary but standardizing drafts are in progress. The diagram below shows a small SP network which uses draft Rosen (MVPN profile 0) for customer multicast transport; this is the only profile currently supported in XRv. There are three customer sites, two of which are dual-homed. The customer has an IP-only MPLS L3VPN. CSR1, CSR2, and CSR7 represent hosts on two different VLANs using QinQ for testing purposes. The goal is to stretch these two VLANs over the SP network between all sites.

The OTV configuration is very straightforward. Each site must have a site-ID which should be common for each OTV-speaker at the site, as well as a site bridge-domain (site VLAN in Nexus) which is used for intra-site communication. An Authoritative Edge Device (AED) is elected at each site and is loosely

analogous to a PIM Bidir designated forwarder (DF). It is responsible for sending/receiving traffic to/from the overlay. Other routers are in place for redundancy. The configuration on all OTV routers is almost identical and only CSR5 is shown for brevity. All routers must agree on the control-group within an overlay as this is used for dynamic discovery; XRv2 is the RP within the MVPN for VRF OTV. This is similar to the MDT default-group used with MVPN profile 0. The data-groups, much like MDT data-groups, do not have to match, and are spawned for non-LL multicast flows. EFPs configured on the LAN-side are configured similarly on the OTV interface and bridged together with BDs. The EFPs must ensure at least one VLAN tag remains on the frames so OTV can properly classify it; for this reason, we use QinQ and pop only the topmost tag. The site-ID and site-BD relate to the AED configuration; CSR6 and CSR5 will have identical values so the two can participate in the AED election. The OTV join-interface is the upstream, SP-facing link where IGMPv3 joins are issued. IGMPv3 technically isn't required unless you are using SSM, which we are not, but PIM passive is enabled to allow the router to process/forward multicast. Because there is no PE-CE routing, a static default is configured on each CE router.

```

```

As a quick note before starting with OTV, all of the flexibility with EFP/EVC VLAN manipulation appears to be supported. The configuration above is a simple approach; I use a more convoluted approach on CSR4/CSR9 to demonstrate the EVC CLI usefulness again. CSR2 is sending traffic to VLANs 101 and 102 when it should be 100 and 200. This is also inside QinQ; CSR4 and CSR9 can do a 2:1 mapping to change those tags to 100 or 200, which stages the proper frame for OTV to process. Provided the symmetric keyword is used, or the proper VLAN tags are pushed in the opposite direction, this approach works for VLAN translations between data centers in conjunction with OTV. The higher layer protocols (IP, IPv6, etc) must still be able to communicate, such as being in the same subnet, etc. The OTV site-BD (AED elections, etc) is still required, as always. CSR4 uses both the “symmetric” and manual strategies between the different “stretched” VLANs. The OTV BD and site-ID match between CSR4 and CSR9 as well, which is critical for the AED election.

```

! CSR4
otv site bridge-domain 3549
otv site-identifier 0000.0000.0004

interface GigabitEthernet2
  service instance 100 ethernet
  encapsulation dot1q 3529 second-dot1q 101
  rewrite ingress tag translate 2-to-1 dot1q 100
  rewrite egress tag translate 1-to-2 dot1q 3529 second-dot1q 101

service instance 200 ethernet
  encapsulation dot1q 3529 second-dot1q 102
  rewrite ingress tag translate 2-to-1 dot1q 200 symmetric
  bridge-domain 200

service instance 3549 ethernet
  encapsulation dot1q 3549 exact
  bridge-domain 3549

```

Assuming a near-identical configuration on the other OTV routers, we can verify the adjacencies are up. The internal system-ID is really an IS-IS NET which was auto-generated by the OTV process. The site-ID was manually configured and should be unique across sites, but common within a site. From CSR9’s perspective, we can see the other 4 OTV routers.

```

R9#show otv adjacency
Overlay Adjacency Database for overlay 1

```

Hostname	System-ID	Dest Addr	Site-ID	Up Time	State

R3	001e.f675.ce00	10.3.12.3	0000.0000.0003	00:20:30	UP
R6	001e.bd8f.6000	10.6.10.6	0000.0000.0005	00:20:31	UP
R4	001e.4977.7c00	10.4.13.4	0000.0000.0004	00:13:37	UP
R5	001e.14ff.9b00	10.5.14.5	0000.0000.0005	00:20:30	UP

We can change the IS-IS NET for routers to make the system-ID more readable, but since OTV carries the hostnames, it isn't really helpful. We also must shutdown the Overlay and the site BD to change the NET. We will also enable IS-IS adjacency logging, which is off by default, on CSR6 as an example. This only shows neighbors that are within the "Site" process which is used for AED elections and intra-site signaling, not overlay peers.

```
! CSR6
otv isis Site
 net 00.0000.beef.0006.00
 log-adjacency-changes all
```

```
%CLNS-5-ADJCHANGE: ISIS (Site): Adjacency to 001E.14FF.9B00 (OTV-Site) Up,
new adjacency
```

We can see the new NET by checking another router's adjacencies.

```
R3#show otv adjacency
Overlay Adjacency Database for overlay 1
```

Hostname	System-ID	Dest Addr	Site-ID	Up Time	State
R9	001e.e58c.1f00	10.9.13.9	0000.0000.0004	00:25:18	UP
R4	001e.4977.7c00	10.4.13.4	0000.0000.0004	00:18:24	UP
R5	001e.14ff.9b00	10.5.14.5	0000.0000.0005	14:05:37	UP
R6	0000.beef.0006	10.6.10.6	0000.0000.0005	00:01:26	UP

CSR5 and CSR6 will not see each other since the SP is not providing L3VPN service between them since they are in the same site. This does not affect OTV directly, provided CSR5 and CSR6 cannot be the ISIS DIS. Since they don't have direct connectivity to all nodes, they should never be elected DIS; this OTV design is similar to E-TREE where CSR5 and CSR6 are leaves. We can configure many ISIS parameters under the OTV interface, to include authentication. We can also remove the hello padding to save some WAN bandwidth cost. We will make these modifications quickly and verify them.

```
! CSR5 and CSR6 only
interface Overlay1
 otv isis priority 0
```

```
! All OTV routers
interface Overlay1
 no otv isis hello padding
 otv isis authentication mode md5
 otv isis authentication key-chain KC_ISIS_AUTH
 otv isis priority 0
```

We can see quite a bit of raw IS-IS information within the OTV process. Looking at the adjacencies, we have L1 adjacencies over the Overlay interfaces as well as the OTV-Site BD. In this case, we know CSR5 and CSR6 cannot form adjacencies over the Overlay due to lack of L3VPN connectivity, but within an entirely different IS-IS process, they form a neighbor to exchange AED information across the OTV BD. We can see both are broadcast networks since the Circuit-ID lists the IS-IS DIS (non-zero N-selector).

```
R5#show otv isis neighbors
```

Dual-homed sites 4 and 5 will conduct an AED election on a per-VLAN basis. This allows for resiliency and load-sharing, assuming that each router selects half of the VLANs. The following debug on CSR5 summarizes the process; the routers compute hashes based on the VLAN ID and determine who will be the AED. In this case, CSR5 said that it is both the old and new AED, possibly because it was configured first. It seems that any custom NET will break the AED election. Neither router participates, and no one will become AED, even after a reload. This totally breaks connectivity, so I have removed the NET configuration on CSR6 as a workaround (not shown). Both routers claim to be inactive for all VLANs. We confirm the NET is no longer the custom string on CSR6.

```
R6#show otv isis protocol
```

Tag Overlay1:

IS-IS Router: Overlay1

```

System Id: 001E.BD8F.6000.00 IS-Type: level-1
Manual area address(es):
    00

    00
Interfaces supported by IS-IS:
    OTV-Site

```

Now, we can examine the AED election. I've stripped some of the chatty debugs to focus on the important aspects.

```

CSR5#debug otv aed-svr-elec
CSR5#debug otv aed-svr-req
OTV-APP-AED-SVR-REQ: otv_aed_election_type_hash for vlan 100

OTV-APP-AED-SVR-REQ: otv_enforce_aed_svr_transaction: me old aed1, me old bkp
0, me new aed 1 me new bkp 0

```

In case you miss the debugs, you can see the AED per VLAN after the election completes. In our case, we were unfortunate not to have any load sharing based on our VLAN IDs. CSR5 is the AED for both VLANs at site 5 which is why there is an asterisk next to its hostname. CSR9 is not the AED for either VLAN and its state is inactive; it cannot forward traffic into the overlay.

```

Total VLAN(s): 2					

We can verify that “MAC routing” is working correctly. CSR5 learns and installs all the remote MAC addresses since it is the AED for both VLANs. CSR6 only installs the remote routes. The output specifically says how the route was learned: IS-IS from a peer or a local BD EFP with service-instance number. We can see the AD of local routes is 40 and remote routes is 50, which can prevent suboptimal routing. Because VLAN 100 and VLAN 200 have the same MAC addresses, I just shown VLAN 100. For CSR6, it only has remote routes for VLAN 200. Since it isn’t the AED, it cannot learn local MAC addresses on its EFP.

```
R5#show otv route vlan 100
```

For additional detail, we can look at the IS-IS VLAN information. I removed the first column, which was “cluster-ID” and always zero. We saw the CSR6 NET earlier as 001E.BD8F.6000, which is “Backup AED” for many of these routes, in both VLANs, since it is not the AED for either (yellow). Below it, we see more backup paths but at site 4; we presume this is the non-AED router (green). We confirm that the system-ID belongs to CSR9 who is indeed not the AED, as we saw earlier. Most of the other entries in the table all show “active” as those are the AED-owned.

```

For even more detail, we can look at the raw IS-IS LSPs and see the TLVs carrying the MAC routes. From CSR4's perspective, we will examine CSR9's LSP for unicast routing. CSR4 is the AED for both VLANs, which is made clear in the LSP. The "ED" (end device) stanza lists the two nodes, CSR4 and CSR9, by their node ID. CSR9 is not the AED (AED: 0) but is the backup AED (Back-up AED: 1) for these VLANs. Like Segment Routing labels, contiguous VLANs can be grouped with step sizes to keep the LSPs smaller. The final AED stanza shows that CSR4 is the AED and CSR9 is the backup AED, once again.

When we looked at VPLS, we ignored the AED column in the BD output when we looked at the MAC tables there. This time, the bit actually means something since the AED relates to OTV. We can see CSR5 is the AED for everything in VLAN 100, and can learn the local MACs via the EFPs. CSR6, on the other hand, marks AED for the broadcast address and the IS-IS routes, but not the local EFP ones. So technically, CSR6 does learn those MAC addresses, but the lack of the AED bit set means they cannot exist in the OTV routing table. CSR1's for example, has a MAC address ending in 1AAA. Only CSR5 can forward traffic for CSR1.

```

It is very rare that one would need to troubleshooting this level of detail with OTV. Below are some additional summary commands to help determine if OTV is working at a glance. Looking at the OTV VLANs, routes, and adjacencies are common and have already been examined. These additional commands show the state of the interfaces, multicast groups, and other basic information. Future versions of OTV will support UDP encapsulation as the current model is GRE. The “Fwd-capable” and “Fwd-ready” fields must be “Yes” or else OTV cannot work. Ensure the site-BD is up and the EFP is configured properly or else OTV cannot start. This is true even at single-homed sites.

```
R3#show otv
Overlay Interface Overlay1
  VPN name           : None
  VPN ID             : 5
  State              : UP

State            : UP
[snip]
```

There is a Tunnel0 shown here despite us never configuring that. We can see the configuration of it and notice that it is a mGRE tunnel. The tunnel endpoints include all of the other sites, plus the multicast group used for OTV signaling. I assume this is how OTV is able to “send” multicast traffic without having to implement draft-Rosen under the hood.

```
R3#show derived-config interface tunnel0

```

The question then arises as to how OTV is able to use a single overlay to carry multiple VLANs. My first guess was to use the 4-byte GRE tunnel key as a multiplexer to encode the VLAN information, but the tunnel key feature is not enabled.

```
R3#show interface tunnel0 | section Tunnel proto
Tunnel protocol/transport multi-GRE/IP
  Key disabled, sequencing disabled
  Checksumming of packets disabled
```

The secret is using an MPLS label as a shim. This is the real reason why MPLS cannot be configured on an OTV router, for the “real” MPLS process would be confused. Reusing MPLS encapsulation was a very smart move so that a new shim did not need to be invented. We can see the encapsulation on CSR5 by

capturing outbound as CSR1 sends packets across VLAN 100 and VLAN 200 to CSR7. The first 18 bytes of both packets is identical and represents the destination and source MAC addresses of the frame (CSR5 to XRv4) inside VLAN 3554 (yellow). The next 20 bytes represents an outer IP header using the GRE IP addressing made by the dynamic tunnels (10.5.14.5 to 10.3.12.3) in green. The next 4 bytes is the GRE header which has no fancy options enable, but specifies the tunneled protocol as MPLS multicast in cyan (it obviously isn't multicast, though). The MPLS label values for the two packets are 132 and 232, respectively, corresponding to VLANs 100 and 200 (pink). I assume that the VLAN-to-label mapping just arithmetically adds 32 to the VLAN ID to derive a label value; likely to steer far away from the reserved MPLS labels (0 to 15). Inside MPLS, we have the original Ethernet frame with no dot1q tags as OTV has no reason to carry it, since the VLAN was signaled inside the MPLS label. This puts the VLAN closer to the "front" of the packet rather than making the router look into the GRE payload to find the first dot1q tag. The tunneled IP source/destination addresses evaluate to 10.0.100.1 to 10.0.100.7 for VLAN 100, and 10.0.200.1 to 10.0.200.7 for VLAN 200. In summary, OTV is using 42 bytes of encapsulation: 20 for IP, 4 for GRE, 4 for the MPLS shim, and 14 for the inner Ethernet header. This doesn't account for the outer-most layer 2 encapsulation which may vary. Of course, the MPLS PEs will impose more MPLS labels onto this traffic since it looks like regular IP unicast traffic, so MTU calculation is important.

Multicast over OTV is similar. Like draft-Rosen, it will encapsulate multicast into GRE but maintain a multicast destination using an address from its range of data-groups. We generate some bogus multicast traffic on CSR1 in both VLANs to test it. Right away, we see it doesn't work, as OTV is a smart multicast router. It has a simplified display for the MRIB, but it reads like the normal IOS MRIB. We can see that OTV is aware of a source on each VLAN, but no receivers, so it does not deliver the traffic anywhere. With VPLS, every node would have received those pings despite showing no interest.

```
R1#ping 225.1.2.3
```

```

R5#show otv mroute vlan 100 source 10.0.100.1 group 225.1.2.3
OTV Multicast Routing Table for Overlay1
Bridge-Domain = 100, s = 10.0.100.1, g = 225.1.2.3
Incoming interface list:
  Service Instance 100, GigabitEthernet2, 0050.56a9.1aaa
Incoming interface count = 1, Outgoing interface count = 0

R5#show otv mroute vlan 200 source 10.0.200.1 group 225.1.2.3
OTV Multicast Routing Table for Overlay1
Bridge-Domain = 200, s = 10.0.200.1, g = 225.1.2.3
Incoming interface list:
  Service Instance 200, GigabitEthernet2, 0050.56a9.1aaa
Incoming interface count = 1, Outgoing interface count = 0

```

We configure CSR7 to listen to this group on both VLAN 100 and 200. CSR5 learns this through OTV control messaging (IGMP snooping style). We can also verify the MRIB by VLAN or BD. Both are shown below.

```

R5#show otv mroute bridge-domain 100
[snip]
Bridge-Domain = 100, s = *, g = 225.1.2.3
Outgoing interface list:
  Overlay1, R3
Incoming interface count = 0, Outgoing interface count = 1

R5#show otv mroute vlan 200
[snip]
Bridge-Domain = 200, s = *, g = 225.1.2.3
Outgoing interface list:
  Overlay1, R3
Incoming interface count = 0, Outgoing interface count = 1

```

Because these are production flows, we expect that some multicast data-groups were allocated to support it. We can verify this within OTV as well. The output is very clean and shows the inner (active) source and destination followed by the tunnel (delivery) source and destination.

```

R5#show otv data-group
No remote data-group mappings
Flags:  D - Local active source dynamically detected
        S - Local active source statically configured
        J - Data group has been joined in the core
        U - Data group has not been joined in the core

```

```

Local Active Sources for Overlay1

```

BD	Active-Source	Active-Group	Delivery-Source	Delivery-Group	Flags
100	10.0.100.1	225.1.2.3	10.5.14.5	239.0.1.0	D
200	10.0.200.1	225.1.2.3	10.5.14.5	239.0.1.1	D

Below are two packets captured on egress from CSR5 for additional verification. For consistency, the same fields are highlighted the same colors as they were for the unicast flow. The outermost layer 2 header is yellow, the outer IP header is green, the GRE header is cyan and the MPLS shim header is cyan. All of this is the same as it was before with the exception of the destination GRE address. Two new data-groups have been spawned to support these multicast flows: 239.0.1.0 for VLAN 100 and 239.0.1.1 for VLAN 200.

What is very interesting is that on CSR3, it sees data-groups allocated by CSR6 also. Although not an AED, CSR6 still allocates groups because it gives the remote routers time to join them. Just like all the OTV routers joined the control-group, CSR3 dynamically issue joins for OTV data-groups as it learns them via IS-IS.

If we check the group membership, we can see IGMPv3 INCLUDE joins are sent. This would work great for SSM, but ASM is also supported and is what we are currently using. It is good to know that this behavior is automatic, provided that IGMPv3 is enabled on the PE-CE link and OTV is configured properly. If the SP network suddenly decided that 239.0.0.0/8 was the SSM range, OTV would still work.

The result of this join means that XRv2, as the RP, will be able to process register messages for this C(S,G) within the core. CSR5 as a source actually has a valid (S,G) entry with RPF towards the ingress PE (XRv4) and an OIL including the PE-CE link to CSR3. The second (S,G) relates to CSR6; even though the state is (S,G), a register was never received, and XR is just recording it this way due to the IGMPv3 join,

even if the group is not SSM. The “RR” flag means register received and this does not apply to CSR6, since no traffic was sourced from that node. The OIL is populated via the IGMPv3 join but nothing more. Again, this is OTV doing as much as possible to support HA for the overlay without wasting bandwidth.

```

OTV also introduces multicast LSPs within IS-IS to carry this information. We can also see the raw information in the IS-IS LSPDB. From CSR6, we check its local “mgroup” LSP. This information carries the VLAN, source, group, and some other data. Sources of 0.0.0.0 represent (*,G) state information; in this case, we see the AutoRP mapping-agent (*,G) state. Of greater importance are the (S,G) states for the VLAN 100 and VLAN 200 sources to group 225.1.2.3. The LSP also contains the “ds” and “dg”, or delivery-source and delivery-group, which is the post-encapsulation addresses. It would be the MDT addressing within the context of MVPN profile 0, as an example. This LSP is how CSR6 signals to CSR3 that it is also an “Active source” for this (S,G).

```

```

CSR6 is also aware that CSR3 has receivers for group 225.1.2.3 in the first place. Otherwise, OTV will not send traffic into the overlay if there are no receivers, so the signaling works both ways. Like BGP c-multicast signaling in MVPN, OTV uses IS-IS for c-multicast signaling.

```
R6#show otv isis database mgroup R3.00-00 verbose

        0.0.0.0
```

Having CSR6 signal the groups is good, but having it duplicate traffic is not. The control-plane seems to indicate traffic is not being duplicated. We can verify that only CSR5 is actually sending traffic into the core for additional certainty. CSR6 just shows some control traffic while CSR5 shows the data packets, which we analyzed earlier. This proves that the AED rule still applies, but for HA purposes, CSR6 can tell the remote node which data-groups to expect. Even if CSR3 is not receiving the traffic, at least we would know that the sending side functions properly. CSR6 is not sending that traffic since it is not the AED, which is ideal.

```
R5#show monitor capture CAP buffer brief
```

#	size	timestamp	source	destination	protocol
0	160	0.000000	10.5.14.5	-> 239.0.1.0	GRE

33. Describe, implement, and troubleshoot Unified MPLS and CSC

33.1 Carrier Supporting Carrier (CSC)

Carrier Supporting Carrier (CSC) or Carrier's Carrier is another L3VPN variation. Similar to UMPLS, this relies on BGP labeled-unicast to provide an additional shim for transparent between a distinct "core" network and disparate "aggregation" networks. Unlike UMPLS, however, this is designed for multiple service provider interaction. If a tier 2 ISP (one without an infrastructure spanning end-to-end) requires transport between customers at remote sites, it can rely on a tier 1 ISP (one that does). Smaller ISPs may use this technique by essentially buying transit bandwidth from a tier 1 ISP and running their own MPLS services independent from the provider. The provider simply provides ordinary L3VPN transport for the tier 2 ISP, with the addition of BGP labeled-unicast in the customer VRF for additional label exchange. Like UMPLS, this supports both L3VPN and L2VPN. Only MVPN profile 0 is supported, and for variety, this design uses PIM SSM with that profile. This MVPN model works on XRv which is convenient as well. The diagram is shown below which shows the tier 1 and tier 2 ISP networks.

In terms of inter-AS transit links, these should be viewed just like normal L3VPN PE-CE customer links. All of the same concepts apply, such as BGP AS-override. At the 4 touch points, 3 of them use BGP + Label (XRV12, CSR8, and CSR9) and one of them uses OSPF+LDP (CSR1). BGP is by far the more popular and better choice in this kind of design, but I demonstrate IGP+LDP as well, which makes things more complex. First, we will examine the basic configuration in the core carrier, which is BGP AS 49 running IS-IS with MPLS-TE supported. The most basic L3VPN component configurations are not shown here. A quick check on CSR1 shows 5 routers in level-2, which is correct given the diagram.

```
CSR1#show isis database level-2
Tag 49:
IS-IS Level-2 Link State Database:
LSPID                LSP Seq Num  LSP Checksum  LSP Holdtime  ATT/P/OL
CSR1.00-00            * 0x000000DB  0x5D72        1189          0/0/0
CSR3.00-00            0x000000DC  0xC00A        588           0/0/0
CSR8.00-00            0x000000DF  0x821E        1060          0/0/0
CSR9.00-00            0x000000DA  0x2BCD        448           0/0/0
XRV12.00-00           0x000000E1  0xFB2C        386           0/0/0
```

We can see the affect of some link cost changes on CSR8 by checking the IS-IS topology; traffic from CSR8 to XRV12 prefers CSR3 and to CSR9 prefers CSR1. This is to have more “hops” in the core carrier for additional feature testing (TE, etc).

```
CSR8#show isis topology level-2
Tag 49:
IS-IS TID 0 paths to level-2 routers
System Id            Metric      Next-Hop  Interface  SNPA
```

CSR1	10	CSR1	Gi2.518	000c.29fb.a339
CSR3	10	CSR3	Gi2.538	000c.29d7.81fe
CSR8	--			
CSR9	20	CSR1	Gi2.518	000c.29fb.a339
XRv12	20	CSR3	Gi2.538	000c.29d7.81fe

The BGP topology is simple as XRv12 is a RR for the VPNv4 and IPv4 MDT AFIs within the core carrier's network. A single VPNv4 route (customer PE endpoint) and IPv4 MDT route (local PE endpoint) are learned from each peer.

```
RP/0/0/CPU0:XRv12#show bgp vpnv4 unicast summary | begin ^Neighbor
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down  St/PfxRcd
1.1.1.1        0    49    9383    8902        45    0    0  00:29:11      1
8.8.8.8        0    49    9366    8892        45    0    0  00:29:12      1
9.9.9.9        0    49     716     686        45    0    0  00:29:12      1
```

```
RP/0/0/CPU0:XRv12#show bgp ipv4 mdt summary | begin ^Neighbor
Neighbor      Spk    AS  MsgRcvd  MsgSent    TblVer  InQ  OutQ  Up/Down  St/PfxRcd
1.1.1.1        0    49    9393    8911        13    0    0  00:30:47      1
8.8.8.8        0    49    9376    8901        13    0    0  00:30:47      1
9.9.9.9        0    49     726     695        13    0    0  00:30:48      1
```

Looking at the VPNv4 routes, XRv12 can see the customer PE endpoints. It also learns an MDT endpoint for each of its local PEs as well. So far this looks like an ordinary L3VPN.

```

*> 12.12.12.12/96  0.0.0.0          0          0 i
```

The difference comes with the label exchange between core carrier PE (CSC-PE) and the customer carrier PE (CSC-CE). Looking at BGP, below are configurations on XRv12, XRv13, CSR8, and CSR10. Notice that AS-override is used on the CSC-PEs so that the CSC-CEs can accept routes from across the L3VPN originating in the same AS. XRv13 advertises CSR5's loopback via BGP locally, while CSR10 runs labeled-unicast directly with CSR2 and learns the route via BGP. This means that redistribution from BGP into

IGP on CSR10 is not required, since other routers on the customer network will learn the remote PEs via BGP. That is why XRv13 redistributes these prefixes from BGP into OSPF as an alternative; both techniques work. Personally, the BGP approach is more straightforward so that routes exchanged in BGP remain in BGP, which makes the CSC design more consistent with UMPLS.

```

We can also use IGP+LDP on one set of transit links instead of BGP. The configurations for XRv14 and CSR1 depict this. I apply a prefix list to only redistribute the proper routes from OSPF into BGP to prevent loops. For example, if CSR1 learned a route to CSR2's loopback via XRv14, this would be undesirable. I also adjust the AD for OSPF external routes on CSR1 within the VRF so that the iBGP routes learned from the core are preferred over OSPF external routes originated by XRv13. These enhancements are not SP-specific and core routing techniques. LDP is also enabled on the sub-interface, and this cannot be configured in conjunction with BGP. The two are mutually exclusive as a CSC-PE can only run one CSC protocol per customer interface.

```

! CSR1
interface GigabitEthernet2.514
  ip ospf network point-to-point
  ip ospf 94 area 0
  mpls ip

ip prefix-list PL_HOST_ROUTE seq 5 permit 5.5.5.5/32

route-map RM_OSPF_TO_BGP permit 10
  match ip address prefix-list PL_HOST_ROUTE

router ospf 94 vrf T2
  router-id 0.0.0.1
  prefix-suppression
  redistribute bgp 49 subnets
  distance ospf external 210

```

```
router bgp 49
 address-family ipv4 vrf T2
 redistribute ospf 94 route-map RM_OSPF_TO_BGP
```

Below are the errors you will see if you try to enable LDP to support CSC when BGP is already configured. I also show the opposite case of having LDP configured then trying to configure BGP. With this second case, you can technically run regular BGP but not labeled BGP. Notice that the basic neighbor commands are accepted, and the parser doesn't complain until we try to enable label exchange. In real life, there would probably never be a combination of BGP and LDP used as the CSC protocol for the same customer carrier.

```
CSR1(config-subif)#mpls ip
% Failed to set CSC protocol to LDP because BGP is already configured for VRF
T2
```

```
CSR1(config-router-af)#neighbor 192.168.1.14 remote-as 94
CSR1(config-router-af)#neighbor 192.168.1.14 activate
CSR1(config-router-af)#neighbor 192.168.1.14 send-label
% Failed to set CSC protocol to BGP because LDP is already configured for VRF
T2
```

Each OSPF island has been configured with MPLS TE as well. CSR4 shows 3 routers with 3 links each (2 transit links and one stub loopback). CSR5 shows 5 total routers, which includes the 4 within the customer network and the CSC-PE of CSR1. CSR1 has one transit link only, while the other routers have several additional links. Since prefix-suppression isn't supported for primary addresses with OSPFv2 on XR at this time, each transit link's stub network is included in the LSA1. This makes the LSA's appear "fatter" than they should be, but the output is otherwise correct.

Looking at the routing on CSR2, it learns the route to 5.5.5.5/32 via BGP with a label from CSR10. This is because the ASBRs in the right side of the customer network are not redistributing the BGP routes into IGP, but are instead exchanging them via BGP. Because the route is BGP-learned, an LDP label is not used, so BGP must allocate a label for these prefixes for MPLS forwarding to work properly. This is similar to UMPLS, as discussed in the next section. We won't trace any LSPs quite yet; we see that the route to CSR10 is an IGP route, which means an additional LDP label will be pushed atop the label stack.

```

```

On the other side of the customer network, CSR5 learns the route to 2.2.2.2/32 via OSPF as an external route. This is because CSR5 is not running IPv4 BGP since the ASBRs are redistributing this BGP-learned route into IGP. ECMP is enabled for this prefix since there are ECMP paths to the ASBRs. Similar to inter-AS MPLS option C, the ASBRs can either advertise the remote PE loopbacks via BGP labeled-unicast (right side) or BGP-to-IGP redistribution (left side).

Last, we quickly verify the "service" BGP sessions (VPNv4, VPNv6, VPLS, etc) to service the customers. CSR2 is a route-reflector for those services and connects to CSR4 and CSR5. Since CSR4 does not run VPLS, that AF is not included in the route-reflection.

```

CSR6 is a CE router which is multi-homed to two PE routers, CSR4 and CSR2. It uses local preference to select best paths for traffic sent towards the SP network. For simplicity, it prefers CSR2 for VRF U1 and CSR4 for VRF U2. This is true for both IPv4 and IPv6 AFIs. The other BGP configurations are omitted, but this path-selection modification is important.

```
! CSR6
route-map RM_LPREF_200 permit 10
set local-preference 200
```

```

router bgp 65000
  address-family ipv4 vrf U1
    neighbor 192.168.102.2 route-map RM_LPREF_200 in

  address-family ipv6 vrf U1
    neighbor FD00:192:168:102::2 route-map RM_LPREF_200 in

  address-family ipv4 vrf U2
    neighbor 192.168.204.4 route-map RM_LPREF_200 in

  address-family ipv6 vrf U2
    neighbor FD00:192:168:204::4 route-map RM_LPREF_200 in

```

33.1.1 L3VPN

Now, we can begin tracing some LSPs. We will begin with CSR5 inside VRF U1 using VPNv6. Looking at the VPNv6 route to CSR6, we see two BGP paths. One originates from CSR2 and is sent to CSR5 without having been reflected, while one originates from CSR4 and is reflected by CSR2. At a glance, it may appear that CSR5 selected CSR2 as the best-path due to having a shorter cluster list length. However, that is not true. It actually picked CSR2 because the BGP RID 2.2.2.2 is less than the originator ID 4.4.4.4. These two fields are directly compared first, and the cluster list length is only compared when the originator is the same. The label used is 2003.

```

CSR5#show bgp vpnv6 unicast vrf U2 ::2:6:6:6/128

    rx pathid: 0, tx pathid: 0x0

```

Although not relevant for CSC particularly, this is an interesting BGP best-path topic. I temporarily adjust CSR4's BGP RID to a number less than 2.2.2.2 to prove that BGP works as I explained above. Now, with RID 1.4.4.4, CSR4 is the best path.

```
! CSR4
router bgp 94
  bgp router-id 1.4.4.4

CSR5#show bgp vpnv6 unicast vrf U2 ::2:6:6:6/128

      mpls labels in/out nlabel/2003
      rx pathid: 0, tx pathid: 0
```

Before continuing, I remove this BGP RID modification from CSR4 (not shown) so CSR2 is the best path again. We proved earlier that this uses label 2003 as allocated by BGP VPNv6. The next-hop is 2.2.2.2, and we find a pair of OSPF routes to this. This implies we will use the LDP labels from CSR7 and XRv14 in load-sharing fashion. The LIB reveals labels 7003 and 94005, both of which are properly programmed into the FIB.

```
CSR5#show mpls ldp bindings 2.2.2.2 32
lib entry: 2.2.2.2/32, rev 147
  local binding:  label: 5007
  remote binding: lsr: 7.7.7.7:0, label: 7003
  remote binding: lsr: 13.13.13.13:0, label: 93005
  remote binding: lsr: 14.14.14.14:0, label: 94005
```

```

CSR5#show ip cef 2.2.2.2
2.2.2.2/32
  nexthop 94.5.7.7 GigabitEthernet2.557 label 7003
  nexthop 94.5.14.14 GigabitEthernet2.554 label 94005

```

We quickly query CEF to see which way the traffic will actually go from CSR5 to CSR2. CEF reports that traffic is being routed to XRv14, so we will continue our verification there. The label stack becomes {94005 2003}.

```

CSR5#show ip cef exact-route virtual 5.5.5.5 2.2.2.2
5.5.5.5 -> 2.2.2.2 => label 94005TAG adj out of GigabitEthernet2.554, addr
94.5.14.14

```

XRv14 is faced with another ECMP decision. The LFIB directs traffic towards CSR1 and XRv3 equally since the RIB shows ECMP paths for 2.2.2.2/32. Since both routes are IGP routes, we know the labels were allocated via LDP, so XRv14 is just a P router performing a label swap in either case.

```

RP/0/0/CPU0:XRv14#show mpls forwarding labels 94005

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94005	1028	2.2.2.2/32	Gi0/0/0/0.514	192.168.1.1	172
	93005	2.2.2.2/32	Gi0/0/0/0.534	94.13.14.13	3932587

```

RP/0/0/CPU0:XRv14#show route ipv4 2.2.2.2
Routing entry for 2.2.2.2/32
  Known via "ospf 94", distance 110, metric 1
  Tag 3489660977, type extern 2

    94.13.14.13, from 13.13.13.13, via GigabitEthernet0/0/0/0.534
      Route metric is 1

```

We can query the LFIB for the exact route based on the source/destination pair between CSR5 and CSR2. Traffic is being sent to XRv13 and the label stack becomes {93005 2003}.

```

RP/0/0/CPU0:XRv14#show mpls forwarding exact-route label 94005 ipv4 5.5.5.5
2.2.2.2

```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94005	93005	2.2.2.2/32	Gi0/0/0/0.534	94.13.14.13	N/A

```

  Via: Gi0/0/0/0.534, Next Hop: 94.13.14.13
  MAC/Encaps: 18/22, MTU: 1500
  Label Stack (Top -> Bottom): { 93005 }
  NHID: 0

```

When XRv13 receives the MPLS packets, it consults its LFIB and performs a swap operation. Looking at the RIB details, we can reveal that the route is BGP learned and see its corresponding label. The LFIB smartly connects the LDP LSP to the BGP LSP by swapping an LDP label with a BGP label. The label stack becomes {92004 2003} and traffic is forwarded into the core carrier PE, XRv12.

```
RP/0/0/CPU0:XRv13#show mpls forwarding labels 93005
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
93005	92004	2.2.2.2/32	Gi0/0/0/0.523	192.168.12.12	14402056

```
[snip]
```

Since XRv12 connects to XRv13 inside a VRF, the label 92004 will be a VPNv4 label from the perspective of XRv12. Specifically, this is XRv12's local label for 2.2.2.2/32, which is just an ordinary L3VPN route. BGP indicates that the best-path is via CSR8 and uses label 8001. This implies that a swap operation will occur, changing the label stack to {8001 2003}.

```

XRv12 may need to push additional labels depending on the route to 8.8.8.8, which is the BGP next-hop. The RIB indicates that the shortest path is via CSR3, which avoids the high-cost direct path. CSR3 allocates LDP label 3000, which will be pushed atop the label stack, resulting in {3000 8001 2003}. If we didn't modify the link cost, the direct path to CSR would have been chosen, which would have resulted in a label stack without 3000 due to having received implicit-null (which is less interesting).

```
RP/0/0/CPU0:XRv12#show route ipv4 8.8.8.8

```

We can confirm this by checking the VRF-aware CEF table to see that the route to 2.2.2.2/32 includes the VPNv4 label (core carrier VPN label) and the transport label via LDP from CSR3. XRv12 is not aware of and does not care about the MPLS service label between CSR2 and CSR5.

```

(0x0), 0x208 (0xa1476280)
Prefix Len 32, traffic index 0, precedence n/a, priority 3
via 8.8.8.8, 3 dependencies, recursive [flags 0x6000]
  path-idx 0 NHID 0x0 [0xa14dfaf4 0x0]
  recursion-via-/32
  next hop VRF - 'default', table - 0xe0000000
  next hop 8.8.8.8 via 92003/0/21
  local label 92004
  next hop 49.3.12.3/32 Gi0/0/0/0.532 labels imposed {3000 8001}
```

When CSR3 receives this packet with label 3000, it pops 3000 from the stack since CSR8 advertised implicit-null for 8.8.8.8/32 via LDP. The label stack becomes {8001 2003} and is forwarded to CSR8.

```
CSR3#show mpls forwarding-table labels 3000

-----
```

Label	Label	or Tunnel Id	Switched	interface	
3000	Pop Label	8.8.8.8/32	70866	Gi2.538	49.3.8.8

```

CSR3#show mpls ldp bindings 8.8.8.8 32 neighbor 8.8.8.8
  lib entry: 8.8.8.8/32, rev 8
    remote binding: lsr: 8.8.8.8:0, label: imp-null

```

When CSR8 receives the packet, it consults its LFIB and performs a label swap. Ignoring CSC for a moment, this is classic L3VPN behavior where the carrier VPN label of 8001 is exposed to the PE. The CSC enhancement shows the label swap, not pop, since the LSP continues towards the customer carrier. Normally the out-label is “no label” in an ordinary L3VPN design. The out-label is 10027 which is CSR10's local label for 2.2.2.2/32, allocated by BGP IPv4 labeled-unicast, which isn't in a VRF on CSR10. CSR8's VPNv4 entry shows the in/out labels for this prefix as seen by BGP. The label stack is now {10027 2003}.

```

      rx pathid: 0, tx pathid: 0x0

```

When CSR10 receives the packet labeled 10027, it pops this label. The route to 2.2.2.2/32 is an OSPF route, which means an LDP label should be used. This happens to be implicit-null since CSR2 is the next-hop and is connected to 2.2.2.2/32. This is another example of how the MPLS process is smart enough to connect BGP labels to LDP labels to make a seamless LSP. The label stack is now {2003}.

```

lib entry: 2.2.2.2/32, rev 190
remote binding: lsr: 2.2.2.2:0, label: imp-null
```

As the remote PE, CSR2 removes the label stack and delivers the traffic into the VRF. We can see the VPN route is in VF U2 and is for the customer prefix ::2:6:6:6/128. The out-label is “no label” since this is the end of the LSP. Using traceroute inside the VPN, we can see the full label stack for confirmation. The only discrepancy with this output is that CSR7 is the first MPLS hop, not XRv14. This is inconsistent with what CEF reported earlier, but rather than troubleshoot software-based ECMP mechanisms, we will ignore the minor discrepancy and continue.

```

Next, we will trace the same set of IPv6 prefixes in the reverse direction, which takes a different path. Because the CE (CSR6) is multi-homed, we begin there. CSR6 prefers the path via CSR4 due to local-preference which is the preferred ingress PE for VRF U2.

```
CSR6#show bgp vpnv6 unicast vrf U2 ::2:11:11:11/128

```

Checking CSR4, we can see that CSR5 has allocated label 5009 for prefix. The next-hop is 5.5.5.5, which has a corresponding BGP route carrying label 9026. Since the next-hop for 5.5.5.5 is connected, the final label stack is {9026 5009} and the packet is sent towards CSR9.

```

```

Behind the scenes, there is more activity. CSR9 learns two VPNv4 routes for this customer prefix from CSR1 and XRv12. CSR1 is chosen as the best-path because it is closer than XRv12 from an IGP perspective, so BGP label 1027 is used instead of 92001.

```

```

We confirm that the IGP cost to CSR1 is 10, and since the route is IS-IS, an LDP label will be pushed onto the label stack to reach this next-hop. CSR1 is advertising explicit-null, so the label stack becomes {0 1027 5009}.

```

CSR1 receives the packet and performs a lookup against label 0. This label is popped and the next-hop is identified as "input table", which means another lookup must occur in the same table in which the packet was received. Since the next label is 1027, the LFIB swaps 1027 for 94000. Normally, when verifying LSPs, you don't need to lookup label 0 since you already know the action is always pop and the follow-on action is another lookup.

```
CSR1#show mpls forwarding-table labels 0

```

Unlike the other 3 CSC PE's, CSR1 is not running BGP IPv4 labeled-unicast with the customer carrier. When label 1027 arrives, BGP claims there is no outgoing label towards XRv14, which is true from a BGP-only perspective. This route is actually originated on CSR1 (not BGP learned), so this output makes sense; it also implies that CSR1's RIB doesn't have the BGP route installed. Instead, the route is learned via VRF-aware OSPF, which is an IGP route requiring an LDP label for transport. This hybrid design is very awkward but illustrates the CSC options.

```

    Route metric is 3, traffic share count is 1
```

We can query the LIB to see the LDP bindings for 5.5.5.5/32 inside the VRF. This reveals label 94000 which the LFIB correctly identified as the out-label along this LSP. Again, the LFIB is smart enough to connect the VPNv4 label to the LDP label to support CSC. The label stack becomes {94000 5009}.

```
CSR1#show mpls ldp bindings vrf T2 5.5.5.5 32 neighbor 14.14.14.14
lib entry: 5.5.5.5/32, rev 4
remote binding: lsr: 14.14.14.14:0, label: 94000
```

When XRv14 receives this packet, it pops the topmost label to reveal label 5009 (VPNv6 label) to the remote PE, CSR5. CSR5 removes all labels from the stack and forwards the IPv6 packet to XRv11 inside VRF U2.

```
RP/0/0/CPU0:XRv14#show mpls forwarding labels 94000

```

We can use traceroute to verify the label stacks. Explicit-null "confuses" traceroute and masks XRv14 as a hop in the path, but otherwise the labels appear correct. This confusion is due to the need for multiple LFIB lookups on a single router.

```
CSR6#traceroute vrf U2 ipv6

33.1.2 L2VPN

This test uses BGP auto-discovery to build VPLS PWs along with BGP signaling for label exchange. As described in the L2VPN section, BGP signaling for VPLS doesn't actually exchange labels, but instead exchanges details about how the label should be derived. In the BGP AD route, we can see label 2020, but this is just the start of the label range allocated by CSR2; it may not actually be the exact label value in use.

```
CSR5#show bgp l2vpn vpls rd 94:567 ve-id 2 block-offset 1

Forwarder [CA000003] VFI VPLS
```

To quickly evaluate the math (described in detail in the L2VPN section), we first compute the VBO. This is defined as $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS}$ of the remote route, which evaluates as $\text{ROUND}(5/10) * 10 = 1$. The math isn't exactly 1, but 1 is considered the smallest usable block offset. Next, a sanity check is performed to ensure that the local VE-ID (5) is within the valid range given the remote VBO and VBS.

Specifically, the local VE-ID must evaluate as follows: $VBO \leq VE-ID < VBO + VBS$. In this case, the formula is true: $1 \leq 5 < 1 + 10$. Last, CSR5 must select a label from this block, and uses the following formula: $LB + VE-ID - VBO$. Again, the VE-ID is the local value while the VBO/VBS are for the received route. In this case, the label evaluates as follows: $2020 + 5 - 1 = 2024$. We confirm this value of 2024 by checking the L2VPN VFI details.

  pseudowire100017   2.2.2.2           2      5024         2024         Y
```

Next, we need to find the route to the next-hop. This resolves to a pair of OSPF routes which is identical to what we saw earlier. Like UMPLS, CSC can support any MPLS service. What is odd is that the label stack, as confirmed by the PW details, is using CSR7 for next-hop recursion.

```
CSR5#show ip route 2.2.2.2
Routing entry for 2.2.2.2/32
  Known via "ospf 94", distance 110, metric 1
  Tag 49, type extern 2, forward metric 2
  Last update from 94.5.14.14 on GigabitEthernet2.554, 3d00h ago
  Routing Descriptor Blocks:
    94.5.14.14, from 13.13.13.13, 3d00h ago, via GigabitEthernet2.554
      Route metric is 1, traffic share count is 1
      Route tag 49
    * 94.5.7.7, from 13.13.13.13, 3d00h ago, via GigabitEthernet2.557
      Route metric is 1, traffic share count is 1
      Route tag 49
```

```
CSR5#show l2vpn atom vc vcid 567 2 detail | include label_stack
Output interface: Gi2.557, imposed label stack {7003 2024}
```

I am unable to find any documentation or show command to verify why this is the case, since CEF directs traffic between 5.5.5.5 and 2.2.2.2 towards XRv14. At least we can confirm that label 7003 is the proper LDP label allocated by CSR7 to represent 2.2.2.2/32. The label stack becomes {7003 2024} as indicated above. This is the same discrepancy noted in the L3VPN LSP trace.

```
CSR5#show ip cef exact-route virtual 5.5.5.5 2.2.2.2
5.5.5.5 -> 2.2.2.2 => label 94005 TAG adj out of GigabitEthernet2.554, addr
94.5.14.14
```

```
CSR5#show mpls ldp bindings 2.2.2.2 32 neighbor 7.7.7.7
```

```
lib entry: 2.2.2.2/32, rev 147
remote binding: lsr: 7.7.7.7:0, label: 7003
```

At this point, we might as well trace the new LSP. When CSR7 receives the packet, it swaps label 7003 for 93005 as a basic P router running LDP. The label stack becomes {93005 2024} and is delivered to XRv13.

```
CSR7#show mpls forwarding-table labels 7003
Local      Outgoing  Prefix          Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id    Switched     interface
7003       93005      2.2.2.2/32      12769639     Gi2.573   94.7.13.13
```

When XRv13 receives the packet, the LDP label 93005 is swapped for the BGP IPv4 labeled-unicast value of 92004 at the CSC CE. The route is BGP-learned, which implies the label is BGP learned as well. The label stack becomes {92004 2024} and is delivered to XRv12.

```
RP/0/0/CPU0:XRv13#show mpls forwarding labels 93005
Local  Outgoing  Prefix          Outgoing  Next Hop      Bytes
Label  Label      or ID           Interface  Next Hop      Switched
-----
93005  92004      2.2.2.2/32      Gi0/0/0/0.523 192.168.12.12 15666830
```

```

```
RP/0/0/CPU0:XRv13#show bgp ipv4 labeled-unicast labels | include 2.2.2
*> 2.2.2.2/32          192.168.12.12    92004          93005
```

XRv12 performs an LFIB lookup and swaps label 92004 for label 8001. These are the CSC VPNv4 labels exchanged to provide IP reachability between the CSC customer sites. The route is BGP learned and the BGP label swapping occurs due to this. The transport LSP is identical to the one traced for L3VPN as only the MPLS service (L3VPN versus L2VPN) has changed.

```

```

XRv12 also must push an additional label to reach CSR8. Since the route is IGP learned, the LDP label of 3000 is used. The label stack is now {3000 8001 2024}. Notice that this label stack is identical to the LSP we traced earlier, service (bottom) label notwithstanding. At this point, we will stop tracing this LSP for the sake of brevity since we already did it once.

```

```

We can quickly verify the LSP using traceroute. Notice I use a probe count of 1, and then run the command a few times until I see CSR7 as the first hop since XRv14 has a 50-50 chance of being selected. This “chance” is the result of the self-generated traceroute probes being processed switched, and thus load-balanced per-packet in software. We run this on the PE routers in the customer carrier since this would not yield valuable results inside the VPN.

```

CSR5#traceroute 2.2.2.2 source 5.5.5.5 probe 1

```

```

We will jump to CSR2 to verify the first few hops of its LSP as well for completeness. First, we need to do the VPLS math to determine the PW label. The BGP route is learned from 5.5.5.5 and carries a VBS of 10 and an LB of 5023. CSR2's local VE-ID is 2.

```
CSR2#show bgp l2vpn vpls rd 94:567 ve-id 5 block-offset 1
BGP routing table entry for 94:567:VEID-5:Blk-1/136, version 19
Paths: (1 available, best #1, table L2VPN-VPLS-BGP-Table)

```

```
CSR2#show l2vpn signaling rib rd 94:567 detail
Route 94:567:5 (epoch:0) from iBGP peer 5.5.5.5
Provisioned (Y) Stale (N)
  Route-Target: 94:567
NLRI [7E000007]
  VE-ID:5 VBO:1 VBS:10 LB:5023
  MTU: 1500 Control Word: off
RIB Filter [23000001]
  Local RD: 94:567
  VE-ID: 2, VBO: 1, VBS: 10 LB: 2020
Forwarder [35000003] VFI VPLS
```

First, we evaluate the VBO: $VBO = \text{ROUND}(\text{VE-ID}/\text{VBS}) * \text{VBS} = \text{ROUND}(2/10) * 10 = 1$. This is displayed above but we verify it for completeness. Next, we perform a sanity check to ensure the router is looking at the proper block of labels for this PW based on the local VE-ID. Evaluate: $VBO \leq \text{VE-ID} < VBO + \text{VBS}$ translates into $1 \leq 2 < 1 + 10$, which is true. CSR2 then selects a label from this block using the formula $\text{LB} + \text{VE-ID} - \text{VBO}$. This evaluates as $5023 + 2 - 1 = 5024$. We can confirm this label by checking the L2VPN VFI summary or the PW details; both are shown below.

```

CSR2#show l2vpn vfi name VPLS
Legend: RT=Route-target, S=Split-horizon, Y=Yes, N=No
VFI name: VPLS, state: up, type: multipoint, signaling: BGP
  VPN ID: 567, VE-ID: 2, VE-SIZE: 10
  RD: 94:567, RT: 94:567
  Bridge-Domain 302 attachment circuits:
  Pseudo-port interface: pseudowire100018
  Interface          Peer Address      VE-ID  Local Label  Remote Label  S
  pseudowire100019   5.5.5.5           5      2024         5024          Y

CSR2#show l2vpn atom vc vcid 567 2 detail | include label_stack
  Output interface: Gi2.520, imposed label stack {10029 5024}

```

We also see label 10029 on the label stack from the PW details. The route to 5.5.5.5 is a BGP route that also carries a label; unlike CSR5, the route to the BGP next-hop is another BGP route since CSR10 is not performing BGP-to-IGP redistribution. Potentially, a third label may be needed to reach 10.10.10.10, which is the BGP next-hop for the labeled-unicast route. Since this is an IGP route directly connected to CSR10, LDP implicit-null is used, so the label stack remains {10029 5024}.

```

CSR2#show ip route 5.5.5.5
Routing entry for 5.5.5.5/32
  Known via "bgp 94", distance 200, metric 0
  Tag 49, type internal
  Last update from 10.10.10.10 3d01h ago
  Routing Descriptor Blocks:
  * 10.10.10.10, from 10.10.10.10, 3d01h ago
    Route metric is 0, traffic share count is 1
    AS Hops 1
    Route tag 49
    MPLS label: 10029

CSR2#show ip route 10.10.10.10
Routing entry for 10.10.10.10/32
  Known via "ospf 94", distance 110, metric 2, type intra area
  Last update from 94.2.10.10 on GigabitEthernet2.520, 4d03h ago
  Routing Descriptor Blocks:
  * 94.2.10.10, from 10.10.10.10, 4d03h ago, via GigabitEthernet2.520
    Route metric is 2, traffic share count is 1

CSR2#show mpls ldp bindings 10.10.10.10 32 neighbor 10.10.10.10
  lib entry: 10.10.10.10/32, rev 124
    remote binding: lsr: 10.10.10.10:0, label: imp-null

```

When CSR10 receives this packet, it swaps label 10029 for label 8028. Since the route to 5.5.5.5/32 is a BGP route, the BGP label of 8028 is used, and we can see how the LFIB connects the LDP and BGP labels seamlessly. The label stack becomes {8028 5024}.

```
CSR10#show mpls forwarding-table labels 10029
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
10029	8028	5.5.5.5/32	18219161	Gi2.580	192.168.8.8

```
CSR10#show ip route 5.5.5.5
Routing entry for 5.5.5.5/32
  Known via "bgp 94", distance 20, metric 0
  Tag 49, type external
  Last update from 192.168.8.8 3d01h ago
  Routing Descriptor Blocks:
    * 192.168.8.8, from 192.168.8.8, 3d01h ago
      Route metric is 0, traffic share count is 1
      AS Hops 1
      Route tag 49
      MPLS label: 8028
```

When CSR8 receives the packet, it consults its LFIB which shows a label swap to 1027. This is the VPNv4 label learned from CSR1. We can see the route is installed in the VRF routing table as a BGP route with an MPLS label and a flag indicating that MPLS must be used for transport. This is the result of the CSC architecture.

```
CSR8#show mpls forwarding-table labels 8028
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Label Switched	Outgoing interface	Next Hop
8028	1027	5.5.5.5/32 [V]	18923482	Gi2.518	49.1.8.1

```
CSR8#show ip route vrf T2 5.5.5.5
Routing Table: T2
Routing entry for 5.5.5.5/32
  Known via "bgp 49", distance 200, metric 3, type internal
  Last update from 1.1.1.1 3d01h ago
  Routing Descriptor Blocks:
    * 1.1.1.1 (default), from 12.12.12.12, 3d01h ago
      Route metric is 3, traffic share count is 1
      AS Hops 0
      MPLS label: 1027
      MPLS Flags: MPLS Required
```

For completeness, we can see that CSR8 learned two BGP routes for 5.5.5.5/32 inside the VPN. The route to CSR1 was chosen because the AS path to CSR1 is shorter than the one to Xrv12.

```
CSR8#show bgp vpnv4 unicast vrf T2 5.5.5.5/32

  Connector Attribute: count=1
    type 1 len 12 value 49:1:1.1.1.1
  mpls labels in/out 8028/1027
  rx pathid: 0, tx pathid: 0x0

```

CSR8 also may need to push a null label to reach CSR1. In this case, explicit-null is added to the stack, resulting in {0 1027 5024}.

```

CSR8#show mpls ldp bindings 1.1.1.1 32 neighbor 1.1.1.1
  lib entry: 1.1.1.1/32, rev 136
    remote binding: lsr: 1.1.1.1:0, label: exp-null

```

CSR1 performs two lookups in quick succession: one to remove the explicit-null label (typically used for QoS uniform and long-pipe modes), and one to observe the BGP transport label of 1027. This is swapped for label 94000 which was allocated by XRv14.

```

CSR1#show mpls forwarding-table labels 0
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id  Switched     interface
explicit   Pop Label   ipv4 exp-null 33242335     aggregate/<input table>

CSR1#show mpls forwarding-table labels 1027
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id  Switched     interface
1027       94000      5.5.5.5/32 [V] 18231011     Gi2.514    192.168.1.14

```

Since the route to 5.5.5.5/32 is an IGP route, CSR1 will use an LDP label to reach it. XRv14 allocated 94000 as its local LDP label for this prefix. CSR1 connects the VPNv4 label (CSC core carrier VPN label) with the LDP label (CSC customer transport label) within the VRF and sends the packet to XRv14. The label stack is now {94000 5024}.

```

CSR1#show ip route vrf T2 5.5.5.5

```

Routing Table: T2

Routing entry for 5.5.5.5/32

33.1.3 MVPN (Profile 0 with SSM)

To test multicast over CSC, we will use PIM/GRE since XRv actually supports that fully. Cisco documentation suggests that only MVPN profile 0 is supported for CSC as well. Both CSR2 and CSR5 use identical MDT configurations for VRFs U1 and U2. SSM is enabled for all multicast transport in the customer and core carrier networks for simplicity.

```

    mdt default 232.94.94.252
    mdt data 232.94.62.0 0.0.0.127

```

As mentioned earlier, IPv4 MDT is used to exchange the MDT information between the customer PE endpoints. Looking at the MDT route from CSR5 inside VRF U1 on CSR2, we can see the route carries the PE loopback address and the MDT default group, which is used for PIM c-mcast signaling. We also verify the opposite on CSR5 to ensure it learns CSR2's route with the matching MDT address.

```

CSR2#show bgp ipv4 mdt rd 49:105 5.5.5.5/32

```

The customer PEs won't actually form PIM neighbors until multicast transport is provided between the two endpoints. This is the responsibility of the core carrier, which could use any other kind of MVPN transport, but in this case also uses PIM/GRE with SSM. XRv12 is the route-reflector that learns the MDT routes from all core carrier PEs. Since L3VPN routes are only exchanged east-to-west (that is, CSR8/CSR9 and XRv12/CSR1 don't exchange routes), the MVPN cannot loop as RPF will fail. Looking into the specific route exchange between CSR8 and XRv12, we can see they share an MDT default address for the T2 VRF.

```

PIM also must be enabled on any P routers as well. Looking at CSR3, we can see it is in the transit path for all 4 of the SPT trees; this is a result of the link cost adjustments since the P(S,G) joins travel up the reverse path towards the source.

```

With the MDTs properly built, we can verify that there are PIM neighbors inside the T2 VRF. This will provide multicast transport across the core carrier for the customer carrier.

```
RP/0/0/CPU0:XRv12#show pim vrf T2 neighbor | begin Neighbor
```

Neighbor Address	Interface	Uptime	Expires	DR pri	Flags
192.168.12.12*	GigabitEthernet0/0/0/0.523	3d20h	00:01:34	1	B P E
192.168.12.13	GigabitEthernet0/0/0/0.523	3d19h	00:01:32	1	(DR) B P
1.1.1.1	mdtT2	3d19h	00:01:26	1	P
8.8.8.8	mdtT2	3d19h	00:01:16	1	P
9.9.9.9	mdtT2	3d19h	00:01:17	1	P

```
12.12.12.12*      mdtT2                3d20h      00:01:22 1 (DR) P
```

```
CSR8#show ip pim vrf T2 neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime/Expires	Ver	DR Prio/Mode
1.1.1.1	Tunnel0	3d18h/00:01:37	v2	1 / S P G
9.9.9.9	Tunnel0	3d18h/00:01:28	v2	1 / S P G
12.12.12.12	Tunnel0	3d19h/00:01:33	v2	1 / DR P G
192.168.8.10	GigabitEthernet2.580	3d19h/00:01:27	v2	1 / DR S P G

Now, we can backtrack to the customer PEs to see if PIM neighbors have formed there. If they have, this is an indication that the customer carrier default MDT has end-to-end connectivity, which means the core carrier MVPN transport is also working. We will verify PIM neighbors inside VRF U1 on CSR2 and CSR5 for brevity.

```
CSR5#show ip pim vrf U1 neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime/Expires	Ver	DR Prio/Mode
192.168.105.11	GigabitEthernet2.105	3d19h/00:01:36	v2	1 / DR P G
4.4.4.4	Tunnel3	3d18h/00:01:22	v2	1 / S P G
2.2.2.2	Tunnel3	3d19h/00:01:26	v2	1 / S P G

```
CSR2#show ip pim vrf U1 neighbor | begin ^Neighbor
```

Neighbor Address	Interface	Uptime/Expires	Ver	DR Prio/Mode
5.5.5.5	Tunnel3	3d19h/00:01:42	v2	1 / DR S P G
4.4.4.4	Tunnel3	3d19h/00:01:43	v2	1 / S P G
192.168.102.6	GigabitEthernet2.102	3d18h/00:01:29	v2	1 / DR S P G

To test it, we will configure some IGMPv3 SSM joins on XRv11 within both VRF U1 and U2. Since XRv11 is running PIM with CSR5, the joins are configured on the loopback, which means CSR5 should receive C(S,G) joins. Before continuing, we verify that the IGMP joins are seen on XRv11's loopbacks.

```
! XRv11
router igmp
vrf U1
  interface Loopback1
    join-group 232.1.1.1 1.6.6.6

vrf U2
  interface Loopback2
    join-group 232.2.2.2 2.6.6.6
```

```
RP/0/0/CPU0:XRv11#show igmp vrf U1 groups 232.1.1.1
```

```
IGMP Connected Group Membership
```

Group Address	Interface	Uptime	Expires	Last Reporter

232.1.1.1	Loopback1	3d19h	never	1.11.11.11

```
RP/0/0/CPU0:XRv11#show igmp vrf U2 groups 232.2.2.2
```

IGMP Connected Group Membership

Group Address	Interface	Uptime	Expires	Last Reporter
232.2.2.2	Loopback2	3d19h	never	2.11.11.11

Next, we verify the PIM C(S,G) state on XRv11 and CSR5. We can see XRv11 receives traffic from CSR5 and CSR5 receives traffic from the MDT tunnel. We can see that a data MDT has been spawned for this group for P(S,G) transport and uses the MDT data group 232.94.41.0. The big 'Y' indicates that this multicast state entry receives traffic from an MDT data group (as opposed to the default group). CSR2, the source-connected PE, originates these data-MDT TLVs inside the MDT default tree to signal receivers that a more optimal group should be used.

```
RP/0/0/CPU0:XRv11#show pim vrf U1 topology 232.1.1.1 1.6.6.6 | begin 232
(1.6.6.6,232.1.1.1)SPT SSM Up: 3d19h
```

```
JP: Join(00:00:06) RPF: GigabitEthernet0/0/0/0.105,192.168.105.5 Flags:
Loopback1 3d19h fwd LI II LH
```

```
CSR5#show ip mroute vrf U1 232.1.1.1 1.6.6.6 | begin \
(1.6.6.6, 232.1.1.1), 3d19h/00:02:39, flags: sTY
```

```
Incoming interface: Tunnel3, RPF nbr 2.2.2.2,
MDT: [2.2.2.2,232.94.41.0]/00:02:01
```

Outgoing interface list:

```
GigabitEthernet2.105, Forward/Sparse, 1d00h/00:02:39
```

If we check the MDT data group in the global table, we can see it is an MDT tunnel (big 'Z') and that it supports VRF U1. Traffic is sourced from 2.2.2.2 which is the remote tunnel endpoint. CSR5 sends the P(S,G) join to XRv14 since it has a higher IP address than CSR7 and is therefore the RPF neighbor towards 2.2.2.2. XRv14 forwards it onto CSR1 which also has the higher neighbor IP address as the ECMP tie breaker for RPF.

```
CSR5#show ip mroute 232.94.41.0 2.2.2.2 | begin \
(2.2.2.2, 232.94.41.0), 1d00h/stopped, flags: sTIZ
```

```

To answer the question of why CSR5 selected CSR2 as the remote PE and not CSR4, we can look at BGP. We examined this earlier; CSR2 is the bestpath because the BGP RID 2.2.2.2 is less than the originator ID of 4.4.4.4.

```
CSR5#show bgp vpvv4 unicast vrf U1 1.6.6.6

```

CSR1 sees this join inside of VRF T2, which looks like an ordinary MVPN profile 0 customer. The customer-facing interface is added to the OIL as expected. Just like CSR5, this is mapped to an MDT data group for efficient transport across the core. For lack of a better term, I will call this second layer of MDT the CSC(S,G) state information, which wraps the P(S,G) encapsulation, which wraps the C(S,G) native traffic. We can see that this CSC(S,G) join is sent towards CSR8 because CSR9 is only originating the path towards 4.4.4.4, which isn't the tunnel endpoint. The big 'Y' and 'Z' represent reception of traffic on an MDT data group and an MDT tunnel state entry, respectively.

```
CSR1#show ip mroute vrf T2 232.94.41.0 2.2.2.2 | begin \

      mpls labels in/out nlabel/8001
      rx pathid: 0, tx pathid: 0x0
```

When CSR8 receives the join, it sees that it is the root of the tree. Looking at VRF T2, we can see that this P(S,G) group is mapped to the CSC(S,G) group we just verified. Notice that these two entries have little 'z' and little 'y'; this indicates sending to an MDT data group, which makes sense since CSR8 is the ingress CSC PE, not the egress one. CSR8 indicates sending the P(S,G) join to CSR10.

```
CSR8#show ip mroute 232.49.4.3 | begin \
(8.8.8.8, 232.49.4.3), 1d00h/00:02:56, flags: sTz
  Incoming interface: Loopback0, RPF nbr 0.0.0.0
  Outgoing interface list:
    GigabitEthernet2.518, Forward/Sparse, 1d00h/00:02:56

CSR8#show ip mroute vrf T2 232.94.41.0 2.2.2.2 | begin \
(2.2.2.2, 232.94.41.0), 1d00h/00:02:38, flags: sTy
  Incoming interface: GigabitEthernet2.580, RPF nbr 192.168.8.10
  Outgoing interface list:
    Tunnel0, Forward/Sparse, 1d00h/00:02:38
```

When CSR10 receives it, it forwards the P(S,G) state to CSR2. CSR2 is the root of the tree and identifies itself as a sending for MDT data within the provider network (little 'z'). Using the verbose option on CSR2 inside VRF U1, we can see the original C(S,G) state is mapped to the P(S,G) state we just verified. This VRF mroute entry has a little 'y' to indicate sending to an MDT data group within the tier 2 provider network.

```
CSR10#show ip mroute 232.94.41.0 2.2.2.2 | begin \

```

Last, CSR2 sends the C(S,G) join to CSR6 who is ultimately the root of the customer tree. Traffic is "incoming" from loopback1, so we will use this for our tests. The entire path, from source to receiver, is CSR6 > CSR2 > CSR10 > CSR8 > CSR1 > XRv14 > CSR5 > XRv11. A quick traceroute reveals this, except for the presence of explicit-null masks XRv14 in the path.

```

CSR6#show ip mroute vrf U1 232.1.1.1 1.6.6.6 | begin \

Below is the packet dump from CSR1. First, we see the multicast destination MAC address of 0100.5e31.0403, which includes the low-order 23 bits of the multicast destination address (yellow). The CSC multicast group for MDT data transfer was 232.49.4.3, and we can see the hexadecimal representations of 49, 4, and 3 in the MAC address highlighted MAC address (0x310403). The payload of this frame is IP (0x0800 also in yellow), not MPLS, since we are using GRE encapsulation for MDT transport. Next, we can see the beginning of the outermost IP header with TOS set to 0x20, which is 00100000 in binary, or 32 in decimal (DSCP CS1) and is colored green. The destination IP address is 232.49.4.3 which is the CSC MDT data group, and is shown in cyan. The next IP header is the customer carrier MDT data group which also has DSCP CS1 (green) and has destination IP address 232.94.41.0 (pink). The third IP header is the original customer multicast packet that also has DSCP CS1 (green) with multicast destination 232.1.1.1 (grey). In this way, we can see three layers of GRE encapsulation in a CSC MVPN profile 0 design.

33.1.4 TE and TE-FRR

TE isn't very exciting for CSC because there isn't a way to maintain end-to-end TE paths between the customer carrier. Each individual island can run the full set of TE features as one would expect, but they generally don't cross between domains. First, we will create a basic TE tunnel from CSR2 to CSR10 that transits CSR4. We will remove the need for an LDP label to reach the BGP next-hop in this way, and expect the LFIB to automatically connect the RSVP-TE and BGP LSPs. A quick check on CSR2 shows that all three routers are in the TE topology, and all of their OSPF area 0 links are included. The routers are basically in a triangle with both links TE-enabled.

```

CSR2#show mpls traffic-eng topology brief | include IGP_Id

```

```

  tunnel mpls traffic-eng path-option 10 explicit name EP_2_4_10

CSR2#show mpls traffic-eng tunnels tunnel 200 | section RSVP Path
  RSVP Path Info:
    My Address: 94.2.4.2
    Explicit Route: 94.2.4.4 94.4.10.10 10.10.10.10
    Record Route: NONE
    Tspec: ave rate=0 kbits, burst=1000 bytes, peak rate=0 kbits

```

Following the route recursion, CSR2 will receive IPv4 traffic within VRF U1 from CSR6 to XRv11 and use label 5014. CSR2 has a route to CSR5's loopback (VPNv4 next-hop) via 10.10.10.10, which hasn't changed. This includes BGP label 10029. The route to 10.10.10.10 is now via the TE tunnel (thanks to autoroute) which imposes label 4019 from RSVP-TE. Having BGP here obviates the need for LDP to be enabled on this tunnel, since label 10029 directs us to the remote PE. Normally tLDP is required for this in intra-AS TE designs without BGP labeled-unicast. Since the BGP label will be exposed correctly to the tunnel tail-end, tLDP is not required. The label stack becomes {4019 10029 5014} towards CSR4.

A quick traceroute shows us that the traffic still works from within the VPN, except now we see a 3-label stack at CSR4, which normally wasn't in the transit path. This isn't CSC-specific but the point is to show that CSC architectures support TE for intra-AS transport within the tier 2 customer carrier islands.

One of the issues with this approach is that PIM-based MVPN is broken to CSR2. During this test, CSR2 shows many angry syslog messages to show that the VRF-aware PIM sessions for all MVPN instances have failed. Checking CSR2 and CSR5, we see a strange asymmetry of PIM neighbors. CSR5 sees CSR2 as a neighbor but not vice versa.

```

! CSR2
%PIM-5-NBRCHG: VRF U1: neighbor 5.5.5.5 DOWN on interface Tunnel3 DR
%PIM-5-NBRCHG: VRF U2: neighbor 5.5.5.5 DOWN on interface Tunnel4 DR

```

```

```

Similar issues were observed in the inter-AS MPLS and MVPN sections. The reason for these errors is a newly-introduced RPF failure due to our TE tunnel. CSR2 can still send traffic to CSR5, who receives the tunneled PIM hellos, which is sufficient to declare a PIM neighbor up. However, CSR2 drops the ingress PIM hellos due to RPF failure. This is because the unicast route to 5.5.5.5 is via the TE tunnel, which is not PIM enabled. It isn't a VRF multicast issue since there is still a PIM tunnel within the VRF (despite the PIM neighbor being broken at the moment). Earlier we saw that, once the route recursion unwinds, the path to 5.5.5.5 is via the TE tunnel.

```

CSR2#show ip rpf 5.5.5.5
failed, no route exists

```

```

CSR2#show ip rpf vrf U1 1.11.11.11
RPF information for ? (1.11.11.11)
RPF interface: Tunnel3
RPF neighbor: ? (5.5.5.5)
RPF route/mask: 1.11.11.11/32
RPF type: unicast (bgp 94)
Doing distance-preferred lookups across tables
BGP originator: 5.5.5.5
RPF topology: ipv4 multicast base, originated from ipv4 unicast base

```

We can't realistically enable PIM on a TE tunnel because that logically makes no sense (it only makes sense in passive mode for P2MP TE, which we are not doing here). Instead, we can tell OSPF to ignore these TE tunnels as RPF interfaces. The unicast routing for MPLS LSPs still uses the TE tunnels, but MVPN profile 0 GRE encapsulation can use whatever interface OSPF would have normally selected without considering TE. Now, RPF passes and the PIM neighbors work again. CEF still directs unicast traffic into the TE tunnel as expected which means the unicast LSP remains the same.

```

! CSR2
router ospf 94
mpls traffic-eng multicast-intact

```

```

CSR2#show ip rpf 5.5.5.5
RPF information for ? (5.5.5.5)

RPF neighbor: ? (94.2.10.10)
RPF route/mask: 5.5.5.5/32
RPF type: unicast (bgp 94)
Doing distance-preferred lookups across tables
RPF topology: ipv4 multicast base, originated from ipv4 unicast base

```

```
CSR2#show ip cef 5.5.5.5
5.5.5.5/32
  nexthop 10.10.10.10 Tunnel200 label 10029
```

We quickly test multicast again to ensure it works while coexisting with the TE tunnel. Even though we are sending traffic from right to left, the joins (signaling) traversed from left to right, which implies that the RPF path from CSR2's perspective is functional.

```
CSR6#ping vrf U1
Protocol [ip]:
Target IP address: 232.1.1.1
Repeat count [1]: 10
Datagram size [100]:
Timeout in seconds [2]:
Extended commands [n]: y
Interface [All]: loopback1
Time to live [255]:
Source address or interface: loopback1
[snip]
Sending 10, 100-byte ICMP Echos to 232.1.1.1, timeout is 2 seconds:

```

```
Reply to request 0 from 1.11.11.11, 26 ms
[snip]
Reply to request 9 from 1.11.11.11, 21 ms
```

We can also test TE in the core carrier, and for variety, I couple it with TE-FRR. To make this interesting and complex, I will use inbound local preference on XRv12 in the core carrier to draw traffic out of the AS using XRv12. Specifically, this will change how AS 49 reaches 5.5.5.5/32 within VRF T2. The current best-path is selected as CSR1 due to a shorter AS path length, so adjusting MED won't help. We will use this as a temporary measure to create a longer LSP through the core carrier, which makes TE-FRR more interesting.

```
! XRv12
route-policy RPL_IN
  set local-preference 200
end-policy
```

Now, CSR9 selects XRv12 as the next-hop for 5.5.5.5/32 inside the CSC VPN. This makes the LSP much longer since CSR1, CSR8, and CSR3 are now in the transit path assuming we use LDP transport. A quick OAM check from CSR9 to XRv12 confirms this long dynamic path.

```
CSR9#show bgp vpnv4 unicast vrf T2 5.5.5.5/32
BGP routing table entry for 49:9:5.5.5.5/32, version 31
Paths: (2 available, best #1, table T2)

Next, we will build a TE tunnel from CSR9 to CSR3 following the path via CSR8 (high-cost link). The tunnel also requests 4 Mbps of bandwidth, although this isn't specific to CSC. We confirm the tunnel comes up and recurses over the proper path. The TE tunnel requests FRR protection but there are no backup tunnels yet. We also have to run LDP on this tunnel because it is PE-P, so CSR9 needs to push CSR3's LDP label for 12.12.12.12/32 before the TE transport label. We could potentially use BGP labeled-unicast for this as an extreme workaround, but there is no good reason to run this in the core carrier when LDP can do the job with a targeted session.

```

! CSR9
ip explicit-path name EP_9_8_3 enable
  next-address 8.8.8.8
  next-address 3.3.3.3

interface Tunnel201
  description BASIC TE TO CSR3
  ip unnumbered Loopback0
  mpls ip
  tunnel mode mpls traffic-eng
  tunnel destination 3.3.3.3
  tunnel mpls traffic-eng autoroute announce
  tunnel mpls traffic-eng priority 7 7
  tunnel mpls traffic-eng bandwidth 4000
  tunnel mpls traffic-eng path-option 10 explicit name EP_9_8_3
  tunnel mpls traffic-eng fast-reroute

CSR9#show mpls traffic-eng tunnels tunnel 201 | section RSVP Path
  RSVP Path Info:
    My Address: 49.8.9.9
    Explicit Route: 49.8.9.8 49.3.8.3 3.3.3.3
    Record Route: NONE
    Tspec: ave rate=4000 kbits, burst=1000 bytes, peak rate=4000 kbits

```

Before continuing, we already know that this TE tunnel is going to break the MDT traffic since the RPF process won't have a route to 12.12.12.12 via a PIM enabled interface. We can instruct IS-IS to ignore the TE tunnel when doing RPF checks just like we did for OSPF in the customer carrier; the command is identical.

```

! CSR9
router isis 49

```

```
mpls traffic-eng multicast-intact
```

CSR9 will use auto-tunnel backup to automatically build NHOP tunnels for TE LSPs traversing through it that request FRR protection. We can see that tunnel210 was spawned to protect the original LSP. CSR9 is also the tunnel head, but we want to protect the high-cost link so we can use FRR via CSR1 to reach CSR8. If FRR is in use, label 1000 is pushed atop the stack to use CSR1 as a backup path.

```
! CSR9
mpls traffic-eng auto-tunnel backup nhop-only
mpls traffic-eng auto-tunnel backup tunnel-num min 210 max 219
```

```
CSR9#show mpls traffic-eng tunnels backup
CSR9_t210
  LSP Head, Admin: up, Oper: up
  Tun ID: 210, LSP ID: 1, Source: 9.9.9.9
  Destination: 8.8.8.8
  Fast Reroute Backup Provided:
    Protected i/fs: Gi2.589
    Protected LSPs/Sub-LSPs: 1, Active: 0
  Backup BW: any pool unlimited; inuse: 4000 kbps
  Backup flags: 0x0
```

We can confirm this on CSR9 by checking the FRR database. NHOP protection is available and the router is the tunnel head as well. We can see the original TE label of 8017 and the FRR label of 1000.

```
CSR9#show mpls traffic-eng fast-reroute database role head state ready
P2P Headend FRR information:
Protected tunnel      In-label Out intf/label    FRR intf/label    Status

```

We will quickly trace the transport label stack within the core. The route to 12.12.12.12 is learned via a TE tunnel via IS-IS, but since this is not the tunnel endpoint, CSR9 must push CSR3's label for 12.12.12.12, which is 3001. Then, the route to 3.3.3.3 is via a TE tunnel and is the destination, so the RSVP label is used. The stack becomes {8017 3001}, where 8017 is the tunnel label we saw earlier.

```

```

Before continuing, we perform a quick traceroute inside VRF U1 from CSR6 to XRv11. We can see up to 4 labels in the stack in the core carrier as a result of the PE-P tunnel. Normally, there were only 3 labels, where the third label was the CSC transport label bound by LDP. The fourth label is a result of using a PE-P tunnel, requiring an LDP label plus a TE label.

```

Before breaking the link between CSR8 and CSR9, we will quickly check to ensure BFD is enabled with TE-FRR bound to it. RSVP is configured to rely on BFD to determine when TE tunnels should be re-routed, which is critical for TE-FRR to work properly.

```
CSR9#show bfd neighbors ipv4 49.8.9.8 details | include Regist
Registered protocols: ISIS CEF TE/FRR FRR
```

```
CSR9#show ip rsvp hello
Hello:
  RSVP Hello for Fast-Reroute/Reroute: Disabled
  Statistics: Disabled
  BFD for Fast-Reroute/Reroute: Enabled
  RSVP Hello for Graceful Restart: Disabled
```

To break the link, I change the VLAN encapsulation on CSR8 so the link fails (not shown). CSR9 only has one explicit path option, so it can never recompute a new path, which gives us time to verify FRR. CSR9

shows the entry for tunnel201 as "active" which means FRR is in use; the tunnel protection details for the original LSP also show this. The backup tunnel label of 1000 is added to the existing label stack, which allows for NHOP facility backup (N:1) through CSR1. This tunnels traffic around the failed link to provide the original 4-label stack to CSR8.

```
CSR9#show mpls traffic-eng fast-reroute database role head state active

```

Verifying traceroute from inside the VPN, we can see the full label stacks. When we activate TE-FRR, this will become 5 labels at CSR1, which is the deepest stack we have seen so far. From inner-most to outermost, I list them below as a general summary. I also color-code each label description to match the color of the label in the stack for clarity.

1. **VPNv4 label**: allocated by CSR5 to describe the route to 2.11.11.11. Stays the same for entire LSP.
2. **BGP label**: allocated by XRv12 to describe the route to 5.5.5.5. Appears as a VPNv4 label on the CSC PEs but uses IPv4 labeled-unicast to exchange it with the CSC CEs.
3. **LDP label**: allocated by CSR3 to describe the route to 12.12.12.12 through the TE tunnel.
4. **TE label**: allocated by CSR8 (RSVP-TE) to describe the route to 3.3.3.3, the TE tunnel destination.
5. **FRR label**: allocated by CSR1 (RSVP-TE) to describe the route to 8.8.8.8 for NHOP protection.

Additional Reading – Reference configurations "csc"

33.2 Unified (seamless) MPLS

Unified MPLS is a technique to create end-to-end LSPs across different OSPF areas, different IS-IS levels, or totally independent IGPs without having to leak PE loopbacks between the disparate domains. For the purpose of this section an “end-to-end LSP” is an LSP whereby the bottom-most service label does not change. To achieve this (let’s use L3VPN as an example), the VPN routes must never have their BGP next-hops changed; doing so causes VPNv4/v6 BGP to allocate a new VPN label which terminates the LSP. Traffic can still be label-switched end-to-end, but having a consistent LSP simplifies things like MVPN (obviates need for PIM vector and BGP connector mechanisms). ***This technique DOES NOT introduce entirely new technologies, just new ideas with minor configuration modifications.***

Leaking loopbacks between areas, levels, or totally different IGPs within a domain is difficult to manage and scales poorly. Instead, IPv4 labeled-unicast BGP is used to transport these loopbacks between IGP islands so that specific route leaking is not necessary. The IGP border routers will be route-reflectors for this AFI/SAFI to service all PEs within the IGP island; P routers do not need to run IPv4 labeled-unicast as it is expected that LSPs will be tunneled across them using transport labels from RSVP-TE, LDP, or even Segment Routing.

The key is ensuring the border routers set “next-hop-self” on iBGP-reflected routes so that PEs in the IGP islands have reachability to it. The VPNv4 next-hops, however, should never be changed. We are essentially using this extra BGP-bound label to transport traffic to the remote PE and relying on the ABRs to swap this middle label.

Unified MPLS works on very old code, such as 12.4T which can be emulated in GNS3. The trick on old code is to manually use a route-map to set the next-hop to yourself (in some versions, “peer-address” also works) but also set the “mpls-label”. Because IOS platforms do not have a separate configuration construct for the IPv4 labeled-unicast SAFI, applying an outbound route-map for filtering in the IPv4 unicast SAFI also filters labels unless they are explicitly permitted. The “send-label” command just activates the IPv4 labeled-unicast SAFI but outbound filters may prevent those labels from being sent to a given neighbor. Without setting the “mpls-label”, the routes will appear everywhere, but the IPv4 labeled-unicast routes will look like regular IPv4 unicast routes without MPLS labels.

A typical label stack at imposition would look something like this:

1. Topmost: LDP or RSVP-TE allocated label to reach the ABR (changes hop by hop)
2. Middle: BGP IPv4 labeled-unicast label to reach the remote PE (changes at the ABRs)
3. Bottom: BGP VPNv4 label to reach the final destination (never changes)

Key notes:

- In IOS, use “next-hop-self all” on the ABRs, which are RRs, for the IPv4 labeled-unicast SAFI.
 - A route-map manually setting the next-hop to the peer-address or static IPv4 address also works as discussed earlier.
 - A route-map manually setting a static IPv4 address works too, same pitfall as above.
- In XR, use “ibgp policy out enforce-modifications” on the ABRs.
 - If you don’t, nothing effects the reflected iBGP prefixes, not even a manual RPL.
 - Once this is done, use ordinary “next-hop-self” on the iBGP peers.
 - An RPL with “next-hop self” also works.
 - Because XR has an explicit IPv4 labeled-unicast SAFI, you don’t need to manually set label allocation in an RPL match stanza unless you want to specify the label value (can’t do that in IOS or XE).
 - A manual cluster-ID appears necessary for the IPv4 labeled-unicast and VPNv4 SAFIs in order for RRs to operate. The BGP update debugs indicate a lack of a cluster ID otherwise.
- Like a classic L3VPN, only the true PEs need to run the VPN signaling protocol:
 - VPNv4, VPNv6, L2VPN variants, pseudo-wire, etc
- The ABRs must be RRs and must apply “next-hop-self” for IPv4 labeled-unicast SAFI
 - This should be in the both directions. We assume IGP routes are not leaked either direction. The examples below show some alternative interpretations of this rule.
- Mild leaking might be necessary, but it’s essentially one route per ABR, not per PE
 - ABR loopback in the IGP island should be leaked into the higher layer for BGP peering reachability
 - ABR loopback in the higher layer should be leaked into the IGP island, same reason
 - Recommend “redistribute connected” or a direct IGP advertisement
 - Redistributing from a protocol could be dangerous if the filter is wrong

Below is a network diagram for the IS-IS portion of the lab. The configurations shown below are universal (generally speaking) for both IS-IS or OSPF, so they are verified first.

The configurations are very extensive for this setup, so the key parts are summarized. The BGP topology is generally the same regardless of IGP, so configurations for that are shown first. Different "types" of UMPLS are tested here which explains the variance in configuration. The "service" topologies, such as L3VPN and L2VPN for customers, can be completely different than the transport topologies such as LDP and BGP IPv4 labeled-unicast. Below is the RR configuration on the L1L2 routers XRV13 and XRV14; reflected routes have their next-hops changed in both directions, which ensures traffic in both directions will transit these routers. It also guarantees the allocation of a local label for BGP IPv4 labeled-unicast, which is important for UMPLS scalability.

```
! XRV13 and XRV14
route-policy RPL_ADVERTISE_FROM_R5
  if next-hop in (5.5.5.5) then
    pass
  endif

  use af-group IPV4_LUCAST

```

The other set of ABRs have a slightly different (simpler but less scalable) policy. They do not change the next-hops when reflecting routes to the "core" RRs, which means they do not allocate new labels for these prefixes. For variety, I also show an alternative method to setting the next-hop by using a route-map. The pitfall discussed earlier would be to omit the "set mpls-label" command, which would allow the prefix to be processed by the route-map (permitted) but no label assigned. Minor differences appear between CSR4 and CSR10; since CSR4 is a PE also, its loopback is redistributed into BGP, but CSR10's is not. CSR4 uses the new "next-hop-self all" command rather than the clunky route-map, which was introduced specifically to support UMPLS in newer code releases. It always adjusts the BGP next-hop, even for reflected routes.

```

! CSR10
ip prefix-list PL_HOST_ROUTE seq 5 permit 0.0.0.0/0 ge 32

route-map RM_NHOP_SELF permit 10
  match ip address prefix-list PL_HOST_ROUTE

```

The "service" topology is very simple as CSR7 is the RR for VPNv4, VPNv6, IPv4 MVPN, IPv6 MVPN, and L2VPN VPLS. I omit the L3VPN BGP PE configurations since those are simple. I compress this configuration since it is highly redundant. CSR7 peers with the core RRs as well so it can advertise its loopback into BGP IPv4 labeled-unicast for UMPLS transport. This mechanism is the same technique used on CSR2, CSR4, and CSR5 as PE routers. The difference is that those only peer with CSR7 but negotiate the same AFls. CSR4 does not run VPLS, but otherwise, everything is the same across all PE routers.

```

```

The core RRs peer with all ABRs in the topology, at a minimum. Due to the MVPN design, I also include the other core routers so that they have reachability to the P2MP roots (PE routers) in different areas. They would need BGP connectivity in order to see these loopbacks in a proper UMPLS design. In this case, I demonstrate policy inheritance in the event that a non-RR neighbor needs to be added in the

future. The configuration is very similar on XRv12 as well, except that the core routers CSR1 and CSR9 are not peered to it. For simplicity, I only configured them to peer with CSR8 as a quick way to repair MVPN P2MP tree issues.

```
! CSR8
route-map RM_CONN_TO_BGP permit 10
  match interface Loopback0

CSR6 is a CE router which is multi-homed to two PE routers, CSR4 and CSR2. It uses local preference to select best paths for traffic sent towards the SP network. For simplicity, it prefers CSR2 for VRF U1 and CSR4 for VRF U2. This is true for both IPv4 and IPv6 AFIs. The other BGP configurations are omitted, but this path-selection modification is important. This was shown in the CSC section but is repeated for clarity.

```

```

33.2.1 IS-IS

This large demonstration shows many MPLS services over unified/seamless MPLS. The network is split into different IS-IS areas/levels with various levels of filtering at the L1/L2 routers. CSR5, CSR7, CSR2, and CSR4 are the PEs that offer VPNv4, VPNv6, VPLS, and MVPN services. The lab is very configuration-intensive so only certain pieces of configuration are shown. The network diagram is shown below, which is identical to the one used for the basic UMPLS verifications above.

Because this is such a complex topology, we will verify all of the individual components before beginning as a best practice. A very fast way of checking IS-IS for configuration errors is to check the IS-IS data on an L1/L2 router at each area boundary. They all agree on the L2 topology (at least, the number of link-state packets). We can check this against the diagram along with the independent L1 topologies in each area. CSR7 is an L2-only router since there are no other areas in 49.CAFE in which to form an L1 adjacency. Each L1/L2 router shows the proper routers in each level, so we can continue. All we are doing is checking the router hostnames for this cursory check.

We will check LDP adjacencies quickly by selecting three routers spread throughout the network. This is imprecise, but is a good spot check. CSR8 has many links and covers most of the core, while CSR2 and CSR5 exist at the network extremities. Since VPLS with LDP signaling is enabled, we get the added benefit of verifying targeted LDP sessions on CSR2 and CSR5, which connect to CSR7 in a triangle. Those sessions are highlighted for clarity. CSR4 does not participate in VPLS.

```

Next, we will check IPv4 labeled-unicast BGP. This was verified in the general UMPLS verification but we quickly check it again. This is a key component of UMPLS since it allows disjoint IGP islands to communicate with one another. Using BGP to distribute VPN next-hops scales better than IGP redistribution and comes at the low cost of one additional MPLS shim header. Since XRv2 and CSR8 are the RRs for this AFI, we will check their session counts. So long as those routers are receiving one prefix from each peer, we can assume things are working to some extent. CSR1 and CSR9 are just core routers but are running IPv4 labeled-unicast as well. This was done as a workaround for UMPLS mLDP and is discussed later and has to do with tree construction between the islands. The reason there is only 1 prefix is because there is only 1 PE per island in this design, which is the only loopback that needs to be advertised into the core. In a real design, there would be many more PEs since the primary use-case of UMPLS is high scalability. It is assumed that the core has reachability to the ABR loopbacks via the core IGP.

```

The labeled-unicast service is critical to the operation of UMPLS. Since XRv12 is running labeled-unicast as evidenced by the show command above, CSR8 may not be, so we can verify this negotiation was successful by checking the neighbor details.

```

CSR8#show bgp ipv4 unicast neighbors | include ^BGP|Label_cap
BGP neighbor is 1.1.1.1, remote AS 49, internal link
  ipv4 MPLS Label capability: advertised and received
BGP neighbor is 4.4.4.4, remote AS 49, internal link

    ipv4 MPLS Label capability: advertised and received
BGP neighbor is 14.14.14.14, remote AS 49, internal link
    ipv4 MPLS Label capability: advertised and received

```

Finally, we will review the MPLS service-related BGP configurations. CSR7 is the route-reflector for all of these AFIs, and we check the neighbor status quickly. CSR7 is connected to and receiving "routes" from all BGP peers in the relevant service AFIs. Another alternative (and a better design for scalability) is to have an RR in each IGP island. This means that the individual islands are "self-sufficient" since the RRs will peer together and still service their intra-island PEs. In this design, we minimize the number of RRs while increasing dependence on the core network.

```

```

With the basic control-plane verifications complete, we will detail the UMPLS transport architecture. We will begin with CSR5. Examining the IS-IS LSP in detail, we can see that CSR5's IPv4 loopback is advertised into IGP. This means everyone in the IGP island (in this case, IS-IS level-1) will have reachability to it. It also means they should use an LDP label when sending MPLS-encapsulated traffic towards it. CSR5 allocates implicit-null for this prefix since it is directly connected.

```
CSR5#show isis database level-1 CSR5.00-00 detail | begin Hostname
Hostname: CSR5
Metric: 10          IS-Extended XRv13.00
Metric: 10          IS-Extended XRv14.00
Metric: 10          IS (MT-IPv6) XRv13.00
Metric: 10          IS (MT-IPv6) XRv14.00
IP Address: 5.5.5.5
Metric: 0           IP 5.5.5.5/32
```

```
CSR5#show mpls ldp bindings 5.5.5.5 32 local
lib entry: 5.5.5.5/32, rev 2
local binding: label: imp-null
```

Since the level-1 topology only contains two other connected routers, both XRv13 and XRv14 will use this label to reach 5.5.5.5. Breaking links or changing IGP costs within the L1 topology can change this behavior as we will see later.

```
RP/0/0/CPU0:XRv13#show cef ipv4 5.5.5.5 | utilit egrep 'via|labels'
via 49.5.13.5, GigabitEthernet0/0/0/0.553, 5 dependencies, weight 0, class
0 [flags 0x0]
local label 93000 labels imposed {ImplNull}
```

```
RP/0/0/CPU0:XRv14#show cef ipv4 5.5.5.5 | utilit egrep 'via|labels'
via 49.5.14.5, GigabitEthernet0/0/0/0.554, 5 dependencies, weight 0, class
0 [flags 0x0]
local label 94008 labels imposed {ImplNull}
```

CSR5 also advertises this loopback into BGP. Although the ABRs could have done this advertisement, doing it on the PEs is simpler to manage, and the ABR will prefer the IGP route over the iBGP route anyway. As with LDP, CSR5 allocates implicit-null for this prefix in BGP.

```
CSR5#show bgp ipv4 unicast 5.5.5.5/32
BGP routing table entry for 5.5.5.5/32, version 2
Paths: (1 available, best #1, table default)
Advertised to update-groups:
1
Refresh Epoch 1
Local
0.0.0.0 from 0.0.0.0 (5.5.5.5)
Origin incomplete, metric 0, localpref 100, weight 32768, valid,
sourced, best
```

```
mpls labels in/out imp-null/nolabel
rx pathid: 0, tx pathid: 0x0
```

We confirm that the ABRs learn this prefix and corresponding implicit-null label (value of 3). The reason XRv14 has alternate paths via CSR8 and XRv12 is because they are RRs. CSR8 selected XRv13 as the best path due to having a lower neighbor ID than XRv14, then reflected the best-path down to all clients. XRv12 selected XRv13 because the IGP cost to 13.13.13.13 was lower than 14.14.14.14. This isn't significant, but a good observation.

```
RP/0/0/CPU0:XRv13#show bgp ipv4 labeled-unicast 5.5.5.5/32 | begin Local,

```

For completeness, though not directly related to UMPLS, we will verify the claims above. CSR8 doesn't tell us why it chose XRv13 over XRv14, but we can see its due to the lower neighbor ID. Normally, the RIDs would be compared, but when RRs exist (XRv13 and XRv14 are RRs for this AFI), the originator ID is compared, which is a tie. XRv12 clearly shows the difference in IGP metric and states so in plain English below the non-best-path.

```

```

XRv13 and XRv14 implements the textbook-correct, high-scalability version of UMPLS where IGP routes between aggregation and core islands do not cross at all. This is not the default IS-IS behavior since all L1 routes are converted to L2 routes at the L1/L2 router. UMPLS suggests the “core” and “aggregation” IGPs must be totally separate with no redistribution between the two. Using OSPF areas or IS-IS levels actually complicates UMPLS since manual filtering must be applied to break inter-area routing. We can disable this behavior with a deny-all RPL to stop all L1 to L2 propagation. In normal circumstances, this would break L1 to L2 connectivity. Since CSR5's loopback is known via IGP within its island and BGP beyond its island, this is an acceptable strategy when coupled with MPLS in the data plane. Tunneling

inside MPLS implies the core routers don't need routes to these endpoints provided the traffic can be label-switched across them (at least for L3VPN and L2VPN). We can verify this on any L2 router by checking the LSPs of XRv13 and XRv14 to ensure 5.5.5.5/32 does not appear. In fact, only the local ABR loopbacks exist in the L2 topology since the ABRs could not originate 5.5.5.5/32 into L2.

```

For even stricter control, we can clear the attached bit (ATT-bit) which allows L1 routers in an area to install a default route via the ABRs. This is somewhat unrelated to UMPLS since there is no label for the default route, but we will disable it anyway. In an IP routing environment, this would break connectivity as well.

```
! XRv13 and XRv14
router isis 49
  address-family ipv4 unicast
    attached-bit send never-set
```

A quick check on CSR5 shows the ATT bit is cleared for those two LSPs. This is shown in contrast to CSR2, where CSR4 and CSR10 are setting the ATT bit. These outputs were shown earlier during the initial IS-IS verification, but are verified again for completeness.

We verified that CSR8 and XRv12 had CSR5's loopback in BGP. Next, we verify the L1/L2 routers in area 49.BEEF (remote island) have these routes. These L1/L2 routers are the RRs that will reflect these iBGP routes to the PE routers. CSR4 happens to be both a PE and L1/L2 router. There is no reason for the core RRs to change the BGP next-hops for these routes since the L1/L2 routers have IGP routes to all other L1/L2 routers. Technically, the core RRs could do this, but it would be highly inefficient as those RRs would place themselves in the data plane, which is undesirable.

CSR2 must learn these routes from CSR4 and CSR10. Due to the link metric adjustments, CSR2 prefers the path via CSR10 (cost to BGP next hop). Notice that the next-hops have been changed to represent the L1/L2 routers, which is a fundamental concept of unified MPLS. Technically this would not be required in this case since CSR2 has BGP routers for CSR8 and XRv12, but this isn't a typical, and was done for flexible testing only. The output below shows the "textbook" unified MPLS setup.

```

33.2.1.1 L3VPN

Now that the UMPLS building blocks have been verified, we will trace some L3VPN LSPs. The basic VRF U1 and VRF U2 configurations are shown below on CSR5. The L3VPNs are fully meshed with the exception of CSR2 and CSR4. Since they service the same customer, there is little reason for them to import one another's RTs. The RT values are self-documenting since the last digit represents the PE number.

```

```

Next, we will send traffic from CSR6 to XRv11 within VRF U1. This is classic MPLS L3VPN service wrapped inside UMPLS transport. CSR2 learns label 5012 from CSR5, the remote PE in a different IGP island, which is the bottom label. This label represents the final destination within the VPN and should never be swapped.

```

CSR2#show bgp vpnv4 unicast vrf U1 1.11.11.11/32
BGP routing table entry for 49:102:1.11.11.11/32, version 144

```

```
mpls labels in/out nlabel/5012
rx pathid: 0, tx pathid: 0x0
```

The route to the VPNv4 next-hop also happens to be a BGP route. The routing table reveals the MPLS label used for this destination since labeled-unicast was negotiated for IPv4 BGP. This represents CSR10's label to reach 5.5.5.5/32, which is the remote PE.

```
CSR2#show ip route 5.5.5.5
Routing entry for 5.5.5.5/32
  Known via "bgp 49", distance 200, metric 0, type internal
  Last update from 10.10.10.10 4d21h ago
  Routing Descriptor Blocks:
    * 10.10.10.10, from 10.10.10.10, 4d21h ago
      Route metric is 0, traffic share count is 1
      AS Hops 0
      MPLS label: 10010
```

The route to the IPv4 labeled-unicast next-hop is an IS-IS route, which means an LDP label will be used (no TE in play, yet). Since CSR10 is directly connected, CSR2 uses implicit-null, which effectively means no third label is pushed in this case. CSR10 will receive a label stack of {10010 5012}.

```
CSR2#show ip route 10.10.10.10
Routing entry for 10.10.10.10/32
  Known via "isis", distance 115, metric 10, type level-1
  Redistributing via isis 49
  Last update from 49.2.10.10 on GigabitEthernet2.520, 4d21h ago
  Routing Descriptor Blocks:
    * 49.2.10.10, from 10.10.10.10, 4d21h ago, via GigabitEthernet2.520
      Route metric is 10, traffic share count is 1
```

```
CSR2#show mpls ldp bindings 10.10.10.10 32 neighbor 10.10.10.10
lib entry: 10.10.10.10/32, rev 135
remote binding: lsr: 10.10.10.10:0, label: imp-null
```

Upon receipt, CSR10 consults its LFIB since the ingress packet was MPLS encapsulated. We will examine the control-plane structure first for extra verification. Since label 10010 was a BGP-allocated label as CSR10 changed the next hop, it is assumed CSR10 will perform a swap operation on this label. CSR10's next-hop for 5.5.5.5/32 is XRv13 who allocated label 93000. This implies that CSR10 swaps 10010 for 93000 which directs traffic to XRv13. The label stack is now {93000 5012}.

```
CSR10#show bgp ipv4 unicast 5.5.5.5/32 bestpath

  Originator: 5.5.5.5, Cluster list: 8.8.8.8, 13.13.13.13
  mpls labels in/out 10010/93000
  rx pathid: 0, tx pathid: 0x0
```

Next, CSR10 needs to determine the path to reach 13.13.13.13/32. This is an IGP route, which means CSR10 selects an LDP label. Looking at the RIB and FIB for brevity, we can see this IS-IS route points towards CSR8 using label 8006. CSR10 pushes this third label onto the stack, resulting in {8006 93000 5012}.

```
CSR10#show ip route 13.13.13.13

           No output feature configured
```

In the path to XRv13, CSR8 is a P router that performs a simple swap operation between LDP labels. The label stack becomes {92001 10010 5012}.

```
CSR8#show mpls forwarding-table labels 8006
Local      Outgoing  Prefix          Bytes Label  Outgoing  Next Hop
Label      Label     or Tunnel Id    Switched     interface

XRv13 receives the MPLS packet with BGP label exposed. BGP shows the local (incoming) label of 93000 with an LDP-learned received (outgoing) label of 3 towards CSR5. Label 3 is implicit-null, which implies XRv13 will perform a pop operation of the BGP label. This is important because although the BGP label would also be implicit-null, technically the LDP one is used since the route is learned via IGP. The combination of popping the BGP label and not adding an LDP label exposes the VPN label to CSR5. The label stack becomes {5012}.

```

We can make some minor adjustments to this topology to change the label stack slightly. We temporarily shut down the link between CSR5 and XRv13 (not shown). The IS-IS session will fail but the iBGP session will not, which means XRv13 will still be the preferred ingress point for traffic coming from the core. This is suboptimal, but for testing it is beneficial since we can see additional label impositions on XRv13. The label stack all the way up to XRv13 remains the same, but when XRv13 receives packets from the core labeled 93000, it performs a different operation. We can see that the BGP label is still popped, but a new LDP label must be pushed. XRv13 must route via XRv14 to reach CSR5 now, so XRv13 pushes XRv14's LDP label for 5.5.5.5/32 onto the stack. The label stack becomes {94008 5012}.

```

RP/0/0/CPU0:XRv13#show route ipv4 5.5.5.5
Routing entry for 5.5.5.5/32
  Known via "isis 49", distance 115, metric 20, type level-1
  Routing Descriptor Blocks
    49.13.14.14, from 5.5.5.5, via GigabitEthernet0/0/0/0.534
      Route metric is 20
  No advertising protos.

```

```
RP/0/0/CPU0:XRv13#show mpls ldp bindings 5.5.5.5/32 neighbor 14.14.14.14
5.5.5.5/32, rev 46
```

```
Local binding: label: 93000
```

```
Remote bindings: (1 peers)
```

Peer	Label
14.14.14.14:0	94008

XRv14 receives packets labeled 94008, pops this label, and delivers the singly-labeled packet to CSR5. CSR5's operation is not shown again since it did not change.

```
RP/0/0/CPU0:XRv14#show mpls forwarding labels 94008
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
94008	Pop	5.5.5.5/32	Gi0/0/0/0.554	49.5.14.5	7089319

Using traceroute, we can verify another hop in the network along with the additional label. Note that simply counting the number of labels is not a valid way to determine what type of label is used at each point in the stack. For example, hop 5 has a BGP-IPv4/BGP-VPNv4 label stack, while hop 6 has an LDP/BGP-VPNv4 label stack. RSVP-TE could be used in the network also which is tested later. One would have to actually know the network architecture to understand the source of each label seen in a traceroute.

```
CSR6#traceroute vrf U1 1.11.11.11 source 1.6.6.6
```

```
Type escape sequence to abort.
```

```
Tracing the route to 1.11.11.11
```

```

 8 192.168.105.11 41 msec * 48 msec
```

Before continuing, we will restore the link between CSR5 and XRv13. We will now break the link between CSR2 and CSR10. This will cause CSR10 to maintain an iBGP session with CSR2, but traffic is forced over the high-cost link between CSR2 and CSR4. This changes the label stack once again. The VPNv4 route of 1.11.11.11/32 has not changed as 5.5.5.5 is still the next-hop using label 5012.

```
CSR2#show bgp vpnv4 unicast vrf U1 labels
```

Network	Next Hop	In label/Out label
Route Distinguisher: 49:102 (U1)		

1.3.3.3/32	7.7.7.7	nolabel/7011
1.6.6.6/32	192.168.102.6	2019/nolabel
1.11.11.11/32	5.5.5.5	nolabel/5012

Now, CSR5 prefers CSR4 as the BGP bestpath since the cost to CSR4 is less than to CSR10 (high speed link directly to CSR10 was shutdown).

```
CSR2#show ip route 5.5.5.5

      mpls labels in/out 4003/93000
      rx pathid: 0, tx pathid: 0x0

```

It is interesting to note that CSR4's route to 13.13.13.13 has a next-hop via CSR10. This is because the cost through CSR10 is less than through CSR9 as it transits four IS-IS hops. Using CSR9, this would be five IS-IS hops with a path cost of 50. This implies that CSR4 must push CSR10's local label for 13.13.13.13/32 onto its stack, which is label 10004. The label stack becomes {10004 93000 5012}.

```

CSR4#show ip route 13.13.13.13
Routing entry for 13.13.13.13/32

remote binding: lsr: 10.10.10.10:0, label: 10004

```

Following the LSP evaluated earlier, we expect CSR10 to switch this packet towards CSR8. CSR10 merges this with the LSP we saw earlier by swapping to label 8006 (also seen earlier), essentially putting the traffic back onto the same path through the core and remote IGP island as seen before.

```

CSR10#show mpls forwarding-table labels 10004
Local      Outgoing  Prefix          Bytes Label  Outgoing  Next Hop
Label      Label     or Tunnel Id    Switched     interface
10004      8006      13.13.13.13/32  50008        Gi2.580    49.8.10.8

```

Rather than verify the same LSP again from CSR8 forward, we will confirm the new LSP via traceroute on CSR6. The label stacks at each hop match what we verified above.

```
CSR6#traceroute vrf U1 1.11.11.11 source 1.6.6.6

```

Traffic in the opposite direction would, in a real deployment, work exactly the same way. However, I demonstrate an alternative UMPLS architecture in the reverse direction. This introduces more variety in our testing and is more interesting than tracing the same thing twice. This is not the "correct" way to implement UMPLS since it is less scalable by leaking aggregation loopbacks into the core. CSR4 and CSR10 are L1/L2 routers for area 49.BEEF. We saw earlier that they changed the BGP next-hop to be themselves when advertising routes to CSR2 (island PE); towards the core RRs, they do not set the next-hop to themselves. This is because the L1-to-L2 propagation is not manually filtered as it was on XRv13 and XRv14; as such, all L2 routers will have IS-IS L2 routes for CSR2's loopback. This obviates the need for BGP to shim another label onto the stack for core transport since all L1/L2 routers can use LDP labels to reach the remote PEs across the core. To visualize the difference, we can check CSR8's route for 2.2.2.2/32. We compare it to the route to 5.5.5.5/32 seen earlier, since the routes to CSR5 have next-hops of the L1/L2 routers while CSR2's route is marked as a RIB-failure.

```

It's good that CSR2's route was marked as a RIB failure since the next-hop is the same as the prefix which would cause a recursive routing logic failure. We verify that CSR8 has an IS-IS route in the RIB, which explains the BGP RIB failure. We compare this to the BGP route to 5.5.5.5/32 seen earlier. CSR8 reaches 2.2.2.2/32 via CSR10 and binds label 10000 to this prefix, which is learned via LDP.

```

```

CSR4 and CSR10 also do not clear the ATT-bit when sending their L1 LSPs into area 49.BEEF, which isn't terribly relevant for UMPLS but demonstrates that we don't have to modify IS-IS. We saw this earlier but it is shown again for clarity.

```
CSR2#show isis database level-1

```

Now that we have seen the difference, we will trace an LSP from XRv11 to CSR6 using VPNv6 inside VRF U2. Since CSR6 is multi-homed to two PEs (CSR2 and CSR4), CSR5 learns two VPNv6 routes. CSR2 wins due to having a lower originator-ID, which uses label 2007 and an IPv4 next-hop of 2.2.2.2/32.

```
CSR5#show bgp vpnv6 unicast vrf U2 ::2:6:6:6/128

```

The route to CSR2 is via XRv13 learned using BGP. Quickly checking the BGP table, we see that XRv13 wins by having a lower neighbor ID. CSR5 uses BGP label 93008 to reach 2.2.2.2/32. The label stack is now {93008 2007}.

```
CSR5#show ip route 2.2.2.2
```

    remote binding: lsr: 13.13.13.13:0, label: imp-null

```

XRv13 performs a very interesting function. It's BGP route, regardless of which one is selected (CSR8 is best due to lower neighbor ID), is reachable via 2.2.2.2/32. Since this is just a copy of the same path that passed through CSR4, the label binding is also the same, which is implicit-null. This is because CSR4 did not change the next-hop when it advertised these routes to the core RRs, which means it also did not

change the label binding originally allocated by CSR2. Based on this logic, the label stack would become {2007} as label 93008 is popped in ingress. At a glance, this does not make sense.

```

Exposing the VPN label to the core is going to break the LSP. Continuing the RIB lookup process, XRv13 performs a route lookup for 2.2.2.2 and finds an IS-IS route via XRv13. Again, this is not customary for UMPLS, but since the area 49.BEEF L1/L2 routers propagated L1 routes into L2, all L2 routers have IS-IS routes for those remote loopbacks. Checking the LIB, XRv13 binds label 92007 to CSR2's loopback prefix and pushes this onto the stack, which becomes {92007 2007}. The BGP route shown above is not used at all for label operations on XRv13 for this particular LSP, but it can be a challenging distraction.

```
RP/0/0/CPU0:XRv13#show route ipv4 2.2.2.2/32
Routing entry for 2.2.2.2/32
  Known via "isis 49", distance 115, metric 40, type level-2
  Routing Descriptor Blocks
    49.12.13.12, from 10.10.10.10, via GigabitEthernet0/0/0/0.523
      Route metric is 40
  No advertising protos.
```

```
RP/0/0/CPU0:XRv13#show mpls ldp bindings 2.2.2.2/32 neighbor 12.12.12.12
2.2.2.2/32, rev 76
  Local binding: label: 93008
  Remote bindings: (2 peers)
    Peer          Label
    -----
    -----
```

12.12.12.12:0 92007

The LFIB evaluates this operation as a "swap" operation. This is essentially how a BGP label can be swapped for an LDP label with no change in label stack depth. Looking only at the BGP labels, though, the swap is not obvious since BGP isn't aware of the full picture.

```
RP/0/0/CPU0:XRv13#show mpls forwarding labels 93008
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
93008	92007	2.2.2.2/32	Gi0/0/0/0.523	49.12.13.12	24291332

Since XRv13 has a route to the remote PE, the entire remainder of the LSP is simply LDP-based label swapping. I quickly show the hops along the remainder of the path. The path is as follows: XRv12, CSR8, CSR10 (PHP), and CSR2. CSR2 receives label 2007 and delivers it into VRF U2 for the specific destination prefix.

```
RP/0/0/CPU0:XRv12#show mpls forwarding labels 92007
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92007	8010	2.2.2.2/32	Gi0/0/0/0.582	49.8.12.8	25373558

```

```

33.2.1.2 L2VPN

The basic L2VPN configuration consists of a QinQ access circuit where both tags are pushed and popped symmetrically. BGP auto-discovery is used with LDP signaling to build a full-mesh of PWs between CSR2, CSR5, and CSR7. CSR4 does not participate in VPLS. Only CSR5 is shown for brevity since the configuration related to L2VPN is identical on all PEs. The control-word and sequencing are enabled as best practices for L2VPN designs.

```
! CSR5
interface GigabitEthernet2
 service instance 305 ethernet
 encapsulation dot1q 3551 second-dot1q 305
 rewrite ingress tag pop 2 symmetric

template type pseudowire VPLS_TEMPLATE
 encapsulation mpls
 sequencing both
 control-word include

l2vpn vfi context VPLS
 vpn id 567
 autodiscovery bgp signaling ldp template VPLS_TEMPLATE

router bgp 49
 address-family l2vpn vpls
 neighbor 7.7.7.7 activate
```

Because L2VPN is using the same LDP/BGP labeled-unicast paths as all other MPLS services, tracing the LSP will be identical as it is for L3VPN. The only difference is the PW label. We can reveal the PW label of 5019 using a number of commands, two of which are shown below. The purpose of demonstrating L2VPN is to show that UMPLS is not limited to only L3VPN (IP-based) services.

```
CSR2#show l2vpn atom vc vcid 567 destination 5.5.5.5 detail | include
label_stack
  Output interface: Gi2.520, imposed label stack {10010 5019}
```

```

CSR2#show l2vpn atom binding 5.5.5.5 | section 567
Destination Address: 5.5.5.5, VC ID: 567
Local Label: 2016
    Cbit: 1,    VC Type: Ethernet,    GroupID: n/a
    MTU: 1500,    Interface Desc: n/a
    VCCV: CC Type: RA [2], TTL [3]
    CV Type: LSPV [2]
Remote Label: 5019
    Cbit: 1,    VC Type: Ethernet,    GroupID: n/a
    MTU: 1500,    Interface Desc: n/a
    VCCV: CC Type: RA [2], TTL [3]
    CV Type: LSPV [2]

```

Tracing L2VPN from the customer's perspective won't reveal any of the MPLS details, so we will use OAM instead. Combining an ordinary traceroute from the PE with PW-aware OAM reveals all of the labels which reveals the same LSP traced earlier. The PW label is 5019 which is the bottom-most label. Appending this to the bottom of the label stacks seen in the traceroute, we can have the full stack. I use an 800-byte packet so that it stands out inside the EPC capture happening next.

```

```

As a quick verification of all L2VPN components, including the control-word, we use EPC outbound on CSR10 to capture this OAM ping. The label stack {8006 93000 5019} is highlighted in yellow and the control-word is highlighted in green. The hex values of 0x1F46, 0x16B48, and 0x139B represent the correct labels. The beginning of the CW is 0x1, which is 0001 in binary, representing a PW-ACH which is specific to MPLS OAM, and the trailing 0x21 represents an IPv4 OAM packet.

```

[snip]

```

As another quick test, we will look at the path from CSR3 to XRv11. The L2VPN show command reveals the entire label stack at imposition, which is 3 labels deep as expected. This single command is very useful for verifying the individual MPLS forwarding components.

```

CSR7#show l2vpn atom vc vcid 567 destination 5.5.5.5 detail | include
label_stack
Output interface: Gi2.572, imposed label stack {92001 93000 5004}

```

For additional verification, I also verify the basis of each individual label below. The PW label of 5004 is allocated by LDP and is seen in the AToM bindings, which describes the MPLS service. The middle transport label of 93000 is allocated by BGP labeled-unicast to describe the path to CSR5 via XRv13. The route to XRv13 is an IGP route, so the LDP label 92001 is used.

```

CSR7#show l2vpn atom binding 5.5.5.5 | section 567

```

Finally, we perform outbound EPC on CSR7 to verify the label stack and CW. To ensure sequencing works, I will send some large pings inside the L2VPN from CSR2 to XRv11. Using this technique versus OAM allows us to verify that CW sequencing is working. The label stack {92001 93000 5004} is shown in yellow with the CW shown in green. Notice that the CW begins with 0x0, which means this is a regular AToM packet as opposed to an OAM packet (no PW-ACH indications here), and the low-order 16 bits represents the sequence number which increments as follows: 0x2DED, 0x2DEE, and 0x2DEF.

```

33.2.1.3 MVPN (mLDP profiles 1 and 17)

Next, we will examine two flavors of mLDP in the network. VRF U1 uses BGP-AD to build P2MP trees for the default MDT (profile 17) while VRF U2 uses a statically configured MP2MP default MDT (profile 1). Since only MVPN profile 0 works for CSC, we will use other profiles for variety. A quick verification on CSR7 shows the trees. The P2MP trees with GID 65536 are IPv4 MDTs and there is one rooted in each PE per MVPN instance. The second set of P2MP trees with GID 131072 are for IPv6 within the same MVPN. There is a single MP2MP tree for the second MVPN instance which is shared by for IPv4 and IPv6. The IPv4 GIDs are shown in yellow with IPv6 GIDs shown in green. IPv4 trees appear to always end with 0x10000 (65536 in decimal) while IPv6 doubles that number to 0x20000 (131072). The single MP2MP tree represents the VPN U2 default DTM.

```
CSR7#show mpls mldp database summary
```

LSM ID	Type	Root	Decoded Opaque Value	Client
Cnt.				
3	P2MP	2.2.2.2	[gid 65536 (0x00010000)]	1
5	P2MP	4.4.4.4	[gid 65536 (0x00010000)]	1
7	P2MP	5.5.5.5	[gid 65536 (0x00010000)]	1
1	P2MP	7.7.7.7	[gid 65536 (0x00010000)]	3
4	P2MP	2.2.2.2	[gid 131072 (0x00020000)]	1
6	P2MP	4.4.4.4	[gid 131072 (0x00020000)]	1
8	P2MP	5.5.5.5	[gid 131072 (0x00020000)]	1
2	P2MP	7.7.7.7	[gid 131072 (0x00020000)]	3
B	MP2MP	8.8.8.8	[mdt 49:222 0]	1

We will perform a basic verification of the mLDP control-plane for both VRFs, beginning with U2 since it's much simpler. When CSR7 has to send LSM traffic to other nodes in the MVPN, it sends traffic towards the MP2MP root. The MP2MP is bidirectional, so there is an upstream label to send traffic

towards the root, and a downstream label to receive traffic along the same tree. In this case, label 8025 is used to send traffic upstream towards CSR8.

```
CSR7#show mpls mldp database id B | section Upstream
Upstream client(s) :
  8.8.8.8:0      [Active]
    Expires      : Never          Path Set ID   : B
    Out Label (U) : 8025          Interface    : GigabitEthernet2.578*
    Local Label (D) : 7016        Next Hop     : 49.7.8.8
```

When CSR8 receives it, it must replicate the traffic in several directions towards the remote PEs. In this case, traffic arrives with local label 8025 from CSR7, so it is distributed to CSR10 and XRv12, which are in the paths towards CSR2 and CSR5, respectively. We also verify this in the LFIB which shows the LSM replication.

```
CSR8#show mpls mldp database opaque_type mdt 49:222 0 | begin Replicat
Replication client(s):
  10.10.10.10:0
    Uptime       : 2d03h          Path Set ID   : E
    Out label (D) : 10019         Interface    : GigabitEthernet2.580*
    Local label (U) : 8022        Next Hop     : 49.8.10.10
  7.7.7.7:0
    Uptime       : 2d03h          Path Set ID   : 11
    Out label (D) : 7016          Interface    : GigabitEthernet2.578*
    Local label (U) : 8025        Next Hop     : 49.7.8.7
  12.12.12.12:0
    Uptime       : 1d02h          Path Set ID   : 14
    Out label (D) : 92019         Interface    : GigabitEthernet2.582*
    Local label (U) : 8021        Next Hop     : 49.8.12.12
```

```
CSR8#show mpls forwarding-table labels 8025
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label      or Tunnel Id Switched     interface
8025       10019      [mdt 49:222 0] 1144008     Gi2.580   49.8.10.10
           92019      [mdt 49:222 0] 619936     Gi2.582   49.8.12.12
```

First, we will follow the path to CSR2 and CSR4. CSR10 receives packets labeled 10019 from CSR8, which is for traffic heading down the MDT. This downstream label is swapped for 2017 and forwarded to CSR2 as shown in the mLDP database and LFIB. The same action occurs for label 4014 towards CSR4.

```
CSR10#show mpls mldp database opaque_type mdt 49:222 0 | begin Upstream

```

CSR4 receives packets with label 4014 and replicated it to the LSM virtual interface bound to VRF U2. The LFIB also shows this label being removed with traffic associated with the proper VRF and LSP-VIF interface.

```

Going back to CSR8 (MP2MP root), packets also travel towards CSR5. XRv12 receives packets labeled 92019 from CSR8 and swaps this for label 93019 towards XRv13. The 0x00008 is the LSM-ID which is automatically generated when database state is created. Unlike XE's LFIB, XR's LFIB does not show the opaque information, but the LSM-ID instead. The LSM-ID isn't terribly significant except for cross-referencing different show/debug command outputs.

```

RP/0/0/CPU0:XRv12#show mpls mldp database opaquetype mdt 49:222
mLDP database
LSM-ID: 0x00008    Type: MP2MP    Uptime: 1d02h

Using OAM, we can verify the LSPs are functional from CSR7. All three of the remote PEs are responding as expected. We can see that UMPLS did not introduce any snags into the mLDP design, but this success is somewhat coincidental. Like inter-AS option C, a mechanism may be necessary for core routers to have build MDTs properly. The PIM vector may be used in some designs (MVPN profile 0) so that core routers can resolve RPF in the “direction” of the remote PE. In this network, although not seen yet, BGP

is running on all core routers. While not a common design, this quickly fixes the issue of mLDP tree construction.

```

Next, we will verify VRF U1 multicast connectivity. Because there are many different (but very similar) P2MP trees, we will only examine the IPv4 tree rooted at CSR2. We will verify this from tail to head, which is technically how mLDP LSPs are built, which means the signaling begins on CSR7 and CSR5. Focusing on CSR7, it receives an MVPN Type-1 route (I-PMSI) from CSR2 which describes the default MDT tunnel attributes. We can see it is an mLDP P2MP tunnel (tunnel type 2) rooted at 2.2.2.2. Based on this, CSR7 creates the tree upstream towards the root by advertising downstream labels in that direction. In this case, the label mapping message is sent to CSR8. Notice that there is no upstream label since P2MP trees are always unidirectional, so there is never a case where CSR7 can send traffic to CSR2 along this tree. Instead, CSR7 can only receive downstream traffic using label 7018 and deliver it to its MVPN customer.

```

CSR5 does the exact same thing. It has the same BGP type-1 route from CSR2 (not shown again) and sends a label mapping message to XRv13. XRv13 sends a label mapping message to XRv12, who sends one to CSR8. Those steps are highly redundant and not shown. CSR5 is allowed to receive downstream traffic from XRv3 only.

```

```

CSR8 receives label mapping messages from CSR7 and XRv12, making it a branch point for LSM. It sends a label mapping to CSR10 with label 8001 to receive traffic, and replicates downstream traffic to CSR7 and XRv12 using labels 7018 and 92010, respectively.

```
CSR8#show mpls mldp database id 1 | begin Upstream

```

Local label (U): None Next Hop : 49.8.12.12

CSR10 sends a label mapping message to CSR2 with downstream label 10011. CSR2 is the root of the tree and has no upstream neighbors, so it programs label 10011 from CSR10 as the first hop in the delivery tree. Notice that CSR4 did not join this P2MP tree; this is because the VPN route-targets were not exchanged by CSR2 and CSR4. This was done intentionally to show that mLDP is smart enough to build the trees in accordance with the RT policies as the BGP AD routes carry the RTs.

```
CSR10#show mpls mldp database id 1 | begin Upstream
Upstream client(s) :
  2.2.2.2:0        [Active]

```

Using OAM, we verify this LSP. Traffic can only flow in one direction in an mLDP P2MP tree, so the ping must be originated at the root of the tree. Again, we see no significant impact due to UMPLS. XE doesn't have a built in code for auto-discovered P2MP trees within the OAM command syntax tree, but it is 0x1 as discussed in the MVPN section.

```
CSR2#ping mpls mldp p2mp 2.2.2.2 hex 0x01 00010000 verbose

33.2.1.4 Inter-area TE and TE-FRR

Next, we will look at using RSVP-TE in conjunction with UMPLS LSPs. This is a good way to demonstrate inter-area TE techniques (or inter-level TE for ISIS). The most obvious method to do inter-area TE is to stitch tunnels together at the ABRs or L1/L2 routers. This is configuration intensive but offers the most control over paths in each area/level. It also implies that some tunnels may require LDP label exchange inside of them since the tunnels are P-P and PE-P. All LSRs are configured to accept targeted-LDP sessions as well as allow mLDP to use TE tunnels (not shown). Currently, CSR2 is the head-end of a TE tunnel to CSR10 [ID 100]. Normally these stitched tunnels require LDP, but in this case, LDP is not required. The real reason for needing LDP on stitched tunnels is to learn the label for the remote PE, but CSR2 is already learning it via BGP; for this reason, LDP is not needed on CSR2's tunnel. There is a second tunnel from CSR10 to CSR7 which does not require LDP for unicast connectivity since the tunnel destination is the PE. The goal is to ensure these two tunnels are stitched together properly.

```
! CSR2
ip explicit-path name EP_4_10 enable
  next-address 4.4.4.4
  next-address 10.10.10.10

interface Tunnel100
  description PATH TO R10 VIA R4
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 10.10.10.10
  tunnel mpls traffic-eng autoroute announce
  tunnel mpls traffic-eng path-option 10 explicit name EP_4_10

! CSR10
ip explicit-path name EP_8_12_7 enable
  next-address 8.8.8.8
  next-address 12.12.12.12
  next-address 7.7.7.7

interface Tunnel100
  description PATH TO R7 VIA R8 AND XRV12
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 7.7.7.7
  tunnel mpls traffic-eng autoroute announce
  tunnel mpls traffic-eng path-option 10 explicit name EP_8_12_7
```

We quickly verify that CSR2's tunnel is up to CSR10. The path cost of 60 suggests that the high-cost link to CSR4 is in use, as expected. We also include the label value of 4008 which is used to send traffic to CSR4.

```

CSR2#show mpls traffic-eng tunnels tunnel 100 | section Status|Label
Status:
  Admin: up      Oper: up      Path: valid      Signalling: connected
  path option 10, type explicit EP_4_10 (Basis for Setup, path weight 60)

InLabel  : -
OutLabel : GigabitEthernet2.524, 4008

```

The recursive routing lookups dictate the label usage. CSR2 still learns the route to CSR7 via BGP, which has a next-hop of the L1/L2 router and exiting BGP label of 10006. This is the reason LDP is not needed; CSR7 is already being provided the "middle" label so that the bottom label is not exposed to the tunnel tail. Since CSR10 is the next-hop of this BGP route and also the tunnel tail, the proper label is exposed to CSR10 and the LSP should function. The route to CSR10 points of a TE tunnel, which means the RSVP label of 4008 is used. The label stack is now {4008 10006}.

```

CSR2#show ip route 7.7.7.7
Routing entry for 7.7.7.7/32
  Known via "bgp 49", distance 200, metric 0, type internal
  Last update from 10.10.10.10 00:22:09 ago
  Routing Descriptor Blocks:
  * 10.10.10.10, from 10.10.10.10, 00:22:09 ago
    Route metric is 0, traffic share count is 1
    AS Hops 0
    MPLS label: 10006

```

```

CSR2#show ip route 10.10.10.10
Routing entry for 10.10.10.10/32
  Known via "isis", distance 115, metric 10, type level-1
  Redistributing via isis 49
  Last update from 10.10.10.10 on Tunnel100, 00:19:38 ago
  Routing Descriptor Blocks:
  * 10.10.10.10, from 10.10.10.10, 00:19:38 ago, via Tunnel100
    Route metric is 10, traffic share count is 1

```

CSR4 pops label 4008 on ingress to expose the next label, which is 10006, to CSR10.

```

CSR4#show mpls forwarding-table labels 4008
Local      Outgoing  Prefix          Bytes Label  Outgoing  Next Hop
Label      Label     or Tunnel Id    Switched     interface
4008       Pop Label  2.2.2.2 100 [5]  257066      Gi2.540     49.4.10.10

```

The label operations on CSR10 are tricky. CSR10 does not install the BGP route to 7.7.7.7/32 since it has an IGP route for it via a TE tunnel. This means the TE label should be used. When merging BGP and LDP paths, we saw that the LFIB cleanly associated the labels in a swap operation. When interworking between BGP and TE labels, the LFIB is less clear. The BGP label is popped and the TE label is pushed, and the LFIB shows this correctly but only in the "detail" output. Label 8023 is the TE label from CSR8

which is effectively swapped onto the stack at CSR10. With BGP/LDP connections in the LFIB, this was more fluid.

```

CSR8 and XRv12 perform basic label swap and pop (PHP) operations, respectively. This reveals the MPLS service label to the PE, CSR7. In our case, we are not tracing a particular MPLS service, so the IPv4 packet would be revealed.

```
CSR8#show mpls forwarding-table labels 8023
```

Local Label	Outgoing Label	Prefix or Tunnel Id	Bytes Switched	Outgoing interface	Next Hop

We can verify the fully stitched LSP using OAM. The command output needs improvement, says the Cisco developer, as there wouldn't have been another third label in this stack on the first hop (even if it were not implicit-null). Ignoring the implicit-nulls that don't belong, the label stack is as we described it.

```
CSR2#traceroute mpls ipv4 7.7.7.7/32
```

more work needed here to demux the tfs subtlv and to display the right output

There is an alternative method to inter-area TE which is a relatively new feature. While tunnel stitching works, it is configuration-intensive and requires configuring many devices. Loose-hop expansion was designed to carry a TE tunnel through all the ABRs in the network by only configuring the head-end. The PCALC expansion algorithm comes into play which essentially computes paths between the loose hops based on cost, which means the administrator has less control. This is the same technique used for inter-AS MPLS option C except the tunnel is crossing IGP boundaries, not AS boundaries. We will configure this feature on CSR5 building a path to CSR2.

```
! CSR5
ip explicit-path name EP_14_10_2_LOOSE enable
  next-address loose 14.14.14.14
  next-address loose 10.10.10.10
  next-address loose 2.2.2.2
```

```
interface Tunnel101
  description PATH TO R2 VIA XRV14 AND R10
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 2.2.2.2
```

```
tunnel mpls traffic-eng path-option 10 explicit name EP_14_10_2_LOOSE
```

To see this tunnel in action, we will enable debugging on CSR5 (head), XRv14 (local L1/L2), and CSR10 (remote L1/L2). Each one of these routers have special responsibilities for ensuring the path is built between areas/levels since the L1-only and L2-only routers have limited visibility.

```
! CSR5, CSR10, and XRv14
debug mpls traffic-eng path lookup
```

CSR5's output begins with a traditional PCALC invocation with an explicit-path. The tunnel destination node of 5.5.5.5 cannot be found in the local L1 topology, so PCALC evaluates the first loose hop. This first loose hop of 14.14.14.14 does exist in the local L1 topology and is an L1/L2 router. As a result, CSR5 computes a path to XRv14 within the L1 topology. Notice that CSR5 expands the ERO in the PATH message to include the strict hops within the L1 topology to reach XRv14, and uses this new ERO for signaling.

```

As a mechanism of loop prevention, the RSVP PATH RRO is introduced. This is similar to the RSVP RESV RRO except is used to record PHOPs along the path so that downstream routers don't accidentally compute paths through those nodes again. When using loose-hop expansion, multiple routers are running PCALC, which is not common for TE; normally the head-end runs PCALC, encodes the TE path in an RSVP PATH ERO, and signals the path using RSVP. When XRv14 receives this PATH message, it can see that it needs to compute a path to CSR10, the first loose hop in the ERO. It calls the PCALC "expand" mechanism which computes the path to this loose hop using any dynamic path that satisfies the tunnel constraints. XRv14 selects the path from CSR1, to CSR8 to CSR10. The ERO shown below shows CSR10 as a loose hop, and the outgoing path identifies all the L2 topology hops and retrains CSR2 as the last loose-hop. Technically this last loose-hop for the tunnel destination is not required, but is added for clarity. XRv14 also excludes CSR5 from the computation (doesn't matter since the computation is happening in L2, so 5.5.5.5 is an unknown node) because it is carried in the RSVP PATH RRO shown below. The XR debug is verbose but unedited since this is the only place where it is shown. The details are highlighted but I leave all of the output for reference.

```

CSR10 receives the PATH message from CSR8 which contains CSR2 as a loose hop. Like XRv14, CSR10 invokes the LSP path expansion process to determine a dynamic path to CSR2. Also note that existing transit routers, such as CSR8, CSR1, and XRv14, are removed from consideration. It also tries to exclude CSR5 but cannot see its TE RID as it resides in a remote L1 topology. Again, CSR10 knows about these previous hops since they are contained in the RSVP PATH RRO. CSR2 is directly connected to CSR10, which is selected as the shortest path.

```

```

When we configured this tunnel, we did not configure a mechanism for routing. Auto-route announce and forwarding adjacency cannot work on these tunnels; notice that the destination TE ID cannot be seen by the head-end router, which breaks the auto-route announce logic. Forwarding-adjacency also would not make sense since it builds a link in the graph, which is not suitable between OSPF areas or IS-IS levels.

```
! CSR5
interface Tunnel101
 tunnel mpls traffic-eng autoroute announce
```

```

CSR5#show mpls traffic-eng autoroute
MPLS TE autorouting enabled
  destination 0-0-0-0-0-0-0, area isis level-1, has 1 tunnels
    Tunnel101 (load balancing metric 0, nexthop 2.2.2.2)
              (flags: Announce)

```

Instead, we can use autoroute destination on this tunnel since the destination actually is the real tail end. This strategy does not work on stitched tunnels, though. This means that CSR5 and CSR2 have a complete, end-to-end connection. This means that UMPLS architecture is totally bypassed; we no longer need BGP IPv4 labeled-unicast. The downside is that this solution defeats the purpose of UMPLS, which is to achieve better scalability. Stitched TE tunnels between ABRs in the core, or between ABRs/PEs in the aggregation islands, may scale better than PE to PE tunnels in this design. TE also may have negative effects on MVPN, which has been discussed many times in many other chapters.

```

! CSR5
interface Tunnel101
  tunnel mpls traffic-eng autoroute destination

```

Verifying L3VPN connectivity, we can see traffic from CSR5 to CSR2 has only two labels: the bottom BGP VPNv6 label and the top RSVP-TE label.

```

```

Next, we will examine TE-FRR with UMPLS. CSR1, CSR9, CSR8, CSR4, and CSR10 are running BFD between all links upon which they connect. BFD is disabled on all other routers. The goal will be to provide NHOP and NNHOP protection in various points in the network. Since tunnel stitching is just two ordinary TE tunnels, providing FRR for them is nothing new. Instead, we will configure the inter-area tunnel with the headend at CSR5 to request FRR. We can quickly confirm this is successful by verifying label bindings for each hop in the RSVP RESV RRO. Additionally, we will configure a bandwidth reservation to ensure bandwidth can be backed up between areas/levels.

```

First, we will provide basic NHOP protection in the core to protect the link from CSR1 to CSR8. CSR1 creates this NHOP tunnel and acts as the PLR. It will backup 7 Mbps of bandwidth from any pool. We quickly verify the FRR database on the PLR and the RSVP RESV RRO on the headend to ensure the tunnel is protected. We can use CSR1's local label shown in the RRO to see the specific FRR database entry.

```

We also quickly verify that the backup bandwidth is working. The RRO indicates that the NHOP protection "has BW" but we can verify it on the PLR as well. For extra verification, we use OAM to verify the path avoids the link between CSR1 and CSR8. This is also shown in the RSVP PATH ERO shown above.

```

We can also configure NNHOP protection across IS-IS level boundaries using loose-hop expansion. We will configure this tunnel on CSR8 going to CSR2, effectively bypassing CSR10. This tunnel will use a combination of strict and loose hops to reach the final destination. We cannot simply exclude CSR10 since CSR8 won't find an intra-area/level path to CSR2. We ensure the tunnel comes up and avoids CSR10 completely using a more explicit method.

```

```

First, we check the RSVP RESV RRO on the headend to ensure the NNHOP tunnel backs up the TE tunnel, also offering bandwidth. The PLR shows the FRR database entry as well, and we reference it by local label as derived by the RRO. RSVP is smart enough to know that a tunnel offers NHOP protection when its destination is the NHOP. Likewise, when a tunnel's destination is the NNHOP, regardless of how the tunnel was configured, RSVP considers it an NNHOP protection tunnel.

```

First, we will test the NHOP tunnel. The FRR label that CSR1 (PLR) pushes to tunnel traffic through CSR9 is 9014 as shown below. We use this, along with label 8018, to see traffic in the FRR tunnel using EPC.

```
CSR1#show mpls traffic-eng tunnels tunnel 110 | include Label
InLabel   : -
OutLabel  : GigabitEthernet2.519, 9014
```

BFD takes about 2.7 seconds to detect a failure in this setup. We change the encapsulation on CSR8 towards CSR1 after starting a ping within the L3VPN. After those 3 seconds, the packets are forwarded in the TE tunnel for a short time (only one packet in this instance, since the tunnel head is very close to the PLR). The single packet that ended up in the TE-FRR tunnel is highlighted green in the ping output. The label stack is {9014 8018 2007} as highlighted in cyan. This shows that NHOP protection works as expected when using inter-area tunnels. The reason we cannot reasonably use traceroute is because convergence happens so fast with dynamic or loose-explicit paths.

```

```

We will bring the CSR1-CSR8 link back up, reoptimize the tunnel, and test NNHOP protection next. This is a little more interesting since both the protected and protecting tunnels are inter-area with

loose-hops, but the RSVP signaling process is still the same. We will break the link between CSR10 and CSR8, then check the RSVP information. We don't need to use EPC because I managed to quickly capture the relevant information via show-commands (with the NHOP test above, I wasn't fast enough). CSR5 shows the NNHOP tunnel actually "in use". The NHOP tunnel is still available but is no longer "in use". This shows that the head-end was still notified by the PLR that FRR was activated. We won't do all of the TE-FRR verification details as this is sufficient to show that loose-hop tunnels can be both protected and protecting tunnels. Additional TE verification commands are show in the dedicated TE section.

Additional Reading – Reference configurations "umpls-isis"

33.2.2 OSPF (summarized)

We also analyze UMPLS using OSPF instead of IS-IS. The concepts are all identical, so this section is summarized to highlight the differences. The area boundaries are in the same places, so the routers that were L1/L2 routers for IS-IS are now ABRs for OSPF. XRv21 and CSR8 are also ABRs now; despite CSR7 being in a different IS-IS area earlier, it was still a level-2 router, so there was no additional complexity involved; UMPLS did not come into play. In this case, the topology is a little more complex as a result of added ABRs. There are different area types in use here mostly to demonstrate that UMPLS can work with any area type. Unlike IS-IS, we have to carefully select how to advertise loopback interfaces in areas. I use a combination of aggregation area and core area advertisement, along with LSA3 filtering to allow routes to leak. Area 0.0.43.173 and area 0.0.202.254 follow a classic UMPLS model where the ABRs don't allow routes to leak between areas and set next-hop-self on reflected BGP routes for IPv4

labeled-unicast. Area 0.0.190.239 is a relaxed variant where the OSPF inter-area routes leak into area 0 (as with a normal OSPF design) so the LDP LSP can be used. The BGP verifications are the same and are not repeated, since we will see them when verifying the MPLS services. The area 0.0.43.173 ABR configuration points of interest are shown below; notice that the loopbacks are advertised into the NSSA (not traditional) and are leaked into area 0.

```
! XRV13 (XRV14 is identical with different RPL)
route-policy RPL_LEAK_LOOPBACK
  if destination in (13.13.13.13/32) then
    pass
  endif
end-policy

router ospf 49
 network point-to-point
 area 0
  route-policy RPL_LEAK_LOOPBACK in

 area 0.0.43.173
  nssa no-summary
  interface Loopback0
  passive enable
```

The ABRs for area 0.0.202.254 are slightly different. The loopbacks are advertised into area 0 and are leaked outbound into all non-zero areas. This is similar logic as above except in the reverse direction. Additionally, all LSA3s are filtered from non-zero areas into area 0, which means BGP will be adjusting the next-hop. Setting the next-hop in an RPL doesn't appear to work for iBGP, even with iBGP modifications enforced, so we ignore this on XRv12. On CSR8, the OSPF filtering logic is identical with different syntax.

```
! XRv12
route-policy RPL_DROP
  drop
end-policy

route-policy RPL_LEAK_LOOPBACK
  if destination in (12.12.12.12/32) then
    pass
  endif
end-policy

router ospf 49
  network point-to-point
  area 0
    route-policy RPL_DROP in
    route-policy RPL_LEAK_LOOPBACK out
  interface Loopback0
    passive enable

area 0.0.202.254

! CSR8
interface Loopback0
  ip ospf 49 area 0

ip prefix-list PL_DROP seq 5 deny 0.0.0.0/0 le 32
ip prefix-list PL_LEAK_LOOPBACK seq 5 permit 8.8.8.8/32

router ospf 49
  area 0 filter-list prefix PL_DROP in
  area 0 filter-list prefix PL_LEAK_LOOPBACK out
```

The ABRs for area 0.0.190.239 has no filtering applied, other than the stub area configuration. This means all routers inside the non-zero areas can flood into area 0, implying that the ABRs do not need to adjust the BGP next-hop when advertising IPv4 labeled-unicast prefixes into the core. Since the ABRs are only advertising default routes, they must adjust the BGP next-hop when advertising routes to the PEs inside area 0.0.190.239 (the only PE is CSR2).

```
! CSR4 and CSR10
interface Loopback0
```

```
ip ospf 49 area 0.0.190.239

router ospf 49
area 0.0.190.239 stub no-summary
```

33.2.2.1 L3VPN

We will trace some L3VPN LSPs to ensure UMPLS is working correctly. First, we will test VRF U2 connectivity between XRv11 and CSR3 for IPv6. CSR5 has a VPNv6 route for ::2:3:3:3/128 with label 7010. This is the VPN label which, in UMPLS, never changes. The BGP next-hop is an IPv4 address of 7.7.7.7.

```
CSR5#show bgp vpnv6 unicast vrf U2 ::2:3:3:3/128
BGP routing table entry for [49:205]::2:3:3:3/128, version 232

CSR5's route to 7.7.7.7/32 is via XRv14. I adjusted local-preference on XRv14 to 200 earlier (it was not shown for brevity, though), because I wanted to use XRv14 as well, since XRv13 was in the transit path for all the IS-IS tests. The label for this destination is 94004, which was allocated by XRv14. Its next-hop is 14.14.14.14 for which CSR5 should have an IGP route and LDP label.

```

```

The route to XRv14's loopback is an OSPF route via a non-TE tunnel interface, which means an LDP label will be used as we predicted above. Since XRv14 is directly connected, that label value is implicit-null. The label stack is now {94004 7010}.

```

CSR5#show ip route 14.14.14.14
Routing entry for 14.14.14.14/32

    remote binding: lsr: 14.14.14.14:0, label: imp-null

```

When XRv14 receives this packet, it swaps the label from 94004 to 8002. The reason the path via XRv12 is invalid is because there is no route to 7.7.7.7/32 without causing a recursive routing loop. XR appears incapable of adjusting next-hops in RPLs for iBGP neighbors, which we attempted to configure on XRv12. “next-hop-self” works when applied to neighbors but not inside a custom RPL. As such, CSR8 is the ingress point for area 0.0.202.254. The label stack is now {8002 7010}.

```

```

Next, XRv14 needs to lookup the route for the BGP next-hop, which is 8.8.8.8 via OSPF towards CSR1. The corresponding LDP label from CSR1 is 1016. The label stack is now {1016 8002 7010}.

```

RP/0/0/CPU0:XRv14#show route ipv4 8.8.8.8

  Remote bindings: (2 peers)
    Peer          Label
    -----
    1.1.1.1:0     1016

```

CSR1 is a pure P router and only looks at the top-most label since there are no ECMP paths. OSPF says the next-hop is towards CSR8 directly, so implicit-null is advertised by CSR8, forcing CSR1 to pop the top-most label. The label stack is now {8002 7010}.

```

CSR1#show ip route 8.8.8.8
Routing entry for 8.8.8.8/32
  Known via "ospf 49", distance 110, metric 2, type intra area
  Last update from 49.1.8.8 on GigabitEthernet2.518, 01:44:40 ago

Label      Label      or Tunnel Id  Switched     interface
1016      Pop Label  8.8.8.8/32   80067        Gi2.518   49.1.8.8

```

When CSR8 receives the packets, the BGP label is removed. Notice that the BGP route is not in the routing table due to a RIB failure; this is because CSR8 has an OSPF route to 7.7.7.7 as they share an area. CSR7 allocates implicit-null via LDP for prefix 7.7.7.7/32, causing CSR8 to pop the BGP label. The label stack is now 7010, which reveals the VPN label of 7010 to CSR7. Although BGP and LDP both dictate that the out-label operation is “pop”, the LDP implicit-null is the one that is actually processed.

```

```

Next, we will trace the LSP from CSR6 to XRv11 inside VRF U2. We will notice some asymmetry in the forwarding path due to BGP adjustments along the way. First, we verify that CSR6 (CE) is sending traffic to 2.11.11.11 via CSR4 versus CSR2. This is a result of the BGP local-preference changes shown earlier.

```

CSR6#show bgp vpnv4 unicast vrf U2 2.11.11.11/32

```

All of the core routers are involved in this LSP. CSR9, CSR1, and CSR8 all are P routers along this path and perform basic label swaps of LDP labels. XRv12 is the PHP router along the LDP LSP and pops the LDP label to reveal the IPv4 labeled-unicast label of 93000 to XRv13. The show commands are displayed below, and the label stack becomes {93000 5002}.

```
CSR9#show mpls forwarding-table labels 9003
Local      Outgoing  Prefix      Bytes Label  Outgoing  Next Hop
Label      Label     or Tunnel Id  Switched     interface
9003      1001      13.13.13.13/32  1458         Gi2.519   49.1.9.1
```

```
CSR1#show mpls forwarding-table labels 1001

8000      92002      13.13.13.13/32      286255      Gi2.582      49.8.12.12
```

```
RP/0/0/CPU0:XRv12#show mpls forwarding labels 92002
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92002	Pop	13.13.13.13/32	Gi0/0/0/0.523	49.12.13.13	764630

When XRv13 receives packets with label 93000, it pops the label. The "Received Label" of 3 means implicit-null but does not apply here since XRv13 has an OSPF route for 5.5.5.5/32, thus using the LDP label. It is also implicit-null, and as we have seen many times before, can be tricky to understand which "implicit-null" is being used. This reveals label 5002 to the remote PE. I constantly show this as a "trick" because the in-label is BGP allocated, but the out-label cannot be used since the route is not installed via BGP. In this case, the LDP and BGP labels are both 3, but this is not always the case.

33.2.2.2 L2VPN

Like IS-IS, the verification for L2VPN is based mostly on the transport path plus the binding of the PW labels. Tracing the LSP from CSR6 to CSR3 inside the L2VPN, we can determine the PW label by checking the AToM bindings. In this case, the remote PW label is 7034.

```
CSR2#show l2vpn atom binding 7.7.7.7
Destination Address: 7.7.7.7, VC ID: 567
Local Label: 2018
  Cbit: 1, VC Type: Ethernet, GroupID: n/a
  MTU: 1500, Interface Desc: n/a
  VCCV: CC Type: RA [2], TTL [3]
  CV Type: LSPV [2]
Remote Label: 7034
  Cbit: 1, VC Type: Ethernet, GroupID: n/a
  MTU: 1500, Interface Desc: n/a
```

```
VCCV: CC Type: RA [2], TTL [3]
      CV Type: LSPV [2]
```

We will quickly determine the transport label stack as well. The route to CSR7, the remote PW endpoint, is a BGP route with label 10029 via CSR10. The route to 10.10.10.10 is an OSPF route bound to implicit-null, also via CSR10. The label stack is now {10029 7034}.

```
CSR2#show ip route 7.7.7.7

CSR2#show mpls ldp bindings 10.10.10.10 32 neighbor 10.10.10.10
lib entry: 10.10.10.10/32, rev 61
remote binding: lsr: 10.10.10.10:0, label: imp-null
```

CSR10 selects CSR8 as the BGP bestpath towards 7.7.7.7/32 due to having a lower neighbor ID (worst tie breaker). As seen earlier, the route via XRv12 is invalid due to the infinite recursive lookups that would occur. This swaps label 10029 for 8002; we confirm this in the LFIB also. The label stack is now {8002 7034}.

```
CSR10#show bgp ipv4 unicast 7.7.7.7/32
BGP routing table entry for 7.7.7.7/32, version 82
Paths: (2 available, best #2, table default)

CSR10#show mpls forwarding-table labels 10029

Local	Outgoing	Prefix	Bytes Label	Outgoing	Next Hop
Label	Label	or Tunnel Id	Switched	interface	
10029	8002	7.7.7.7/32	338367	Gi2.580	49.8.10.8

As seen earlier in the L3VPN verification, CSR8 pops this BGP label due to receiving an LDP-bound implicit-null for 7.7.7.7/32. The LDP label is used because the route to prefix 7.7.7.7/32 is an IGP route. This reveals the PW label of 7034 to CSR7.

CSR8#show ip route 7.7.7.7

Routing entry for 7.7.7.7/32

Known via "ospf 49", distance 110, metric 2, type intra area

Last update from 49.7.8.7 on GigabitEthernet2.578, 01:47:55 ago

Routing Descriptor Blocks:

* 49.7.8.7, from 7.7.7.7, 01:47:55 ago, via GigabitEthernet2.578

Route metric is 2, traffic share count is 1

CSR8#show mpls ldp bindings 7.7.7.7 32 neighbor 7.7.7.7

lib entry: 7.7.7.7/32, rev 22

remote binding: lsr: 7.7.7.7:0, label: imp-null

We can verify the transport label path using MPLS OAM. Ignoring the extraneous "implicit-nulls", the label stack is as we verified it above. Looking at the L2VPN PW details, we can see the label stack including the PW label as well.

CSR2#traceroute mpls ipv4 7.7.7.7/32 source 2.2.2.2

more work needed here to demux the tfs subtlv and to display the right output
[snip]

Type escape sequence to abort.

```
0 49.2.10.2 MRU 1500 [Labels: implicit-null/10029 Exp: 0/0]

L 2 49.8.10.8 MRU 1500 [Labels: implicit-null Exp: 0] 29 ms
! 3 49.7.8.7 20 ms
```

CSR2#show l2vpn atom vc vcid 567 destination 7.7.7.7 detail | include label_stack

Output interface: Gi2.520, imposed label stack {10029 7034}

We will also verify the PW from CSR7 to CSR5 for extra practice. The PW label is 5009 as shown by the AToM bindings below.

```
CSR7#show l2vpn atom binding 5.5.5.5 | include Label
Local Label: 7021
Remote Label: 5009
```

The route to the PW endpoint of 5.5.5.5 is a BGP route, implying that we use the BGP label to reach it. Notice that the reason CSR8 was selected was due to having a lower neighbor ID.

```
CSR7#show ip route 5.5.5.5
Routing entry for 5.5.5.5/32
  Known via "bgp 49", distance 200, metric 0, type internal
  Last update from 8.8.8.8 01:14:05 ago

    8.8.8.8 (metric 2) from 8.8.8.8 (8.8.8.8)
      Origin incomplete, metric 0, localpref 100, valid, internal, best
      Originator: 5.5.5.5, Cluster list: 8.8.8.8, 13.13.13.13
      mpls labels in/out nolabel/8004
      rx pathid: 0, tx pathid: 0x0
```

The route to the BGP next-hop of 8.8.8.8 is an OSPF route, implying that the LDP label should be pushed atop the BGP one. The LDP label is implicit-null, so the label stack becomes {8004 5009}.

```
CSR7#show ip route 8.8.8.8
Routing entry for 8.8.8.8/32
  Known via "ospf 49", distance 110, metric 2, type inter area
  Last update from 49.7.8.8 on GigabitEthernet2.578, 01:17:49 ago
  Routing Descriptor Blocks:
```

```
* 49.7.8.8, from 8.8.8.8, 01:17:49 ago, via GigabitEthernet2.578
Route metric is 2, traffic share count is 1
```

```
CSR7#show mpls ldp bindings 8.8.8.8 32 neighbor 8.8.8.8
lib entry: 8.8.8.8/32, rev 145
remote binding: lsr: 8.8.8.8:0, label: imp-null
```

Checking the LFIB, we can see that label 8004 is swapped for label 93000, with label 92002 pushed on top of that. The swap is conducted by BGP since the remote label from either XRv13 or XR14 was allocated by BGP also. CSR5 selects XRv13 as the bestpath due to the peer having a lower neighbor ID.

```
CSR8#show mpls forwarding-table labels 8004 detail

```

The push operation occurs because CSR8 has to reach XRv13 across the MPLS core, so it pushes an LDP label from XRv12 for 13.13.13.13/32. The label stack is now {92002 93000 5009}.

```
CSR8#show ip route 13.13.13.13
Routing entry for 13.13.13.13/32
  Known via "ospf 49", distance 110, metric 3, type inter area
  Last update from 49.8.12.12 on GigabitEthernet2.582, 01:53:55 ago
  Routing Descriptor Blocks:
  * 49.8.12.12, from 13.13.13.13, 01:53:55 ago, via GigabitEthernet2.582
    Route metric is 3, traffic share count is 1
```

```
CSR8#show mpls ldp bindings 13.13.13.13 32 neighbor 12.12.12.12
  lib entry: 13.13.13.13/32, rev 90
    remote binding: lsr: 12.12.12.12:0, label: 92002
```

This same in-label was seen earlier in the L3VPN section, but we verify again. The LDP label is popped revealing the BGP label to the ABR, XRv13.

```
RP/0/0/CPU0:XRv12#show mpls forwarding labels 92002
```

Local Label	Outgoing Label	Prefix or ID	Outgoing Interface	Next Hop	Bytes Switched
92002	Pop	13.13.13.13/32	Gi0/0/0/0.523	49.12.13.13	1032102

XRv13 pops the BGP label since the path to 5.5.5.5/32 is an IGP route that has an implicit-null LDP label. This reveals the PW label of 5009 to CSR5.

```
RP/0/0/CPU0:XRv13#show route ipv4 5.5.5.5/32
Routing entry for 5.5.5.5/32
  Known via "ospf 49", distance 110, metric 2, type intra area

```

A quick verification on CSR3 shows that the L2VPN E-LAN is working. There is a full-mesh of EIGRP neighbors for both IPv4 and IPv6, as expected. Since the Q-count is zero, we can assume that multicast and unicast connectivity has been achieved bidirectionally across the L2VPN.

```
CSR3#show eigrp address-family ipv4 vrf U3 neighbors

33.2.2.3 MVPN (mLDP profiles 1 and 17)

The mLDP connectivity works identically regardless of the IGPs in use. We quickly verify the tree construction on CSR2 and CSR5 as examples. Because CSR2 and CSR4 do not import one another's RTs, the MVPN BGP AD type-1 routers are not imported, so they don't join one another's P2MP trees. That is why CSR2 is not joined to a P2MP rooted at CSR4, but CSR5 is. As seen earlier, IPv4 P2MP trees are highlighted in yellow while IPv6 P2MP trees are highlighted in green.

```
CSR2#show mpls mldp database summary
```

```

We can also use OAM to check the P2MP trees from the root of that tree. In this case, we test the MVPNv6 tree from CSR5 to see that CSR2, CSR4, and CSR7 join. We also run the same test from CSR4 and only see responses from CSR5 and CSR7. This is expected because CSR2 did not join this P2MP tree.

```

For extra verification, we can see the BGP MVPNV6 routes on CSR4. Only CSR5 and CSR7 routes exist (plus the local one from CSR4), which is additional proof that CSR2 and CSR4 are not exchanging MVPN routes. The details of the CSR7 BGP AD Type-1 (I-PMSI) route are shown below. The format is identical for MVPNV4 and MVPNV6, which is discussed in detail in the MVPN section. This concludes the verification for this section; the OAM checks were sufficient to ensure the MVPN, from an SP perspective, is functional.

```
CSR4#show bgp ipv6 mvpn vrf U1 | begin Network
      Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 49:104 (default for vrf U1)
*> [1][49:104][4.4.4.4]/12
      ::                                32768 ?
* i [1][49:104][5.5.5.5]/12
      5.5.5.5                        0    100    0 ?

      rx pathid: 0, tx pathid: 0x0

```

33.2.2.4 MPLS TE and TE-FRR

Inter-area TE is similar between IS-IS levels and OSPF areas. The same constraints and techniques apply. We will quickly test both the tunnel stitching and loose-hop expansion methods. First, we have a stitched LSP from CSR2 to CSR7. For variety, we will adjust the tunnel in area 0.0.190.239 to terminate on CSR4; this is one hop away, which makes it a primary one-hop tunnel as well.

```

! CSR2
ip explicit-path name EP_4_DIRECT enable
  next-address 49.2.4.4
  next-address 4.4.4.4

interface Tunnel100
  description PATH TO R4 (DIRECT)
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 4.4.4.4
  tunnel mpls traffic-eng autoroute announce
  tunnel mpls traffic-eng path-option 10 explicit name EP_4_DIRECT

```

Unlike IS-IS, this area boundary with CSR7 actually matters to OSPF. IS-IS considered the inter-area link level-2, so the fact that CSR7 was in a separate area made no difference to IS-IS in that specific design. The tunnel originating from CSR4 cannot terminate on CSR7 for this reason. Instead, we terminate it on CSR8 by looping through other core routers; because this was the cost-based dynamic best-path, we don't make an explicit-path for simplicity. We verify this path with OAM.

```

! CSR4
interface Tunnel100
  description PATH TO CSR8 (DYNAMIC)
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 8.8.8.8
  tunnel mpls traffic-eng autoroute announce
  tunnel mpls traffic-eng path-option 10 dynamic

```

```
CSR4#trace mpls traffic-eng tunnel 100
Tracing MPLS TE Label Switched Path on Tunnel100, timeout is 2 seconds
[snip]
```

Type escape sequence to abort.

```
0 49.4.9.4 MRU 1500 [Labels: 9019 Exp: 0]
L 1 49.4.9.9 MRU 1500 [Labels: 1004 Exp: 0] 2 ms
L 2 49.1.9.1 MRU 1500 [Labels: implicit-null Exp: 0] 9 ms
! 3 49.1.8.8 13 ms
```

Rather than configure a tunnel in area 0.0.202.254, we will merge the TE path with the LDP path. We don't necessarily need to stitch tunnels everywhere, so we can continue to use LDP towards CSR7 from the ABRs servicing that area. First, we have several routing issues to fix. On CSR2, the route to 7.7.7.7 ultimately recurses towards CSR10 outside of the TE tunnel. We can fix this with a static route, or the more elegant approach; adjust BGP.

```
CSR2#show ip route 7.7.7.7
Routing entry for 7.7.7.7/32

      Route metric is 2, traffic share count is 1
```

CSR2 has selected CSR10 as the best-path for the route to 7.7.7.7/32 due to it being "closer" to CSR7 than CSR4 is. This generally makes sense and is the reason why BGP considers the IGP metric to the BGP next-hop in the first place.

```
CSR2#show bgp ipv4 unicast 7.7.7.7/32

```

We temporarily increase CSR10's cost on its loopback to 2. This means that CSR4 will become the winner based on having the lower neighbor ID. If we used a number greater than 2, CSR4 would still win, but as a result of having a lower IGP metric to the BGP next-hop. I form an IGP metric tie in this case just for fun. Label 4024 is now used within the LSP. Because CSR4 is the tail end of the tunnel, the next label in the stack should be a local label of that tail-end router. Using CSR10's local label would break the LSP as CSR4 would not know how to label-switch those 10000-series labels.

```

```

To verify that this works, we follow the route lookups on CSR2. Now that 4.4.4.4 is the BGP next-hop for 7.7.7.7, the traffic is routed into the tunnel via auto-route. Ignoring MPLS service labels (L3VPN, L2VPN, etc), the label stack is now {4024}. Also, ignoring mLDP requirements, LDP is not required on this tunnel despite it not being end-to-end because BGP can be used for the intermediate label bindings normally required for PE-P or P-P tunnels.

```

CSR2#show ip route 7.7.7.7

The same logic is true on CSR4. Checking the route recursion, 7.7.7.7 is reachable via 8.8.8.8, which is reachable via the TE tunnel. The label stack becomes {9019 8002}. In short, creating P-P to PE-P tunnels that terminate on routers that swap BGP labels (UMPLS ABRs, for example) is an acceptable alternative to using tLDP.

BGP details this operation as well. When label 4024 arrives, it is swapped to another BGP label of 8002, which is CSR8's local label for 7.7.7.7/32. Then, as seen above, traffic to 8.8.8.8 is tunneled inside MPLS using RSVP-bound labels. The LFIB details show these swap and push operations, which occur in that specific sequence. As expected, BGP doesn't have the "full picture" of other things happening beyond its purview, but the LFIB does.

```

CSR8 receives packets with only label 8002. Because CSR8's next-hop is CSR7, which was the original next-hop, the BGP label is removed which reveals the service label, if it exists. Beware of the BGP output; the BGP route is not installed in the RIB, which means CSR8 is learning the route another way. Specifically, it is an OSPF route and has an LDP binding for implicit-null. It just happens to be the same label binding as the BGP route, but technically, the implicit-nulls are different and mean different things about the forwarding path.

```

A quick MPLS service check for L3VPN indicates that the tunnel works. The transport labels from LDP, RSVP, and BGP are all the same, with the additional VPN label at the bottom. We confirm this value is 7007 by checking BGP VPNv4, then use traceroute to verify the rest of the label stack. The key point is that targeted LDP was not enabled on either tunnel, yet they were successfully stitched together. Although this tunneling design causes issues with MVPN as described in other sections section, it does work well with UMPLS.

The loose-expansion tunnel works exactly the same in OSPF as it does for IS-IS. For this reason, we don't have to change the tunnel configuration on CSR5 at all for tunnel101. The configuration is shown again for reference but remains unchanged.

```

! CSR5
ip explicit-path name EP_14_10_2_LOOSE enable
  next-address loose 14.14.14.14
  next-address loose 10.10.10.10
  next-address loose 2.2.2.2

interface Tunnel101
  description PATH TO R2 VIA XRV14 AND R10
  ip unnumbered Loopback0
  tunnel mode mpls traffic-eng
  tunnel destination 2.2.2.2
  tunnel mpls traffic-eng autoroute destination
  tunnel mpls traffic-eng priority 7 7
  tunnel mpls traffic-eng bandwidth 5000
  tunnel mpls traffic-eng path-option 10 explicit name EP_14_10_2_LOOSE
  tunnel mpls traffic-eng fast-reroute

```

First, CSR5 computes a strict path to the local ABR which is XRV14. This uses the directly connected interface between CSR5 and XRV14.

```
CSR5#show ip rsvp sender detail filter session-type 7 destination 2.2.2.2 |
section ERO
```

```
ERO: (incoming)
  5.5.5.5 (Strict IPv4 Prefix, 8 bytes, /32)
  49.5.14.14 (Strict IPv4 Prefix, 8 bytes, /32)
  14.14.14.14 (Strict IPv4 Prefix, 8 bytes, /32)
  10.10.10.10 (Loose IPv4 Prefix, 8 bytes, /32)
  2.2.2.2 (Loose IPv4 Prefix, 8 bytes, /32)
ERO: (outgoing)
  49.5.14.14 (Strict IPv4 Prefix, 8 bytes, /32)
  14.14.14.14 (Strict IPv4 Prefix, 8 bytes, /32)
  10.10.10.10 (Loose IPv4 Prefix, 8 bytes, /32)
  2.2.2.2 (Loose IPv4 Prefix, 8 bytes, /32)
```

When XRv14 receives the PATH message, it runs the PCALC expansion process to compute a strict path to the first loose hop, which is CSR10. This path routes via CSR1 and CSR8.

```
RP/0/0/CPU0:XRv14#show rsvp sender session-type lsp-p2p destination 2.2.2.2
detail | begin Explicit
```

```
Explicit Route (Incoming):
  Strict, 49.5.14.14/32
  Strict, 14.14.14.14/32
  Loose, 10.10.10.10/32
  Loose, 2.2.2.2/32
Explicit Route (Outgoing):
  Strict, 49.1.14.1/32

  2.2.2.2 (Strict IPv4 Prefix, 8 bytes, /32)
```

Since each router in the path appended its local interface to the RSVP PATH RRO, CSR2 can see the full path back to source, to include inter-area hops. The RRO also shows available TE-FRR protection along the way, which is something normally the tail-end does not see. These TE-FRR backup tunnels were

configured in the previous section and remain intact here. No labels are included in the PATH RRO since there is no MPLS forwarding along this path (it is not an LSP), which is different than the RESV RRO also shown below. This is the RRO we are used to seeing, which includes the per-hop RSVP-allocated labels along with any protection capabilities along the LSP. The labels, in sequence, are 94018 > 1032 > 8006 > 10021 > implicit-null.

```

We quickly verify the LSP is operational using OAM from CSR5 and verify the labels at the same time. Notice that this technique, unlike tunnel stitching, does not rely on an additional (third) BGP label in the stack to achieve scalability. An end-to-end TE design like this defeats the purpose of UMPLS because it scales poorly, but is a valid technique.

```
CSR5#traceroute mpls traffic-eng tunnel 101

We also use traceroute within the VPN on XRv11 to test VPNv6 reachability to CSR6. CSR5 selects the path via CSR2 as best due to having a lower originator ID, so the VPN label of 2002 is used. The top-most transport labels are the same RSVP-allocated labels we verified with OAM.

```

We saw earlier that this inter-area tunnel was protected by FRR as evidenced by the PATH and RESV RROs. CSR1 offers NHOP protected and is protecting the LSP with in-label 1032. It provides 7 Mbps bandwidth backup for any pool.

```
CSR1#show mpls traffic-eng fast-reroute database labels 1032 | begin P2P LSP
P2P LSP midpoint frr information:
LSP identifier          In-label Out intf/label  FRR intf/label  Status
-----
5.5.5.5 101 [81]       1032     Gi2.518:8006      Tu110:8006      ready
```

```
CSR1#show mpls traffic-eng tunnels tunnel 110 backup
INTER-AREA NHOP PROTECTION
  LSP Head, Admin: up, Oper: up
  Tun ID: 110, LSP ID: 66, Source: 1.1.1.1
  Destination: 8.8.8.8
  Fast Reroute Backup Provided:
    Protected i/fs: Gi2.518
    Protected LSPs/Sub-LSPs: 1, Active: 0
    Backup BW: any pool; limit: 7000 kbps, inuse: 5000 kbps (BWP inuse: 0
kbps)
    Backup flags: 0x0
```

Additionally, CSR8 provides NNHOP protection to completely avoid CSR10. This is also an inter-area tunnel using loose-hop expansion, which is valid and was verified in detail earlier. The protected LSP has a local label of 8020 and since the NNHOP is the tunnel destination, the FRR label becomes implicit-null since there isn't a need to instruct the merge point to forward the packet further (MP is the tail end). We can also see the backup bandwidth which is available for the protected LSP.

```
CSR8#show mpls traffic-eng fast-reroute database labels 8020 | begin P2P LSP
P2P LSP midpoint frr information:
LSP identifier          In-label Out intf/label  FRR intf/label  Status
-----
5.5.5.5 101 [83]       8020     Gi2.580:10012    Tu111:implicit-n ready
```

```
CSR8#show mpls traffic-eng tunnels tunnel 111 backup

34. Describe, implement, and troubleshoot LISP

Locator/ID Separation Protocol (LISP) is less of a routing protocol and more of a dynamic tunneling protocol, somewhat similar to MPLS and mGRE encapsulations. It uses UDP encapsulation on port 4341 for data traffic and UDP port 4342 for LISP control traffic. It was developed by Cisco and is currently an experimental RFC within the IETF (RFC 6830). The basic premise of LISP is, as the name states, to separate WHERE a host is from WHO it is. IP routing relies on a host being part of a network (subnet) which is both its location on the network and its identity concurrently. LISP does not re-invent IP routing nor does it advertise IP routes. It uses routing locations (RLOC) to specify WHERE a host is and endpoint-IDs (EID) to specify WHO the host is. This is basic tunneling; the RLOCs are the outer encapsulation in the tunnel and are expected to be reachable via some existing IP routing protocol, just like normal IP tunneling mechanisms. The EIDs don't have to be routed between sites with a dedicated routing protocols provided they are registered to a central location where LISP speakers can determine where the EIDs are. This EID resolution is similar to DNS where a set of central devices can map EIDs to RLOCs.

LISP decouples the roles of resolving EID-to-RLOC mappings and mapping registration into two components:

MS: The central mechanism used for RLOC/EID registration is known as a map server (MS). ETRs (discussed later) register their EID-to-RLOC mappings with the MS. This process is loosely analogous to the NHRP registration process of mapping overlay (VPN tunnel) addresses to underlay (NBMA) addresses. Map-requests are forwarded from the MR (discussed later) to the MS, who will perform an EID-database lookup. Assuming there is a match, it will forward the map-request directly to the ETR who registered the EID; the ETR is responsible for sending the map-reply to the original ITR.

MR: The map resolver (MR) is the target of all map-request messages. When an ITR (discussed later) sends a map-request to the MR, the request is forwarded to the MS over the ALT (discussed later). The MR does very little work in that its entire purpose is to receive map-requests and forward them to the MS, who actually has the mappings. In order to actually forward map-requests to the MS, the MR needs to have BGP routes inside the ALT for the EID destinations; this is how the MR knows which MS has the correct mappings if multiple MS devices exist.

ALT: Not a component of LISP so much as it is a virtual network used for inter MR/MS communication. It relies on VRFs, GRE, and BGP so that the MR and MS can exist on separate devices. Although uncommon, the ALT would be required when the MR and MS are separated, which might be good for availability/scalability. **The MR and MS roles are commonly combined on a single router for simplicity, known as the MR/MS.**

Two types of LISP tunneling routers are used at the customer sites for encapsulation and decapsulation:

ITR: An ingress tunnel router (ITR) is used for communicating with the MR to finding EID-to-RLOC mappings based on traffic being sent towards the provider (that is to say, traffic outbound from the

customer). The ITR role is typically assigned to a CE and runs on a Cisco ISR or ASR, for example. When a packet arrives on the LAN side on an ITR (inside EID space), the ITR sends a map-request to the MR. As discussed earlier, the MR forwards the map-request to the MS. If the MS has a mapping for this EID, the map-request is forwarded to the ETR that registered the EID. If not, the MS sends a map-reply that indicates that the destination of the original packet is not an EID (no mapping). The ITR then creates a negative cache entry to blackhole traffic.

ETR: An egress tunnel router (ETR) communicates with the MS to register EID-to-RLOC mappings. These mappings are sent in map-register messages. When LISP-encapsulated packets arrive on an ETR destined to one of its RLOCs (incoming traffic from the provider), verifies that the inner-header is destined to one of its registered EIDs, and forwards the packet natively on the LAN-side (inside EID space). Upon receiving a forwarded map-request from the MS, it verifies that it has the EID being requested (it should, otherwise the MS wouldn't have sent it, but this is a sanity check). It replies directly to the ITR that originated the map-request using the ITR RLOCs listed in the message.

The ITR and ETR roles are commonly combined on a single router for simplicity, known as the **xTR**.

To enable communication with non-LISP domains, two additional LISP router variants are introduced:

PITR: The Proxy ITR performs ITR functions on behalf of non-LISP sites. These are typically deployed at Internet exchange points to provide interworking from non-LISP to LISP sites. Non-LISP sites will route traffic towards the PITR for encapsulation and forwarding to LISP sites. For scalability, aggregation should be used so that the PITR does not have to advertise many specific routes. No additional configuration is needed on the ITRs when the PITR is deployed.

PETR: The Proxy ETR performs ETR functions on behalf of LISP sites. The PETR is deployed similarly to the PITR, except is used to provide interworking from LISP to non-LISP. This would normally be used when the SP will not allow private (EID) space to be routed over its core. ETRs must specify the PETR address to use the PETR service.

The PITR and PETR roles are commonly combined on a single router for simplicity, known as the **PxTR**.

LISP supports two main variations of virtualization:

Shared Model: EID spaces exist in varying VRFs with a single upstream RLOC table. For example, CSR9 has its RLOC in global space while its EIDs are in varying VRFs. Each EID VRF has its own instance ID (IID) specified on the ETR and MS so that the EID-to-RLOC mappings are kept separate. Just like BGP VPNv4/v6, overlap can exist in different VRFs, so this IID has a similar function to the BGP RD. CSR10 also uses this model except the RLOC is in a VRF, much like a front-door VRF (FVRF) model commonly used in overlay networking.

Parallel Model: EID spaces are in N VRFs with N upstream RLOCs which correspond to each different VRF. This is a more traditional model of splitting the router into VRFs and not having any inter-VRF communication between EID and RLOC namespaces. This generally means a different layer 3 interface per EID VRF towards the provider. This is implemented on CSR2, where there are two subinterfaces in two different VRFs to service two different EID spaces. This also requires two separate LISP processes.

The network diagram below shows an SP core inside AS 41 that provides IPv4/v6 transport between the PE-CE connected routes only. There is no PE-CE protocol exchange anywhere. There are three customer sites that communicate using LISP (CSR10, CSR9, and CSR2). These sites use a variety of LISP virtualization models discussed later; many of the test endpoints are loopbacks on these routers for simplicity. CSR3 is an MR/MS and CSR4 is an MR only; the two communicate over an ALT. CSR5 is a public Internet site which uses the PxTR configured on CSR6 to communicate to and from the LISP customer sites. To test multicast, CSR1 is an ordinary end host and multicast source. CSR1 is also used to test mobility by moving between LANs hosted on CSR10 (home) and CSR9 (foreign); this particular feature is deemed out of scope for CCIE SP and is not tested here.

The relevant configurations for CSR9 and CSR10 are shown below. We will begin with the basic components to understand the control-plane mechanisms. CSR9 has both RLOC and EIDs in the global table (no virtualization yet) while CSR10 has the RLOC in a front-door VRF (shared virtualization model).

Each of them register their loopbacks with the MS, which is 10.3.6.3 (CSR3). The MR is 10.4.6.4 (CSR4) which is separated from the MS.

```
! CSR9
interface GigabitEthernet2.579
 ip address 10.7.9.9 255.255.255.0

router lisp 1
 eid-table default instance-id 0

  ipv4 etr map-server 10.3.6.3 key CSR10

ip route vrf UP 0.0.0.0 0.0.0.0 10.7.10.7
```

Before any traffic can flow, the ETRs must register their EID-to-RLOC mappings with the MS (CSR3). Both CSR10 and CSR9 must do this; notice that the map-register message also contains the IID so the MS knows in which table to store the mappings. This IID serves as a method to distinguished EID routes between customers, much like the BGP RD does for MPLS VPNs. IID 0 represents the global table, which is how we can sort through the debugs to eliminate other duplicate prefixes of 10.10.10.10/32 and 10.9.9.9/32 in other VRFs. LISP debugs are some of the best debugs in IOS; very detailed with many granular options. Notice that the map-register messages use UDP port 4342 as this is used only for LISP signaling. This registration occurs once every 60 seconds.

```
! CSR9

LISP-0: MS registration IID 0 prefix 10.9.9.9/32 10.7.9.9 site CSR9,
Updating.
```

A summary view of this IID 0 table shows the following registered prefixes with the MS. Looking into the details of 10.9.9.9/32, most of this information is the same as what we saw in the debug message. This is useful for troubleshooting more advanced LISP functionality like PxTR, load sharing, and dynamic EID creation. The priority/weight values are discussed later.

```

```

Because CSR3 is not an MR for IID 0, it needs to somehow receive map-requests from CSR4, which is the MR for IID 0. This is doing using the ALT; there is a P2P GRE tunnel between CSR3 and CSR4 inside of a VRF called LISPALT. BGP is running inside this VRF to connect the two sites using the IPv4 AF within the VRF. The significant configuration snippets are shown below and are explained next.

```

! CSR3
interface Tunnel34
  vrf forwarding LISPALT
  ip address 10.3.4.3 255.255.255.0

  address-family ipv6 vrf LISPALT
    neighbor 2001:10:3:4::3 remote-as 34
    neighbor 2001:10:3:4::3 activate

```

When CSR3 receives map-registrations, it originates an exact-match route into the ALT for advertisement to the MRs. CSR3 has originated routes for both 10.9.9.9/32 and 10.10.10.10/32 as LISP routes with AD 10 pointing to Null0. In this way, they are present in the RIB for the ALT VRF. This allows them to be redistributed into BGP for advertisement over the ALT. The routes don't direct traffic but are important to facilitate communication between disparate MR and MS devices.

```
CSR3#show vrf LISPALT
```

Name	Default RD	Protocols	Interfaces
LISPALT	34:3	ipv4, ipv6	Tu34

```
CSR3#show ip route vrf LISPALT lisp | begin Gateway
```

```
Gateway of last resort is not set
```

```

      10.0.0.0/8 is variably subnetted, 4 subnets, 2 masks

1       10.10.10.10/32 [10/1], 4d19h, Null0

```

```

CSR3#show bgp vpnv4 unicast vrf LISPALT | begin Network
      Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 34:3 (default for vrf LISPALT)
*> 10.9.9.9/32          0.0.0.0          1          32768 ?
*> 10.10.10.10/32       0.0.0.0          1          32768 ?

```

CSR4 is the MR for IID 0 and needs to know where to forward map-requests it receives from ITRs. Without these BGP routes, the MR has no idea where to forward the map-requests and the ITR will never be able to LISP-encapsulate any packets. A quick check on CSR4 shows that the routes were learned from CSR4 via iBGP through the P2P GRE tunnel.

```

CSR4#show vrf LISPALT
      Name          Default RD          Protocols  Interfaces
      LISPALT        34:4          ipv4,ipv6  Tu34

CSR4#show bgp vpnv4 unicast vrf LISPALT | begin Network
      Network          Next Hop          Metric LocPrf Weight Path
Route Distinguisher: 34:4 (default for vrf LISPALT)
*>i 10.9.9.9/32        10.3.4.3          1    100      0 ?
*>i 10.10.10.10/32     10.3.4.3          1    100      0 ?

```

Now, we will send traffic from CSR9 to CSR10. LSIP control-plane debugging is enabled on each device so each step can be visualized. First, traffic is sourced from EID space on CSR10 destined to EID space on CSR9. As an ITR, CSR10 issues a map-request to the MR which is CSR4 (10.4.6.4). CSR10 has no idea how to reach 10.9.9.9/32 as there is no EID-to-RLOC mapping for it currently. The ITR also includes all of its RLOCs in this message (10.7.10.10 and 2001:10:7:10::10), which is why ITR RLOCs reads as 2. This is included so the ETR knows how to respond to the map-request. Notice the timestamp in the comment.

```
! CSR10, time 15:10:58.345
```

```

LISP-1: IID 0 Request processing of remote EID prefix map requests to IPv4.
LISP: Send map request type remote EID prefix
LISP: Send map request for EID prefix IID 0 10.9.9.9/32
LISP-1: Remote EID IID 0 prefix 10.9.9.9/32, Send map request (1) (sources:
<signal>, state: incomplete, rlocs: 0).
LISP-1: EID-AF IPv4, Sending map-request from 10.9.9.9 to 10.9.9.9 for EID
10.9.9.9/32, ITR-RLOCs 2, nonce 0x5AB0F557-0xEEBD265C (encap src 10.7.10.10,
dst 10.4.6.4).

```

When the MR (CSR4) receives the map-request from the ITR (CSR9), it immediately forwards it towards to MS (CSR3) inside the ALT. The reason the MR even knows about the EID prefix 10.9.9.9/32 in the first place is because of BGP in the ALT, which we saw earlier. Without this BGP route, the MR cannot sufficiently resolve the request as it is not aware of any map-servers that are authoritative for this EID. The debug says it is forwarding the map-request “to 10.9.9.9”, but resolving this recursively really means 10.3.4.4 as the BGP routes above reveal.

```

! CSR4
LISP: Processing received Map-Request(1) message on GigabitEthernet2.546 from
10.9.9.9:4342 to 10.9.9.9:4342
LISP: Received map request for IID 0 10.9.9.9/32, source_eid IID 0
10.10.10.10, ITR-RLOCs: 10.7.10.10 2001:10:7:10::10, records 1, nonce
0x5AB0F557-0xEEBD265C
LISP-0: AF IID 0 IPv4, Forwarding map request to 10.9.9.9 on the ALT.

```

When the MS receives it from the MR, it checks its IID 0 database and sees RLOC 10.7.9.9 for the EID prefix 10.9.9.9/32. There were the RLOCs that were included in the map-register message initially sent to the MS by CSR9 (as an ETR). The MS forwards the map-request down to the ETR who send the map-register, which is CSR9, using the ETR RLOC specified in the database.

```

! CSR3
LISP: Processing received Map-Request(1) message on Tunnel34 from
10.9.9.9:4342 to 10.9.9.9:4342
LISP: Received map request for IID 0 10.9.9.9/32, source_eid IID 0
10.10.10.10, ITR-RLOCs: 10.7.10.10 2001:10:7:10::10, records 1, nonce
0x5AB0F557-0xEEBD265C
LISP-0: MS EID IID 0 prefix 10.9.9.9/32 site CSR9, Forwarding map request to
ETR RLOC 10.7.9.9.

```

When the ETR receives it from the MS, the ETR verifies that this map-request is actually for an EID that it has locally registered and was destined to a valid RLOC. It sends a map-reply directly to the "better" ITR RLOC which is determined by priorities. Prioritization is discussed later, but in this case it selected the IPv4 RLOC over the IPv6 RLOC.

```

! CSR10
LISP: Processing received Map-Request(1) message on GigabitEthernet2.579 from
10.9.9.9:4342 to 10.9.9.9:4342
LISP: Received map request for IID 0 10.9.9.9/32, source_eid IID 0
10.10.10.10, ITR-RLOCs: 10.7.10.10 2001:10:7:10::10, records 1, nonce
0x5AB0F557-0xEEBD265C
LISP: Processing map request record for EID prefix IID 0 10.9.9.9/32
LISP-1: Sending map-reply from 10.7.9.9 to 10.7.10.10.

```

When the ITR receives the final map-reply from the ETR, it effectively learns the remote RLOC (LISP tunnel destination) it needs to use for encapsulation. Most of the debug below includes low-level table updates, but the first few lines show the remote RLOC clearly. The RTT is also shown, and although I have removed the timestamps, the entire process from ITR map-request to ETR map-reply was exactly 26ms. I included timestamps in the comment below for comparison against the timestamp shown above.

```

! CSR10, time 15:10:58.371
LISP: Received map reply nonce 0x5AB0F557-0xEEBD265C, records 1

```

```

LISP: Processing Map-Reply mapping record for IID 0 10.9.9.9/32, ttl 1440,
action none, authoritative, 1 locator
      10.7.9.9 pri/wei=10/10 LpR
LISP-1: Map Request IID 0 prefix 10.9.9.9/32 remote EID prefix[LL], Received
reply with rtt 26ms.
LISP: Processing mapping information for EID prefix IID 0 10.9.9.9/32

LISP-1: Remote EID IID 0 prefix 10.9.9.9/32, Starting idle timer (delay
00:02:30) (sources: <map-rep>, state: reused, rlocs: 0).
LISP-1: AF IID 0 IPv4, Persistent db: ignore writing request, disabled.
LISP-1: Remote EID IID 0 prefix 10.9.9.9/32, Change state to complete
(sources: <map-rep>, state: reused, rlocs: 0).

```

This entire process happens in the reverse direction since bidirectional communication is the goal. CSR9 would be the ITR and CSR10 would be the ETR for this process. The process is identical except reversed and is not shown again. To prove connectivity is working, we will send packets from CSR10 to CSR9 and use EPC in both directions on CSR9. Two packets are shown below. The first packet has an outer UDP (0x11, protocol 17, green) header and sends traffic from 10.7.10.10 to 10.7.9.9 (yellow) using port 4341 (0x10F5, cyan). This is the LISP data packet encapsulation and uses IP addressing from the RLOC space. The inner packet is ICMP (0x01, protocol 1, green) from 10.10.10.10 to 10.9.9.9 (yellow), which is in EID space. The second packet is the reply; the same fields are highlighted in the same colors for the return traffic.

```

After connectivity is validated, we check the LISP mapping tables on both routers to see their new entries. Each of them has the other router's EID prefix along with a valid RLOC to reach it. Both of these entries were learned via the dynamic map-request/map-reply process.

```

CSR9#show ip lisp 1 map-cache

```

LISP IPv4 Mapping Cache for EID-table default (IID 0), 2 entries

0.0.0.0/0, uptime: 2d19h, expires: never, via static send map-request

Locator	Uptime	State	Pri/Wgt
10.7.9.9	00:10:08	up	10/10

If we look at the FIB, we see interesting output. The first command is misleading because we have an exact match /32 but it says no route. Normally the lack of a route would show "0.0.0.0/0" followed by "no route". Looking at the details, we see that LISP is working behind the scenes and performing "action encap" to get the traffic over the network. The reason it says "no route" is because the RLOC space is in a VRF on CSR10; it's a shared front-door VRF used by all EID spaces across all tables. On CSR10, the EID namespace has 10.10.10.10/32 in the global table which has no routes aside from this loopback (shown in the routing table summary). The lack of any routes, or only having a default, is required to trigger LISP mapping resolution. Ultimately, the FIB recurses to having no route and should be dropped, but LISP steps in and performs the encapsulation. This is somewhat similar to the DMVPN phase 3 operation where the NHRP cache augments the FIB.

static	0	0	0	0	0
lisp	0	0	0	0	0
internal	1				368
Total	1	1	0	96	656

On CSR9, the output is a little different. Because both the EID prefix and RLOC namespace are in the global table, the FIB does recurse to a valid route since there is a default route in the global table, just like there is a default route in the FVRF on CSR10. The behavior is exactly the same in terms of LISP encapsulation, but the outputs are slightly different due to route recursion. LISP still trumps the FIB. There is still a specific entry for the EID prefix learned from LISP, and the action remains "action encap". Notice that the next-hops shown with "LISP1" are IPv4 addresses of the remote RLOC in use.

LISP does an excellent job of tracking statistics. We will look at CSR9 and CSR3 as examples. Notice the high number of map-registers sent from the ETR and received on the MS. The MS also shows the map-requests forwarded. Note: When using LISP show commands, you often need to include the process number. Notice on CSR9, I must include the "1" or else the show command does not work. On CSR3, I use the general LISP process with no PID.

```

In many environments, the MR/MS are consolidated onto a single device. Although the MR and MS roles remain the same, the actual forwarding of the map-request from MR to MS occurs in software within the router. That is, there is no need for an ALT in this model. At present, the ALT feature only appears to support EIDs in IID 0, so for testing EID prefixes inside VRFs, we consolidate the MR/MS services on CSR3. When configuring EID prefixes not within the default IID, you must explicitly specify the IID when defining the EID prefix. All three sites have prefixes in both IID 101 and 102 as shown below. The “accept-more-specifics” option allows a more generic registration to occur where the MS does not need to enumerate individual prefixes that are contiguous. I also introduce IPv6, but LISP does an excellent job of providing feature and configuration parity between IPv4 and IPv6. The concepts are identical.

```
! CSR3
router lisp
site CSR10

```

We also introduce CSR2 using the parallel virtualization model. The relevant configurations for that are below. The EID prefixes in VRF C1 and C2 are not included as those are simply endpoints. Each LISP process maps to an IID (VRF) because each LISP process can only specify a single “locator-table”. The configurations are largely redundant but this creates additional isolation between LISP virtual instances on a since xTR.

```

```

For practice, we will trace the LISP control-plane process again, except this time we will send traffic between CSR10 and CSR2 within a customer's VRF EID space (VRF C2). This VRF uses IID 102. As a quick check, we can verify that the MS knows about the 10.10.10.10/32 and 10.2.2.2/32 EID prefixes from each site within IID 102.

```

CSR3#show lisp site instance-id 102
LISP Site Registration Information
* = Some locators are down or unreachable
Site Name      Last      Up    Who Last      Inst      EID Prefix
                Register    Registered    ID
CSR10          00:00:26  yes   10.7.10.10   102       10.10.10.10/32

```

	00:00:07	yes	10.7.10.10	102	2001:10:10:10::10/128
CSR2	00:00:17	yes	10.8.2.2	102	10.2.2.2/32
	never	no	--	102	2001:10:2:2::2/127
	00:00:43	yes	10.8.2.2	102	2001:10:2:2::2/128
CSR9	00:00:51	yes	10.7.9.9	102	10.9.9.9/32
	00:00:50	yes	10.7.9.9	102	2001:10:9:9::9/128

A quick debug on CSR3 shows CSR10 and CSR2 registering their IID 102 prefixes. Notice that each prefix has an IPv4 and IPv6 RLOC.

```

```

For another test, we originate traffic on CSR2, which uses the parallel model for virtualization. This means there is a direct link to the SP inside this VRF, which implies there is also a default route if LISP is going to be used for lookups. We confirm this before continuing.

```

CSR2#show ip route vrf C2 0.0.0.0 0.0.0.0
Routing Table: C2
Routing entry for 0.0.0.0/0, supernet
Known via "static", distance 1, metric 0, candidate default path

```

Routing Descriptor Blocks:

* 10.8.2.8

Route metric is 0, traffic share count is 1

When CSR2 sends traffic (sourced from within the proper VRF), it issues a map-request to the MR, which is CSR3 for IID 102. This is CSR2's way of asking for the valid RLOCs for EID prefix 10.10.10.10/32 within the context of IID 102.

! CSR2, time 17:15:25.650

LISP-2: IID 102 Request processing of remote EID prefix map requests to IPv4.

LISP: Send map request type remote EID prefix

LISP: Send map request for EID prefix IID 102 10.10.10.10/32

LISP-2: Remote EID IID 102 prefix 10.10.10.10/32, Send map request (1)
(sources: <signal>, state: incomplete, rlocs: 0).

LISP-2: EID-AF IPv4, Sending map-request from 10.10.10.10 to 10.10.10.10 for
EID 10.10.10.10/32, ITR-RLOCs 2, nonce 0x9701B20F-0x8488F010 (encap src
10.8.2.2, dst 10.3.6.3).

When CSR3 receives the map-request (as the MR), it knows that it's also an MS so there is no need to consult the ALT for a BGP route. Instead, the local database on the MS is checked against the current EID-to-RLOC mappings. The check is successful, and the ETR who registered this mapping is CSR10. The MS forwards the map-request for CSR10.

! CSR3

LISP: Processing received Map-Request(1) message on GigabitEthernet2.536 from
10.10.10.10:4342 to 10.10.10.10:4342

LISP: Received map request for IID 102 10.10.10.10/32, source_eid IID 102
10.2.2.2, ITR-RLOCs: 10.8.2.2 2001:10:8:2::2, records 1, nonce 0x9701B20F-
0x8488F010

LISP-0: MS EID IID 102 prefix 10.10.10.10/32 site CSR10, Forwarding map
request to ETR RLOC 10.7.10.10.

When CSR10 receives the map-request (as the ETR), it performs a sanity check to ensure the EID-to-RLOC mappings are correct, then sends the map-reply directly to the ITR, which is CSR2. Interestingly, CSR10 uses the IPv6 RLOCs for this map-reply for the transport mechanism.

! CSR10

LISP: Processing received Map-Request(1) message on GigabitEthernet2.570 from
10.10.10.10:4342 to 10.10.10.10:4342

LISP: Received map request for IID 102 10.10.10.10/32, source_eid IID 102
10.2.2.2, ITR-RLOCs: 10.8.2.2 2001:10:8:2::2, records 1, nonce 0x9701B20F-
0x8488F010

LISP: Processing map request record for EID prefix IID 102 10.10.10.10/32

LISP-1: Sending map-reply from 2001:10:7:10::10 to 2001:10:8:2::2.

When CSR10 receives the map-reply (as the ITR), it measures the time for the LISP signaling process to occur, which was 33 ms. CSR2 then installs this EID-to-RLOC mapping as valid and uses these mappings to augment the FIB. The debug didn't show the RLOC mappings here; I cannot explain why.

```
! CSR2, time 17:15:25.683
LISP-2: Map Request IID 102 prefix 10.10.10.10/32 remote EID prefix[LL],

LISP-2: Remote EID IID 102 prefix 10.10.10.10/32, Change state to complete
(sources: <map-rep>, state: reused, rlocs: 0).
```

Again, we use EPC to validate the traffic flow on CSR7, this time facing CSR10. Two packets are shown below. The first packet is UDP (0x11, protocol 17, green) and sends traffic from 10.8.2.2 to 10.7.10.10 (yellow) using port 4341 (0x10F5, cyan). This is the LISP encapsulation and uses IP addressing from the RLOC space. The inner packet is ICMP (0x01, protocol 1, green) from 10.2.2.2 to 10.10.10.10 (yellow), which is in EID space. The second packet is the reply; the same fields are highlighted in the same colors for the return traffic.

```
CSR7#show monitor capture CAP buffer dump
0000: 000C2949 7164000C 29664C2C 81000DF2 ..) Iqd..) fL,....

[snip]
```

Earlier we saw that both of these prefixes had multiple RLOCs. Specifically, one was IPv4 and one was IPv6. The lower priorities are preferred; right now the IPv4 RLOCs have priority 10 while IPv6 RLOCs have 15. IPv6 RLOCs are defined identically to the IPv4 ones and are not detailed in the inline configuration snippets. After increasing the IPv4 RLOC priorities to 20 on both CSR2 and CSR10, we still have reachability. The EPC shows that the LISP encapsulation (RLOC space) is using IPv6 while the inner

packet (EID space) still uses IPv4. This permits any combination of IPvX in IPvX tunneling. Before sending traffic, we can validate that the MS knows about these RLOC priority changes.

```
CSR3#show lisp site 10.2.2.2/32 instance-id 102 | begin Locator
Locator      Local  State  Pri/Wgt  Scope
10.8.2.2     yes   up     20/10    IPv4 none
2001:10:8:2::2 yes   up     15/10    IPv6 none
```

```
CSR3#show lisp site 10.10.10.10/32 instance-id 102 | begin Locator
Locator      Local  State  Pri/Wgt  Scope
10.7.10.10   yes   up     20/10    IPv4 none
2001:10:7:10::10 yes   up     15/10    IPv6 none
```

First, we need to clear the map-cache entries on both CSR2 and CSR10 so they can re-signal the LISP path with the MR/MS.

```
CSR2#clear ip lisp 2 map-cache *
CSR10#clear ip lisp 1 map-cache *
```

The EPC is shown again below after sending traffic from CSR2 to CSR10. We can immediately see the packet is significantly larger, which hints towards the usage of IPv6. Two packets are shown below. The first packet has an outer IP header which wraps UDP (0x11, protocol 17, green) and sends traffic from 2001:10:8:2::2 to 2001:10:7:10::10 (yellow) using port 4341 (0x10F5, cyan). This is the LISP encapsulation and uses IP addressing from the RLOC space. The inner packet is ICMP (0x01, protocol 1, green) from 10.2.2.2 to 10.10.10.10 (yellow), which is in EID space. The second packet is the reply; the same fields are highlighted in the same colors for the return traffic.

```

```

We can verify the map-cache entries on both CSR2 and CSR10. We use the summary view on CSR2 and the detailed view on CSR10 for variety. Note that the xTR maintains all of the RLOCs assigned to an EID prefix, and locally selects the best one based on the advertised priorities. It is not prescribed by a remote LISP node; the remote node influences the decision via the priority settings.

```
CSR2#show ip lisp 2 instance-id 102 map-cache

Verifying the FIB, we see the specific EID prefix with "action encaps" on both sides. Notice that the LISP next-hops are the IPv6 RLOCs now since it was the "better" RLOC per our manual priority modifications. Due to virtualization in play, the "LISP" interfaces have subinterfaces with a number matching the IID.

```

```

A more common usage of IPv6 with LISP would be to tunnel it inside IPv4 to connect two disjoint IPv6 "islands". We just demonstrated the opposite which, while possible, has much less utility. Assuming the SP did not provide VPNv6 transport, we can use LISP as an IPv6 transition/tunneling mechanism. We won't trace all the signaling debugs since the IPv4/IPv6 RLOCs are carried in the same LISP mapping messages. First, we check the MS (CSR3) to ensure it knows about CSR2 and CSR10 IID 102 IPv6 prefixes. These are 2001:10:2:2::2/128 and 2001:10:10:10::10/128, respectively. Notice that there is an entry for 2001:10:2:2::2/127 also (less specific); I configured the MS for the /127 but told it to accept longer-matches, which is why the /128 was able to register successfully. The configuration snippets shown above demonstrated this option.

```

CSR3#show lisp site instance-id 102
LISP Site Registration Information
* = Some locators are down or unreachable

```

Site Name	Last Register	Up	Who Last Registered	Inst ID	EID Prefix
CSR10	00:00:02	yes	10.7.10.10	102	10.10.10.10/32
	00:00:53	yes	10.7.10.10	102	2001:10:10:10::10/128
CSR2	00:00:59	yes	10.8.2.2	102	10.2.2.2/32
	never	no	--	102	2001:10:2:2::2/127
CSR9	00:00:35	yes	10.8.2.2	102	2001:10:2:2::2/128
	00:00:27	yes	10.7.9.9	102	10.9.9.9/32
	00:00:40	yes	10.7.9.9	102	2001:10:9:9::9/128

The MS also knows the priorities of the different RLOCs. In this case, IPv4 RLOCs have a lower (better) priority, so we expect those to be used for traffic forwarding. This is the opposite test of what we just did; we transition from IPv4-in-IPv6 to IPv6-in-IPv4. We simply change the priority of the IPv4 RLOCs back to 10 to re-baseline the network.

```

CSR3#show lisp site 2001:10:2:2::2/128 instance-id 102 | begin Locator
Locator      Local  State  Pri/Wgt  Scope
10.8.2.2     yes    up     10/10    IPv4 none

```

```
2001:10:8:2::2  yes      up          15/10    IPv6 none
```

```
CSR3#show lisp site 2001:10:10:10::10/128 instance-id 102 | begin Locator
```

Locator	Local	State	Pri/Wgt	Scope
10.7.10.10	yes	up	10/10	IPv4 none
2001:10:7:10::10	yes	up	15/10	IPv6 none

When we send traffic between the two sites, we can look for the IPv6-in-IPv4 encapsulation on CSR7 outbound towards CSR10. Two packets are shown below. The first packet has an outer UDP protocol type (0x11, protocol 17, green) and sends traffic from 10.8.2.2 to 10.7.10.10 (yellow) using port 4341 (0x10F5, cyan). This is the LISP encapsulation and uses IP addressing from the RLOC space. The inner packet is IPv6-ICMP (0x3A, protocol 58, green) from 2001:10:2:2::2 to 2001:10:10:10::10 (yellow), which is in EID space. The second packet is the reply; the same fields are highlighted in the same colors for the return traffic.

```

```

The minor difference in outputs is due to CSR2 having a default route within the VRF (required for parallel model virtualization) while CSR10 has no routes within the VRF C2 other than the connected/local loopbacks. This has no effect on connectivity.

```
CSR2#show ipv6 route vrf C2 ::/0

```

Next, we will look at using CSR6 as a Pitr to provide interworking from a non-LISP site (CSR5) to a LISP site (CSR9) within IID 101 specifically. The Pitr provides the opposite, giving access from LISP to non-LISP sites. Because we are using virtualization and the VRF on CSR9 has no routes, we need the Pitr also. The xTr has no idea about the Pitr but must be configured to use the Pitr. The PxTr services can exist inside a VRF, and since CSR6 is the MPLS L3VPN PE, the PxTr address will be 22.5.6.6 within VRF NONLISP.

```
! CSR6
interface GigabitEthernet2.556
  vrf forwarding NONLISP
  ip address 22.5.6.6 255.255.255.0
  ipv6 address 2001:22:5:6::6/64

router lisp
  locator-table vrf NONLISP
```

```

eid-table vrf NONLISP instance-id 101
  map-cache 10.1.10.0/24 map-request
  map-cache 10.2.2.2/32 map-request
  map-cache 10.9.9.9/32 map-request
ipv4 proxy-etr
ipv4 proxy-itr 22.5.6.6
ipv4 itr map-resolver 10.3.6.3

! CSR9
router lisp 1
  eid-table vrf C1 instance-id 101
  ipv4 use-petr 22.5.6.6

```

CSR9, as an ITR, sends a normal map-request to the MR. The MR is CSR3 for IID 101 and should receive the map-request from CSR9 once the customer in the VRF starts sending traffic. CSR9 is looking for the public address 22.5.6.5 which is in RLOC space, not EID space.

```

dst 10.3.6.3).

```

The MR/MS receives the map-request from the ETR (CSR9) and sees that it does not have any EID-to-RLOC mappings for this prefix within IID 101. It returns a "negative" reply with a course aggregate of 16.0.0.0/4 (which covers 22.5.6.5).

```

! CSR3
LISP: Processing received Map-Request(1) message on GigabitEthernet2.536 from
22.5.6.5:4342 to 22.5.6.5:4342
LISP: Received map request for IID 101 22.5.6.5/32, source_eid IID 101
10.9.9.9, ITR-RLOCs: 10.7.9.9 2001:10:7:9::9, records 1, nonce 0xCE3DD210-
0x48740DDB
LISP-0: sending negative map-reply from 10.3.6.3 to 10.7.9.9 for IID 101
16.0.0.0/4.

```

The ETR (CSR9) receives the negative reply directly from the MS (CSR3) and adds an entry to its LISP map-cache and FIB for 16.0.0.0/4. We examine this in more detail once the LISP control-plane converges. The lack of an RLOC means that LISP has no choice but to forward the traffic natively, at least so far. Notice the time difference was about ~22 ms.

```

! CSR9, time 14:19:07.209

```

```

LISP: Received map reply nonce 0xCE3DD210-0x48740DDB, records 1
LISP: Processing Map-Reply mapping record for IID 101 16.0.0.0/4, ttl 15,
action forward, authoritative, 0 locators
LISP-1: Map Request IID 101 prefix 22.5.6.5/32 remote EID prefix[LL],
Received reply with rtt 22ms.
LISP: Processing mapping information for EID prefix IID 101 16.0.0.0/4
LISP-1: AF IID 101 IPv4, Persistent db: ignore writing request, disabled.
LISP-1: Remote EID IID 101 prefix 16.0.0.0/4, Change state to forward-native
(sources: <map-reply>, state: unknown, rlocs: 0).

```

At this point, CSR9 is sending encapsulated LISP packets to the PETR at 22.5.6.6 (CSR6). Without the PETR, the traffic would have actually been natively forwarded, but the whole purpose of the PETR is to provide an ETR service for CSR9 when talking to a non-LISP site. The ITR (CSR9) will have a CEF entry for this /4 prefix. The outputs between the LISP map-cache and FIB appear inconsistent. The FIB says "action encap" while the map-cache says forward-native. The action is actually encap; at the bottom of the map-cache output, it mentions that LISP encap is actually being used to the PETR, so the FIB resolves this and presents the final result as we expect. The LISP-encapsulated next-hop is the PETR IP address.

```

```

The PITR has not been in play yet since it has not received any traffic inbound from the non-LISP site. A quick EPC is used to verify packets are, at this point, getting to the non-LISP destination at 22.5.6.5 (CSR5). The capture from CSR7 inbound (facing CSR9) is shown below. Notice it is a LISP-encapsulated packet destined for the PETR's IP address (22.5.6.6) as CSR9's FIB directs. The PETR will decapsulate the packet and send the native ICMP packet to CSR5. Two captures are shown below: the first is CSR7 inbound (LISP) and the second is CSR5 inbound (ICMP). The first packet dump shows the full IP packet inside LISP for proof. The inner packet is ICMP (0x01, protocol 1, green) from 10.9.9.9 to 22.5.6.5, where

the source is in EID space and the destination is in RLOC space. The outer encapsulation is UDP (0x11, protocol 17, green) and sends traffic from 10.7.9.9 to 22.5.6.6 (yellow) using port 4341 (0x10F5, cyan). The destination of the LISP frame is the PETR address as discussed earlier. CSR6 decapsulated those packets and forwards them to CSR5 as native ICMP.

```

When CSR5 goes to respond towards 10.9.9.9, it follows its default route. The SP has no idea how to reach 10.9.9.9 since this exists in EID space only and is not part of any VPNv4 BGP table. This is where the PITR is used (interworking from non-LISP to LISP). The PITR is statically configured to issue map-requests for a number of ranges, including 10.9.9.9/32, and it does so just like a normal ITR. The fact that it is a PITR is specified in the map-request.

```
! CSR6, time 14:19:03.302
LISP-0: IID 101 Request processing of remote EID prefix map requests to IPv4.
LISP: Send map request type remote EID prefix
LISP: Send map request for EID prefix IID 101 10.9.9.9/32
LISP-0: Remote EID IID 101 prefix 10.9.9.9/32, Send map request (1) (sources:
<signal|send map-req>, state:incomplete, rlocs: 0).
LISP-0: EID-AF IPv4, Sending map-request from 10.9.9.9 to 10.9.9.9 for EID
10.9.9.9/32, ITR-RLOCs 1, nonce 0x6A7FF8D5-0x207A06EF (encap src 22.5.6.6,
dst 10.3.6.3), FromPITR.
```

When this map-request gets to the MR/MS (CSR3), it sees a valid EID-to-RLOC mapping and forwards this down to the ETR that registered the EID-to-RLOC mapping (CSR9).

```
! CSR3
LISP: Processing received Map-Request(1) message on GigabitEthernet2.536 from
10.9.9.9:4342 to 10.9.9.9:4342
```

```
LISP: Received map request for IID 101 10.9.9.9/32, source_eid IID 101
22.5.6.5, ITR-RLOCs: 22.5.6.6, records 1, nonce 0x6A7FF8D5-0x207A06EF,
FromPITR
LISP-0: MS EID IID 101 prefix 10.9.9.9/32 site CSR9, Forwarding map request
to ETR RLOC 10.7.9.9.
```

When this map-request gets to the ETR (CSR9), it validates that the EID was originated from itself and replies directly to the PITR (CSR6) to the map-request with a map-reply. This is what it would normally do for a regular ITR.

```
! CSR9
LISP: Processing received Map-Request(1) message on GigabitEthernet2.579 from
10.9.9.9:4342 to 10.9.9.9:4342
LISP: Received map request for IID 101 10.9.9.9/32, source_eid IID 101
22.5.6.5, ITR-RLOCs: 22.5.6.6, records 1, nonce 0x6A7FF8D5-0x207A06EF,
FromPITR
LISP: Processing map request record for EID prefix IID 101 10.9.9.9/32
LISP-1: Sending map-reply from 10.7.9.9 to 22.5.6.6
```

When the map-reply from the ETR (CSR9) reaches the PITR (CSR6), it performs the ordinary ITR duties of adding LISP encapsulation to traffic from CSR5 destined to LISP sites. Notice the time for this second map-request/map-reply process took about ~19 ms.

```
! CSR6, time 14:19:03.321
LISP: Processing received Map-Reply(2) message on GigabitEthernet2.561 from
10.7.9.9:4342 to 22.5.6.6:4342
LISP: Received map reply nonce 0x6A7FF8D5-0x207A06EF, records 1
LISP: Processing Map-Reply mapping record for IID 101 10.9.9.9/32, ttl 1440,
action none, authoritative, 1 locator
ei=10/10 LpR
LISP-0: Map Request IID 101 prefix 10.9.9.9/32 remote EID prefix[LL],
Received reply with rtt 19ms.
LISP: Processing mapping information for EID prefix IID 101 10.9.9.9/32
LISP-0: Remote EID IID 101 prefix 10.9.9.9/32, Change state to reused
(sources: <map-rep|send map-req>, state: incomplete, rlocs: 0).
LISP-0: AF IID 101 IPv4, Persistent db: ignore writing request, disabled.
LISP-0: Remote EID IID 101 prefix 10.9.9.9/32, Change state to complete
(sources: <map-rep|send map-req>, state: reused, rlocs: 0).
```

At this point, the PITR is performing ITR duties on behalf of the non-LISP site and the PETR is performing ETR duties on behalf of the LISP site. An outbound capture on CSR7's interface facing CSR9 shows the returning traffic flow. We already saw the original flow earlier when examining the PETR behavior. The inner packet is ICMP (0x01, protocol 1, green) from 22.5.6.5 to 10.9.9.9, where the source is in RLOC space and the destination is in EID space. The outer encapsulation has a UDP (0x11, protocol 17, green) header and sends traffic from 22.5.6.6 to 10.7.9.9 (yellow) using port 4341 (0x10F5, cyan). This source is

the P1TR address. CSR9 will perform local ETR duties and decapsulate these LISP packets, and then deliver them to the VRF C1 customer inside IID 101 (loopback1).
