| <b>Description</b> | This command configures the time the client transitions to a rebinding state.<br><br>The <b>no</b> form of the command removes the time from the configuration.             |
| <b>Default</b>     | n/a                                                                                                                                                                         |

**Parameters**     *time* — specifies the lease rebind time

**Values**

|         |           |
|---------|-----------|
| days    | 0 to 3650 |
| hours   | 0 to 23   |
| minutes | 0 to 59   |
| seconds | 0 to 59   |

## lease-renew-time

**Syntax**     **lease-renew-time** [**days** *days*] [**hrs** *hours*] [**min** *minutes*] [**sec** *seconds*]  
**no lease-renew-time**

**Context**     config>service>vprn>dhcp>server>pool>options

**Description**     This command configures the time the client transitions to a renew state.  
  
The **no** form of the command removes the time from the configuration.

**Default**     n/a

**Parameters**     *time* — specifies the lease renew time

**Values**

|         |           |
|---------|-----------|
| days    | 0 to 3650 |
| hours   | 0 to 23   |
| minutes | 0 to 59   |
| seconds | 0 to 59   |

## lease-time

**Syntax**     **lease-time** [**days** *days*] [**hrs** *hours*] [**min** *minutes*] [**sec** *seconds*]  
**no lease-time**

**Context**     config>service>vprn>dhcp>server>pool>options

**Description**     This command configures the amount of time that the DHCP server grants to the DHCP client permission to use a particular IP address.  
  
The **no** form of the command removes the lease time parameters from the configuration.

**Default**     n/a

**Parameters**     *time* — specifies the lease time

**Values**

|       |           |
|-------|-----------|
| days  | 0 to 3650 |
| hours | 0 to 23   |

|         |         |
|---------|---------|
| minutes | 0 to 59 |
| seconds | 0 to 59 |

| <b>Description</b> | This command enables local DHCP Server pool management for PPPoXv4 clients. A pool of IP addresses can be shared between IPoE clients that rely on DHCP protocol (lease renewal process) and PPPoX clients where address allocation is not dependent on DHCP messaging but instead an IP address allocation within the pool is tied to the PPPoX session. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | This command will render the subscriber-interface non operation for the given amount of time once the node is rebooted or once the interface is enabled (no-shutdown). The purpose of this timer is to stall the operation of the subscriber-interface until the MCS database is synchronized. |

A typical use case for this timer would be to prevent IP lease duplication for PPPoE clients using local PPPoXv4/v6 pools in redundant DHCPv4/v6 server configuration. Since there is no classical DHCP lease state maintained for local PPPoXv4/v6 pools, the IP addresses will not be synchronized via DHCP Server. Instead they will be synchronized via PPPoX clients whose state is maintained in the router. Once the PPPoX subscriber host is synchronized between the two nodes, the respective IP address lease will be updated in the respective local pool.

One artifact of this behavior (IP address assignment in local DHCP pools is synchronized via PPPoX clients and not via DHCP server synchronization mechanism) is that during the node boot, the DHCP server must wait for the completion of PPPoX subscriber synchronization via MCS so that it learns which addresses/prefixes are already allocated on the peering node. Since the DHCP server can theoretically start assigning IP addresses before the PPPoX sync is completed, a duplicate address assignment may occur. For example an IP address lease can be granted via DHCP local pools while PPPoX sync is still in progress. Once the PPPoX sync is completed, the DHCP server may discover that the granted IP lease has already been allocated by the peering node. The most recent lease will be kept and the other will be removed from both systems. To prevent this scenario, a configurable timer is set to an arbitrary value that will render sub-if non-operational until the timer expires. The purpose of this timer is to allow the PPPoX sync to complete before subscribers under the sub-intf can be served.

| <b>Description</b> | This command creates a subnet of IP addresses to be served from the pool. The subnet cannot include any addresses that were assigned to subscribers without those addresses specifically excluded. When the subnet is created no IP addresses are made available until a range is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>ip-address</i> — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 to 223.255.255.255 (with support of /31 subnets).</p> <p><i>mask</i> — The subnet mask in dotted decimal notation. Allowed values are dotted decimal addresses in the range 128.0.0.0 to 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.</p> <p><i>netmask</i> — specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains</p> <p><b>create</b> — Keyword used to create the entity. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context.</p> |

## address-range

| <b>Description</b> | <p>This command configures a range of IP addresses to be served from the pool. All IP addresses between the start and end IP addresses will be included (other than specific excluded addresses).</p> <p>The only two valid failover combinations between the two redundant DHCP nodes are:</p> <ul style="list-style-type: none"> <li>• local - remote</li> <li>• access-driven - access-driven</li> </ul> |
| <b>Default</b>     | failover local                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>start-ip-address</i> — Specifies the start address of this range to include. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p>                                                                                                                        |

*end-ip-address* — Specifies the end address of this range to include. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

**failover** — This command designates an address range as local, remote or access-driven. This is used when multi-chassis synchronization is enabled.

**local** — An IPv4 address-range designated as local is used for new lease grants or to renew the existing lease grants. Local address-range designation should be always paired with the remote designation of the same address-range on the peering node. The IP address range configured as local on one node can only be configured as remote on the other node. No other combination is allowed between the two nodes for an IP address ranges that is configured as local.

The dhcp relay could point to both IP DHCP server addresses—the one hosting the local IP address range and the one hosting the corresponding remote IP address range. Under normal circumstances the new lease will always be allocated from the local IP address range while the leases can be renewed from either IP address range (local or remote). Under network failure, the remote IP address range can be taken over according to the intercommunication link state transitions and associated timers.

**remote** — An IPv4 address-range designated as remote is used only to renew the existing DHCP leases. The new leases will be delegated from it only after the maximum-client-lead-time + partner-down-delay time elapses. At that point we say that the remote IP address range has been taken over.

To ensure faster takeover, the partner-down-delay can be set to 0 and the MCLT time can be ignored. Extra caution should be exercised when enabling this mode of operation, as described in the configuration guides.

The IP address range configured as remote on one node can only be configured as local on the other node. No other combination is allowed between the two nodes for an IP address ranges that is configured as remote.

**access-driven** — An IPv4 address-range designated as access-driven is used for new lease grants or to renew the existing lease grants regardless of the state of the intercommunication link (operational or failed). In this mode of operation the IP address-range is actively shared between the two DHCP server nodes. This can be used on both DHCP servers only in cases where the access protection mechanism (SRRP or MC-LAG) will ensure that there is only a single active path for DHCP clients using the same IP address range available to one of the redundant DHCP nodes.

The IP address range configured as access-driven on one node can only be configured as access-driven on the other node. No other combination is allowed between the two nodes for an IP address ranges that is configured as access-driven.

There MUST be no crosslinks between the DHCP servers that have IP address ranges configured in access-driven failover mode. In other words, each node must have the dhcp-relay pointing to the IP address of the local DHCP server. This IP address must be the same on both nodes. For example, both DHCP servers should have a loopback address configured with the same IP address (IPv4 or IPv6) and a DHCP server associated with this loopback address. Those IP addresses MUST not be advertised outside of each box. The DHCP relay in each node would point to its local DHCP server via this loopback IP address.

## drain

|                    |                                                                                                                                                                                                                                                           |

| <b>Description</b> | This command specifies a range of IP addresses that excluded from the pool of IP addresses in this subnet.                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>start-ip-address</i> — Specifies the start address of this range to exclude. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).<br><br><i>end-ip-address</i> — Specifies the end address of this range to exclude. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). |

## maximum-declined

|               |                                                                               |
|---------------|-------------------------------------------------------------------------------|
| <b>Syntax</b> | <b>maximum-declined</b> <i>maximum-declined</i><br><b>no maximum-declined</b> |
|---------------|-------------------------------------------------------------------------------|

---

|                    |                                                                                      |
|--------------------|--------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>dhcp>server>pool>subnet                                          |
| <b>Description</b> | This command configures the maximum number of declined addresses allowed.            |
| <b>Default</b>     | 64                                                                                   |
| <b>Parameters</b>  | <i>maximum-declined</i> — specifies the maximum number of declined addresses allowed |
| <b>Values</b>      | 0 to 4294967295                                                                      |

## minimum-free

|                    |                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>minimum-free</b> <i>minimum-free</i> [percent] [event-when-depleted]<br><b>no minimum-free</b>                                                                                                    |
| <b>Context</b>     | config>service>vprn>dhcp>server>pool>subnet                                                                                                                                                          |
| <b>Description</b> | This command configures the minimum number of free addresses in this subnet. If the actual number of free addresses in this subnet falls below this configured minimum, a notification is generated. |
| <b>Default</b>     | 1                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>minimum-free</i> — specifies the minimum number of free addresses in this subnet                                                                                                                  |
| <b>Values</b>      | 0 to 255                                                                                                                                                                                             |
|                    | <b>percent</b> — indicates the value indicates a percentage                                                                                                                                          |
|                    | <b>event-when-depleted</b> — enables a system-generate event when all available addresses in the pool/subnet of local DHCP server are depleted                                                       |

## default-router

|                    |                                                                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-router</b> <i>ip-address</i> [ <i>ip-address...</i> (up to 4 max)]<br><b>no default-router</b>                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>dhcp>server>pool>subnet                                                                                                                                                                                                                       |
| <b>Description</b> | This command configures the IP address of the default router for a DHCP client. Up to four IP addresses can be specified.<br><br>The <b>no</b> form of the command removes the address(es) from the configuration.                                                |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address of the default router. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). |

## subnet-mask

|                    |                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>subnet-mask</b> <i>ip-address</i><br><b>no subnet-mask</b>                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>dhcp>server>pool>subnet                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command specifies the subnet-mask option to the client. The mask can either be defined (for supernetting) or taken from the pool address.</p> <p>The <b>no</b> form of the command removes the address from the configuration.</p>                      |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>ip-address</i> — Specifies the IP address of the subnet mask. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 to 223.255.255.255 (with support of /31 subnets). |

## use-gi-address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] use-gi-address</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>dhcp>server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command enables the use of gi-address matching. If the gi-address flag is enabled, a pool can be used even if a subnets is not found. If the local-user-db-name is not used, the gi-address flag is used and addresses are handed out by GI only. If a user must be blocked from getting an address the server maps to a local user database and configures the user with no address.</p> <p>A pool can include multiple subnets. Since the GI is shared by multiple subnets in a subscriber-interface the pool may provide IP addresses from any of the subnets included when the GI is matched to any of its subnets. This allows a pool to be created that represents a sub-int.</p> |
| <b>Default</b>     | no use-gi-address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## use-pool-from-client

|                    |                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] use-pool-from-client</b>                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>dhcp>server<br>config>service>vprn>dhcp6>server                                                                                                                                                                          |
| <b>Description</b> | <p>This command specifies if the IP address pool to be used by this server is the pool indicated by the vendor-specific sub-option 13 of the DHCP Option 82.</p> <p>When enabled, the pool indicated by the sub-option 13 is to be used.</p> |

The **no** form of the command indicates that the pool selection is specified by the value of **use-gi-address** setting.

## user-db

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>user-db</b> <i>local-user-db-name</i><br><b>no user-db</b>           |
| <b>Context</b>     | config>service>vprn>dhcp>server                                         |
| <b>Description</b> | This command configures a local user database for authentication.       |
| <b>Default</b>     | no user-db                                                              |
| <b>Parameters</b>  | <i>local-user-db-name</i> — specifies the name of a local user database |

### 3.9.2.5 IGMP Commands

## igmp

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] igmp</b>                                                                                                       |
| <b>Context</b>     | config>service>vprn                                                                                                    |
| <b>Description</b> | This command enables the context to configure IGMP parameters.<br><br>The <b>no</b> form of the command disables IGMP. |
| <b>Default</b>     | disabled                                                                                                               |

## group-interface

|                    |                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] group-interface</b> <i>ip-int-name</i><br><b>[no] group-interface fwd-service</b> <i>service-id ip-int-name</i> |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                |
| <b>Description</b> | This command configures IGMP group interfaces.<br><br>The <b>no</b> form of the command reverts to the default.         |
| <b>Default</b>     | n/a                                                                                                                     |

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><i>ip-int-name</i> — Specifies the name of the IP interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.</p> <p><b>fw-d-service</b> <i>service-id</i> — Specifies the service ID. This is only configured in the retailer VRF. This construct references the wholesaler service under which the group-interface (and the subscriber) is actually defined.</p> <p><b>Values</b> 1 to 2147483650, svc-name up to 64 char maximum</p> <p><b>Default</b> n/a</p> |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## disable-router-alert-check

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] disable-router-alert-check</b>                                                                                             |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>igmp-host-tracking<br>config>service>vprn>igmp>grp-if<br>config>service>vprn>igmp>if          |
| <b>Description</b> | This command enables the IGMP router alert check option.<br><br>The <b>no</b> form of the command disables the router alert check. |

## import

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>import</b> <i>policy-name</i><br><b>no import</b>                       |
| <b>Context</b>     | config>service>vprn>igmp>grp-if<br>config>service>vprn>igmp>if             |
| <b>Description</b> | This command specifies the policy that is to be applied on this interface. |
| <b>Parameters</b>  | <i>policy-name</i> — specifies the policy to filter IGMP packets           |

## max-groups

|                |                                                                |
|----------------|----------------------------------------------------------------|
| <b>Syntax</b>  | <b>max-groups</b> <i>value</i><br><b>no max-groups</b>         |
| <b>Context</b> | config>service>vprn>igmp>grp-if<br>config>service>vprn>igmp>if |

**Description** This command configures the maximum number of groups for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of groups, the groups that are already accepted are not deleted. Only new groups will not be allowed.

The **no** form of the command removes the value.

**Parameters** *value* — specifies the maximum number of groups for this interface

**Values** 1 to 16000

## max-sources

**Syntax** **max-sources** *max-sources*  
**no max-sources**

**Context** config>service>vprn>igmp>grp-if  
config>service>vprn>igmp>if

**Description** This command specifies the maximum number of sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of sources, the sources that are already accepted are not deleted. Only new sources will not be allowed.

**Parameters** *sources* — specifies the maximum number of sources for this interface

**Values** 1 to 1000

## max-grp-sources

**Syntax** **max-grp-sources** *max-group-sources*  
**no max-grp-sources**

**Context** config>service>vprn>igmp>grp-if  
config>service>vprn>igmp>if

**Description** This command configures the maximum number of group sources for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than currently accepted number of group sources, the group sources that are already accepted are not deleted. Only new group sources will not be allowed.

The **no** form of the command reverts to the default.

**Default** 0

---

**Parameters**    **1 to 32000** — specifies the maximum number of group source  
                       **Values**        1 to 32000

## mcac

**Syntax**        **mcac**

**Context**        config>service>vprn>igmp>group-interface  
                       config>service>vprn>igmp>interface  
                       config>service>vprn>mld>group-interface  
                       config>service>vprn>mld>interface  
                       config>service>vprn>pim>interface

**Description**    This command configures multicast CAC policy and constraints for this interface.

**Default**        n/a

## if-policy

**Syntax**        **if-policy** *mcac-if-policy-name*  
                       **no if-policy**

**Context**        config>service>vprn>igmp>grp-if>mcac  
                       config>service>vprn>igmp>interface>mcac  
                       config>service>vprn>mld>grp-if>mcac  
                       config>service>vprn>mld>interface>mcac  
                       config>service>vprn>pim>interface>mcac

**Description**    This command assigns existing MCAC interface policy to this interface.  
                       The **no** form of the command removes the MCAC interface policy association.

**Default**        no if-policy

**Parameters**    *mcac-if-policy-name* — specifies an existing MCAC interface policy

## mc-constraints

**Syntax**        **mc-constraints**

**Context**        config>service>vprn>igmp>grp-if>mcac  
                       config>service>vprn>igmp>interface>mcac  
                       config>service>vprn>mld>grp-if>mcac  
                       config>service>vprn>mld>interface>mcac  
                       config>service>vprn>pim>interface>mcac

**Description** This command enables the context to configure multicast CAC constraints.

**Default** n/a

## level

**Syntax** **level** *level-id* **bw** *bandwidth*  
**no level** *level-id*

**Context** config>service>vprn>igmp>interface>mcac>mc-constraints  
config>service>vprn>mld>interface>mcac>mc-constraints  
config>service>vprn>pim>interface>mcac>mc-constraints

**Description** This command configures interface levels and associated bandwidth for multicast CAC policy.

**Parameters** *level-id* — specifies an entry for the multicast CAC policy constraint level configured on this system

**Values** 1 to 8

*bandwidth* — specifies the bandwidth in kb/s for the level

**Values** 1 to 2147483647

## number-down

**Syntax** **number-down** *number-lag-port-down* **level** *level-id*  
**no number-down**

**Context** config>service>vprn>igmp>interface>mcac>mc-constraints  
config>service>vprn>mld>interface>mcac>mc-constraints  
config>service>vprn>pim>interface>mcac>mc-constraints

**Description** This command configures the number of ports down and level for interface's multicast CAC policy.

**Default** not enabled

**Parameters** *number-lag-port-down* — If the number of ports available in the LAG is reduced by the number of ports configured in this command here then bandwidth allowed for bundle and/or interface will be as per the levels configured in this context.

**Values** 1 to 64 (for 64-link LAG)  
1 to 32 (for other LAGs)

*level-id* — specifies an entry for the multicast CAC policy constraint level configured on this system

**Values** 1 to 8

---

## use-lag-port-weight

|                    |                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] use-lag-port-weight</b>                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>igmp>interface>mcac>mc-constraints<br>config>service>vprn>mld>interface>mcac>mc-constraints<br>config>service>vprn>pim>interface>mcac>mc-constraints                                                                                |
| <b>Description</b> | This command enables port weight to be used when determining available bandwidth per level when LAG ports go down/come up. The command is required for proper operation on mixed port-speed LAGs and can be used for non-mixed port-speed LAGs as well. |
| <b>Default</b>     | no use-lag-port-weight - port number is used when determining available bandwidth per level when LAG ports go down/come up.                                                                                                                             |

## policy

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>policy <i>policy-name</i></b><br><b>no policy</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>igmp>grp-if>mcac<br>config>service>vprn>igmp>interface>mcac<br>config>service>vprn>mld>grp-if>mcac<br>config>service>vprn>mld>interface>mcac<br>config>service>vprn>pim>interface>mcac                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command references the global channel bandwidth definition policy that is used for HMCAC and HQoS Adjust.</p> <p>HQoS Adjustment is supported with redirection enabled or per-host-replication disabled. In other words, the policy from the redirected interface is used for HQoS Adjustment.</p> <p>Hierarchical MCAC (HMCAC) is supported with redirection enabled or per-host-replication disabled. In HMCAC, the subscriber is checked first against its bandwidth limits followed by the check on the redirected interface against the bandwidth limits defined under the redirected interface. In the HMCAC case, the channel definition policy must be referenced under the redirected interface level.</p> |
| <b>Default</b>     | No policy is referenced.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>policy-name</i> — specifies the name of the global MCAC channel definition policy defined under the hierarchy <b>configure&gt;router&gt;mcac&gt;policy</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | This command configures the bandwidth for the interface's multicast CAC policy traffic. When disabled ( <b>no unconstrained-bw</b> ) there will be no checking of bandwidth constraints on the interface level. When enabled and a policy is defined, enforcement is performed. The allocated bandwidth for optional channels should not exceed the <b>unconstrained-bw</b> minus the <b>mandatory-bw</b> and the mandatory channels have to stay below the specified value for the <b>mandatory-bw</b> . After this interface check, the bundle checks are performed.                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>bandwidth</i> — the bandwidth assigned for the interface's MCAC policy traffic in kb/s<br><b>Values</b> 0 to 2147483647<br><b>mandatory-bw</b> <i>mandatory-bw</i> — specifies the bandwidth pre-reserved for all the mandatory channels on a given interface, in kb/s<br>If the <i>bandwidth</i> value is 0, no mandatory channels are allowed. If <i>bandwidth</i> is not configured, then all mandatory and optional channels are allowed.<br>If the value of <i>mandatory-bw</i> is equal to the value of <i>bandwidth</i> , then all the unconstrained bandwidth on a given interface is allocated to mandatory channels configured through multicast CAC policy on that interface and no optional groups (channels) are allowed.<br>The value of <i>mandatory-bw</i> should always be less than or equal to that of <i>bandwidth</i> , An attempt to set the value of <i>mandatory-bw</i> greater than that of <i>bandwidth</i> , will result in inconsistent value error.<br><b>Values</b> 0 to 2147483647 |

## query-src-ip

|                    |                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command enables local subnet checking for IGMP.</p> <p>The <b>no</b> form of the command disables local subnet checking for IGMP.</p> |

## version

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>version</b> <i>version</i><br><b>no version</b>                                                                |
| <b>Context</b>     | config>service>vprn>igmp>grp-if                                                                                   |
| <b>Description</b> | <p>This command configures the version of IGMP.</p> <p>The <b>no</b> form of the command removes the version.</p> |

**Parameters** *version* — specifies the IGMP version

**Values** 1, 2, or 3

## grp-if-query-src-ip

**Syntax** **grp-if-query-src-ip** *ip-address*  
**no grp-if-query-src-ip**

**Context** config>service>vprn>igmp

**Description** This command configures the query source IP address for all group interfaces.  
The **no** form of the command removes the IP address.

**Default** n/a

## interface

**Syntax** **interface** *ip-int-name*  
**no interface**

**Context** config>service>vprn>igmp

**Description** This command enables the context to configure IGMP interface parameters.

**Parameters** *ip-int-name* — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

**Values** 1 to 32 characters maximum

## import

**Syntax** **import** *policy-name*  
**no import**

**Context** config>service>vprn>igmp>if

**Description** This command imports a policy to filter IGMP packets. The **no** form of the command removes the policy association from the IGMP instance.

**Default** no import — No import policy specified.

**Parameters** *policy-name* — The import route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

---

The specified name(s) must already be defined.

## max-groups

| <b>Description</b> | This command specifies the maximum number of groups for which IGMP can have local receiver information based on received IGMP reports on this interface. When this configuration is changed dynamically to a value lower than the currently accepted number of groups, the groups that are already accepted are not deleted. Only new groups will not be allowed. |
| <b>Default</b>     | 0, no limit to the number of groups                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>value</i> — Specifies the maximum number of groups for this interface.<br><b>Values</b> 1 to 16000                                                                                                                                                                                                                                                             |

| <b>Description</b> | This command adds a static multicast group either as a (*,G) or one or more (S,G) records. Use IGMP static group memberships to test multicast forwarding without a receiver host. When IGMP static groups are enabled, data is forwarded to an interface without receiving membership reports from host members.<br><br>When static IGMP group entries on point-to-point links that connect routers to a rendezvous point (RP) are configured, the static IGMP group entries do not generate join messages toward the RP. |

| <b>Context</b>     | config>service>vprn>igmp>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command specifies the IGMP version. If routers run different versions of IGMP, they will negotiate the lowest common version of IGMP that is supported by hosts on their subnet and operate in that version. For IGMP to function correctly, all routers on a LAN should be configured to run the same version of IGMP on that LAN.</p> <p>For IGMPv3, a multicast router that is also a group member performs both parts of IGMPv3, receiving and responding to its own IGMP message transmissions as well as those of its neighbors.</p> |
| <b>Default</b>     | 3                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>version</i> — specifies the IGMP version number                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|                    |                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-last-member-interval</b> <i>seconds</i>                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                                                                                                                                |
| <b>Description</b> | This command configures the frequency at which the querier sends group-specific query messages including messages sent in response to leave-group messages. The lower the interval, the faster the detection of the loss of the last member of a group. |
| <b>Default</b>     | 1                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>seconds</i> — specifies the frequency, in seconds, at which query messages are sent<br><b>Values</b> 1 to 1024                                                                                                                                       |

## query-response-interval

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>query-response-interval</b> <i>seconds</i>                                                                                                  |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                       |
| <b>Description</b> | This command specifies how long the querier router waits to receive a response to a host-query message from a host.                            |
| <b>Default</b>     | 10                                                                                                                                             |
| <b>Parameters</b>  | <i>seconds</i> — specifies the length of time to wait to receive a response to the host-query message from the host<br><b>Values</b> 1 to 1023 |

## robust-count

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>robust-count</b> <i>robust-count</i><br><b>no robust-count</b>                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>igmp                                                                                                                                                                                |
| <b>Description</b> | This command configures the robust count. The robust-count variable allows tuning for the expected packet loss on a subnet. If a subnet anticipates losses, the robust-count variable can be increased. |
| <b>Default</b>     | 2                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>robust-count</i> — specifies the robust count value<br><b>Values</b> 2 to 10                                                                                                                         |

## ssm-translate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ssm-translate</b>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>igmp<br>config>service>vprn>igmp>if                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command enables the context to configure group ranges which are translated to SSM (S,G) entries. If the static entry needs to be created, it has to be translated from a IGMPv1 IGMPv2 request to a Source Specific Multicast (SSM) join. An SSM translate source can only be added if the <b>starg</b> command is not enabled. An error message is generated if you try to configure the <b>source</b> command with <b>starg</b> command enabled. |

## grp-range

|                    |                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] grp-range</b> <i>start end</i>                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>igmp>ssm-translate                                                                                                                                                                                                      |
| <b>Description</b> | This command is used to configure group ranges which are translated to SSM (S,G) entries.                                                                                                                                                   |
| <b>Parameters</b>  | <i>start</i> — an IP address that specifies the start of the group range<br><i>end</i> — An IP address that specifies the end of the group range. This value should always be greater than or equal to the value of the <i>start</i> value. |

## source

|                    |                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] source</b> <i>ip-address</i>                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>igmp>ssm-translate>grp-range                                                                                                                                                                                                                                  |
| <b>Description</b> | This command specifies the source IP address for the group range. Whenever a (*,G) report is received in the range specified by <b>grp-range</b> <i>start</i> and <i>end</i> parameters, it is translated to an (S,G) report with the value of this object as the source address. |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP address that will be sending data                                                                                                                                                                                                            |

## igmp-host-tracking

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>igmp-host-tracking</b>                                                    |
| <b>Context</b>     | config>service>vprn<br>config>service>vprn>sap                               |
| <b>Description</b> | This command enables the context to configure IGMP host tracking parameters. |

## expiry-time

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>expiry-time</b> <i>expiry-time</i><br><b>no expiry-time</b>                                                                                                          |
| <b>Context</b>     | config>service>vprn>igmp-trk<br>config>service>vprn>sap>igmp-trk                                                                                                        |
| <b>Description</b> | This command configures the time that the system continues to track inactive hosts.<br><br>The <b>no</b> form of the command removes the values from the configuration. |
| <b>Default</b>     | no expiry-time                                                                                                                                                          |
| <b>Parameters</b>  | <i>expiry-time</i> — specifies the time, in seconds, that this system continues to track an inactive host<br><br><b>Values</b> 1 to 65535                               |

## import

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>import</b> <i>policy-name</i><br><b>no import</b>                                                                                                 |
| <b>Context</b>     | config>service>vprn>sap>igmp-trk                                                                                                                     |
| <b>Description</b> | This command associates an import policy to filter IGMP packets.<br><br>The <b>no</b> form of the command removes the values from the configuration. |
| <b>Default</b>     | no import                                                                                                                                            |
| <b>Parameters</b>  | <i>policy-name</i> — specifies the import policy name                                                                                                |

| <b>Description</b> | <p>This command specifies the maximum number of remote IPv6 routes that can be held within a VPN routing/ forwarding (VRF) context. The <b>local</b>, <b>host</b>, <b>static</b> and <b>aggregate</b> routes are not counted.</p> <p>The VPRN service ID must be in a shutdown state in order to modify maximum-routes command parameters.</p> <p>If the <b>log-only</b> parameter is not specified and the maximum-routes value is set below the existing number of routes in a VRF, then the offending RIP peer (if applicable) is brought down (but the VPRN instance remains up). BGP peering will remain up but the exceeding BGP routes will not be added to the VRF.</p> <p>The maximum route threshold can dynamically change to increase the number of supported routes even when the maximum has already been reached. Protocols will resubmit their routes which were initially rejected.</p> <p>The <b>no</b> form of the command disables any limit on the number of routes within a VRF context. Issue the <b>no</b> form of the command only when the VPRN instance is shutdown.</p> |
| <b>Default</b>     | 0 or disabled — The threshold will not be raised.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>number</i> — an integer that specifies the maximum number of routes to be held in a VRF context</p> <p><b>Values</b> 1 to 2147483647</p> <p><b>log-only</b> — Specifies that if the maximum limit is reached, only log the event. <b>log-only</b> does not disable the learning of new routes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**threshold percentage** — The percentage at which a warning log message and SNMP trap should be set. There are two warnings, the first is a mid-level warning at the threshold value set and the second is a high-level warning at level between the maximum number of routes and the mid-level rate  $([mid+max] / 2)$ .

**Values** 0 to 100

## maximum-routes

|                    |                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>filter ip</b> <i>ip-filter-id</i><br><b>filter ipv6</b> <i>ipv6-filter-id</i><br><b>no filter</b> [ <b>ip</b> <i>ip-filter-id</i> ] [ <b>ipv6</b> <i>ipv6-filter-id</i> ]                                                                             |
| <b>Context</b>     | config>service>vprn>network>ingress                                                                                                                                                                                                                      |
| <b>Description</b> | This command configures a network ingress filter for IPv4 or IPv6 traffic arriving over explicitly defined spokes or auto-bind network interfaces for the VPRN service.<br><br>The <b>no</b> form of the command removes an IPv4, IPv6, or both filters. |
| <b>Default</b>     | no filter                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>ip-filter-id/ipv6-filter-id</i> — specifies an existing IP/IPv6 filter policy of a scope template<br><br><b>Values</b> [1..65535]   <i>name</i><br><i>name</i> : 64 characters maximum                                                                |

## ptp

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ptp</b>                                                                    |
| <b>Context</b>     | config>service>vprn                                                                |
| <b>Description</b> | This command enables the context to configure PTP parameters for the VPRN service. |

## peer-limit

|                    |                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer-limit</b> <i>limit</i><br><b>no peer-limit</b>                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>ptp                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command specifies an upper limit to the number of discovered peers permitted within the routing instance. This can be used to ensure that a routing instance does not consume all the possible discovered peers and blocking discovered peers in other routing instances. |

If it is desired to reserve a fixed number of discovered peers per router instance, then all router instances supporting PTP should have values specified with this command and the sum of all the peer-limit values must not exceed the maximum number of discovered peers supported by the system.

If the user attempts to specify a peer-limit, and there are already more discovered peers in the routing instance than the new limit being specified, the configuration will not be accepted.

|                   |                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no limit                                                                                        |
| <b>Parameters</b> | <i>limit</i> — specifies the maximum number of discovered peers allowed in the routing instance |
| <b>Values</b>     | 0 to 50                                                                                         |
| <b>Default</b>    | 0 (The maximum number of discovered peers supported by the system.)                             |

| <b>Description</b> | <p>This command configures a remote PTP peer. It provides the context to configure parameters for the remote PTP peer.</p> <p>Up to 20 remote PTP peers may be configured.</p> <p>The <b>no</b> form of the command deletes the specified peer.</p> <p>If the clock-type is ordinary slave or boundary, and PTP is no shutdown, the last peer cannot be deleted. This prevents the user from having PTP enabled without any peer configured and enabled.</p> <p>Peers are created within the routing instance associated with the context of this command. All configured PTP peers must use the same routing instance.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the message interval used for unicast event messages. It defines the message interval for both Sync and Delay_Resp messages that are requested during unicast negotiation to the specific peer. This controls the Sync and Delay_Resp message rate sent from remote peers to the local node. It does not affect the Sync or Delay_Resp packet rate that may be sent from the local node to remote peers. Remote peers may request a Sync or Delay_Resp packet rate anywhere within the acceptable grant range.</p> <p>The <b>log-sync-interval</b> cannot be changed unless the peer is shutdown.</p> <p>This command only applies to the 7450 ESS and 7750 SR.</p> |
| <b>Default</b>     | <p>-6 (64 packets per second) for 1588-2008 or</p> <p>-6 (64 packets per second) for g8265dot1-2010 or</p> <p>-4 (16 packets per second) for g8275dot1-2014</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>log-interval</i> — specifies the sync message interval, in log form</p> <p><b>Values</b>      [-6 to 0]</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vprn>ptp>peer                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command configures the local priority used to choose between PTP masters in the best master clock algorithm (BMCA). This setting is relevant when the profile is set to either g8265dot1-2010 or g8275dot1-2014. The parameter is ignored when any other profile is selected.</p> <p>The value 1 is the highest priority and 255 is the lowest priority. The priority of a peer cannot be configured if the PTP profile is ieee1588-2008.</p> <p>For g8265dot1-2010, this parameter configures the priority used to choose between master clocks with the same quality (see G.8265.1 for more details).</p> <p>For g8275dot1-2014, this parameter sets the value of the <b>localPriority</b> associated with the Announce messages received from external clocks (<b>ptp&gt;peer</b> or <b>ptp&gt;port</b>), or the local clock (<b>ptp</b>). See G.8275.1 for more detailed information.</p> |
| <b>Default</b>     | 128                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>local-priority</i> — specifies the value of the local priority</p> <p><b>Values</b>      1 to 255</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command sets the identifier attached to routes the VPN belongs to. Each routing instance must have a unique (within the carrier's domain) route distinguisher associated with it. A route distinguisher must be defined for a VPRN to be operationally active.</p> <p>Alternatively, the <b>auto-rd</b> option allows the system to automatically generate a Route Distinguisher (RD) based on the <b>bgp-auto-rd-range</b> command configured at the service level.</p>                                                                                                                |
| <b>Default</b>     | no route-distinguisher                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><b>route distinguisher</b> — The route distinguisher is a 6-byte value that can be specified in one of the following formats:</p> <p><i>ip-address:number</i> — Specifies the IP address in dotted decimal notation. The assigned number must not be greater than 65535.</p> <p><i>asn:number</i> — The ASN is a 2-byte value less than or equal to 65535. The assigned number can be any 32-bit unsigned integer value.</p> <p><b>auto-rd</b> — the system will generate an RD for the service according to the IP address and range configured in the <b>bgp-auto-rd-range</b> command</p> |

## router-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command sets the router ID for a specific VPRN context.</p> <p>When configuring the router ID in the base instance of OSPF it overrides the router ID configured in the <b>config&gt;router</b> context. The default value for the base instance is inherited from the configuration in the <b>config&gt;router</b> context. If the router ID in the <b>config&gt;router</b> context is not configured, the following applies:</p> <ul style="list-style-type: none"><li>• The system uses the system interface address (which is also the loopback address).</li><li>• If a system interface address is not configured, use the last 32 bits of the chassis MAC address.</li></ul> <p>If neither the router ID nor system interface are defined, the router ID from the base router context is inherited.</p> <p>This is a <b>required</b> command when configuring multiple instances and the instance being configured is not the base instance.</p> <p>When configuring a new router ID, the instance is not automatically restarted with the new router ID. The next time the instance is initialized, the new router ID is used.</p> <p>To force the new router ID to be used, issue the <b>shutdown</b> and <b>no shutdown</b> commands for the instance, or reboot the entire router.</p> <p>It is possible to configure an SR OS to operate with an IPv6 only BOF and no IPv4 system interface address. When configured in this manner, the operator must explicitly define IPv4 router IDs for protocols such as OSPF and BGP as there is no mechanism to derive the router ID from an IPv6 system interface address.</p> <p>The <b>no</b> form of the command removes the router ID definition from the given VPRN context.</p> |
| <b>Default</b>     | no router-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>ip-address</i> — the IP address must be given in dotted decimal notation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures an optional service name, up to 64 characters in length, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider/administrator to identify and manage services within the 7450 ESS and 7750 SR platforms.</p> <p>All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created.</p> |
| <b>Parameters</b>  | <p><i>service-name</i> — Specifies a unique service name to identify the service. Service names may not begin with an integer (0-9).</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## sgt-qos

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sgt-qos</b>                                                                                  |
| <b>Context</b>     | config>service>vprn                                                                             |
| <b>Description</b> | This command enables the context to configure DSCP/Dot1p re-marking for self-generated traffic. |

## application

| <b>Description</b> | This command configures DSCP/Dot1p re-marking for self-generated traffic. When an application is configured using this command, then the specified DSCP name/value is used for all packets generated by this application within the router instance it is configured. |

Using the value configured in this command:

- Sets the DSCP bits in the IP packet.
- Maps to the FC. This value will be signaled from the CPM to the egress forwarding complex.
- Based on this signaled FC the egress forwarding complex QoS policy sets the IEEE802.1 dot1P and LSP EXP bits.
- The Dot1P and the LSP EXP bits are set by the egress complex for all packets based on the signaled FC. This includes ARP and IS-IS packets that, due to their nature, do not carry DSCP bits.
- The DSCP value in the egress IP header will be as configured in this command. The egress QoS policy will not overwrite this value.

Only one DSCP name/value can be configured per application, if multiple entries are configured then the subsequent entry overrides the previous configured entry.

The **no** form of this command reverts back to the default value.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | This command creates a mapping between the DiffServ Code Point (DSCP) of the self generated traffic and the forwarding class. |

Self generated traffic that matches the specified DSCP will be assigned to the corresponding forwarding class. Multiple commands can be entered to define the association of some or all sixty-four DiffServ code points to the forwarding class. For undefined code points, packets are assigned to the forwarding class specified under the default-action command.

All DSCP names that defines a DSCP value must be explicitly defined.

The **no** form of this command removes the DiffServ code point to forwarding class association. The default-action then applies to that code point value.

| <b>Description</b> | <p>This command configures OSPF, OSPFv3 and IS-IS to set overload when the router has fewer than the full set of SFMs functioning, which reduces forwarding capacity. Setting overload enables a router to still participate in exchanging routing information, but routes all traffic away from it.</p> <p>The conditions to set overload are as follows:</p> <ul style="list-style-type: none"> <li>• 7750 SR-12/SR-7/SR-c12 and 7450 ESS-12/ESS-7/ESS-6 platforms: protocol sets overload if one of the SF/CPMs fails</li> <li>• 7950 XRS and 7750 SR-12e platforms: protocol sets overload if two SFMs fail</li> </ul> <p>The <b>no</b> form of this command configures the router to not set overload if an SFM fails.</p> |
| <b>Default</b>     | no single-sfm-overload                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><i>holdoff-time</i> — specifies the delay between detecting SFM failures and setting overload</p> <p><b>Values</b>      1 to 600 seconds</p> <p><b>Default</b>      0 seconds</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Syntax</b>      | <b>[no] access</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>snmp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command enables/disables SNMP access on the VPRN interface. This command allows SNMP queries destined to the VPRN interface IP addresses for this VPRN (including VPRN interfaces that are bound to R-VPLS services) to be processed by the SNMP agent on the router. SNMP queries that arrive on VPRN interfaces but are destined to IP addresses in the Base routing context that can be accessed in the VPRN (for example, the router system address via grt leaking) do not require snmp-access to be enabled but do require allow-local-management to be enabled. |

Refer to the 7450 ESS, 7750 SR, and 7950 XRS System Management Guide for detailed information about SNMP.

## community

|                    |                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>community</b> <i>community-name</i> [ <b>hash</b>   <b>hash2</b> ] [ <b>access-permissions</b> ] [ <b>version</b> <i>SNMP-version</i> ] [ <b>src-access-list</b> <i>list-name</i> ]<br><b>no community</b> [ <i>community-name</i> ]                                                                          |
| <b>Context</b>     | config>service>vprn>snmp                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command sets the SNMP community name(s) to be used with the associated VPRN instance. These VPRN community names are used to associate SNMP v1/v2c requests with a particular vprn context and to return a reply that contains VPRN-specific data or limit SNMP access to data in a specific VPRN instance. |

VPRN snmp communities configured with an access permission of 'r' are automatically associated with the default access group "snmp-vprn-ro" and the "vprn-view" view (read only). VPRN snmp communities configured with an access permission of 'rw' are automatically associated with the default access group "snmp-vprn" and the "vprn-view" view (read/write).

The community in an SNMP v1/v2 request determines the SNMP context (i.e., the vprn# for accessing SNMP tables) and not the VPRN of the incoming interface on which the request was received. When an SNMP request arrives on VPRN 5 interface “ringo” with a destination IP address equal to the “ringo” interface, but the community in the SNMP request is the community configured against VPRN 101, then the SNMP request will be processed using the VPRN 101 context. (the response will contain information about VPRN 101). It is recommended to avoid using a simple series of vprn snmp-community values that are similar to each other (for example, avoid my-vprncomm-1, my-vprn-comm-2, etc).

The **no** form of the command removes the SNMP community name from the given VPRN context.

- Default** n/a — The SNMP community must be explicitly specified.
- Parameters**
- community-name* — Specifies the SNMP v1/v2c community name. This is a secret/confidential key used to access SNMP and specify a context (base vs vprn1 vs vprn2).
  - hash** — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified
  - hash2** — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.
  - version** *SNMP-version* — specifies the SNMP version
    - Values** v1, v2c, both
  - access-permissions* — specifies the access rights to MIB objects
    - Values**
      - r** — Grants only read access to MIB objects. Creates an association of the community-name with the **snmp-vprn-ro** access group.
      - rw** — Grants read and write access to MIB objects. Creates an association of the community-name with the **snmp-vprn** access group.
  - list-name* — Configures the **community** to reference a specific **src-access-list** (created under **configure system security snmp**), which will be used to validate the source IP address of all received SNMP requests that use this **community**. Multiple **community** (vprn or base router) and **usm-community** instances can reference the same **src-access-list**.

## source-address

**Syntax** source-address

|                    |                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn                                                                                                            |
| <b>Description</b> | This command enables the context to specify the source address and application that should be used in all unsolicited packets. |

## application

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | This command specifies the IPv6 source address and application.                                                                                                                                                          |
| <b>Parameters</b>  | <i>app</i> — specifies the application name<br><br><b>Values</b> cflowd, dns, ftp, ntp, ping, radius, snmptrap, syslog, tacplus, telnet, traceroute, icmp6-error<br><br><i>ipv6-address</i> — specifies the IPv6 address |

## static-route-entry

|                    |                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>static-route-entry</b> { <i>ip-prefix</i>   <i>prefix-length</i> } [ <b>mcast</b> ]<br><b>no static-route-entry</b> { <i>ip-prefix</i>   <i>prefix-length</i> } [ <b>mcast</b> ] |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                 |
| <b>Description</b> | This command creates a static route entry for both the network and access routes. A prefix and netmask must be specified.                                                           |

Once the static route context for the specified prefix and netmask has been created, additional parameters associated with the static route(s) may be specified through the inclusion of additional static-route parameter commands

The **no** form of the command deletes the static route entry. If a static route needs to be removed when multiple static routes exist to the same destination, then as many parameters to uniquely identify the static route must be entered

IPv6 static routes are not supported on the 7450 ESS except in mixed mode.

|            |                                                                              |                                                         |
|------------|------------------------------------------------------------------------------|---------------------------------------------------------|
| Default    | No static routes are defined.                                                |                                                         |
| Parameters | <i>ip-prefix/prefix-length</i> — the destination address of the static route |                                                         |
|            | Values                                                                       | The following values apply to the 7750 SR and 7950 XRS: |
|            | ipv4-prefix                                                                  | a.b.c.d (host bits must be 0)                           |
|            | ipv4-prefix-length                                                           | 0 to 32                                                 |
|            | ipv6-prefix                                                                  | x:x:x:x:x:x:x (eight 16-bit pieces)                     |
|            |                                                                              | x:x:x:x:x:d.d.d.d                                       |

| Description | <p>This command specifies the directly connected next hop IP address or interface used to reach the destination. If the next hop is over an unnumbered interface or a point-to-point interface, the <b>ip-int-name</b> of the unnumbered or point-to-point interface (on this node) can be configured.</p> <p>If the next hop is over an unnumbered interface in the 7450 ESS router, the <i>ip-int-name</i> of the unnumbered interface (on this node) can be configured.</p> <p>The configured <i>ip-address</i> can be either on the network side or the access side on this node. The address must be associated with a network directly connected to a network configured on this node.</p> |

| <b>Description</b>  | <p>This command specifies that the route is indirect and specifies the next hop IP address used to reach the destination.</p> <p>The configured <i>ip-address</i> is not directly connected to a network configured on this node. The destination can be reached via multiple paths. The indirect address can only be resolved from dynamic routing protocol. Another static route cannot be used to resolve the indirect address.</p> <p>The <i>ip-address</i> configured here can be either on the network side or the access side and is typically at least one hop away from this node.</p> |
| <b>Default</b>      | no indirect                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>   | <i>ip-address</i> — the IP address of the IP interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Parameters</b>  | <i>name</i> — IPsec tunnel name; maximum length up to 32 characters                                                                                                                                                                                                                                                                                     |

## bfd-enable

|                    |                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] bfd-enable                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>static-route-entry>next-hop                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command associates the static route state to a BFD session between the local system and the configured nexthop.</p> <p>The remote end of the BFD session must also be configured to originate or accept the BFD session controlling the static route state.</p> |

The **no** form of this command removes the association of the static route state to that of the BFD session.

**Default** no bfd-enable

community

**Syntax** [no] **community** *comm-id*

**Context** config>service>vprn>static-route-entry>indirect  
config>service>vprn>static-route-entry>ip-sec-tunnel  
config>service>vprn>static-route-entry>next-hop

**Description** This configuration option associates a BGP community with the static route. The community can be matched in route policies and is automatically added to BGP routes exported from the static route.

The **no** form of this command removes the community association.

**Default** no community

**Parameters** *comm-id* — specifies the community identifier

Values

|                 |                                              |
|-----------------|----------------------------------------------|
| comm-id         | asn:comm-val, well-known-comm                |
| asn             | 0 to 65535                                   |
| comm-val        | 0 to 65535                                   |
| well-known-comm | no-advertise, no-export, no-export-subconfed |

cpe-check

**Syntax** [no] **cpe-check** *cpe-ip-address*

**Context** config>service>vprn>static-route-entry>indirect  
config>service>vprn>static-route-entry>next-hop

**Description** This command enables CPE-check and specifies the IP address of the target CPE device.

This option initiates a background ICMP ping test to the configured target IP address. The IP address can either be an IPv4 address for IPv4 static routes or an IPv6 address for IPv6 static routes. The target-ip-address cannot be in the same subnet as the static route subnet itself to avoid possible circular references. This option is mutually exclusive with BFD support on a given static route.

The **no** form of this command disables the **cpe-check** option.

---

|                   |                                                                    |
|-------------------|--------------------------------------------------------------------|
| <b>Default</b>    | no cpe-check                                                       |
| <b>Parameters</b> | <i>cpe-ip-address</i> — specifies the IP address of the CPE device |

## drop-count

|                    |                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] drop-count</b> <i>count</i>                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>static-route-entry>indirect>cpe-check<br>config>service>vprn>static-route-entry>next-hop>cpe-check                                              |
| <b>Description</b> | This optional parameter specifies the number of consecutive ping-replies that must be missed to declare the CPE down and to deactivate the associated static route. |
| <b>Default</b>     | 3                                                                                                                                                                   |
| <b>Parameters</b>  | <i>count</i> — an integer count value<br><b>Values</b> 1 to 255                                                                                                     |

## interval

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] interval</b> <i>seconds</i>                                                                                    |
| <b>Context</b>     | config>service>vprn>static-route-entry>indirect>cpe-check<br>config>service>vprn>static-route-entry>next-hop>cpe-check |
| <b>Description</b> | This optional parameter specifies the interval between ICMP pings to the target IP address.                            |
| <b>Default</b>     | 1                                                                                                                      |
| <b>Parameters</b>  | <i>seconds</i> — an integer interval value<br><b>Values</b> 1 to 255                                                   |

## padding-size

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] padding-size</b> <i>padding-size</i>                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>static-route-entry>indirect>cpe-check<br>config>service>vprn>static-route-entry>next-hop>cpe-check                                                                                  |
| <b>Description</b> | This optional parameter specifies the amount of padding to add to the ICMP packet in bytes. The parameter is only applicable when the <b>cpe-check</b> option is used with the associated static route. |
| <b>Default</b>     | 0                                                                                                                                                                                                       |

**Parameters**    *padding-size* — an integer value  
**Values**        0 to 16384 bytes

## log

**Syntax**        **[no] log**

**Context**        config>service>vprn>static-route-entry>indirect>cpe-check  
                   config>service>vprn>static-route-entry>next-hop>cpe-check

**Description**    This optional parameter enables the ability to log transitions between active and in-active based on the CPE connectivity check. Events will be sent to the system log, syslog and SNMP traps.

**Default**        no log

## description

**Syntax**        **[no] description** *description-string*

**Context**        config>service>vprn>static-route-entry>indirect  
                   config>service>vprn>static-route-entry>next-hop  
                   config>service>vprn>static-route-entry>black-hole  
                   config>service>vprn>static-route-entry>grt  
                   config>service>vprn>static-route-ipsec-tunnel

**Description**    This command creates a text description stored in the configuration file for a configuration context.

                  The **no** form of the command removes the description string from the context

**Default**        no description

**Parameters**    *description-string* — The description character string. Allowed values are any string up to 80 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

## destination-class

**Syntax**        **[no] destination-class** *dest-index*

**Context**        config>service>vprn>static-route-entry>indirect  
                   config>service>vprn>static-route-ipsec-tunnel

---

|                    |                                                                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the policy accounting destination-class index to be used when incrementing accounting statistic for traffic matching the associated static route.</p> <p>The <b>no</b> form of the command removes the associated destination-class from the associated static route nexthop.</p> |
| <b>Default</b>     | no destination-class                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>dest-index</i> — the destination index integer value                                                                                                                                                                                                                                                      |
|                    | <b>Values</b> 1 to 255                                                                                                                                                                                                                                                                                       |

## generate-icmp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command extends the LDP synchronization feature to a static route. When an interface comes back up, it is possible that a preferred static route using the interface as next-hop for a given prefix is enabled before the LDP adjacency to the peer LSR comes up on this interface. In this case, traffic on an SDP that uses the static route for the far-end address would be black-holed until the LDP session comes up and the FECs exchanged.</p> <p>This option when enabled delays the activation of the static route until the LDP session comes up over the interface and the ldp-sync-timer configured on that interface has expired</p> |
| <b>Default</b>     | no ldp-sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command specifies the cost metric for the static route, expressed as a decimal integer. This value is used when importing the static route into other protocols such as OSPF. When the metric is configured as 0 then the metric configured in OSPF, default-import-metric, applies. When modifying the metric of an existing static route, the preference will not change unless specified. This value is also used to determine which static route to install in the forwarding table.</p> <p>If there are multiple static routes with the same preference but different metrics then the lower cost (metric) route will be installed.</p> <p>The <b>no</b> form of this command returns the metric to the default value</p> |
| <b>Default</b>     | no ldp-sync                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Values</b>      | 0 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## preference

|                |                                                |
|----------------|------------------------------------------------|
| <b>Syntax</b>  | <b>[no] preference <i>preference-value</i></b> |
| <b>Context</b> | config>service>vprn>static-route-entry>grt     |

```
config>service>vprn>static-route-entry>indirect
config>service>vprn>static-route-entry>ipsec-tunnel
config>service>vprn>static-route-entry>black-hole
```

**Description** This command specifies the route preference to be assigned to the associated static route. The lower the preference value the more preferred the route is considered.

Table 37 shows the default route preference based on the route source.

**Table 37** Default Route Preference

| Label                  | Preference | Configurable |
|------------------------|------------|--------------|
| Direct attached        | 0          | No           |
| Static route           | 5          | Yes          |
| OSPF Internal routes   | 10         | Yes          |
| IS-IS level 1 internal | 15         | Yes          |
| IS-IS level 2 internal | 18         | Yes          |
| OSPF external          | 150        | Yes          |
| IS-IS level 1 external | 160        | Yes          |
| IS-IS level 2 external | 165        | Yes          |
| BGP                    | 170        | Yes          |

The **no** form of this command returns the associated static route preference to its default value.

**Default** 5

**Parameters** *preference-value* — specifies the route preference value

**Values** 1 to 255

## prefix-list

**Syntax** [no] **prefix-list** *name* {**all** | **none** | **any**}

**Context** config>service>vprn>static-route-entry>indirect  
config>service>vprn>static-route-entry>next-hop  
config>service>vprn>static-route-entry>black-hole

**Description** This command associates a new constraint to the associated static route such that the static route is only active if **any**, **none**, or **all** of the routes in the prefix list are present and active in the route-table.

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no prefix-list                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b> | <p><i>name</i> — specifies the name of a currently configured prefix-list</p> <p><b>all</b> — specifies that the static route condition is met if all prefixes in the prefix-list must be present in the active static route</p> <p><b>none</b> — specifies that the static route condition is met if none of the prefixes in the named prefix-list can be present in the active static route</p> <p><b>any</b> — specifies that the static route condition is met if any prefixes in the prefix-list are present in the active static route</p> |

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] shutdown                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>static-route-entry>black-hole<br>config>service>vprn>static-route-entry>grt<br>config>service>vprn>static-route-entry>indirect<br>config>service>vprn>static-route-entry>ipsec-tunnel<br>config>service>vprn>static-route-entry>next-hop |
| <b>Description</b> | This command causes the static route to be placed in an administratively down state and removed from the active route-table                                                                                                                                  |

**Default** no shutdown

## source-class

**Syntax** [no] **source-class** *source-index*

**Context** config>service>vprn>static-route-entry>indirect  
config>service>vprn>static-route-entry>ipsec-tunnel  
config>service>vprn>static-route-entry>next-hop

**Description** This command configures the policy accounting source-class index to be used when incrementing accounting statistic for traffic matching the associated static route.

If source route policy accounting is enabled and a source-class index is configured, traffic with a source IP address matches the associated static route, the source accounting statistics for the specified class will be incremented.

The **no** form of the command removes the associated destination-class from the associated static route nexthop.

**Default** no source-class

**Parameters** *source-index* — specifies an integer value for the accounting source class index

**Values** 1 to 255

## tag

**Syntax** [no] **tag** *tag-value*

**Context** config>service>vprn>static-route-entry>indirect  
config>service>vprn>static-route-entry>ipsec-tunnel  
config>service>vprn>static-route-entry>next-hop

**Description** This command adds a 32-bit integer tag to the associated static route.

The tag value can be used in route policies to control distribution of the route into other protocols.

**Default** 1

**Parameters** *tag-value* — specifies an integer tag value

**Values** 32 bit integer

## validate-next-hop

**Syntax** [no] **validate-next-hop**

---

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>type</b> [ <b>hub</b>   <b>spoke</b>   <b>subscriber-split-horizon</b> ]<br><b>no type</b>                                                                                                                    |
| <b>Context</b>     | config>service>vprn>                                                                                                                                                                                             |
| <b>Description</b> | This command designates the type of VPRN instance being configured for hub and spoke topologies. Use the <b>no</b> form to reset to the default of a fully meshed VPRN.                                          |
| <b>Default</b>     | no type                                                                                                                                                                                                          |
| <b>Parameters</b>  | <b>hub</b> — Specifies a hub VPRN which allows all traffic from the hub SAPs to be routed to the destination directly, while all traffic from spoke VPRNs or network interfaces can only be routed to a hub SAP. |

**spoke** — Specifies a spoke VPRN which allows traffic from associated SAPs or spoke terminations to only be forwarded through routes learned from separate VPRN, which should be configured as a type Hub VPRN.

**subscriber-split-horizon** — Controls the flow of traffic for wholesale subscriber applications.

## vrf-export

| <b>Description</b> | <p>This command is used to specify route policies that control how routes are exported from the local VRF to other VRFs on the same or remote PE routers (via MP-BGP). Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context.</p> <p>The <b>vrf-export</b> command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine final action to accept or reject the route.</p> <p>Only one of the 15 objects referenced by the <b>vrf-export</b> command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.</p> <p>When multiple <b>vrf-export</b> commands are issued, the last command entered overrides the previous command.</p> <p>Aggregate routes are not advertised via MP-BGP protocols to the other MP-BGP peers.</p> <p>The <b>no</b> form of the command removes all route policy names from the <b>vrf-export</b> list.</p> |
| <b>Default</b>     | no vrf-export                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command is used to specify route policies that control how VPN-IP routes exported by other VRFs, on the same or remote PEs, are imported into the local VRF. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context.</p> <p>The <b>vrf-import</b> command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine final action to accept or reject the route</p> <p>Only one of the 15 objects referenced by the <b>vrf-import</b> command is allowed to be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.</p> <p>When multiple <b>vrf-import</b> commands are issued, the last command entered overrides the previous command.</p> <p>The <b>no</b> form of the command removes all route policy names from the import list</p> <p>Note that unless the preference value is changed by the policy, BGP-VPN routes imported with a vrf-import policy have the preference value of 170 when imported from remote PE routers, or retain the protocol preference value of the exported route when imported from other VRFs on the same router.</p> |
| <b>Default</b>     | no vrf-import                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>plcy-or-long-expr</i> — the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long)</p> <p><i>plcy-or-expr</i> — the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vpn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command facilitates a simplified method to configure the route target to be added to advertised routes or compared against received routes from other VRFs on the same or remote PE routers (via MP-BGP).</p> <p>BGP-VPN routes imported with a vrf-target statement will use the BGP preference value of 170 when imported from remote PE routers, or retain the protocol preference value of the exported route when imported from other VRFs in the same router.</p> <p>Specified <b>vrf-import</b> or <b>vrf-export</b> policies override the <b>vrf-target</b> policy.</p> <p>The no form of the command removes the vrf-target</p> |
| <b>Default</b>     | no vrf-target                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

**Parameters** *ext-comm* — An extended BGP community in the **type:x:y** format. The value **x** can be an integer or IP address. The **type** can be the target or origin. **x** and **y** are 16-bit integers.

**Values**  
*<ext-community>* : target:{<ip-addr:comm-val> | <2byte-asnumber:ext-comm-val> | <4byte-asnumber:comm-val>}  
 ip-addr: a.b.c.d  
 comm-val: [0 to 65535]  
 2byte-asnumber: [0 to 65535]  
 ext-comm-val: [0 to 4294967295]  
 4byte-asnumber: [0 to 4294967295]

**import** *ext-community* — specifies communities allowed to be accepted from remote PE neighbors

**export** *ext-community* — specifies communities allowed to be sent to remote PE neighbors

### weighted-ecmp

**Syntax** **weighted-ecmp**  
**no weighted-ecmp**

**Context** config>service>vprn

**Description** This command enables weighted load-balancing for IS-IS ECMP routes in the VPRN instance. Weighted ECMP can be performed only when all the next-hops are associated with the same neighbor and all of them are configured with (non-zero) load-balancing weights. The weighted ECMP support for IS-IS ECMP routes applies to both IPv4 and IPv6.

The **no** form of the command restores regular ECMP spraying of packets to IS-IS route destinations.

**Default** no weighted-ecmp

### 3.9.2.6 IPSec Configuration Commands

#### ipsec

**Syntax** **ipsec**

**Context** config>service>vprn>ipsec

**Description** This command enables the context to configure IPSec policies.

**Default** n/a

## security-policy

**Syntax** **security-policy** *security-policy-id* [**create**]  
**no security-policy** *security-policy-id*

**Context** config>service>vpn>ipsec

**Description** This command configures a security policy to use for an IPSec tunnel.

**Default** n/a

**Parameters** *security-policy-id* — specifies a value to be assigned to a security policy

**Values** 1 to 8192

**create** — Creates the security policy instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## entry

**Syntax** **entry** *entry-id* [**create**]  
**no entry** *entry-id*

**Context** config>service>vpn>ipsec>sec-plcy

**Description** This command configures an IPSec security policy entry.

**Parameters** *entry-id* — specifies the IPSec security policy entry

**Values** 1 to 16

**create** — Creates the security policy entry instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## local-ip

**Syntax** **local-ip** {*ip-prefix/prefix-length* | *ip-prefix netmask* | **any**}

**Context** config>service>vpn>ipsec>sec-plcy>entry

**Description** This command configures the local (from the VPN ) IP prefix/mask for the policy parameter entry.

Only one entry is necessary to describe a potential flow. The **local-ip** and **remote-ip** commands can be defined only once. The system will evaluate the local IP as the source IP when traffic is examined in the direction of VPN to the tunnel and as the destination IP when traffic flows from the tunnel to the VPN. The remote IP will be evaluated as the source IP when traffic flows from the tunnel to the VPN when traffic flows from the VPN to the tunnel.

**Parameters** *ip-prefix* — the destination address of the aggregate route in dotted decimal notation.

**Values** a.b.c.d (host bits must be 0)  
prefix-length: 1 to 32

*netmask* — the subnet mask in dotted decimal notation

**any** — specifies that it can be any address

## remote-ip

**Syntax** **remote-ip** *ip-prefix/prefix-length* | *ip-prefix netmask* | **any**}

**Context** config>service>vpn>ipsec>sec-plcy>entry

**Description** This command configures the remote (from the tunnel) IP prefix/mask for the policy parameter entry.

Only one entry is necessary to describe a potential flow. The **local-ip** and **remote-ip** commands can be defined only once. The system will evaluate the local IP as the source IP when traffic is examined in the direction of VPN to the tunnel and as the destination IP when traffic flows from the tunnel to the VPN. The remote IP will be evaluated as the source IP when traffic flows from the tunnel to the VPN when traffic flows from the VPN to the tunnel.

**Parameters** *ip-prefix* — the destination address of the aggregate route in dotted decimal notation

**Values** a.b.c.d (host bits must be 0)  
prefix-length: 1 to 32

*netmask* — the subnet mask in dotted decimal notation

**any** — specifies that it can be any address

## interface

**Syntax** **interface** *ip-int-name* [**create**] [**tunnel**]  
**no interface** *ip-int-name*

**Context** config>service>vpn

**Description** This command creates a logical IP routing interface for a Virtual Private Routed Network (VPRN). Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within VPRN service IDs. The **interface** command can be executed in the context of an VPRN service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber internet access.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config router interface** and **config service vprn interface**. Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

The available IP address space for local subnets and routes is controlled with the **config router service-prefix** command. The **service-prefix** command administers the allowed subnets that can be defined on service IP interfaces. It also controls the prefixes that may be learned or statically defined with the service IP interface as the egress interface. This allows segmenting the IP address space into **config router** and **config service** domains.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All VPRN IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The no form of this command removes IP the interface and all the associated configuration. The interface must be administratively shutdown before issuing the **no interface** command.

For VPRN services, the IP interface must be shutdown before the SAP on that interface may be removed. VPRN services do not have the **shutdown** command in the SAP CLI context. VPRN service SAPs rely on the interface status to enable and disable them.

**Parameters**    *ip-int-name* — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

**Values**        1 to 32 characters maximum

**tunnel** — Specifies that the interface is configured as tunnel interface, which could be used to terminate IPsec or GRE runnells in the private service.

**create** — Creates the IPsec interface instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## address

**Syntax**        **[no] address** {*ip-address/mask* | *ip-address netmasks*}

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vprn>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command assigns an IP address/IP subnet to the interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>ip-address</i> — Specifies the base IP address of the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).</p> <p><i>mask</i> — The subnet mask in dotted decimal notation. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.</p> <p><i>netmask</i> — Specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains.</p> |

## ip-mtu

|                    |                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ip-mtu</b> <i>octets</i><br><b>no ip-mtu</b>                                                                                                              |

| <b>Syntax</b>      | <b>ipsec-tunnel</b> <i>ipsec-tunnel-name</i> [create]<br><b>no ipsec-tunnel</b> <i>ipsec-tunnel-name</i>                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>if>sap                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command specifies an IPSec tunnel name. An IPSec client sets up the encrypted tunnel across public network. The 7750 SR IPSec MDA acts as a concentrator gathering, and terminating these IPSec tunnels into an IES or VPRN service. This mechanism allows as service provider to offer a global VPRN service even if node of the VPRN are on an uncontrolled or insecure portion of the network. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>ipsec-tunnel-name</i> — specifies an IPSec tunnel name up to 32 characters in length                                                                                                                                                                                                                                                                                                                |

**create** — Creates the IPsec tunnel instance. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## bfd-designate

|                    |                                                                                |

| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command assign a BFD session provide heart-beat mechanism for given IPsec tunnel. There can be only one BFD session assigned to any given IPsec tunnel, but there can be multiple IPsec tunnels using same BFD session. BFD control the state of the associated tunnel, if BFD session goes down, system will also bring down the associated non-designated IPsec tunnel. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <b>service service-id</b> — specifies where the service-id that the BFD session resides<br><b>interface interface-name</b> — specifies the name of the interface used by the BFD session<br><b>dst-ip ip-address</b> — specifies the destination address to be used for the BFD session                                                                                        |

## clear-df-bit

|                    |                                                                                                                                                                                   |

| <b>Description</b> | This command configures the information required for manual keying SA creation.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>security-entry-id</i> — specifies the ID of an SA entry</p> <p><b>Values</b> 1 to 16</p> <p><b>encryption-key</b> <i>encryption-key</i> — specifies the key used for the encryption algorithm</p> <p><b>Values</b> none or 0x0 to 0xFFFFFFFF...(max 64 hex nibbles)</p> <p><b>authentication-key</b> <i>authentication-key</i> — specifies the key used for the authentication algorithm</p> <p><b>Values</b> none or 0x0 to 0xFFFFFFFF...(max 40 hex nibbles)</p> <p><b>spi</b> <i>spi</i> — Specifies the SPI (Security Parameter Index) used to look up the instruction to verify and decrypt the incoming IPsec packets when the direction is inbound. When the direction is outbound, the SPI that will be used in the encoding of the outgoing packets. The remote node can use this SPI to lookup the instruction to verify and decrypt the packet.</p> <p><b>Values</b> 256 to 16383</p> <p><b>transform</b> <i>transform-id</i> — specifies the transform entry that will be used by this SA entry. This object should be specified for all the entries created which are manual SAs. If the value is dynamic, then this value is irrelevant and will be zero.</p> <p><b>Values</b> 1 to 2048</p> <p><b>direction</b> {<b>inbound</b>   <b>outbound</b>} — specifies the direction of an IPsec tunnel</p> |

## replay-window

|----------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>replay-window</b> { <b>32</b>   <b>64</b>   <b>128</b>   <b>256</b>   <b>512</b> }<br><b>no replay-window</b> |
| <b>Context</b> | config>ipsec>tnl-temp<br>config>service>vprn>if>sap>ipsec-tunnel                                                 |

---

|                    |                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies the size of the anti-replay window. The anti-replay window protocol secures IP against an entity that can inject messages in a message stream from a source to a destination computer on the Internet. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                           |
| <b>Parameters</b>  | {32   64   128   256   512} — specifies the size of the SA anti-replay window                                                                                                                                                 |

## security-policy

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>security-policy</b> <i>security-policy-id</i><br><b>no security-policy</b>                                                 |
| <b>Context</b>     | config>service>vpn>if>sap>ipsec-tunnel                                                                                        |
| <b>Description</b> | This command configures an IPSec security policy. The policy may then be associated with tunnels defined in the same context. |
| <b>Default</b>     | n/a                                                                                                                           |
| <b>Parameters</b>  | <i>security-policy-id</i> — specifies the IPSec security policy entry that the tunnel will use<br><b>Values</b> 1 to 8192     |

### 3.9.2.7 Log Commands

## log

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Syntax</b>      | <b>log</b>                                                          |
| <b>Context</b>     | config>service>vpn<br>config>service>vpn>log-id                     |
| <b>Description</b> | This command enables the context to configure event stream logging. |

## filter

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] filter</b> <i>filter-id</i>                                                                                                                    |
| <b>Context</b>     | config>service>vpn>log<br>config>service>vpn>log>log-id                                                                                                |
| <b>Description</b> | This command creates a context for an event filter. An event filter specifies whether to forward or drop an event or trap based on the match criteria. |

Filters are configured in the **filter** *filter-id* context and then applied to a log in the **log-id** *log-id* context. Only events for the configured log source streams destined to the log ID where the filter is applied are filtered.

Any changes made to an existing filter, using any of the sub-commands, are immediately applied to the destinations where the filter is applied.

The **no** form of the command removes the filter association from log IDs which causes those logs to forward all events.

|                   |                                                                 |
|-------------------|-----------------------------------------------------------------|
| <b>Default</b>    | No event filters are defined.                                   |
| <b>Parameters</b> | <i>filter-id</i> — the filter ID uniquely identifies the filter |
| <b>Values</b>     | 1 to 1000                                                       |

## default-action

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-action</b> {drop   forward}<br><b>no default-action</b>                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>log>filter                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>The default action specifies the action that is applied to events when no action is specified in the event filter entries or when an event does not match the specified criteria.</p> <p>When multiple <b>default-action</b> commands are entered, the last command overwrites the previous command.</p> <p>The <b>no</b> form of the command reverts the default action to the default value (forward).</p> |
| <b>Default</b>     | default-action forward — the events which are not explicitly dropped by an event filter match are forwarded                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><b>drop</b> — the events which are not explicitly forwarded by an event filter match are dropped</p> <p><b>forward</b> — the events which are not explicitly dropped by an event filter match are forwarded</p>                                                                                                                                                                                              |

## entry

|                    |                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>entry</b> <i>entry-id</i>                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>vprn>log>filter                                                                                                                                                                                                                                        |
| <b>Description</b> | This command is used to create or edit an event filter entry. Multiple entries may be created using unique <i>entry-id</i> numbers. The TiMOS implementation exits the filter on the first match found and executes the action in accordance with the action command. |

Comparisons are performed in an ascending entry ID order. When entries are created, they should be arranged sequentially from the most explicit entry to the least explicit. Matching ceases when a packet matches an entry. The entry action is performed on the packet, either drop or forward. To be considered a match, the packet must meet all the conditions defined in the entry.

An entry may not have any match criteria defined (in which case, everything matches) but must have at least the keyword action for it to be considered complete. Entries without the action keyword will be considered incomplete and are rendered inactive.

The **no** form of the command removes the specified entry from the event filter. Entries removed from the event filter are immediately removed from all log-id's where the filter is applied.

|                   |                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | No event filter entries are defined. An entry must be explicitly configured.                                                                                                                                                                                                                          |
| <b>Parameters</b> | <i>entry-id</i> — The entry ID uniquely identifies a set of match criteria corresponding action within a filter. Entry ID values should be configured in staggered increments so you can insert a new entry in an existing policy without renumbering the existing entries.<br><b>Values</b> 1 to 999 |

## action

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>action {drop   forward}</b><br><b>no action</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>log>filter>entry                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | This command specifies a drop or forward action associated with the filter entry. If neither <b>drop</b> nor <b>forward</b> is specified, the <a href="#">default-action</a> will be used for traffic that conforms to the match criteria. This could be considered a No-Op filter entry used to explicitly exit a set of filter entries without modifying previous actions.<br><br>Multiple action statements entered will overwrite previous actions.<br><br>The <b>no</b> form of the command removes the specified <a href="#">action</a> statement. |
| <b>Default</b>     | Action specified by the <a href="#">default-action</a> command will apply.                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <b>drop</b> — specifies packets matching the entry criteria will be dropped<br><b>forward</b> — specifies packets matching the entry criteria will be forwarded                                                                                                                                                                                                                                                                                                                                                                                          |

## match

|                |                                      |
|----------------|--------------------------------------|
| <b>Syntax</b>  | [no] match                           |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command creates context to enter/edit match criteria for a filter entry. When the match criteria is satisfied, the action associated with the entry is executed.</p> <p>If more than one match parameter (within one match statement) is specified, then all the criteria must be satisfied (AND functional) before the action associated with the match is executed.</p> <p>Use the <a href="#">match</a> command to display a list of the valid applications.</p> <p>Match context can consist of multiple match parameters (application, event-number, severity, subject), but multiple <b>match</b> statements cannot be entered per entry.</p> <p>The <b>no</b> form of the command removes the match criteria for the <i>entry-id</i>.</p> |
| <b>Default</b>     | no match                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | This command adds system messages as a match criterion.<br><br>The <b>no</b> form of the command removes messages as a match criterion.                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <b>eq</b> — determines if the matching criteria should be equal to the specified value<br><b>neq</b> — determines if the matching criteria should not be equal to the specified value<br><b>pattern</b> <i>pattern</i> — specifies a message up to 400 characters to be used in the match criteria<br><b>regexp</b> — Specifies the type of string comparison to use to determine if the log event matches the value of <b>message</b> command parameters. When the <b>regexp</b> keyword is not specified, the default matching algorithm used is a basic substring match. |

## number

| <b>Description</b> | This command adds an event severity level as a match criterion. Only one severity command can be entered per event filter entry. The latest severity command overwrites the previous command.<br><br>The <b>no</b> form of the command removes the severity match criterion. |
| <b>Default</b>     | no severity — no severity level match criterion is specified                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <b>eq   neq   lt   lte   gt   gte</b> — Specifies the type of match. Valid operators are listed below.                                                                                                                                                                       |

| Values | Operator   | Notes                    |
|--------|------------|--------------------------|
|        | <b>eq</b>  | equal to                 |
|        | <b>neq</b> | not equal to             |
|        | <b>lt</b>  | less than                |
|        | <b>lte</b> | less than or equal to    |
|        | <b>gt</b>  | greater than             |
|        | <b>gte</b> | greater than or equal to |

*severity-name* — The ITU severity level name. [Table 38](#) lists severity names and corresponding numbers per ITU standards M.3100 X.733 & X.21 severity levels.

**Table 38**      **Severity Levels**

| Severity Number | Severity Name        |
|-----------------|----------------------|
| 1               | cleared              |
| 2               | indeterminate (info) |
| 3               | critical             |
| 4               | major                |
| 5               | minor                |
| 6               | warning              |

**Values**      cleared, intermediate, critical, major, minor, warning

| <b>Context</b>     | config>service>vprn>log>filter>entry>match                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command adds an event subject as a match criterion.</p> <p>The subject is the entity for which the event is reported, such as a port. In this case the port-id string would be the subject. Only one <b>subject</b> command can be entered per event filter entry. The latest <b>subject</b> command overwrites the previous command.</p> <p>The <b>no</b> form of the command removes the subject match criterion.</p> |
| <b>Default</b>     | no subject — no subject match criterion specified                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <b>eq   neq</b> — This operator specifies the type of match. Valid operators are listed below.                                                                                                                                                                                                                                                                                                                                  |

### Values

| Operator   | Notes        |
|------------|--------------|
| <b>eq</b>  | equal to     |
| <b>neq</b> | not equal to |

*subject* — a string used as the subject match criterion

**regex** — Specifies the type of string comparison to use to determine if the log event matches the value of **subject** command parameters. When the **regex** keyword is specified, the string in the **subject** command is a regular expression string that will be matched against the subject string in the log event being filtered.

When **regex** keyword is not specified, the **subject** command string is matched exactly by the event filter.

## log-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] log-id log-id</b>                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>log                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command creates a context to configure destinations for event streams.</p> <p>The <b>log-id</b> context is used to direct events, alarms/traps, and debug information to respective destinations.</p> <p>A maximum of 10 logs can be configured.</p> <p>Before an event can be associated with this log-id, the <b>from</b> command identifying the source of the event must be configured.</p> |

Only one destination can be specified for a *log-id*. The destination of an event stream can be an in-memory buffer, console, session, snmp-trap-group, syslog, or file.

Use the **event-control** command to suppress the generation of events, alarms, and traps for all log destinations.

An event filter policy can be applied in the log-id context to limit which events, alarms, and traps are sent to the specified log-id.

Log-IDs 99 and 100 are created by the agent. Log-ID 99 captures all log messages. Log-ID 100 captures log messages with a severity level of major and above.

Log-ID 99 provides valuable information for the admin-tech file. Removing or changing the log configuration may hinder debugging capabilities. It is strongly recommended not to alter the configuration for Log-ID 99.

The **no** form of the command deletes the log destination ID from the configuration.

**Default** No log destinations are defined.

**Parameters** *log-id* — the log ID number, expressed as a decimal integer  
**Values** 1 to 100

to snmp

**Syntax** **to snmp** [*size*]

**Context** config>service>vprn>log>log-id

**Description** This is one of the commands used to specify the log ID destination. This parameter is mandatory when configuring a log destination. This command instructs the alarms and traps to be directed to the **snmp-trap-group** associated with *log-id*.

A local circular memory log is always maintained for SNMP notifications sent to the specified snmp-trap-group for the *log-id*.

The source of the data stream must be specified in the **from** command prior to configuring the destination with the **to** command.

The **to** command cannot be modified or re-entered. If the destination or maximum size of an SNMP or memory log needs to be modified, the log ID must be removed and then re-created.

**Default** n/a

**Parameters** *size* — the *size* parameter defines the number of events stored in this memory log  
**Default** 100  
**Values** 50 to 1024

---

to syslog

| <b>Context</b>     | config>service>vpn>log>log-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command selects the source stream to be sent to a log destination.</p> <p>One or more source streams must be specified. The source of the data stream must be identified using the <b>from</b> command before you can configure the destination using the <b>to</b> command. The <b>from</b> command can identify multiple source streams in a single statement (for example: <b>from main change debug-trace</b>).</p> <p>Only one <b>from</b> command may be entered for a single <i>log-id</i>. If multiple <b>from</b> commands are configured, then the last command entered overwrites the previous <b>from</b> command.</p> <p>The <b>no</b> form of the command removes all previously configured source streams.</p> |
| <b>Default</b>     | No source stream is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

- Parameters**
- main** — Instructs all events in the main event stream to be sent to the destination defined in the **to** command for this destination *log-id*. The main event stream contains the events that are not explicitly directed to any other event stream. To limit the events forwarded to the destination, configure filters using the **filter** command.
  - change** — Instructs all events in the user activity stream to be sent to the destination configured in the **to** command for this destination *log-id*. The change event stream contains all events that directly affect the configuration or operation of this node. To limit the events forwarded to the change stream destination, configure filters using the filter command.

## time-format

- Syntax** **time-format** {**local** | **utc**}
- Context** config>service>vprn>log>log-id
- Description** This command specifies whether the time should be displayed in local or Coordinated Universal Time (UTC) format.
- Default** time-format utc
- Parameters**
- local** — specifies that timestamps are written in the system's local time
  - utc** — Specifies that timestamps are written using the UTC value. This was formerly called Greenwich Mean Time (GMT) and Zulu time.

## syslog

- Syntax** [**no**] **syslog** *syslog-id*
- Context** config>service>vprn>log
- Description** This command creates the context to configure a syslog target host that is capable of receiving selected syslog messages from this network element.
- A valid *syslog-id* must have the target syslog host address configured.
- A maximum of 10 syslog-ids can be configured.
- No log events are sent to a syslog target address until the syslog-id has been configured as the log destination (**to**) in the log-id node.
- The syslog ID configured in the **configure/service/vprn** context has a local VPRN scope and only needs to be unique within the specific VPRN instance. The same ID can be reused under a different VPRN service or in the global log context under **config>log**.
- Default** No syslog IDs are defined.

---

|                   |                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>syslog-id</i> — the syslog ID number for the syslog destination, expressed as a decimal integer |
| <b>Values</b>     | 1 to 10                                                                                            |

## address

The ipv6-address applies to the 7750 SR.

## facility

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>facility</b> <i>syslog-facility</i><br><b>no facility</b>                           |
| <b>Context</b>     | cconfig>service>vpn>log>syslog                                                         |
| <b>Description</b> | This command configures the facility code for messages sent to the syslog target host. |

Multiple syslog IDs can be created with the same target host but each syslog ID can only have one facility code. If multiple facility codes are entered, the last *facility-code* entered overwrites the previous facility-code.

If multiple facilities need to be generated for a single syslog target host, then multiple **log-id** entries must be created, each with its own filter criteria to select the events to be sent to the syslog target host with a given facility code.

The **no** form of the command reverts to the default value.

**Default** local7 — syslog entries are sent with the local7 facility code

**Parameters** *syslog-facility* — The syslog facility name represents a specific numeric facility code. The code should be entered in accordance with the syslog RFC. However, the software does not validate if the facility code configured is appropriate for the event type being sent to the syslog target host.

**Values** kernel, user, mail, systemd, auth, syslogd, printer, netnews, uucp, cron, authpriv, ftp, ntp, logaudit, logalert, cron2, local0, local1, local2, local3, local4, local5, local6, local7  
Valid responses per RFC3164, *The BSD syslog Protocol*, are listed in the table below [Table 39](#).

**Table 39 Syslog Facility Codes**

| Numerical Code | Facility Code |
|----------------|---------------|
| 0              | kernel        |
| 1              | user          |
| 2              | mail          |
| 3              | systemd       |
| 4              | auth          |
| 5              | syslogd       |
| 6              | printer       |
| 7              | net-news      |
| 8              | uucp          |
| 9              | cron          |
| 10             | auth-priv     |
| 11             | ftp           |
| 12             | ntp           |
| 13             | log-audit     |

**Table 39 Syslog Facility Codes (Continued)**

| Numerical Code | Facility Code |
|----------------|---------------|
| 14             | log-alert     |
| 15             | cron2         |
| 16             | local0        |
| 17             | local1        |
| 18             | local2        |
| 19             | local3        |
| 20             | local4        |
| 21             | local5        |
| 22             | local6        |
| 23             | local7        |

Values: 0 to 23

## log-prefix

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>vprn>log>syslog                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command adds the string prepended to every syslog message sent to the syslog host.</p> <p>RFC3164, <i>The BSD syslog Protocol</i>, allows a alphanumeric string (tag) to be prepended to the content of every log message sent to the syslog host. This alphanumeric string can, for example, be used to identify the node that generates the log entry. The software appends a colon (:) and a space to the string and it is inserted in the syslog message after the date stamp and before the syslog message content.</p> <p>Only one string can be entered. If multiple strings are entered, the last string overwrites the previous string. The alphanumeric string can contain lowercase (a-z), uppercase (A-Z) and numeric (0-9) characters.</p> <p>The <b>no</b> form of the command removes the log prefix string.</p> |
| <b>Default</b>     | no log-prefix — no prepend log prefix string defined                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>log-prefix-string</i> — An alphanumeric string of up to 32 characters. Spaces and colons ( : ) cannot be used in the string.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Syntax</b>      | <b>[no] snmp-trap-group</b> <i>log-id</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>log                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command creates the context to configure a group of SNMP trap receivers and their operational parameters for a given log-id.</p> <p>A group specifies the types of SNMP traps and specifies the log ID which will receive the group of SNMP traps. A trap group must be configured in order for SNMP traps to be sent.</p> <p>To suppress the generation of all alarms and traps see the <b>event-control</b> command. To suppress alarms and traps that are sent to this log-id, see the <b>filter</b> command. Once alarms and traps are generated they can be directed to one or more SNMP trap groups. Logger events that can be forwarded as SNMP traps are always defined on the main event source.</p> <p>The <b>no</b> form of the command deletes the SNMP trap group.</p> |
| <b>Default</b>     | There are no default SNMP trap groups.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>log-id</i> — The log ID value of a log configured in the <a href="#">log-id</a> context. Alarms and traps cannot be sent to the trap receivers until a valid <i>log-id</i> exists.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Values</b>      | 1 to 99                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## trap-target

|                    |                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Context</b>     | config>service>vprn>log>snmp-trap-group                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command adds/modifies a trap receiver and configures the operational parameters for the trap receiver. A trap reports significant events that occur on a network device such as errors or failures.</p> <p>Before an SNMP trap can be issued to a trap receiver, the <a href="#">log-id</a>, <a href="#">snmp-trap-group</a> and at least one <a href="#">snmp-trap-group</a> must be configured.</p> |

The `snmp-trap-group` command is used to add/remove a trap receiver from an `snmp-trap-group`. The operational parameters specified in the command include:

- The IP address of the trap receiver
- The UDP port used to send the SNMP trap
- SNMP version
- SNMP community name for SNMPv1 and SNMPv2c receivers.
- Security name and level for SNMPv3 trap receivers.

A single **snmp-trap-group** *log-id* can have multiple trap-receivers. Each trap receiver can have different operational parameters.

An address can be configured as a trap receiver more than once as long as a different port is used for each instance.

To prevent resource limitations, only configure a maximum of 10 trap receivers.

If the same **trap-target** *name* **port** *port* parameter value is specified in more than one SNMP trap group, each trap destination should be configured with a different *notify-community* value. This allows a trap receiving an application, such as NMS, to reconcile a separate event sequence number stream for each router event log when multiple event logs are directed to the same IP address and port destination.

The **no** form of the command removes the SNMP trap receiver from the SNMP trap group.

**Default** No SNMP trap targets are defined.

**Parameters** *name* — specifies the name of the trap target up to 28 characters in length  
**address** *ip-address* — The IP address of the trap receiver in dotted decimal notation.  
 Only one IP address destination can be specified per trap destination group.

#### Values

|              |                                                                                                                                                                              |
|--------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ipv4-address | a.b.c.d (host bits must be 0)                                                                                                                                                |
| ipv6-address | x:x:x:x:x:x:x[-interface]<br>x:x:x:x:x:x.d.d.d.d[-interface]<br>x: [0 to FFFF]H<br>d: [0 to 255]D<br>interface: 32 characters maximum, mandatory<br>for link local addresses |

The ipv6-address applies to the 7750 SR.

*port port* — The destination UDP port used for sending traps to the destination, expressed as a decimal integer. Only one port can be specified per **trap-target** statement. If multiple traps need to be issued to the same address then multiple ports must be configured.

**Values** 1 to 65535

**Default** 162

*snmpv1 | snmpv2c | snmpv3* — Specifies the SNMP version format to use for traps sent to the trap receiver.

The keyword **snmpv1** selects the SNMP version 1 format. When specifying **snmpv1**, the **notify-community** must be configured for the proper SNMP community string that the trap receiver expects to be present in alarms and traps messages. If the SNMP version is changed from **snmpv3** to **snmpv1**, then the **notify-community** parameter must be changed to reflect the community string rather than the *security-name* that is used by **snmpv3**.

The keyword **snmpv2c** selects the SNMP version 2c format. When specifying **snmpv2c**, the **notify-community** must be configured for the proper SNMP community string that the trap receiver expects to be present in alarms and traps messages. If the SNMP version is changed from **snmpv3** to **snmpv2c**, then the **notify-community** parameter must be changed to reflect the community string rather than the *security-name* that is used by **snmpv3**.

The keyword **snmpv3** selects the SNMP version 3 format. When specifying **snmpv3**, the **notify-community** must be configured for the SNMP *security-name*. If the SNMP version is changed from **snmpv1** or **snmpv2c** to **snmpv3**, then the **notify-community** parameter must be changed to reflect the *security-name* rather than the community string used by **snmpv1** or **snmpv2c**.

Pre-existing conditions are checked before the *snmpv3SecurityName* is accepted. These are:

- The user name must be configured.
- The v3 access group must be configured.
- The v3 notification view must be configured.

**Values** snmpv1, snmpv2c, snmpv3

**Default** snmpv3

*notify-community community | security-name* — Specifies the community string for **snmpv1** or **snmpv2c** or the **snmpv3** *security-name*. If no **notify-community** is configured, then no alarms nor traps will be issued for the trap destination. If the SNMP version is modified, the **notify-community** must be changed to the proper form for the SNMP version.

*community* — The community string as required by the **snmpv1** or **snmpv2c** trap receiver. The community string can be an ASCII string up to 31 characters in length.

*security-name* — The *security-name* as defined in the `config>system>security>user` context for SNMP v3. The *security-name* can be an ASCII string up to 31 characters in length.

*security-level {no-auth-no-privacy | auth-no-privacy | privacy}* — Specifies the required authentication and privacy levels required to access the views configured on this node when configuring an **snmpv3** trap receiver.

The keyword **no-auth-no-privacy** specifies no authentication and no privacy (encryption) are required.

The keyword **auth-no-privacy** specifies authentication is required but no privacy (encryption) is required. When this option is configured the *security-name* must be configured for **authentication**.

The keyword **privacy** specifies both authentication and privacy (encryption) is required. When this option is configured the *security-name* must be configured for **authentication** and **privacy**.

**Values**      no-auth-no-privacy, auth-no-privacy, privacy

**Default**      no-auth-no-privacy. This parameter can only be configured if SNMPv3 is also configured.

**replay** — Enable replay of missed events to target. If replay is applied to an SNMP trap target address, the address is monitored for reachability. Reachability is determined by whether or not there is a route in the routing table by which the target address can be reached. Before sending a trap to a target address, the SNMP module asks the PIP module if there is either an in-band or out-of-band route to the target address. If there is no route to the SNMP target address, the SNMP module saves the sequence-id of the first event that will be missed by the trap target. When the routing table changes again so that there is now a route by which the SNMP target address can be reached, the SNMP module replays (for example, retransmits) all events generated to the SNMP notification log while the target address was removed from the route table. Because of route table change convergence time, it is possible that one or more events may be lost at the beginning or end of a replay sequence. The cold-start-wait and route-recovery-wait timers under config>log>app-route-notifications can help reduce the probability of lost events.

| <b>Description</b> | <p>This command enables MVPN membership auto-discovery through BGP. When auto-discovery is enabled, PIM peering on the inclusive provider tunnel is disabled. Changing auto-discovery configuration requires shutdown of this VPRN instance.</p> <p>The <b>no</b> form of the command disables MVPN membership auto-discovery through BGP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Default</b>     | default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>default</b> — enable s AD route exchange based on format defined in ng-MVPN (RFC6514)</p> <p><b>mdt-safi</b> — enables AD route exchange based on mdt-safi format defined in <i>draft-rosen-vpn-mcast</i></p> <p>This command allows optionally to specify a <b>source-address</b> - an IP address to be used by Rosen M-VPN for core diversity non-default IGP instances (not using system IP). Two unique IP addresses for all MVPNs are supported. For instances using default System IP, source address configuration should not be specified to avoid consuming one of the addresses.</p> <p>Explicitly defined <b>source-address</b> allows GRE-encapsulated Rosen MVPN multicast traffic (Default and Data MDT) to originate from a configured IP address, so the source IP address of the GRE packets won't be the default system IP address.</p> <p>Value:</p> <p><i>ip-address</i> — an IPv4 address. To achieve the desired functionality the address should be a pre-configured non-default ISIS or OSPF loopback address for an IGP instance using loopback address different from the system IP loopback.</p> |

## c-mcast-signaling

| <b>Description</b> | This command specifies whether to use inter-site shared C-trees or not. Optional parameters allow enabling additional inter-site shared functionality. Not specifying an optional parameter when executing the command disables that parameter.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Default</b>     | intersite-shared                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><b>persistent-type5-adv</b> — when specified for inter-site shared trees enabled, this parameter ensures that Type 5 SA routes are generated for the multicast source even if no joins are present for that source. When the parameter is not specified, the Type 5 SA routes are withdrawn where the prune from the last receiver is received for the multicast source.</p> <p><b>kat-type5-adv-withdraw</b> — when specified for inter-site shared trees, this parameter allows operators to enable KeepAlive Timers (KAT) on source PEs for ng-MVPN inter-site shared deployments. On a multicast source failure, a KAT expiry on source PEs will trigger a withdrawal of Type-5 Source-Active (S-A) route and switch from (C-S,C-G) to (C-*,C-G). When receiver PEs process reflected Type-5 S-A route withdrawals, they will withdraw their Type-7 ng-MVPN routes to the failed multicast source. The following conditions apply:</p> <ul style="list-style-type: none"> <li>• KAT must only be enabled on source PEs.</li> <li>• Functionality is supported with mLDP and RSVP-TE in the P-instance.</li> <li>• Local receiver per (C-S, C-G) must be configured on source PEs running KAT.</li> </ul> |

| <b>Description</b> | <p>This command allows restricting MVPN instance per PE node to a specific role. By default, MVPN instance on a given PE node assumes the role of being a sender as well as receiver. This creates a mesh of MDT/PMSI across all PE nodes from this PE.</p> <p>This command provides an option to configure either a sender-only or receiver-only mode per PE node. Restricting the role of a PE node prevents creating full mesh of MDT/PMSI across all PE nodes that are participating in MVPN instance.</p> <p><b>auto-rp-discovery</b> cannot be enabled together with <b>mdt-type sender-only</b> or <b>mdt-type receiver-only</b>, or <b>wildcard-spmsi</b> configurations.</p> <p>The <b>no</b> version of this command restores the default (sender-receiver).</p> |

|                   |                                                                                                                                                                                                                            |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | mdt-type sender-receiver                                                                                                                                                                                                   |
| <b>Parameters</b> | <b>sender-receiver</b> — MVPN has both sender and receivers connected to PE node<br><b>sender-only</b> — MVPN has only senders connected to PE node<br><b>receiver-only</b> — MVPN has only receivers connected to PE node |

| <b>Context</b>     | config>service>vprn>mvpn>rpf-select>core-mvpn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures multicast group IPv4 prefixes for the MVPN with per-group mapping extranet functionality. Multiple lines are allowed. Duplicate prefixes are ignored.<br><br>When the starg option is specified, extranet functionality is enabled for PIM ASM as for the specified group. When the option is not specified (not recommended with PIM ASM), the PIM ASM join will be mapped and data plane will be established, but the control plane will not be updated on SPT switchover, unless the switchover is driven by a CPE router on a receiver side. |

The **no** form of the command deletes specified prefix from the list, or removes mapping of all prefixes if group-prefix any was specified.

|                   |                                                                                |
|-------------------|--------------------------------------------------------------------------------|
| <b>Default</b>    | n/a                                                                            |
| <b>Parameters</b> | <i>ip-address/mask</i> — specifies the IPv4 multicast address prefix with mask |

## provider-tunnel

|                    |                                                                           |
|--------------------|---------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>provider-tunnel</b>                                                    |
| <b>Context</b>     | config>service>vprn>mvpn                                                  |
| <b>Description</b> | This command enables context to configure tunnel parameters for the MVPN. |

## inclusive

|                    |                                                                            |
|--------------------|----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inclusive</b>                                                           |
| <b>Context</b>     | config>service>vprn>mvpn>pt                                                |
| <b>Description</b> | This command enables the context for specifying inclusive provider tunnels |

## bsr

|                    |                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bsr {unicast   spmsi}</b><br><b>no bsr</b>                                                                                                  |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>inclusive                                                                                             |
| <b>Description</b> | This command configures the type of BSR signaling used.<br><br>The no form of the command restores the default.                                |
| <b>Default</b>     | no bsr                                                                                                                                         |
| <b>Parameters</b>  | <b>unicast</b> — BSR PDUs are sent/forwarded using unicast PDUs (default)<br><b>spmsi</b> — BSR PDUs are sent/forwarded using S-PMSI full mesh |

## mldp

|                |                                                    |
|----------------|----------------------------------------------------|
| <b>Syntax</b>  | <b>mldp</b><br><b>no mldp</b>                      |
| <b>Context</b> | config>service>vprn>mvpn>provider-tunnel>inclusive |

---

**Description** This command enables use of mLDp LSP for the provider tunnel.

**Default** no mldp

## shutdown

**Syntax** **shutdown**  
**no shutdown**

**Context** config>service>vprn>mvpn>provider-tunnel>inclusive>mldp

**Description** This command administratively disables and enables use of mLDp LSP for the provider tunnel.

**Default** no shutdown

## pim

**Syntax** **pim {asm | ssm} grp-ip-address**  
**no pim**

**Context** config>service>vprn>mvpn>pt>inclusive

**Description** This command specifies the PIM mode to use, ASM or SSM, for PIM-based inclusive provider tunnels and the multicast group address to use. Also enables the context for specifying parameters for PIM peering on the inclusive provider tunnel.

Auto-discovery must be enabled in order for SSM to operate.

The **no** form of the command removes the pim context including the statements under the context.

**Default** no pim

**Parameters** **asm** — specifies to use PIM ASM for inclusive provider tunnels  
**ssm** — specifies to u PIM SSM for inclusive provider tunnels  
**group-address** — specifies the multicast group address to use

## hello-interval

**Syntax** **hello-interval** *hello-interval*  
**no hello-interval**

**Context** config>service>vprn>mvpn>provider-tunnel>inclusive>pim

---

|                    |                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies the interval at which PIM Hello messages are transmitted on the PIM inclusive provider tunnel.<br><br>The <b>no</b> form of this command reverts to the default value. |
| <b>Default</b>     | 30 seconds                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>hello-interval</i> — specifies the hello interval, in seconds. A 0 (zero) value disables the sending of Hello messages<br><br><b>Values</b> 0 to 255                                       |

## hello-multiplier

|                    |                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-multiplier</b> <i>deci-units</i><br><b>no hello-multiplier</b>                                                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>inclusive>pim                                                                                                                                                                                                                                        |
| <b>Description</b> | This command specifies the hello multiplier. The hello-multiplier in conjunction with the hello-interval determines the hold time for a PIM neighbor.<br><br>Hold time = (hello-interval * hello-multiplier) / 10.<br><br>The <b>no</b> form of the command reverts the value to the default. |
| <b>Default</b>     | 35                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>deci-units</i> — specifies the value, in multiples of 0.1, for the formula used to calculate the hold time<br><br><b>Values</b> 20 to 100                                                                                                                                                  |

## improved-assert

|                    |                                                                                                                                                                   |

| <b>Description</b> | <p>This command specifies the data rate threshold that triggers the switch from the inclusive provider tunnel to the selective provider tunnel for (C-S, C-G) within the group range. Optionally, PE thresholds for creating/deleting ng-MVPN S-PMSI may also be specified. Omitting the PE thresholds, preserves currently set value (or defaults if never set). Multiple statements (one per a unique group) are allowed in the configuration.</p> <p>This command is not applicable to multi-stream S-PMSI,</p> <p>The <b>no</b> form of the command removes the values from the configuration.</p>                                                                                                                                                                                                                                              |
| <b>Default</b>     | no data-threshold                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>group-address/mask</i> — specifies a multicast group address and netmask length</p> <p><i>c-grp-ip-addr/mask</i>   <i>c-grp-ip-addr netmask</i> — specifies an IPv4 multicast group address and netmask length or network mask</p> <p><i>c-grp-ipv6-addr/prefix-length</i> — specifies an IPv6 multicast group address and prefix length</p> <p><i>s-pmsi-threshold</i> — Specifies the rate, in kb/s. If the rate for a (C-S, C-G)) within the specified group range exceeds the threshold, traffic for the (C-S, C-G) will be switched to the selective provider tunnel.</p> <p><i>s-pmsi-threshold-add</i> — Specifies the number of receiver PEs for creating S-PMSI. When the number of receiver PEs for a given multicast group configuration is non-zero and below the threshold and BW threshold is satisfied, S-PMSI is created.</p> |

*s-pmsi-threshold-delete* — Specifies the number of receiver PEs for deleting S-PMSI. When the number of receiver PEs for a given multicast group configuration is above the threshold, S-PMSI is deleted and the multicast group is moved to I-PMSI or a wildcard S-PMSI. It is recommended that the delete threshold be significantly larger than the add threshold, to avoid re-signaling of S-PMSI as the receiver PE count fluctuates.

**Values**

|                         |                                                                              |
|-------------------------|------------------------------------------------------------------------------|
| <i>c-grp-ip-addr</i>    | : multicast group address a.b.c.d                                            |
| <i>mask</i>             | [4 to 32]                                                                    |
| <i>netmask</i>          | : a.b.c.d (network bits all 1 and host bits all 0)                           |
| <i>s-pmsi-threshold</i> | : [1 to 4294967294](threshold in kbps)                                       |
| <i>c-grp-ipv6-addr</i>  | : multicast ipv6-address x:x:x:x:x:x:x (eight 16-bit pieces)                 |
|                         | x:x:x:x:x:d.d.d.d                                                            |
|                         | x [0 to FFFF]H                                                               |
|                         | d [0 to 255]D                                                                |
|                         | prefix-length [1 to 128]                                                     |
| pe-threshold-add:       | [1 to 65535], if never specified, 65535 is used (add threshold always met)   |
| pe-threshold-delete:    | [2 to 65535], if never specified, 65535 is used (delete threshold never met) |

| <b>Context</b>     | config>service>vprn>mvpn>pt>selective                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command creates a multi-stream S-PMSI policy. Having multiple multi-stream S-PMSIs per MVPN creates a link list, in which the first match (lowest index) will be chosen for a multicast stream. The number of configured multi-stream S-PMSIs cannot exceed the configured maximum S-PMSI for a given MVPN. |

**Parameters**     *index* — specifies the index number

**Values**            1 to 1024

group

**Syntax**            **[no] group** *ip-address* [*/mask*]

**Context**           config>service>vprn>mvpn>pt>selective>multistream-spmsi

**Description**       This command creates group prefixes that map to the multicast stream. At least one source must be specified for the policy to be active.

**Parameters**       *ip-address/mask* — specifies the IP address

**Values**

|             |                |                                     |  |
|-------------|----------------|-------------------------------------|--|
| ipv4-prefix | a.b.c.d        |                                     |  |
|             | ipv4-prefix-le | [0..32]                             |  |
| ipv6-prefix |                | x:x:x:x:x:x:x (eight 16-bit pieces) |  |
|             |                | x:x:x:x:x:d.d.d.d                   |  |
|             | x              | [0..FFFF]H                          |  |
|             | d              | [0..255]D                           |  |
|             | ipv6-prefix-le | [0..128]                            |  |

source

**Syntax**            **[no] source** *ip-address* [*/mask*]  
**[no] source any**

**Context**           config>service>vprn>mvpn>pt>selective>multistream-spmsi>group

**Description**       This command creates source prefixes for specific groups that map to the multicast stream.

**Parameters**       *ip-address/mask* — specifies the IP address of the group

**Values**

|             |                |                                     |  |
|-------------|----------------|-------------------------------------|--|
| ipv4-prefix | a.b.c.d        |                                     |  |
|             | ipv4-prefix-le | [0..32]                             |  |
| ipv6-prefix |                | x:x:x:x:x:x:x (eight 16-bit pieces) |  |
|             |                | x:x:x:x:x:d.d.d.d                   |  |
|             | x              | [0..FFFF]H                          |  |
|             | d              | [0..255]D                           |  |
|             | ipv6-prefix-le | [0..128]                            |  |

## sp-template

|                    |                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] lsp-template</b> <i>name</i>                                                                                                         |
| <b>Context</b>     | config>service>vprn>mvpn>pt>selective>multistream-spmsi                                                                                      |
| <b>Description</b> | This command creates a RSVP-TE LSP template for S-PSMI. Multi-stream S-PMSIs can share a single template or can each use their own template. |
| <b>Parameters</b>  | <i>name</i> — specifies the LSP template name, up to 32 characters                                                                           |

## shutdown

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                      |
| <b>Context</b>     | config>service>vprn>mvpn>pt>selective>multistream-spmsi                                   |
| <b>Description</b> | This commands enables multi-stream S-PSMI. At least one group must be active in a policy. |

## pim-asm

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] pim-asm</b> { <i>grp-ip-address/mask</i>   <i>grp-ip-address netmask</i> }                                                     |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>selective                                                                                     |
| <b>Description</b> | This command specifies the range of PIM-ASM groups to use on the sender PE to setup ASM multicast tree for draft Rosen based Data MDT. |

## rsvp

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] rsvp</b>                                                                                         |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>inclusive<br>config>service>vprn>mvpn>provider-tunnel>selective |
| <b>Description</b> | This command enables use of P2MP RSVP as the inclusive or selective provider tunnel.                     |
| <b>Default</b>     | no rsvp                                                                                                  |

## lsp-template

|                |                                                                                                               |
|----------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] lsp-template</b> <i>lsp-template-name</i>                                                             |
| <b>Context</b> | config>service>vprn>mvpn>provider-tunnel>inclusive<br>config>service>vprn>mvpn>provider-tunnel>selective>rsvp |

|                    |                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies the use of automatically created P2MP LSP as the inclusive or selective provider tunnel. The P2MP LSP will be signaled using the parameters specified in the template, such as bandwidth constraints, etc. |
| <b>Default</b>     | no lsp-template                                                                                                                                                                                                                   |

## mldp

|                    |                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] mldp                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>inclusive<br>config>service>vprn>mvpn>provider-tunnel>selective                                                                                                       |
| <b>Description</b> | This command enables use of P2MP mLDP LSP as inclusive or selective PMSI tunnels.<br><br>For multi-stream S-PMSI, either LDP or RSVP-TE must first be configured before multi-stream policy can be configured. |
| <b>Default</b>     | no mldp                                                                                                                                                                                                        |

## maximum-p2mp-spmsi

|                    |                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] maximum-p2mp-spmsi                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>selective                                                                                                                                                                                         |
| <b>Description</b> | This command specifies the maximum number of RSVP P2MP or LDP P2MP S-PMSI tunnels for the mVPN. When the limit is reached, no more RSVP P2MP S-PMSI or LDP P2MP S-PMSI is created and traffic over the data-threshold will stay on I-PMSI. |
| <b>Default</b>     | 10                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>number</i> — specifies the maximum number of RSVP P2MP or LDP P2MP S-PMSI tunnel for the mVPN.                                                                                                                                          |
| <b>Values</b>      | 1 to 4k                                                                                                                                                                                                                                    |
| <b>Default</b>     | 10                                                                                                                                                                                                                                         |

## shutdown

|                |                                                                                                                                                                                                                                                                    |

---

|                    |                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command administratively disables/enables use of P2MP RSVP LSP template or mLDP LSP for inclusive or selective PMSI tunnels. |
| <b>Default</b>     | no shutdown                                                                                                                       |

## enable-asm-mdt

|                    |                                                                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] enable-asm-mdt</b>                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>selective                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command enables Data MDT with PIM-ASM mode on the receiver PE node. PIM-ASM or PIM-SSM operation mode is derived based on the locally configured SSM range on the node.</p> <p>If asm-mode is disabled using this command, then PIM-SSM mode is enabled for all groups, independent of the configured SSM range on the node.</p> |

## pim-ssm

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pim-ssm {grp-ip-address/mask   grp-ip-address netmask}</b><br><b>no pim-ssm</b>  |
| <b>Context</b>     | config>service>vprn>mvpn>provider-tunnel>selective                                  |
| <b>Description</b> | This command specifies the PIM SSM groups to use for the selective provider tunnel. |
| <b>Parameters</b>  | <i>group-address/mask</i> — specifies a multicast group address and netmask length  |

## umh-pe-backup

|                    |                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>umh-pe-backup</b>                                                                                |
| <b>Context</b>     | config>service>vprn>mvpn                                                                            |
| <b>Description</b> | This command enables context to configure primary and standby upstream PE association for the MVPN. |

## umh-pe

|                |                                                                            |
|----------------|----------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>umh-pe ip-address standby ip-address</b><br><b>no umh-pe ip-address</b> |
| <b>Context</b> | config>service>vprn>mvpn>umh-pe-backup                                     |

|                    |                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command assigns a standby PE to each primary PE that must be selected as an alternative PE in case the UFD session on tunnel from primary PE is detected down. Standby for a PE cannot be modified without shutting down the MVPN instance.</p> <p>If a primary PE is not assigned a standby PE then the UMH selection would fall back to the default method.</p> |

| <b>Description</b> | <p>This command specifies which UMH selection mechanism to use, highest IP address, hash based or provider tunnel status.</p> <p>The <b>no</b> form of the command resets it back to default.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>     | umh-selection highest-ip                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><b>highest-ip</b> — specifies that the highest IP address is selected as UMH</p> <p><b>hash-based</b> — specifies that the UMH selection is based on the hash based procedures</p> <p><b>tunnel-status</b> — specifies that UMH selection is based on the state of the tunnel as well as the available unicast routes through the tunnel. Not supported for IPv6.</p> <p><b>unicast-rt-pref</b> — When selected, best unicast route will decide which UMH is chosen. All PE routers shall prefer the same route to the UMH for the UMH selection criterion (for example BGP path selection criteria must not influence one PE to choose different UMH from another PE).</p> |

## vrf-export

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>vrf-export {unicast   <i>plcy-or-long-expr</i> [<i>plcy-or-expr</i> [<i>plcy-or-expr</i>... (up to 14 max)]]}</b><br><b>no vrf-export</b>           |
| <b>Context</b>     | config>service>vprn>mvpn                                                                                                                               |
| <b>Description</b> | This command specifies the export policy (up to 16) to control MVPN routes exported from the local VRF to other VRFs on the same or remote PE routers. |
| <b>Default</b>     | vrf-export unicast                                                                                                                                     |
| <b>Parameters</b>  | <b>unicast</b> — specifies to use unicast VRF export policy for the MVPN                                                                               |

*plcy-or-long-expr* — The route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long). Allowed values are any string up to 255 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes

*plcy-or-expr* — The route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long). Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes

## vrf-import

| <b>Syntax</b>      | <b>vrf-target {unicast   <i>ext-community</i>   export unicast   <i>ext-community</i>   import unicast   <i>ext-community</i>}</b><br><b>no vrf-target</b>                                                                               |
| <b>Context</b>     | config>service>vprn>mvpn                                                                                                                                                                                                                 |
| <b>Description</b> | This command specifies the route target to be added to the advertised routes or compared against the received routes from other VRFs on the same or remote PE routers. vrf-import or vrf-export policies override the vrf-target policy. |

The **no** form of the command removes the vrf-target.

### 3.9.2.9 Redundant Interface Commands

#### redundant-interface

|                    |                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>redundant-interface</b> <i>ip-int-name</i>                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures a redundant interface.                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes. |

#### address

|                    |                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>address</b> { <i>ip-address/mask</i>   <i>ip-address netmask</i> } [ <b>remote-ip</b> <i>ip-address</i> ]<br><b>no address</b>                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>redundant-interface                                                                                                                                                                                                                                         |
| <b>Description</b> | This command assigns an IP address mask or netmask and a remote IP address to the interface.                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><i>ip-address/mask</i> — assigns an IP address/IP subnet format to the interface</p> <p><i>ip-address netmask</i> — specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains</p> |

assigns an IP address netmask to the interface

**remote-ip** *ip-address* — assigns a remote IP to the interface

### 3.9.2.10 Router Advertisement Commands

#### router-advertisement

|                    |                                                                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] router-advertisement</b>                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command configures router advertisement properties. By default, it is disabled for all IPv6 enabled interfaces.</p> <p>The <b>no</b> form of the command disables all IPv6 interface. However, the <b>no interface interface-name</b> command disables a specific interface.</p> |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                 |

#### dns-options

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dns-options</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>router-advertisement<br>config>service>vprn>router-advert>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables the context for configuration of DNS information for Stateless Address Auto-Configuration (SLAAC) hosts.</p> <p>When specified at the router-advertisement level in the routing context, this command allows configuration of service-wide parameters. These can then be inherited at the interface level by specifying the <b>config&gt;service&gt;vprn&gt;router-advert&gt;interface&gt;dns-options&gt;include-dns</b> command.</p> <p>The <b>no</b> form of the command disables configuration of DNS information for Stateless Address Auto-Configuration (SLAAC) hosts.</p> |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

#### server

|               |                                                       |

|                    |                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>router-advert>dns-options<br>config>service>vprn>router-advert>interface>dns-options                                                                                                                                                                                           |
| <b>Description</b> | This command specifies the IPv6 DNS servers to include in the RDNSS option in Router Advertisements. When specified at the router advertisement level this applies to all interfaces that have <b>include-dns</b> enabled, unless the interfaces have more specific <b>dns-options</b> configured. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>ipv6-address</i> — Specify the IPv6 address of the DNS server(s), up to 4 max. Specified as eight 16-bit hexadecimal pieces.                                                                                                                                                                    |

## include-dns

|                    |                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] <b>include-dns</b>                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>router-advert>interface>dns-options                                                                                                                                                                                                                                             |
| <b>Description</b> | This command enables the Recursive DNS Server (RDNSS) Option in router advertisements. This must be enabled for each interface on which the RDNSS option is required in router advertisement messages.<br><br>The <b>no</b> form of the command disables the RDNSS option in router advertisements. |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                                                            |

## rdnss-lifetime

|                    |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rdnss-lifetime</b> { <i>seconds</i>   <b>infinite</b> }<br><b>no rdnss-lifetime</b>                                                                                                                        |
| <b>Context</b>     | config>service>vprn>router-advert>dns-options<br>config>service>vprn>router-advert>interface>dns-options                                                                                                      |
| <b>Description</b> | This command specifies the maximum time that the RDNSS address may be used for name resolution by the client. The RDNSS Lifetime must be no more than twice MaxRtrAdvLifetime with a maximum of 3600 seconds. |
| <b>Default</b>     | rdnss-lifetime infinite                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>infinite</i> — specifies an infinite RDNSS lifetime<br><i>seconds</i> — specifies the time in seconds                                                                                                      |
| <b>Values</b>      | 4to 3600                                                                                                                                                                                                      |

---

## interface

|                    |                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] interface</b> <i>ip-int-name</i>                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>router-advertisement                                                                                                                                      |
| <b>Description</b> | This command configures router advertisement properties on a specific interface. The interface must already exist in the <b>config&gt;router&gt;interface</b> context.        |
| <b>Default</b>     | No interfaces are configured by default.                                                                                                                                      |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the interface name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes. |

## current-hop-limit

|                    |                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>current-hop-limit</b> <i>number</i><br><b>no current-hop-limit</b>                                                                                                     |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                      |
| <b>Description</b> | This command configures the current-hop-limit in the router advertisement messages. It informs the nodes on the subnet about the hop-limit when originating IPv6 packets. |
| <b>Default</b>     | 64                                                                                                                                                                        |
| <b>Parameters</b>  | <i>number</i> — specifies the hop limit<br><b>Values</b> 0 to 255. A value of zero means there is an unspecified number of hops.                                          |

## managed-configuration

|                    |                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] managed-configuration</b>                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command sets the managed address configuration flag. This flag indicates that DHCPv6 is available for address configuration in addition to any address autoconfigured using stateless address autoconfiguration. See RFC 3315, <i>Dynamic Host Configuration Protocol (DHCP) for IPv6</i> . |
| <b>Default</b>     | no managed-configuration                                                                                                                                                                                                                                                                         |

## max-advertisement-interval

|               |                                                       |
|---------------|-------------------------------------------------------|
| <b>Syntax</b> | <b>[no] max-advertisement-interval</b> <i>seconds</i> |
|---------------|-------------------------------------------------------|

|                    |                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                 |
| <b>Description</b> | This command configures the maximum interval between sending router advertisement messages.                                          |
| <b>Default</b>     | 600                                                                                                                                  |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the maximum interval in seconds between sending router advertisement messages.<br><b>Values</b> 4 to 1800 |

## min-advertisement-interval

|                    |                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] min-advertisement-interval <i>seconds</i>                                                                                                                 |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                           |
| <b>Description</b> | This command configures the minimum interval between sending ICMPv6 neighbor discovery router advertisement messages.                                          |
| <b>Default</b>     | 200                                                                                                                                                            |
| <b>Parameters</b>  | <i>seconds</i> — specifies the minimum interval in seconds between sending ICMPv6 neighbor discovery router advertisement messages.<br><b>Values</b> 3 to 1350 |

## mtu

|                    |                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] mtu <i>mtu-bytes</i>                                                                                           |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                |
| <b>Description</b> | This command configures the MTU for the nodes to use to send packets on the link.                                   |
| <b>Default</b>     | no mtu — the MTU option is not sent in the router advertisement messages                                            |
| <b>Parameters</b>  | <i>mtu-bytes</i> — specifies the MTU for the nodes to use to send packets on the link<br><b>Values</b> 1280 to 9212 |

## other-stateful-configuration

|                |                                   |
|----------------|-----------------------------------|
| <b>Syntax</b>  | [no] other-stateful-configuration |
| <b>Context</b> |                                   |

---

|                    |                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command sets the "Other configuration" flag. This flag indicates that DHCPv6lite is available for autoconfiguration of other (non-address) information such as DNS-related information or information on other servers in the network. See RFC 3736, <i>Stateless Dynamic Host Configuration Protocol (DHCP) for IPv6</i> . |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                |                                 |
|----------------|---------------------------------|
| <b>Default</b> | no other-stateful-configuration |
|----------------|---------------------------------|

## prefix

|               |                                         |
|---------------|-----------------------------------------|
| <b>Syntax</b> | [no] prefix [ipv6-prefix prefix-length] |
|---------------|-----------------------------------------|

|                |                                      |
|----------------|--------------------------------------|
| <b>Context</b> | config>service>vprn>router-advert>if |
|----------------|--------------------------------------|

|                    |                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command configures an IPv6 prefix in the router advertisement messages. To support multiple IPv6 prefixes, use multiple prefix statements. No prefix is advertised until explicitly configured using prefix statements. |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|                |     |
|----------------|-----|
| <b>Default</b> | n/a |
|----------------|-----|

|                   |                                                                            |
|-------------------|----------------------------------------------------------------------------|
| <b>Parameters</b> | ip-prefix — the IP prefix for prefix list entry in dotted decimal notation |
|-------------------|----------------------------------------------------------------------------|

### Values

|                    |                                     |
|--------------------|-------------------------------------|
| ipv4-prefix        | a.b.c.d (host bits must be 0)       |
| ipv4-prefix-length | 0 to 32                             |
| ipv6-prefix        | x:x:x:x:x:x:x (eight 16-bit pieces) |
|                    | x:x:x:x:x:x:d.d.d.d                 |
|                    | x: [0 to FFFF]H                     |
|                    | d: [0 to 255]D                      |
| ipv6-prefix-length | 0 to 128                            |

**prefix-length** — specifies a route must match the most significant bits and have a prefix length

|               |          |
|---------------|----------|
| <b>Values</b> | 1 to 128 |
|---------------|----------|

## autonomous

|               |                 |
|---------------|-----------------|
| <b>Syntax</b> | [no] autonomous |
|---------------|-----------------|

|                |                                             |
|----------------|---------------------------------------------|
| <b>Context</b> | config>service>vprn>router-advert>if>prefix |
|----------------|---------------------------------------------|

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies whether the prefix can be used for stateless address autoconfiguration. |
|--------------------|------------------------------------------------------------------------------------------------|

|                |         |
|----------------|---------|
| <b>Default</b> | enabled |
|----------------|---------|

## on-link

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] on-link</b>                                                             |
| <b>Context</b>     | config>service>vprn>router-advert>if>prefix                                     |
| <b>Description</b> | This command specifies whether the prefix can be used for onlink determination. |
| <b>Default</b>     | enabled                                                                         |

## preferred-lifetime

|                    |                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] preferred-lifetime</b> {seconds   infinite}                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command configures the remaining length of time in seconds that this prefix will continue to be preferred, such as, time until deprecation. The address generated from a deprecated prefix should not be used as a source address in new communications, but packets received on such an interface are processed as expected. |
| <b>Default</b>     | 604800                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <b>seconds</b> — specifies the remaining length of time in seconds that this prefix will continue to be preferred<br><br><b>infinite</b> — specifies that the prefix will always be preferred. A value of 4,294,967,295 represents infinity                                                                                        |

## valid-lifetime

|                    |                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> {seconds   infinite}                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command specifies the length of time in seconds that the prefix is valid for the purpose of on-link determination. A value of all one bits (0xffffffff) represents infinity.<br><br>The address generated from an invalidated prefix should not appear as the destination or source address of a packet. |
| <b>Default</b>     | 2592000                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <b>seconds</b> — specifies the remaining length of time in seconds that this prefix will continue to be valid<br><br><b>infinite</b> — specifies that the prefix will always be valid. A value of 4,294,967,295 represents infinity                                                                           |

## reachable-time

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>reachable-time</b> <i>milli-seconds</i><br><b>no reachable-time</b>                                                                              |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                |
| <b>Description</b> | This command configures how long this router should be considered reachable by other nodes on the link after receiving a reachability confirmation. |
| <b>Default</b>     | no reachable-time                                                                                                                                   |
| <b>Parameters</b>  | <i>milli-seconds</i> — specifies the length of time the router should be considered reachable<br><b>Values</b> 0 to 3600000                         |

## retransmit-time

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>retransmit-timer</b> <i>milli-seconds</i><br><b>no retransmit-timer</b>                               |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                     |
| <b>Description</b> | This command configures the retransmission frequency of neighbor solicitation messages.                  |
| <b>Default</b>     | no retransmit-time                                                                                       |
| <b>Parameters</b>  | <i>milli-seconds</i> — specifies how often the retransmission should occur<br><b>Values</b> 0 to 1800000 |

## router-lifetime

|                    |                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>router-lifetime</b> <i>seconds</i><br><b>no router-lifetime</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>router-advert>if                                                                                                                                                                                                             |
| <b>Description</b> | This command sets the router lifetime.                                                                                                                                                                                                           |
| <b>Default</b>     | 1800                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>seconds</i> — the length of time, in seconds, (relative to the time the packet is sent) that the prefix is valid for route determination<br><b>Values</b> 0, 4 to 9000 seconds. 0 means that the router is not a default router on this link. |

| <b>Description</b> | <p>This command enables sending router advertisement messages using the VRRP virtual MAC address, provided that the virtual router is currently the master.</p> <p>If the virtual router is not the master, no router advertisement messages are sent.</p> <p>The <b>no</b> form of the command disables sending router advertisement messages.</p> |
| <b>Default</b>     | no use-virtual-mac                                                                                                                                                                                                                                                                                                                                  |

### 3.9.2.11 Network Time Protocol Commands

## ntp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ntp</b>                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enables the context to configure Network Time Protocol (NTP) and its operation. This protocol defines a method to accurately distribute and maintain time for network elements. Furthermore this capability allows for the synchronization of clocks between the various network elements. Use the no form of the command to stop the execution of NTP and remove its configuration.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                      |

## authenticate

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] authenticate</b>                                |
| <b>Context</b>     | config>service>vprn>ntp                                 |
| <b>Description</b> | This command enables authentication for the NTP server. |

## authentication-check

|                |                                  |
|----------------|----------------------------------|
| <b>Syntax</b>  | <b>[no] authentication-check</b> |
| <b>Context</b> | config>service>vprn>ntp          |

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>This command provides the option to skip the rejection of NTP PDUs that do not match the authentication key-id, type or key requirements. The default behavior when authentication is configured is to reject all NTP protocol PDUs that have a mismatch in either the authentication key-id, type or key.</p> <p>When <b>authentication-check</b> is enabled, NTP PDUs are authenticated on receipt. However, mismatches cause a counter to be increased, one counter for type and one for key-id, one for type, value mismatches. These counters are visible in a show command.</p> <p>The <b>no</b> form of this command allows authentication mismatches to be accepted; the counters however are maintained.</p> |
| Default     | authentication-check — rejects authentication mismatches                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

authentication-key

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Context     | config>service>vprn>ntp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| Description | <p>This command sets the authentication key-id, type and key used to authenticate NTP PDUs sent to or received by other network elements participating in the NTP protocol. For authentication to work, the authentication key-id, type and key value must match.</p> <p>The <b>no</b> form of the command removes the authentication key.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| Default     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Parameters  | <p><b>key-id</b> — Configure the authentication key-id that will be used by the node when transmitting or receiving Network Time Protocol packets.</p> <p>Entering the authentication-key command with a key-id value that matches an existing configuration key will result in overriding the existing entry.</p> <p>Recipients of the NTP packets must have the same authentication key-id, type, and key value in order to use the data transmitted by this node. This is an optional parameter.</p> <p><b>Values</b>        1 to 255</p> <p><b>Default</b>        n/a</p> <p><b>key</b> — The authentication key associated with the configured key-id, the value configured in this parameter is the actual value used by other network elements to authenticate the NTP packet.</p> <p>The key can be any combination of ASCII characters up to 8 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> |

**hash** — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

**hash2** — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

**type** — This parameter determines if DES or message-digest authentication is used. This is a required parameter; either DES or message-digest must be configured.

**Values**      **des** — specifies that DES authentication is used for this key  
                  **message-digest** — specifies that MD5 authentication in accordance with RFC 2104 is used for this key  
                  **des** is not permitted in FIPS-140-2 mode.

## broadcast

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn>ntp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | This command configures the node to transmit NTP packets on a given interface. Broadcast and multicast messages can easily be spoofed, thus, authentication is strongly recommended.<br><br>The <b>no</b> form of this command removes the address from the configuration.                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the local interface on which to transmit NTP broadcast packets. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.<br><br><b>Values</b> 32 character maximum<br><br><b>key-id</b> <i>key-id</i> — Identifies the configured authentication key and authentication type used by this node to receive and transmit NTP packets to and from an NTP server and peers. If an NTP packet is received by this node both authentication key and authentication type must be valid otherwise the packet will be rejected and an event/trap generated.<br><br><b>Values</b> 1 to 255<br><br><b>Default</b> n/a |

**version** *version* — Specifies the NTP version number that is generated by this node.  
This parameter does not need to be configured when in client mode in which case all versions will be accepted.

**Values** 1 to 4

**Default** 4

**tll** *tll* — specifies the IP Time To Live (TTL) value

**Values** 1 to 255

**Default** n/a

### 3.9.2.12 NAT Commands

#### nat

**Syntax** [no] nat

**Context** config>service>vprn  
config>router

**Description** This command configures, creates or deletes a NAT instance.

#### inside

**Syntax** inside

**Context** config>service>vprn>nat  
config>router>nat

**Description** This command enters the “inside” context to configure the inside NAT instance.

#### destination-prefix

**Syntax** [no] destination-prefix *ip-prefix/length*

**Context** config>service>vprn>nat>inside  
config>router>nat>inside

**Description** This command configures a destination prefix. An (internal) static route will be created for this prefix. All traffic that hits this route will be subject to NAT. The system will not allow a destination-prefix to be configured if the configured nat-policy refers to an IP pool that resides in the same service (as this would result in a routing loop).

|                   |                                                                        |
|-------------------|------------------------------------------------------------------------|
| <b>Parameters</b> | <i>ip-prefix</i> — specifies the IP prefix; host bits must be zero (0) |
| <b>Values</b>     | a.b.c.d                                                                |
|                   | <i>length</i> — specifies the prefix length                            |
| <b>Values</b>     | 0 to 32                                                                |

dual-stack-lite

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dual-stack-lite</b>                                                        |
| <b>Context</b>     | config>service>vprn>nat<br>config>router>nat>inside                           |
| <b>Description</b> | This command enables the context to configure Dual-Stack-Lite NAT parameters. |

address

|                    |                                                                                                                                           |                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] address</b> <i>ipv6-address</i>                                                                                                   |                                                                                               |

| <b>Description</b> | This command configures the IPv6 prefix length of the dual-stack-lite subscribers.<br><br>The <b>no</b> form of the command reverts the default. |
| <b>Default</b>     | 128                                                                                                                                              |
| <b>Parameters</b>  | <b>prefix-length</b> <i>prefix-length</i> — specifies the IPv6 prefix length of the dual-stack-lite subscriber                                   |
| <b>Values</b>      | 32 to 64, 128                                                                                                                                    |
| <b>Default</b>     | 128                                                                                                                                              |

## l2-aware

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>l2-aware</b>                                                                         |
| <b>Context</b>     | config>services>vprn>nat>inside                                                         |
| <b>Description</b> | This command enables the context to configure parameters specific to Layer 2-aware NAT. |

## address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] address</b> <i>ip-address/mask</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>services>vprn>nat>inside>l2-aware                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures a Layer 2-aware NAT address. This address will act as a local address of the system. Hosts connected to the inside service will be able to ARP for this address. To verify connectivity, a host can also ping the address. This address is typically used as next hop of the default route of a Layer 2-aware host. The given mask defines a Layer 2-aware subnet. The (inside) IP address used by an Layer 2-aware host must match one of the subnets defined here or it will be rejected. |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP address in a.b.c.d format                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

*mask* — specifies the mask

**Values** 16 to 32

## nat-policy

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>nat-policy</b> <i>nat-policy-name</i><br><b>no nat-policy</b>                              |
| <b>Context</b>     | config>services>vprn>nat>inside<br>config>router>nat>inside                                   |
| <b>Description</b> | This command configures the NAT policy that will be used for large-scale NAT in this service. |
| <b>Parameters</b>  | <i>nat-policy-name</i> — specifies the NAT policy name<br><b>Values</b> 32 chars max          |

## redundancy

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>redundancy</b>                                                      |
| <b>Context</b>     | config>service>vprn>nat>inside<br>config>service>vprn>nat>outside>pool |
| <b>Description</b> | This command enables the context to configure redundancy parameters.   |

## peer

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer</b> <i>ip-address</i><br><b>no peer</b>                                                                 |
| <b>Context</b>     | config>service>vprn>nat>inside>redundancy                                                                       |
| <b>Description</b> | This command configures the IP address of the NAT redundancy peer in the realm of this virtual router instance. |

## steering-route

|                |                                                                           |
|----------------|---------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>steering-route</b> <i>ip-prefix/length</i><br><b>no steering-route</b> |
| <b>Context</b> | config>service>vprn>nat>inside>redundancy                                 |

|                    |                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command configures specifies the IP address and prefix length of the steering route. The steering route is used in the realm of this virtual router instance as an indirect next-hop for all the traffic that must be routed to the large scale NAT function. |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## outside

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>outside</b>                                                                   |
| <b>Context</b>     | config>service>vprn>nat<br>config>router>nat                                     |
| <b>Description</b> | This command enters the “outside” context to configure the outside NAT instance. |

## pool

|                    |                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | This command starts or stops draining this NAT address range. When an address-range is being drained, it will not be used to serve new hosts. Existing hosts, however, will still be able to use the address that was assigned to them even if it is being drained. An address-range can only be deleted if the parent pool is shut down or if the range itself is effectively drained (no hosts are using the addresses anymore). |

## mode

|                    |                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn>nat>outside>pool>redundancy                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>this command installs the export route in the routing table for active NAT pools.</p> <p>Once the export route is in the routing table, it can be advertised in the network via a routing protocol. NAT pools in the standby or disabled state will not advertise the export route.</p> |

A NAT pool will become active when it becomes operationally UP, AND there is no monitoring route (which is also the export route from the peer) present in the routing node (as received from the network). The pool will transition into standby state in case that the monitoring route (or export route from the peer) is already present in the routing table. In other words, the monitoring route is already advertised as an export route from the peering node with active NAT pool.

The export route can be advertised only from:

- The active lead pool.
- Active pool for which fate-sharing is disabled.

**Default** no export

**Parameters** *ip-prefix/length* — specifies the IP prefix and length

**Syntax:**

|                           |                         |                |
|---------------------------|-------------------------|----------------|
| <i>ip-prefix/length</i> : | <i>ip-prefix</i>        | <i>a.b.c.d</i> |
|                           | <i>ip-prefix-length</i> | <i>0 to 32</i> |

**Values** 0, 4, 16

follow

**Syntax** **follow router** *router-instance* **pool** *name*  
**no follow**

**Context** config>service>vprn>nat>outside>pool>redundancy  
config>router> nat>outside>pool>redundancy

**Description** This command implicitly enables Pool Fate-Sharing Group (PFSG) which is required in case of multiple NAT policies per inside routing context. A NAT pool configured with this command will not advertise or monitor any route in order to change its (activity) state but instead it will directly follow the state of the lead pool in the PFSG. Once the lead pool changes its (activity) state, all the remaining pools following the lead pool will change their state accordingly.

**Default** no follow

**Parameters** **router** *router-instance* — specifies the routing instance where the lead pool resides

**Values** <router-name> | <service-id>  
router-name - Base  
service-id - [1to2147483647]

**pool** *name* — the pool whose activity state is being shared up to 32 characters in length

---

| <b>Description</b> | <p>This command configures the monitoring route based on which the NAT multi-chassis switchover is triggered. Monitoring route of a NAT pool on the local node must match the export route of a corresponding NAT pool on the peering node. Presence of the monitoring route in the routing table is an indication that the peering NAT pool is active (since it is advertising its export route). The disappearance of the monitoring route from the routing table is an indication that the peering pool has failed and consequently the nodal switchover is triggered, the local pool becomes active and its export route is consequently advertised. The export route can be advertised only from:</p> <ul style="list-style-type: none"><li>• The active lead pool.</li><li>• Active pool for which fate-sharing is disabled.</li></ul> |                    |           |         |  |                  |         |
| <b>Parameters</b>  | <i>ip-prefix/length</i> — specifies the IP prefix and length                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |                    |           |         |  |                  |         |

**Description** This command configures the local subscriber subnets available on a subscriber IP interface. The configured `ip-address` and mask define the address space associated with the subscriber subnet. Up to 16 IP subnets can be created on a single subscriber IP interface. Each subnet supports a locally owned IP host address within the subnet that is not expected to appear on other routers that may be servicing the same subscriber subnet. For redundancy purposes, the keyword **gw-address** defines a separate IP address within the subnet for Subscriber Routed Redundancy Protocol (SRRP) routing. This IP address must be the same on the local and remote routers participating in a common SRRP instance.

In SRRP, a single SRRP instance is tied to a group IP interface. The group IP interface is contained directly within a subscriber IP interface context and thus directly associated with the subscriber subnets on the subscriber IP interface. The SRRP instance is also indirectly associated with any subscriber subnets tied to the subscriber interface through wholesale/retail VPRN configurations. With the directly-associated and the indirectly-associated subscriber interface subnets, a single SRRP instance can manage hundreds of SRRP gateway IP addresses. This automatic subnet association to the SRRP instance is different from VRRP where the redundant IP address is defined within the VRRP context.

Defining an SRRP gateway IP address on a subscriber subnet is not optional when the subnet is associated with a group IP interface with SRRP enabled. Enabling SRRP (**no shutdown**) will fail if one or more subscriber subnets do not have an SRRP gateway IP address defined. Creating a new subscriber subnet without an SRRP gateway IP address defined will fail when the subscriber subnet is associated with a group IP interface with an active SRRP instance. Once SRRP is enabled on a group interface, the SRRP instance will manage the ARP response and routing behavior for all subscriber hosts reachable through the group IP interface.

The `no` form of the command removes the address from a subscriber subnet. The address command for the specific subscriber subnet must be executed without the `gw-address` parameter. To succeed, all SRRP instances associated with the subscriber subnet must be removed or shutdown.

**Parameters** *ip-address/mask* | *ip-address netmask* — specifies the address space associated with the subscriber subnet

**gw-ip-address** *ip-address* — Specifies a separate IP address within the subnet for SRRP routing purposes. This parameter must be followed by a valid IP interface that exists within the subscriber subnet created by the address command. The defined gateway IP address cannot currently exist as a subscriber host (static or dynamic). If the defined `ip-address` already exists as a subscriber host address, the address command will fail. The specified `ip-address` must be unique within the system.

The `gw-address` parameter may be specified at anytime. If the subscriber subnet was created previously, executing the address command with a `gw-address` parameter will simply add the SRRP gateway IP address to the existing subnet.

If the address command is executed without the `gw-address` parameter when the subscriber subnet is associated with an active SRRP instance, the address will fail. If the SRRP instance is inactive or removed, executing the address command without the `gw-address` parameter will remove the SRRP gateway IP address from the specified subscriber subnet.

If the `address` command is executed with a new `gw-address`, all SRRP instances currently associated with the specified subscriber subnet will be updated with the new SRRP gateway IP address.

**populate-host-routes** — Specifies to populate subscriber-host routes in local FIB. Storing them in FIB benefits topologies only where the external router advertises more specific routes than the one corresponding to locally configured subscriber-interface subnets.

| <b>Syntax</b>      | <b>[no] allow-unmatching-subnets</b>                                                                                                            |
| <b>Context</b>     | config>service>vprn>subscriber-interface                                                                                                        |
| <b>Description</b> | This command specifies whether subscriber hosts with a subnet that does not match any of the subnets configured on this interface, are allowed. |

## group-interface

|                    |                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] group-interface</b> <i>ip-int-name</i>                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>subscriber-interface                                                                                                                                                                                              |
| <b>Description</b> | This command enables the context to configure a group interface. A group interface is an interface that may contain one or more SAPs. This interface is used in triple-play services where multiple SAPs are part of the same subnet. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>ip-int-name</i> — Configures the interface group name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.                                                  |

## arp-host

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-host</b>                                                    |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if                                  |
| <b>Description</b> | This command enables the context to configure ARP host parameters. |

## host-limit

|               |                                        |
|---------------|----------------------------------------|
| <b>Syntax</b> | <b>host-limit</b> <i>max-num-hosts</i> |
|---------------|----------------------------------------|

#### **no host-limit**

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>arp-host                       |
| <b>Description</b> | This command configures the maximum number of ARP hosts.         |
| <b>Parameters</b>  | <i>max-num-hosts</i> — specifies the maximum number of ARP hosts |
| <b>Values</b>      | 1 to 32767                                                       |

### min-auth-interval

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-auth-interval</b> <i>min-auth-interval</i><br><b>no min-auth-interval</b> |
| <b>Context</b>     | onfig>service>vprn>sub-if>grp-if>arp-host                                        |
| <b>Description</b> | This command configures the minimum authentication interval.                     |
| <b>Parameters</b>  | <i>min-auth-interval</i> — specifies the minimum authentication interval         |
| <b>Values</b>      | 1 to 6000                                                                        |

### sap-host-limit

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap-host-limit</b> <i>max-num-hosts-sap</i><br><b>no sap-host-limit</b>                                 |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>arp-host                                                                 |
| <b>Description</b> | This command configures the maximum number of ARP hosts per SAP.                                           |
| <b>Parameters</b>  | <i>max-num-hosts-sap</i> — specifies the maximum number of ARP hosts per SAP allowed on this IES interface |
| <b>Values</b>      | 1 to 32767                                                                                                 |

## 3.9.2.14 Interface Commands

### interface

|                |                                                                               |
|----------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>interface</b> <i>ip-int-name</i><br><b>no interface</b> <i>ip-int-name</i> |
| <b>Context</b> | config>service>vprn                                                           |

**Description** This command creates a logical IP routing interface for a Virtual Private Routed Network (VPRN). Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface.

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within VPRN service IDs. The **interface** command can be executed in the context of an VPRN service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber Internet access.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config router interface** and **config service vprn interface**. Interface names must not be in the dotted decimal notation of an IP address. For example, the name "1.1.1.1" is not allowed, but "int-1.1.1.1" is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

The available IP address space for local subnets and routes is controlled with the **config router service-prefix** command. The **service-prefix** command administers the allowed subnets that can be defined on service IP interfaces. It also controls the prefixes that may be learned or statically defined with the service IP interface as the egress interface. This allows segmenting the IP address space into **config router** and **config service** domains.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All VPRN IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The **no** form of this command removes IP the interface and all the associated configuration. The interface must be administratively shutdown before issuing the **no interface** command.

For VPRN services, the IP interface must be shutdown before the SAP on that interface may be removed. VPRN services do not have the **shutdown** command in the SAP CLI context. VPRN service SAPs rely on the interface status to enable and disable them.

**Parameters** *ip-int-name* — Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service vprn interface** commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

## active-cpm-protocols

|                    |                                                       |
|--------------------|-------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] active-cpm-protocols</b>                      |
| <b>Context</b>     | config>service>vprn>if                                |
| <b>Description</b> | This command enables CPM protocols on this interface. |

## address

|                |                                                                                                                                      |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>address {ip-address/mask   ip-address netmask} [broadcast all-ones   host-ones]<br/>[track-srrp srrp-instance]<br/>no address</b> |
| <b>Context</b> | config>service>vprn>if<br>config>service>vprn>nw-if                                                                                  |

**Description** Assigns an IP address, IP subnet, and broadcast address format to a VPRN IP router interface. Only one IP address can be associated with an IP interface.

An IP address must be assigned to each VPRN IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the 7750 SR.

The local subnet that the **address** command defines must be part of the services address space within the routing context using the **config router service-prefix** command. The default is to disallow the complete address space to services. Once a portion of the address space is allocated as a service prefix, that portion can be made unavailable for IP interfaces defined within the **config router interface** CLI context for network core connectivity with the **exclude** option in the **config router service-prefix** command.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Use the **no** form of this command to remove the IP address assignment from the IP interface. When the **no address** command is entered, the interface becomes operationally down.

---

| Address    | Admin state | Oper state |
|------------|-------------|------------|
| No address | up          | down       |
| No address | down        | down       |
| 1.1.1.1    | up          | up         |
| 1.1.1.1    | down        | down       |

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

- Parameters**
- ip-address* — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).
  - /* — The forward slash is a parameter delimiter and separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the “/” and the *mask-length* parameter. If a forward slash is not immediately following the *ip-address*, a dotted decimal mask must follow the prefix.
  - mask-length* — The subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask-length* parameter. The mask length parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address. Allowed values are integers in the range 0 – 30. A mask length of 32 is reserved for system IP addresses.
  - mask* — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical ‘AND’ function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.
  - broadcast** — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**. The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface.

**Default** host-ones

**all-ones** — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

**host-ones** — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

**track-srrp** — specifies the SRRP instance ID that this interface route needs to track

## allow-directed-broadcasts

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command controls the forwarding of directed broadcasts out of the IP interface.</p> <p>A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address on another IP interface. The <b>allow-directed-broadcasts</b> command on an IP interface enables or disables the transmission of packets destined to the subnet broadcast address of the egress IP interface.</p> <p>When enabled, a frame destined to the local subnet on this IP interface will be sent as a subnet broadcast out this interface. Care should be exercised when allowing directed broadcasts as it is a well-known mechanism used for denial-of-service attacks.</p> <p>When disabled, directed broadcast packets discarded at this egress IP interface will be counted in the normal discard counters for the egress SAP.</p> <p>By default, directed broadcasts are not allowed and will be discarded at this egress IP interface.</p> <p>The <b>no</b> form of this command disables the forwarding of directed broadcasts out of the IP interface.</p> |
| <b>Default</b>     | no allow-directed-broadcasts — Directed broadcasts are dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command specifies the BFD parameters for the associated IP interface. If no parameters are defined the default value are used.</p> <p>The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down and the upper level protocols (OSPF, IS-IS, BGP or PIM) is notified of the fault.</p> <p>The <b>no</b> form of the command removes BFD from the associated IGP protocol adjacency.</p> <div style="margin-top: 10px;">  <p><b>Note:</b> On the 7750 SR and 7950 XRS, the <i>transmit-interval</i>, <b>receive</b> <i>receive-interval</i>, and <b>echo-receive</b> <i>echo-interval</i> values can only be modified to a value less than 100 when:</p> <ol style="list-style-type: none"> <li>1. The <b>type</b> <b>cpm-np</b> option is explicitly configured.</li> <li>2. The interval is specified 10 to 100000.</li> <li>3. he service is shut down (<b>shutdown</b>)</li> <li>4. The service is re-enabled (<b>no shutdown</b>)</li> </ol> <p>To remove the <b>type</b> <b>cpm-np</b> option, re-issue the <b>bfd</b> command without specifying the <b>type</b> parameter.</p> </div> |               |                                      |                |     |               |                                      |                |     |               |        |                |   |               |               |

10 to 100000 (applies to the 7750 SR; see the Caution above)

**Default** 100

**type cpm-np** — specifies that BFD sessions associated with this interface will be created on the CPM network processor to allow for fast timers down to 10ms granularity. This parameter applies to the 7750 SR only.

## cflowd-parameters

| <b>Description</b> | <p>This command creates the configuration context to configure cflowd parameters for the associated IP interfaces.</p> <p><b>cflowd</b> is used for network planning and traffic engineering, capacity planning, security, application and user profiling, performance monitoring, usage-based billing, and SLA measurement.</p> <p>At a minimum, the <b>sampling</b> command must be configured within this context in order to enable cflowd sampling, otherwise traffic sampling will not occur.</p> |
| <b>Default</b>     | no cflowd-parameters                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command enables and configures the cflowd sampling behavior to collect traffic flow samples through a router for analysis.</p> <p>This command can be used to configure the sampling parameters for unicast and multicast traffic separately. If sampling is not configured for either unicast or multicast traffic, then that type of traffic will not be sampled.</p> <p>If cflowd is enabled without either <b>egress-only</b> or <b>both</b> specified or with the <b>ingress-only</b> keyword specified, then only ingress sampling will be enabled on the associated IP interface.</p> |

The **no** form of the command disables the associated type of traffic sampling on the associated interface.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command assigns an existing CPU protection policy to the associated service interface. For these interface types, the per-source rate limit is not applicable. The CPU protection policies are configured in the <b>config&gt;sys&gt;security&gt;cpu-protection&gt;policy</b> <i>cpu-protection-policy-id</i> context.</p> <p>If no CPU protection policy is assigned to a service interface, then a the default policy is used to limit the overall-rate.</p> <p>The <b>no</b> form of the command removes CPU protection policy association from the interface, resulting in no default rate limiting of control packets.</p> |
| <b>Default</b>     | <p>cpu-protection 254 (for access interfaces)</p> <p>cpu-protection 255 (for network interfaces)</p> <p>none (for video-interfaces (where applicable), shown as <b>no cpu-protection</b> in CLI)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                    |

The configuration of **no cpu-protection** returns the interface/SAP to the default policies as shown above.

**Parameters** *policy-id* — specifies an existing CPU protection policy

**Values** 1 to 255

## cpu-protection

**Syntax** **cpu-protection** *policy-id* [**mac-monitoring**]  
**no cpu-protection**

**Context** config>service>vprn>if  
config>service>vprn>if>sap

**Description** This command assigns an existing CPU protection policy to the associated service group interface SAP, interface or MSAP policy. The CPU protection policies are configured in the **config>sys>security>cpu-protection>policy** *cpu-protection-policy-id* context.

If no CPU protection policy is assigned to a service group interface SAP, then a the default policy is used to limit the overall-rate.

**Default** cpu-protection 254 (for access interfaces)

cpu-protection 255 (for network interfaces)

none (for video-interfaces (where applicable), shown as **no cpu-protection** in CLI)

The configuration of **no cpu-protection** returns the interface/SAP to the default policies as shown above.

**Parameters** *policy-id* — specifies an existing CPU protection policy

**Values** 1 to 255

**mac-monitoring** — When specified, the per MAC rate limiting should be performed, using the per-source-rate from the associated cpu-protection policy.

## dad-disable

**Syntax** [**no**] **dad-disable**

**Context** config>service>vprn>if>ipv6

**Description** This command disables duplicate address detection (DAD) on a per-interface basis. This prevents the router from performing a DAD check on the interface. All IPv6 addresses of an interface with DAD disabled, immediately enter a preferred state, without checking for uniqueness on the interface. This is useful for interfaces which enter a looped state during troubleshooting and operationally disable themselves when the loop is detected, requiring manual intervention to clear the DAD violation.

The **no** form of the command turns off **dad-disable** on the interface.

**Default** not enabled

| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>if>nw-if<br>config>service>vprn>if>redundant-if                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command will cause a delay in the activation of an IP interface by the specified number of seconds. The delay is invoked whenever the system attempts to bring the associated IP interface up.</p> <p>The <b>no</b> form of the command removes the command from the active configuration and removes the delay in activating the associated IP interface. If the configuration is removed during a delay period, the currently running delay will continue until it expires.</p> |
| <b>Parameters</b>  | <i>seconds</i> — specifies a delay, in seconds, to make the interface operational                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Values</b>      | 1 to 1200                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command configures the admin group membership of an interface. The user can apply admin groups to an IES, VPRN, network IP, or MPLS interface.</p> <p>Each single operation of the <b>admin-group</b> command allows a maximum of five (5) groups to be specified at a time. However, a maximum of 32 groups can be added to a given interface through multiple operations. Once an admin group is bound to one or more interface, its value cannot be changed until all bindings are removed.</p> <p>The configured admin-group membership will be applied in all levels/areas the interface is participating in. The same interface cannot have different memberships in different levels/areas.</p> <p>Only the admin groups bound to an MPLS interface are advertised area-wide in TE link TLVs and sub-TLVs when the <b>traffic-engineering</b> option is enabled in IS-IS or OSPF. IES and VPRN interfaces do not have their attributes advertised in TE TLVs.</p> <p>The <b>no</b> form of this command deletes one or more of the admin-group memberships of an interface. The user can also delete all memberships of an interface by not specifying a group name.</p> |
| <b>Parameters</b>  | <i>group-name</i> — Specifies the name of the group with up to 32 characters. The association of group name and value should be unique within an IP/MPLS domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Context</b>     | config>service>vpn>if>if-attribute                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command configures the SRLG membership of an interface. The user can apply SRLGs to an IES, VPRN, network IP, or MPLS interface.</p> <p>An interface can belong to up to 64 SRLG groups. However, each single operation of the <b>srlg-group</b> command allows a maximum of five (5) groups to be specified at a time. Once an SRLG group is bound to one or more interface, its value cannot be changed until all bindings are removed.</p> <p>The configured SRLG membership will be applied in all levels/areas the interface is participating in. The same interface cannot have different memberships in different levels/areas.</p> |

Only the SRLGs bound to an MPLS interface are advertised area-wide in TE link TLVs and sub-TLVs when the **traffic-engineering** option is enabled in IS-IS or OSPF. IES and VPRN interfaces do not have their attributes advertised in TE TLVs.

The **no** form of this command deletes one or more of the SRLG memberships of an interface. The user can also delete all memberships of an interface by not specifying a group name.

**Parameters** *group-name* — Specifies the name of the group, up to 32 characters. The association of group name and value should be unique within an IP/MPLS domain.

## ingress

**Syntax** **ingress**

**Context** config>service>vprn>if

**Description** This command enters context to configure ingress parameters for network interfaces.

## policy-accounting

**Syntax** **policy-accounting** <template-name>  
**no policy-accounting**

**Context** config>service>vprn>if>ingress

**Description** This command configures the service vprn interface ingress policy accounting

**Parameters** *template-name* — name of template (32 characters maximum)

## ip-mtu

**Syntax** **ip-mtu** octets  
**no ip-mtu**

**Context** config>service>vprn>if

**Description** This command configures the IP maximum transmit unit (packet) for this interface.

The **no** form of the command returns the default value.

**Default** no ip-mtu

## ipcp

**Syntax** **ipcp**

| <b>Description</b> | This command configures an IPv6 interface. |

### address

|                    |                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>address</b> <i>ipv6-address/mask</i> [ <b>eui-64</b> ] [ <b>preferred</b> ]<br><b>no address</b> <i>ipv6-address/prefix-length</i> |
| <b>Context</b>     | config>service>vprn>if>ipv6                                                                                                           |
| <b>Description</b> | This command assigns an IPv6 address to the VPRN interface.                                                                           |
| <b>Parameters</b>  | <i>ipv6-address/prefix-length</i> — specifies the IPv6 address on the interface                                                       |

| Values               |              |                   |                       |
|----------------------|--------------|-------------------|-----------------------|
| ipv6-address/prefix: | ipv6-address | x:x:x:x:x:x:x     | (eight 16-bit pieces) |
|                      |              | x:x:x:x:x:d.d.d.d |                       |
|                      |              | x                 | [0 to FFFF]H          |
|                      |              | d                 | [0 to 255]D           |
|                      |              | prefix-length     |                       |

**eui-64** — When the **eui-64** keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from MAC address on Ethernet interfaces. For interfaces without a MAC address, for example ATM interfaces, the Base MAC address of the chassis is used.

**preferred** — specifies that the IPv6 address is the preferred IPv6 address for this interface. Preferred address is an address assigned to an interface whose use by upper layer protocols is unrestricted. Preferred addresses maybe used as the source (or destination) address of packets sent from (or to) the interface. Preferred address doesn't go through the DAD process.

## dhcp6-relay

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dhcp6-relay</b>                                                 |
| <b>Context</b>     | config>service>vprn>if>ipv6                                             |
| <b>Description</b> | This command configures DHCPv6 relay parameters for the VPRN interface. |

## dhcp6-server

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dhcp6-server</b>                                                 |
| <b>Context</b>     | config>service>vprn>if>ipv6                                              |
| <b>Description</b> | This command configures DHCPv6 server parameters for the VPRN interface. |

## icmp6

|                    |                                                   |
|--------------------|---------------------------------------------------|
| <b>Syntax</b>      | <b>icmp6</b>                                      |
| <b>Context</b>     | config>service>vprn>if>ipv6                       |
| <b>Description</b> | This command configures ICMPv6 for the interface. |

## link-local-address

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>link-local-address <i>ipv6-address</i> [preferred]</b><br><b>no link-local-address</b> |
| <b>Context</b>     | config>router>if>ipv6<br>config>service>ies>if>ipv6<br>config>service>vprn>if>ipv6        |
| <b>Description</b> | This command configures the IPv6 link local address.                                      |

The no form of the command removes the configured link local address, and the router automatically generates a default link local address.

**Caution:** Removing a manually configured link local address may impact routing protocols or static routes that have a dependency on that address. It is not recommended to remove a link local address when there are active IPv6 subscriber hosts on an IES or VPRN interface.

|                   |                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>preferred</b> — disables duplicated address detection and sets the address to preferred, even if there is a duplicate address |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------|

---

local-proxy-nd

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] local-proxy-nd</b>                                            |
| <b>Context</b>     | config>service>vprn>if>ipv6                                           |
| <b>Description</b> | This command enables or disables neighbor discovery on the interface. |

## neighbor

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>neighbor</b> <i>ipv6-address mac-address</i><br><b>no neighbor</b> <i>ipv6-address</i> |
| <b>Context</b>     | config>service>vprn>if>ipv6                                                               |
| <b>Description</b> | This command configures IPv6-to-MAC address mapping on the interface.                     |
| <b>Parameters</b>  | <i>ipv6-address</i> — specifies the IPv6 address on the interface                         |

**Values**

*ipv6-address*    x:x:x:x:x:x:x (eight 16-bit pieces)  
                   x:x:x:x:x:d.d.d.d  
                   x [0 to FFFF]H  
                   d [0 to 255]D

*mac-address* — Specifies the 48-bit MAC address for the static ARP in the form  
*aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are  
 hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC  
 and non-IEEE reserved MAC addresses.

## neighbor-limit

|                    |                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>neighbor-limit</b> <i>limit</i> [ <b>log-only</b> ] [ <b>threshold</b> <i>percent</i> ]<br><b>no neighbor-limit</b> |
| <b>Context</b>     | config>service>vprn>if>ipv6                                                                                            |
| <b>Description</b> | This command configures the maximum amount of dynamic IPv6 neighbor entries that can be learned on an IP interface.    |

When the number of dynamic neighbor entries reaches the configured percentage of this limit, an SNMP trap is sent. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations will be dropped. Entries that have already been learned will be refreshed.

The **no** form of the command removes the **neighbor-limit**.

---

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 90 percent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b> | <p><b>log-only</b> — Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit will be learned.</p> <p><i>percent</i> — the threshold value (as a percentage) that triggers a warning message to be sent</p> <p><b>Values</b> 0 to 100</p> <p><i>limit</i> — The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic neighbor learning is disabled and no dynamic neighbor entries are learned.</p> <p><b>Values</b> 0 to 102400</p> |

## proxy-nd-policy

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>proxy-nd-policy</b> <i>policy-name</i> [ <i>policy-name...</i> (up to 5 max)]<br><b>no proxy-nd-policy</b> |
| <b>Context</b>     | config>service>vprn>if>ipv6                                                                                   |
| <b>Description</b> | This command configures a proxy neighbor discovery policy for the interface.                                  |
| <b>Parameters</b>  | <i>policy-name</i> — specifies the existing policy name(s)                                                    |

## load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>load-balancing</b>                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>nw-if                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | This command enables the load-balancing context to configure interface per-flow load balancing options that will apply to traffic entering this interface and egressing over a LAG/ECMP on system-egress. This is a per interface setting. For load-balancing options that can also be enabled on the system level, the options enabled on the interface level overwrite system level configurations. |
| <b>Default</b>     | not applicable                                                                                                                                                                                                                                                                                                                                                                                        |

## egr-ip-load-balancing

|               |                                                                                                                          |
|---------------|--------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b> | <b>egr-ip-load-balancing</b> { <i>source</i>   <i>destination</i>   <i>inner-ip</i> }<br><b>no egr-ip-load-balancing</b> |
|---------------|--------------------------------------------------------------------------------------------------------------------------|

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| <b>Description</b> | This command specifies whether the IP header is used in the LAG and ECMP LSR hashing algorithm. This is the per interface setting.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>     | no lsr-load-balancing                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <b>lbl-only</b> — only the label is used in the hashing algorithm<br><b>lbl-ip</b> — the IP header is included in the hashing algorithm<br><b>ip-only</b> — the IP header is used exclusively in the hashing algorithm<br><b>eth-encap-ip</b> — The hash algorithm parses down the label stack (up to 3 labels supported) and once it hits the bottom, the stack assumes Ethernet II non-tagged header follows. At the expected Ethertype offset location, algorithm checks whether the value present is IPv4/v6 (0x0800 or 0x86DD). If the check passes, the hash algorithm checks the first nibble at the expected IP header location for IPv4/IPv6 (0x0100/0x0110). If the secondary check passes, the hash is performed using IP SA/DA fields in the expected IP header; otherwise (if any of the checks failed) label-stack hash is performed. |

| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>sub-if>grp-if<br>config>service>vprn>nw-if                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command enables local proxy ARP. When local proxy ARP is enabled on an IP interface, the system responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and thus will become the forwarding point for all traffic between hosts in that subnet. When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked. |
| <b>Default</b>     | no local-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                               |

## loopback

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] loopback</b>                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>nw-if                                                                                                                                     |
| <b>Description</b> | This command specifies that the associated interface is a loopback interface that has no associated physical interface. As a result, the associated interface cannot be bound to a SAP. |

When using mtrace/mstat in a Layer 3 VPN context then the configuration for the VPRN should have a loopback address configured which has the same address as the core instance's system address (BGP next-hop).

**Default** no loopback

## mac

**Syntax** [no] **mac** *ieee-mac-address*

**Context** config>service>vprn>if  
config>service>vprn>if>vrrp  
config>service>vprn>sub-if>grp-if  
config>service>vprn>nw-if

**Description** This command assigns a specific MAC address to a VPRN IP interface.

The **no** form of this command returns the MAC address of the IP interface to the default value.

**Default** The physical MAC address associated with the Ethernet interface that the SAP is configured on.

**Parameters** *ieee-mac-address* — Specifies the 48-bit MAC address for the static ARP in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

## ntp-broadcast

**Syntax** [no] **ntp-broadcast**

**Context** config>service>vprn>nw-if

**Description** This command enables receiving of NTP/SNTP broadcasts on the interface/

## monitor-oper-group

**Syntax** **monitor-oper-group** *name*  
**no monitor-oper-group**

**Context** config>service>vprn>if

**Description** This command specifies the operational group to be monitored by the object under which it is configured. The oper-group name must be already configured under the config>service context before its name is referenced in this command.

The **no** form of the command removes the association from the configuration.

---

| <b>Description</b> | This command enables a proxy ARP policy for the interface.<br><br>The no form of this command disables the proxy ARP capability.                                                                                                                                                                                                          |
| <b>Default</b>     | no proxy-arp                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>policy-name</i> — The export route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.<br><br>The specified name(s) must already be defined. |

## ptp-hw-assist

|                    |                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ptp-hw-assist</b>                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>if                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the 1588 port based timestamping assist function for the interface. This capability is supported on a specific set of hardware. The command may be blocked if not all hardware has the required level of support.<br><br>If the SAP configuration of the interface is removed, the ptp-hw-assist configuration will be removed. |

If the IPv4 address configuration of the interface is removed, the ptp-hw-assist configuration will be removed.

Only one interface per physical port can have ptp-hw-assist enabled.

**Default** no ptp-hw-assist

## qos-route-lookup

**Syntax** qos-route-lookup [source | destination]  
no qos-route-lookup

**Context** config>service>vprn>if  
config>service>vprn>if>ipv6  
config>service>vprn>sub-if>group-interface  
config>service>vprn>sub-if>grp-if>ipv6

**Description** This command enables QoS classification of the ingress IP packets on an interface based on the QoS information associated with routes in the forwarding table.

If the optional **destination** parameter is specified and the destination address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the sap-ingress or network qos policy associated with the IP interface. If the destination address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the sap-ingress or network QoS policy.

If the optional **source** parameter is specified and the source address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the sap-ingress or network qos policy associated with the IP interface. If the source address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the sap-ingress or network QoS policy.

If neither the optional **source** or **destination** parameter is present, then the default is **destination** address matching.

The functionality enabled by the qos-route-lookup command can be applied to IPv4 packets or IPv6 packets on an interface, depending on whether it is present at the interface context (applies to IPv4) or the interface>ipv6 context (applies to IPv6). The ability to specify source address based QoS lookup is not supported for IPv6. For the 7740 ESS, subscriber management group interfaces also do not support the source QPPB option.

The **no** form of the command reverts to the default.

**Default** destination

**Parameters** **source** — enables QoS classification of incoming IP packets based on the source address matching a route with QoS information

**destination** — enables QoS classification of incoming IP packets based on the destination address matching a route with QoS information

## redundant-interface

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>redundant-interface</b> <i>red-ip-int-name</i><br><b>no redundant-interface</b> |
| <b>Context</b>     | config>service>vprn<br>config>service>vprn>sub-if>grp-if                           |
| <b>Description</b> | This command configures a redundant interface used for dual homing.                |
| <b>Parameters</b>  | <i>red-ip-int-name</i> — specifies the redundant IP interface name                 |

## remote-proxy-arp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | <p>This command enables remote proxy ARP on the interface.</p> <p>Remote proxy ARP is similar to proxy ARP. It allows the router to answer an ARP request on an interface for a subnet that is not provisioned on that interface. This allows the router to forward to the other subnet on behalf of the requester. To distinguish remote proxy ARP from local proxy ARP, local proxy ARP performs a similar function but only when the requested IP is on the receiving interface.</p> |
| <b>Default</b>     | no remote-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | This command assigns an secondary IP address/IP subnet/broadcast address format to the interface.                                                                                                                             |
| <b>Default</b>     | n/a                                                                                                                                                                                                                           |

- Parameters**
- ip-address* — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).
- mask* — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.
- netmask* — specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains
- broadcast** — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**. The broadcast format on an IP interface can be specified when the IP address is assigned or changed. This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface. (Default: *host-ones*)
- all-ones** — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.
- host-ones** — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default used by an IP interface.
- The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.
- igp-inhibit** — The optional **igp-inhibit** parameter signals that the given secondary IP interface should not be recognized as a local interface by the running IGP. For OSPF and IS-IS, this means that the specified secondary IP interfaces will not be injected and used as passive interfaces and will not be advertised as internal IP interfaces into the IGP's link state database. For RIP, this means that these secondary IP interfaces will not source RIP updates.

| <b>Description</b> | <p>This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. This static ARP will appear in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface. If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address.</p> <p>The <b>no</b> form of this command removes a static ARP entry.</p>                                                                            |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><i>ip-address</i> — specifies the IP address for the static ARP in IP address dotted decimal notation</p> <p><i>ieee-mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i>, <i>bb</i>, <i>cc</i>, <i>dd</i>, <i>ee</i> and <i>ff</i> are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><i>unnumbered</i> — Specifies the static ARP MAC for an unnumbered interface. Unnumbered interfaces support dynamic ARP. Once this command is configured, it overrides any dynamic ARP.</p> |

| <b>Description</b> | <p>This command specifies redundant next-hop address on public or private IPsec interface (with public or private tunnel-sap) for static IPsec tunnel. The specified next-hop address will be used by standby node to shunt traffic to master in case of it receives them.</p> <p>The next-hop address will be resolved in routing table of corresponding service.</p> <p>The no form of the command removes the address from the interface configuration.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the static ISA tunnel redundant next-hop address                                                                                                                                                                                                                                                                                                                                                                                 |

## secure-nd

|                    |                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] secure-nd</b>                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>if>ipv6                                                                                                                                     |
| <b>Description</b> | This command enables Secure Neighbor Discovery (SeND) on the IPv6 interface.<br><br>The <b>no</b> form of the command reverts to the default and disabled SeND. |

## allow-unsecured-msgs

|                    |                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] allow-unsecured-msgs</b>                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>if>secure-nd                                                                                                                                                                                                                |
| <b>Description</b> | This command specifies whether unsecured messages are accepted. When Secure Neighbor Discovery (SeND) is enabled, only secure messages are accepted by default.<br><br>The <b>no</b> form of the command disables accepting unsecured messages. |

## link-local-modifier

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>link-local-modifier</b> <i>modifier</i><br><b>[no] link-local-modifier</b>                            |
| <b>Context</b>     | config>service>vprn>if>secure-nd                                                                         |
| <b>Description</b> | This command configures the Cryptographically Generated Address (CGA) modifier for link-local addresses. |
| <b>Parameters</b>  | <i>modifier</i> — specifies the modifier in 32 hexadecimal nibbles<br><br><b>Values</b> 0x0–0xFFFFFFFF   |

## public-key-min-bits

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>public-key-min-bits</b> <i>bits</i><br><b>[no] public-key-min-bits</b>                                                                        |
| <b>Context</b>     | config>service>vprn>if>secure-nd                                                                                                                 |
| <b>Description</b> | This command configures the minimum acceptable key length for public keys used in the generation of a Cryptographically Generated Address (CGA). |
| <b>Parameters</b>  | <i>bits</i> — specifies the number of bits<br><br><b>Values</b> 512–1024                                                                         |

## security-parameter

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>security-parameter</b> <i>sec</i><br><b>[no] security-parameter</b>                                                |
| <b>Context</b>     | config>service>vprn>if>secure-nd                                                                                      |
| <b>Description</b> | This command configures the security parameter used in the generation of a Cryptographically Generated Address (CGA). |
| <b>Parameters</b>  | <i>sec</i> — specifies the security parameter                                                                         |
| <b>Values</b>      | 0–1                                                                                                                   |

## shutdown

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                |
| <b>Context</b>     | config>service>vprn>if>secure-nd                                                    |
| <b>Description</b> | This command enables or disables Secure Neighbor Discovery (SeND) on the interface. |

## stale-time

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>stale-time</b> <i>seconds</i><br><b>no stale-time</b>                                                                                                                        |
| <b>Context</b>     | config>service>vprn>ipv6<br>config>service>vprn>if>ipv6                                                                                                                         |
| <b>Description</b> | This command configures the time a neighbor discovery cache entry can remain stale before being removed.<br><br>The <b>no</b> form of the command removes the stale-time value. |
| <b>Default</b>     | no stale-time                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — the allowed stale time (in seconds) before a neighbor discovery cache entry is removed                                                                         |
| <b>Values</b>      | 60 - 65535                                                                                                                                                                      |

## tcp-mss

|                |                                                      |
|----------------|------------------------------------------------------|
| <b>Syntax</b>  | <b>tcp-mss</b> <i>mss-value</i><br><b>no tcp-mss</b> |
| <b>Context</b> | service>vprn>if                                      |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | service>vprn>if>ipv6                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command statically sets the TCP maximum segment size (MSS) for TCP connections originated from the associated IP interface to the specified value.</p> <p>The <b>no</b> form of the command removes the static value and allows the TCP MSS value to be calculated based on the IP MTU value by subtracting the base IP and TCP header lengths from the IP MTU value (<math>\text{tcp\_mss} = \text{ip\_mtu} - 40</math>).</p> |
| <b>Default</b>     | no tcp-mss                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>mss-value</i> — the TCP MSS value that should be used in the TCP SYN packet during the three-way handshake negotiation of a TCP connection</p> <p><b>Note:</b> 9158 = max-IP_MTU (9198)-40</p> <p><b>Values</b>      536 - 9158 (IPv4)<br/>                  1220 - 9138 (IPv6)</p>                                                                                                                                              |

| <b>Description</b> | <p>This command is used to alter the default trusted state to a non-trusted state. When unset or reverted to the trusted default, the ToS field will not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set, in which case the egress network interface treats all VPRN and network IP interface as untrusted.</p> <p>When the ingress interface is set to untrusted, all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface. The egress network remarking rules also apply to the ToS field of IP packets routed using IGP shortcuts (tunneled to a remote next-hop). However, the tunnel QoS markings are always derived from the egress network QoS definitions.</p> <p>Egress marking and remarking is based on the internal forwarding class and profile state of the packet once it reaches the egress interface. The forwarding class is derived from ingress classification functions. The profile of a packet is either derived from ingress classification or ingress policing.</p> <p>The default marking state for network IP interfaces is trusted. This is equivalent to declaring no tos-marking-state on the network IP interface. When undefined or set to tos-marking-state trusted, the trusted state of the interface will not be displayed when using show config or show info unless the detail parameter is given. The <b>save config</b> command will not store the default tos-marking-state trusted state for network IP interfaces unless the detail parameter is also specified.</p> <p>The <b>no</b> tos-marking-state command is used to restore the trusted state to a network IP interface. This is equivalent to executing the tos-marking-state trusted command.</p> |

| <b>Context</b>     | config>router>sub-if>ipv6<br>config>service>vprn>sub-if>ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command configures the subscriber-interface level setting for delegated prefix length. The delegated prefix length for a subscriber- interface can be either set to a fixed value that is explicitly configured under the subscriber-interface CLI hierarchy or a variable value that can be obtained from various sources. This command can be changed only when no IPv6 prefixes are configured under the subscriber-interface.                                                                                                                                                                                                                                                                                                                                                                |
| <b>Default</b>     | no delegated-prefix-length This means that the delegated prefix length is 64.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <p><i>bits</i> — The delegated prefix length in bits. This value will be applicable to the entire subscriber-interface. In case that the delegated prefix length is also supplied via other means (LUDB, Radius or DHCP Server), such supplied value must match the value configured under the subscriber-interface. Otherwise the prefix instantiation in the router will fail.</p> <p><b>Values</b> 48 to 64</p> <p><i>variable</i> — The delegated prefix value can be of any length between 48 to 64. The value itself can vary between the prefixes and it will be provided at the time of prefix instantiation. The order of priority for the source of the delegated prefix length is:</p> <ul style="list-style-type: none"> <li>• LUDB</li> <li>• Radius</li> <li>• DHCPv6 server</li> </ul> |

## dhcp6

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dhcp6</b>                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6                                                                                                             |
| <b>Description</b> | This command allows access to the DHCP6 context within the group interface configuration. Within this context, DHCP6 parameters can be configured. |
| <b>Default</b>     | no dhcp6                                                                                                                                           |

## option

|                |                                        |
|----------------|----------------------------------------|
| <b>Syntax</b>  | <b>[no] option</b>                     |
| <b>Context</b> | config>service>vprn>sub-if>grp-if>ipv6 |

**Description** This command enables the context to configure DHCPv6 relay information options.  
The **no** form of the command disables DHCPv6 relay information options.

## interface-id

**Syntax** **interface-id**  
**interface-id ascii-tuple**  
**interface-id ifindex**  
**interface-id sap-id**  
**interface-id string**  
**no interface-id**

**Context** config>service>vprn>sub-if>grp-if>ipv6>dhcp6>option

**Description** This command enables the sending of interface ID options in the DHCPv6 relay packet.  
The **no** form of the command disables the sending of interface ID options in the DHCPv6 relay packet

**Parameters** **ascii-tuple** — specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “|”.  
**ifindex** — specifies that the interface index will be used (the If Index of a router interface can be displayed using the command **show>router>if>detail**)  
**sap-id** — specifies that the SAP identifier will be used  
**string** — Specifies a string of up to 32 characters long, composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

## remote-id

**Syntax** [**no**] **remote-id**

**Context** config>service>vprn>sub-if>grp-if>ipv6>dhcp6>option

**Description** This command enables the sending of remote ID option in the DHCPv6 relay packet.  
The client DHCP Unique Identifier (DUID) is used as the remote ID.  
The **no** form of the command disables the sending of remote ID option in the DHCPv6 relay packet.

## proxy-server

|                    |                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-server</b>                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6                                                                                                               |
| <b>Description</b> | This command allows access to the DHCP6 proxy server context. Within this context, DHCP6 proxy server parameters of the group interface can be configured. |
| <b>Default</b>     | no proxy-server                                                                                                                                            |

## renew-timer

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>renew-timer</b> <i>seconds</i><br><b>no renew-timer</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                                                                                |
| <b>Description</b> | This command configures the renew-timer (T1), the time at which the client contacts the server from which the addresses in the IA_NA or IA_PD were obtained to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 1800                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>seconds</i> — Specifies the time duration relative to the current time, expressed in units of seconds. A value of zero leaves the renew-time at the discretion of the client.<br><b>Values</b> 0 to 604800                            |

## rebind-timer

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rebind-timer</b> <i>seconds</i><br><b>no rebind-timer</b>                                                                                                                           |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                              |
| <b>Description</b> | This command configures the rebind-timer (T2), the time at which the client contacts any available server to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 2880                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — T2 is a time duration relative to the current time. A value of zero leaves the rebind-time at the discretion of the client.<br><b>Values</b> 0 to 1209600             |

## preferred-lifetime

|                    |                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>preferred-lifetime</b> [ <i>seconds</i>   <b>infinite</b> ]<br><b>no preferred-lifetime</b>                                                                                 |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                      |
| <b>Description</b> | The preferred lifetime for the IPv6 prefix or address in the option, expressed in units of seconds. When the preferred lifetime expires, any derived addresses are deprecated. |
| <b>Default</b>     | 3600                                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds<br><div><b>Values</b> 600 to 4294967295</div> <b>infinite</b> — specifies a 0xffffffff value, Dec = 4294967295   |

## valid-lifetime

|                    |                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> [ <i>seconds</i>   <b>infinite</b> ]<br><b>no valid-lifetime</b>                                                                                       |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                    |
| <b>Description</b> | The valid lifetime for the IPv6 prefix or address in the option, expressed in units of seconds.                                                                              |
| <b>Default</b>     | 86,400                                                                                                                                                                       |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds<br><div><b>Values</b> 600 to 4294967295</div> <b>infinite</b> — specifies a 0xffffffff value, Dec = 4294967295 |

## client-applications

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>client-applications</b> [ <b>dhcp</b> ] [ <b>ppp</b> ]<br><b>no client-applications</b>                    |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                     |
| <b>Description</b> | This command configures the client host types to which the DHCP6 proxy server is allowed to assign addresses. |
| <b>Parameters</b>  | <b>dhcp</b> — specifies IP over Ethernet hosts<br><b>ppp</b> — specifies PPP over Ethernet hosts              |

## router-advertisements

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] router-advertisements</b>                                               |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6                                          |
| <b>Description</b> | This command enables Router Advertisement transmission on this group interface. |
| <b>Default</b>     | router-advertisements                                                           |

## current-hop-limit

|                    |                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>current-hop-limit</b> <i>hop-count</i><br><b>no current-hop-limit</b>                                                   |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad                                                                           |
| <b>Description</b> | This command specifies the hop-limit advertised to hosts in router advertisements.                                         |
| <b>Default</b>     | 64                                                                                                                         |
| <b>Parameters</b>  | <i>hop-count</i> — specifies the current hop limit (decimal) inserted into router advertisements<br><b>Values</b> 0 to 255 |

## managed-configuration

|                    |                                                                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] managed-configuration</b>                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad                                                                                                                                                                                                                                           |
| <b>Description</b> | This command sets the managed address configuration flag. This flag indicates that DHCPv6 is available for address configuration in addition to any address auto-configured using stateless address auto-configuration. See RFC 3315, Dynamic Host Configuration Protocol (DHCP) for IPv6. |
| <b>Default</b>     | no managed-configuration                                                                                                                                                                                                                                                                   |

## max-advertisement-interval

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-advertisement-interval</b> <i>seconds</i><br><b>no max-advertisement-interval</b>    |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad                                            |
| <b>Description</b> | This command configures the maximum interval between sending router advertisement messages. |

---

|                   |                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 1800                                                                                                     |
| <b>Parameters</b> | <i>seconds</i> — specifies the maximum interval in seconds between sending router advertisement messages |
| <b>Values</b>     | 900 to 1800                                                                                              |

## min-advertisement-interval

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-advertisement-interval</b> <i>seconds</i><br><b>no min-advertisement-interval</b>                   |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad                                                           |
| <b>Description</b> | This command configures the minimum interval between sending router advertisement messages.                |
| <b>Default</b>     | 900                                                                                                        |
| <b>Parameters</b>  | <i>seconds</i> — specifies the minimum interval, in seconds, between sending router advertisement messages |
| <b>Values</b>      | 900 to 1350                                                                                                |

## mtu

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mtu</b> <i>bytes</i><br><b>no mtu</b>                                          |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad                                  |
| <b>Description</b> | This command configures the MTU for the nodes to use to send packets on the link. |
| <b>Default</b>     | no mtu                                                                            |
| <b>Parameters</b>  | <i>bytes</i> — specifies the MTU for the nodes to use to send packets on the link |
| <b>Values</b>      | 1280 to 9212                                                                      |

## other-stateful-configuration

|                    |                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] other-stateful-configuration</b>                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad                                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command sets the “Other configuration” flag. This flag indicates that DHCPv6 is available for auto-configuration of other (non-address) information such as DNS-related information or information on other servers in the network. See RFC 3736, Stateless Dynamic Host Configuration Protocol (DHCP) for IPv6. |

**Default** no other-stateful-configuration

## prefix-options

**Syntax** [no] prefix-options

**Context** config>service>vprn>sub-if>grp-if>ipv6>router-ad

**Description** This command configures router advertisement parameters for IPv6 prefixes returned via RADIUS Framed-IPv6-Prefix. All prefixes will inherit these configuration parameters.

**Default** no prefix-options

## autonomous

**Syntax** [no] autonomous

**Context** config>services>vprn>sub-if>grp-if>ipv6>router-ad>prefix-op

**Description** This command specifies whether the prefix can be used for stateless address auto-configuration.

**Default** no autonomous

## preferred-lifetime

**Syntax** preferred-lifetime [*seconds* | *infinite*]  
no preferred-lifetime

**Context** config>service>vprn>sub-if>grp-if>ipv6>router-ad>prefix-op  
config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server

**Description** This command configures the remaining length of time in seconds that this prefix will continue to be preferred, such as, time until deprecation. The address generated from a deprecated prefix should not be used as a source address in new communications, but packets received on such an interface are processed as expected.

**Default** 3600

**Parameters** *seconds* — specifies a decimal time interval in seconds.

**Values** 0-4294967295

**infinite** — specifies a 0xffffffff value. Dec = 4294967295

## valid-lifetime

|                    |                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> [ <i>seconds</i>   <b>infinite</b> ]<br><b>no valid-lifetime</b>                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>ipv6>router-ad>prefix-op<br>config>service>vprn>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                                                                                  |
| <b>Description</b> | This command specifies the length of time, in seconds, that the prefix is valid for the purpose of on-link determination. A value of all one bits (0xffffffff) represents infinity. The address generated from an invalidated prefix should not appear as the destination or source address of a packet. |
| <b>Default</b>     | 86400                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds<br><b>Values</b> 0-4294967295<br><b>infinite</b> — specifies a 0xffffffff value. Dec = 4294967295                                                                                                                                          |

## reachable-time

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>reachable-time</b> <i>milliseconds</i><br><b>no reachable-time</b>                                                                               |
| <b>Context</b>     | config>services>vprn>sub-if>grp-if>ipv6>router-ad                                                                                                   |
| <b>Description</b> | This command configures how long this router should be considered reachable by other nodes on the link after receiving a reachability confirmation. |
| <b>Default</b>     | no reachable-time                                                                                                                                   |
| <b>Parameters</b>  | <i>milliseconds</i> — the length of time the router should be considered reachable for default router selection<br><b>Values</b> 0-3600000          |

## retransmit-time

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>retransmit-time</b> <i>milliseconds</i><br><b>no retransmit-time</b>                 |
| <b>Context</b>     | config>services>vprn>sub-if>grp-if>ipv6>router-ad                                       |
| <b>Description</b> | This command configures the retransmission frequency of neighbor solicitation messages. |
| <b>Default</b>     | no retransmit-time                                                                      |

**Parameters**    *milliseconds* — specifies how often the retransmission should occur  
**Values**        0 to 1800000

## router-lifetime

**Syntax**        **router-lifetime** *seconds*  
                 **router-lifetime no-default-router**  
                 **no router-lifetime**

**Context**        config>services>vpn>sub-if>grp-if>ipv6>router-ad

**Description**    This command sets the router lifetime. A value of zero indicates this router should not be used by hosts as a default router.

**Default**        4500

**Parameters**    *seconds* — specifies how long this router is valid for default router selection  
**Values**        2700 to 9000

## renew-timer

**Syntax**        **renew-timer** *seconds*  
                 **no renew-timer**

**Context**        config>services>vpn>sub-if>grp-if>ipv6>dhcpv6

**Description**    This command configures the renew-timer (T1). The time at which the client contacts the server from the addresses in the IA\_NA or IA\_PD were obtained to extend the lifetimes of the addresses or prefixes assigned to the client.

**Default**        1800

**Parameters**    *seconds* — Time duration relative to the current time expressed in units of seconds. A value of zero (0) leaves the renew-time at the discretion of the client.  
**Values**        0 to 604800

## rebind-timer

**Syntax**        **rebind-timer** *seconds*  
                 **no rebind-timer**

**Context**        config>services>vpn>sub-if>grp-if>ipv6>dhcpv6

**Description**    This command configures the rebind-timer (T2), the time at which the client contacts any available server to extend the lifetimes of the addresses or prefixes assigned to the client.

---

|                   |                                                                                                                                                                                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 2880                                                                                                                                                                           |
| <b>Parameters</b> | <i>seconds</i> — T2 is a time duration relative to the current time expressed in units of seconds. A value of zero (0) leaves the rebind-time at the discretion of the client. |
| <b>Values</b>     | 0 to 1209600                                                                                                                                                                   |

## delegated-prefix-length

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] delegated-prefix-length</b> <i>prefix-length</i>                                                    |
| <b>Context</b>     | config>service>vpn>sub-if>ipv6                                                                              |
| <b>Description</b> | This command defines the prefix-length used for all DHCPv6 prefix delegations on this subscriber interface. |
| <b>Parameters</b>  | <i>prefix-length</i> — specifies the prefix length in use on this subscriber interface for DHCPv6 IA_PD     |
| <b>Values</b>      | 48 to 64                                                                                                    |
| <b>Default</b>     | 64                                                                                                          |

## subscriber-prefixes

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>subscriber-prefixes</b>                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vpn>sub-if>ipv6                                                                                                                                                                                                                            |
| <b>Description</b> | This command specifies aggregate off-link subscriber prefixes associated with this subscriber interface. Individual prefixes are specified under the prefix context list aggregate routes in which the next-hop is indirect via the subscriber interface. |

## prefix

|                    |                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vpn>sub-if>ipv6>sub-prefixes                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command allows a list of prefixes (using the prefix command multiple times) to be routed to hosts associated with this subscriber interface. Each prefix will be represented in the associated FIB with a reference to the subscriber interface. Prefixes are defined as being for prefix delegation (pd) or use on a WAN interface or host (wan-host). |
| <b>Parameters</b>  | <i>ipv6-address</i> — specifies the 128-bit IPv6 address                                                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | 128-bit hexadecimal IPv6 address in compressed form                                                                                                                                                                                                                                                                                                          |

*prefix-length* — specifies the length of any associated aggregate prefix

**Values**      32 to 63

**pd** — specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation

**wan-host** — specifies that this aggregate is used by IPv6 ESM hosts for local addressing or by a routing gateway's WAN interface

| <b>Description</b> | <p>This command controls the export of subnets to the forwarding service. When this attribute is configured, subnets defined on this retail subscriber interface will no longer be exported to the associated wholesale VPRN and will remain private to the retail VPRN. This is useful in a PPPoE business service context as it allows retail services to use overlapping IP address spaces even if these services are associated with the same wholesale service.</p> <p>PPPoE sessions are actually terminated in the retail service although their traffic transits on a SAP belonging to the wholesale service. This configuration is incompatible, however, with IPoE host management (DHCP, static-host and ARP-host) as these host types require that the retail subnets are exported to the wholesale VPRN. Thus, if PPPoE sessions need to coexist with IPoE hosts, this attribute should not be configured on this retail interface.</p> <p>This command will fail if the subscriber interface is not associated with a wholesale service.</p> <p>If the retail VPRN is of the type <b>hub</b>, this attribute is mandatory. Then, it will be enabled by default and it will not be possible to deconfigure it.</p> |

| <b>Description</b> | This command configures the interface as an unnumbered interface. An unnumbered IP interface is supported on a SONET/SDH access port with the PPP, ATM, Frame Relay, cisco-HDLC encapsulation. It is not supported on access ports that do not carry IP traffic, but are used for native TDM circuit emulation. |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the name of an IP interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.<br><br><i>ip-address</i> — specifies an IP address                                                                       |

| <b>Description</b> | <p>This command associates a network Quality of Service (QoS) policy with a network IP interface. Only one network QoS policy can be associated with an IP interface at one time. Attempts to associate a second QoS policy return an error.</p> <p>Associating a network QoS policy with a network interface is useful for the following purposes:</p> <ul style="list-style-type: none"><li>• To apply classification rules for determining the forwarding-class and profile of ingress packets on the interface.</li><li>• To associate ingress packets on the interface with a queue-group instance applied to the ingress context of the interface's forwarding plane (FP). (This is only applicable to interfaces on IOM3 and later cards.) The referenced ingress queue-group instance may have policers defined in order to rate limit ingress traffic on a per-forwarding class (and forwarding type: unicast vs. multicast) basis.</li><li>• To perform 802.1p, DSCP, IP precedence and/or MPLS EXP re-marking of egress packets on the interface.</li><li>• To associate egress packets on the interface with a queue-group instance applied to the egress context of the interface's port. The referenced egress queue-group instance may have policers and/or queues defined in order to rate limit egress traffic on a per-forwarding class basis.</li></ul> |

The **no** form of the command removes the network QoS policy association from the network IP interface, and the QoS policy reverts to the default.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command configures the type of a Value Added Service (VAS) facing interface. To change the <b>vas-if-type</b>, the <b>shutdown</b> command is required. The <b>vas-if-type</b> and <b>loopback</b> commands are mutually exclusive.</p> <p>The <b>no</b> form of the command removes the VAS interface type configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Default</b>     | no vas-if-type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <p><b>to-from-access</b> — used when two separate (<b>to-from-access</b> and <b>to-from-network</b>) interfaces are used for VAS connectivity. For service chaining, traffic arriving from access interfaces (upstream) is redirected to a PBR target reachable over this interface for upstream VAS processing. Downstream traffic after VAS processing must arrive on this interface, so that the traffic is subject to regular routing but is not subject to AA divert, nor egress subscriber PBR.</p> <p><b>to-from-network</b> — used when two separate (<b>to-from-access</b> and <b>to-from-network</b>) interfaces are used for VAS connectivity. For service chaining, traffic arriving from network interfaces (downstream) is redirected to a PBR target reachable over this interface for downstream VAS processing. Upstream traffic after VAS processing must arrive on this interface, so that regular routing can be applied.</p> <p><b>to-from-both</b> — used when a single interface is used for VAS connectivity (no local-to-local traffic). For service chaining, both traffic arriving from access and from network is redirected to a PBR target reachable over this interface for upstream/downstream VAS processing. Traffic after VAS processing must arrive on this interface, so that the traffic is subject to regular routing but is not subject to AA divert, nor egress subscriber PBR.</p> |

## mode

|                    |                                                                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mode {strict   loose   strict-no-ecmp}</b><br><b>no mode</b>                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>if>urfp-check<br>config>service>vprn>nw-if>urfp-check<br>config>service>vprn>sub-if>grp-if>urpf-check                                                                                                   |
| <b>Description</b> | <p>This command specifies the mode of unicast RPF check.</p> <p>The <b>no</b> form of the command reverts to the default (strict) mode.</p>                                                                                 |
| <b>Default</b>     | strict                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <b>strict</b> — When specified, uRPF checks whether incoming packet has a source address that matches a prefix in the routing table, and whether the interface expects to receive a packet with this source address prefix. |

**loose** — In **loose** mode, uRPF checks whether incoming packet has source address with a corresponding prefix in the routing table. However, the loose mode does not check whether the interface expects to receive a packet with a specific source address prefix. This object is valid only when **urpf-check** is enabled.

**strict-no-ecmp** — When a packet is received on an interface in this mode and the SA matches an ECMP route the packet is dropped by uRPF.

### 3.9.2.15 Network Interface Commands

#### network-interface

|                    |                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>network-interface</b> <i>interface-name</i> [ <b>create</b> ]<br><b>no network-interface</b> <i>interface-name</i>                                   |
| <b>Context</b>     | config>service>vprn                                                                                                                                     |
| <b>Description</b> | This command configures a network interface in a VPRN that acts as a CSC interface to a CSC-CE in a Carrier Supporting Carrier IP VPN deployment model. |

### 3.9.2.16 Interface DHCP Commands

#### dhcp

|                    |                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                                                                                          |
| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>nw-if<br>config>service>vprn>subscriber-interface<br>config>service>vprn>sub-if>grp-if |
| <b>Description</b> | This command enables the context to configure DHCP parameters.                                                                       |

#### client-applications

|                |                                                                                                                                           |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>client-applications dhcp</b><br><b>client-applications ppp</b><br><b>client-applications dhcp ppp</b><br><b>no client-applications</b> |
| <b>Context</b> | config>service>vprn>sub-if>grp-if>dhcp                                                                                                    |

|                    |                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command enables the clients that will try to contact the DHCP server(s).<br><br>The <b>no</b> form of the command removes the server client type from the configuration.                                                          |
| <b>Parameters</b>  | <b>dhcp</b> — specifies that the DHCP relay will forward requests to the DHCP server(s)<br><b>ppp</b> — specifies that PPPoE will attempt to request an IP address for a PPPoE client from the DHCP server(s)ly assigned to PPPoE node |

## action

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | This command configures the processing required when the router receives a DHCP request that already has a Relay Agent Information Option (Option 82) field in the packet.<br><br>The <b>no</b> form of this command returns the system to the default value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Default</b>     | Per RFC 3046, <i>DHCP Relay Agent Information Option</i> , section 2.1.1, <i>Reforwarded DHCP requests</i> , the default is to keep the existing information intact. The exception to this is if the giaddr of the received packet is the same as the ingress address on the router. In that case the packet is dropped and an error is logged.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <b>replace</b> — In the upstream direction (from the user), the existing Option 82 field is replaced with the Option 82 field from the router. In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).<br><b>drop</b> — the packet is dropped, and an error is logged<br><b>keep</b> — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is sent on towards the client.<br><br>The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.<br><br>If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message. |

## circuit-id

|               |                                                                                               |

| <b>Description</b> | <p>When enabled, the router sends the interface index (If Index) in the <b>circuit-id</b> suboption of the DHCP packet. The If Index of a router interface can be displayed using the command <b>show&gt;router&gt;interface&gt;detail</b>. This option specifies data that must be unique to the router that is relaying the circuit.</p> <p>If disabled, the <b>circuit-id</b> suboption of the DHCP packet will be left empty.</p> <p>The <b>no</b> form of this command returns the system to the default.</p>                                                                                                                                                                                                                                                                     |
| <b>Default</b>     | circuit-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><b>ascii-tuple</b> — specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “ ”</p> <p><b>ifindex</b> — specifies that the interface index will be used. The If Index of a router interface can be displayed using the command <b>show&gt;router&gt;interface&gt;detail</b></p> <p><b>sap-id</b> — specifies that the SAP ID will be used</p> <p><b>vlan-ascii-tuple</b> — specifies that the format will include VLAN-id and dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q and qinq ports only. Thus, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.</p> |

## filter

|                    |                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>filter</b> <i>filter-id</i><br><b>no filter</b>                                                                                                          |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>dhcp                                                                                                                      |
| <b>Description</b> | This command configures the DHCP filter for this interface.                                                                                                 |
| <b>Parameters</b>  | <p><i>filter-id</i> — Specifies the filter policy. The filter ID must already exist within the created IP filters.</p> <p><b>Values</b>      1 to 65535</p> |

## gi-address

|                |                                                                                    |
|----------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>gi-address</b> <i>ip-address</i> [ <i>src-ip-addr</i> ]<br><b>no gi-address</b> |
| <b>Context</b> | config>service>vprn>if>dhcp<br>config>service>vprn>nw-if>dhcp                      |

|                    |                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|                    | <pre>config&gt;service&gt;vprn&gt;sub-if&gt;dhcp config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;dhcp</pre>                                                                                                                                                                                                                                     |
| <b>Description</b> | This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between the different subscriber interfaces and potentially between the group interfaces defined. |
| <b>Default</b>     | no gi-address                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the host IP address to be used for DHCP relay packets<br><i>src-ip-address</i> — specifies the source IP address to be used for DHCP relay packets                                                                                                                                                                 |

## lease-populate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <pre>lease-populate [nbr-of-leases] lease-populate [nbr-of-leases] route-populate [pd] na [ta] lease-populate [nbr-of-leases] route-populate pd [na] [ta] [exclude] lease-populate [nbr-of-leases] route-populate [pd] [na] ta no lease-populate</pre>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>if>ipv6>dhcp-relay                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command specifies the maximum number of DHCPv6 lease states allocated by the DHCPv6 relay function, allowed on this interface.</p> <p>Optionally, by specifying “route-populate” parameter, system could:</p> <ul style="list-style-type: none"> <li>• Create routes based on the IA_PD/IA_NA/IA_TA prefix option in relay-reply message.</li> <li>• Create black hole routes based on OPTION_PD_EXCLUDE in IA_PD in relay-reply message.</li> </ul> <p>These routes could be redistributed into IGP/BGP by using route-policy, following protocol types that could be used in “from protocol”:</p> <ul style="list-style-type: none"> <li>• dhcpv6-pd</li> <li>• dhcpv6-na</li> <li>• dhcpv6-ta</li> <li>• dhcpv6-pd-excl</li> </ul> |
| <b>Parameters</b>  | <i>nbr-of-entries</i> — Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCPv6 ACK messages are discarded.                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Values</b>      | 1 to 8000                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

**route-populate** — specifies the route populate on which to allocate DHCPv6 lease states

**Values**      pd/na/ta — create route based on specified option  
                 exclude — create black hole route based on  
                 OPTION\_PD\_EXCLUDE

## neighbor-resolution

**Syntax**      [no] neighbor-resolution

**Context**      config>service>vprn>if>ipv6>dhcp6-relay

**Description**      This command enables neighbor resolution with DHCPv6 relay.  
  
                 The **no** form of the command disables neighbor resolution.

## match-circuit-id

**Syntax**      [no] match-circuit-id

**Context**      config>service>vprn>sub-if>grp-if>dhcp

**Description**      This command enables Option 82 circuit ID on relayed DHCP packet matching. For routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked.

                 When a response is received from the server the virtual router ID, transaction ID, and client hardware MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client hardware MAC address are not guaranteed to be unique.

                 When the **match-circuit-id** command is enabled we use this as part of the key to guarantee correctness in our lookup. This is really only needed when we are dealing with an IP aware DSLAM that proxies the client hardware MAC address.

**Default**      no match-circuit-id

## option

**Syntax**      [no] option

**Context**      config>service>vprn>if>dhcp  
                 config>service>vprn>nw-if>dhcp  
                 config>service>vprn>sub-if>dhcp  
                 config>service>vprn>sub-if>grp-if>dhcp

**Description** This command enables DHCP Option 82 (Relay Agent Information Option) parameters processing and enters the context for configuring Option 82 sub-options.

The **no** form of this command returns the system to the default.

**Default** no option

## copy-82

**Syntax** **[no] copy-82**

**Context** config>service>vprn>nw-if>dhcp>option

**Description** This command enables the copy-82 option.

The **no** form of the command disables the option.

## remote-id

**Syntax** **remote-id [mac | string *string*]**  
**no remote-id**

**Context** config>service>vprn>sub-if>grp-if>dhcp>option  
config>service>vprn>nw-if>dhcp>option

**Description** When enabled, the router sends the MAC address of the remote end (typically the DHCP client) in the **remote-id** suboption of the DHCP packet. This command identifies the host at the other end of the circuit. If disabled, the **remote-id** suboption of the DHCP packet will be left empty.

The **no** form of this command returns the system to the default.

**Default** remote-id

**Parameters** **mac** — specifies the MAC address of the remote end is encoded in the suboption  
**string *string*** — specifies the remote-id

## vendor-specific-option

**Syntax** **[no] vendor-specific-option**

**Context** config>service>vprn>if>dhcp>option  
config>service>vprn>nw-if>dhcp>option  
config>service>vprn>sub-if>grp-if>dhcp>option

**Description** This command configures the Nokia vendor specific suboption of the DHCP relay packet.

## client-mac-address

|                    |                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] client-mac-address</b>                                                                                                                                                                                                                                                |

| <b>Description</b> | This command enables the sending of the SAP ID in the Nokia vendor-specific suboption of the DHCP relay packet.<br><br>The <b>no</b> form of the command disables the sending of the SAP ID in the Nokia vendor specific suboption of the DHCP relay packet. |

## service-id

|                    |                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] service-id</b>                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>if>dhcp>option>vendor<br>config>service>vprn>sub-if>grp-if>dhcp>option>vendor                                                                                                                                                                    |
| <b>Description</b> | This command enables the sending of the service ID in the Nokia vendor specific suboption of the DHCP relay packet.<br><br>The <b>no</b> form of the command disables the sending of the service ID in the Nokia vendor specific suboption of the DHCP relay packet. |

## string

|                    |                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] string <i>text</i></b>                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>if>dhcp>option>vendor<br>config>service>vprn>sub-if>grp-if>dhcp>option>vendor                                                                                        |
| <b>Description</b> | This command specifies the vendor specific suboption string of the DHCP relay packet.<br><br>The <b>no</b> form of the command returns the default value.                                |
| <b>Parameters</b>  | <i>text</i> — The string can be any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" "). |

## system-id

|                |                                                                                           |
|----------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] system-id</b>                                                                     |
| <b>Context</b> | config>service>vprn>if>dhcp>option>vendor<br>config>service>vprn>nw-if>dhcp>option>vendor |

---

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
|                    | <code>config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;dhcp&gt;option&gt;vendor</code>                        |
| <b>Description</b> | This command specifies whether the system-id is encoded in the Nokia vendor specific sub-option of Option 82. |
| <b>Default</b>     | n/a                                                                                                           |

## proxy-server

|                    |                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>proxy-server</b>                                                                                                |
| <b>Context</b>     | <code>config&gt;service&gt;if&gt;dhcp</code><br><code>config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;dhcp</code> |
| <b>Description</b> | This command configures the DHCP proxy server.                                                                     |

## emulated-server

|                    |                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>emulated-server</b> <i>ip-address</i><br><b>no emulated-server</b>                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | <code>config&gt;service&gt;vprn&gt;if&gt;dhcp&gt;proxy</code><br><code>config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;dhcp&gt;proxy-server</code>                                                                                                                                                                                                              |
| <b>Description</b> | This command configures the IP address to be used as the DHCP server address in the context of this service. Typically, the configured address should be in the context of the subnet.<br><br>The <b>no</b> form of this command reverts to the default setting. The local proxy server will not become operational without a specified emulated server address. |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the emulated server address<br><br><b>Default</b> For a retail interface, the default is the local interface.                                                                                                                                                                                                                      |

## lease-time

|                    |                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lease-time</b> [ <i>days days</i> ] [ <i>hrs hours</i> ] [ <i>min minutes</i> ] [ <i>sec seconds</i> ] [ <i>radius-override</i> ]<br><b>no lease-time</b>                                                         |
| <b>Context</b>     | <code>config&gt;service&gt;vprn&gt;if&gt;dhcp&gt;proxy</code><br><code>config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;dhcp&gt;proxy-server</code>                                                                  |
| <b>Description</b> | This command defines the length of lease-time that will be provided to DHCP clients. By default the local-proxy-server will always make use of the lease-time information provide by either a RADIUS or DHCP server. |

The no form of this command disables the use of the lease-time command. The local-proxy-server will use the lease-time offered by either a RADIUS or DHCP server.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command specifies a list of servers where requests will be forwarded. The list of servers can entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCP relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list. There can be a maximum of 8 DHCP servers configured.</p> <p>The flood command is applicable only in the VPLS case. There is a scenario with VPLS where the VPLS node only wants to add Option 82 information to the DHCP request to provider per-subscriber information, but it does not do full DHCP relay. In this case, the server is set to "flood". This means the DHCP request is still a broadcast and is sent through the VPLS domain. A node running at L3 further upstream then can perform the full L3 DHCP relay function.</p> |
| <b>Default</b>     | no server                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>server</i> — specifies the DHCP server IP address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | Relay unicast client DHCPv4 request (renew) messages. In the upstream direction: update the source-ip address and add the gateway IP address (gi-address) field before sending the message to the intended DHCP server (the message is not broadcasted to all configured DHCP servers). In the downstream direction: remove the gi-address and update the destination IP address to the value of the yiaddr (your IP address) field. |

By default, unicast DHCPv4 release messages are forwarded transparently.

Additionally when the optional flag “relay-unicast-msg” is enabled, then the gi address and source IP address of relayed DHCPv4 messages can be configured to any local configured IP address in the same routing instance.

|                   |                                                                                                              |
|-------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no relay-unicast-msg                                                                                         |
| <b>Parameters</b> | <b>release-update-src-ip</b> — updates the source IP address with the value used for relayed DHCPv4 messages |

## snoop

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] snoop</b>                                                                                                            |
| <b>Context</b>     | config>service>vprn>nw-if>dhcp                                                                                               |
| <b>Description</b> | This command enables snooping of DHCP packets on this interface.<br><br>The <b>no</b> form of the command disables snooping. |

## trusted

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>According to RFC 3046, <i>DHCP Relay Agent Information Option</i>, a DHCP request where the giaddr is 0.0.0.0 and which contains a Option 82 field in the packet, should be discarded, unless it arrives on a “trusted” circuit.</p> <p>If trusted mode is enabled on an IP interface, the relay agent router will modify the request's giaddr to be equal to the ingress interface and forward the request.</p> <p>This behavior only applies when the action in the Relay Agent Information Option is “keep”. In the case where the Option 82 field is being replaced by the relay agent (action = replace), the original Option 82 information is lost anyway, and there is thus no reason for enabling the trusted option.</p> <p>The <b>no</b> form of this command returns the system to the default.</p> |
| <b>Default</b>     | not enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## egress

|                    |                                                                                                 |

|                    |                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dynamic-tunnel-redundant-next-hop</b> <i>ip-address</i><br><b>no dynamic-tunnel-redundant-next-hop</b>                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vpn>if                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command specifies redundant next-hop address on public or private IPsec interface (with public or private tunnel-sap) for dynamic IPsec tunnel. The specified next-hop address will be used by standby node to shunt traffic to master in case of it receives them.</p> <p>The next-hop address will be resolved in routing table of corresponding service.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                     |

---

**Parameters**    *ip-address* — specifies the dynamic ISA tunnel redundant next-hop address

## egr-ip-load-balancing

**Syntax**    **egr-ip-load-balancing {source | destination | inner-ip}**  
**no egr-ip-load-balancing**

**Context**    config>service>vprn>if>load-balancing  
config>service>vprn>if>nw-if>load-balancing

**Description**    This command specifies whether to include source address or destination address or both in LAG/ECMP hash on IP interfaces. Additionally, when I4-load-balancing is enabled the command applies also to inclusion of source/destination port in the hash inputs.

The **no** form of this command includes both source and destination parameters.

**Default**    no egr-ip-load-balancing

**Parameters**    *source* — specifies using source address and (if I4-load balancing is enabled) source port in the hash, ignore destination address/port

*destination* — specifies using destination address and (if I4-load balancing is enabled) destination port in the hash, ignore source address/port

*inner-ip* — specifies use of the inner IP header parameters instead of outer IP header parameters in LAG/ECMP hash for IPv4 encapsulated traffic

## enable-ingress-stats

**Syntax**    **[no] enable-ingress-stats**

**Context**    config>router>interface  
config>service>ies >interface  
config>service>vprn>interface  
config>service>ies>sub-if>grp-if  
config>service>vprn>sub-if>grp-if

**Description**    This command enables the collection of ingress interface IP stats. This command is only applicable to IP statistics, and not to uRPF statistics.

If enabled, then the following statistics are collected:

- IPv4 offered packets
- IPv4 offered octets
- IPv6 offered packets
- IPv6 offered octets
- Octet statistics for IPv4 and IPv6 bytes at IP interfaces include the layer 2 frame overhead.

**Default** no enable-ingress-stats

## enable-mac-accounting

**Syntax** [no] enable-mac-accounting

**Context** config>service>vprn>if

**Description** This command enables MAC accounting functionality on this interface.  
The **no** form of the command disables MAC accounting functionality on this interface.

## host-connectivity-verify

**Syntax** **host-connectivity-verify** [source {vrrp | interface}] [interval *interval*] [action {remove | alarm}] [timeout *retry-timeout*] [retry-count *count*]  
**host-connectivity-verify** [interval *interval*] [action {remove | alarm}] [timeout *retry-timeout*] [retry-count *count*] [family *family*]

**Context** config>service>vprn>if  
config>service>vprn>sub-if>grp-if  
config>service>vprn>sub-if>grp-if>dhcp

**Description** This command enables subscriber host connectivity verification on a given SAP within a service.  
This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.

**Default** no host-connectivity-verify

**Parameters** *source {vrrp | interface}* — Specifies the source to be used for generation of subscriber host connectivity verification packets. The **interface** keyword forces the use of the interface mac and ip addresses. There are up to 16 possible subnets on a given interface, therefore subscriber host connectivity verification tool will use always an address of the subnet to which the given host is pertaining. In case of group-interfaces. one of the parent subscriber-interface subnets (depending on host's address) will be used.

**interval *interval*** — The interval, expressed in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.

**Values** 1to 6000 (A zero value can be used by the SNMP agent to disable host-connectivity-verify.)

**action {remove | alarm}** — Defines the action taken on a subscriber host connectivity verification failure for a given host. The **remove** keyword raises an alarm and removes dhcp-state and releases all allocated resources (queues, table entries, etc.). DHCP-RELEASE will be signaled to corresponding DHCP server. Static hosts will never be removed. The **alarm** keyword raises an alarm indicating that the host is disconnected.

**timeout** *retry-timeout* — specifies the timeout in seconds between consecutive retries of subscriber host connectivity verification checks, in case the host does not respond

**Values** 10to 60 seconds

**retry-count** *count* — specifies the number of retries that will be carried out before a subscriber host is considered to have failed the SHCV check

**Values** 2to 29

**family** *family* — Indicates the IP address family for which subscriber host connectivity verification checks will be enabled. It can be set to ipv4 or ipv6 only, or both.

**Values** 2to 29

hold-time

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Syntax      | hold-time                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| Context     | config>service>vprn>interface<br>config>service>vprn>network-interface<br>config>service>vprn>subscriber-interface<br>config>service>vprn>redundant-interface                                                                                                                                                                                                                                                                                                                                                                               |
| Description | <p>This command creates the CLI context to configure interface level hold-up and hold-down timers for the associated IP interface.</p> <p>The <b>up</b> timer controls a delay for the associated IPv4 or IPv6 interface so that the system will delay the deactivation of the associated interface for the specified amount of time.</p> <p>The <b>down</b> timer controls a delay for the associated IPv4 or IPv6 interface so that the system will delay the activation of the associated interface for the specified amount of time</p> |

up

|         |                                                                                                                 |
|---------|-----------------------------------------------------------------------------------------------------------------|
| Syntax  | up ip seconds<br>no up ip<br>up ipv6 seconds<br>no up ipv6                                                      |
| Context | config>service>vprn>if>hold-time<br>config>service>vprn>nw-if>hold-time<br>config>service>vprn>sub-if>hold-time |

```
config>service>vprn>red-if>hold-time
```

**Description** This command will cause a delay in the deactivation of the associated IP interface by the specified number of seconds. The delay is invoked whenever the system attempts to bring the associated IP interface down.

The **no** form of the command removes the command from the active configuration and removes the delay in deactivating the associated IP interface. If the configuration is removed during a delay period, the currently running delay will continue until it expires.

**Parameters** *seconds* — the time delay, in seconds, to make the interface operational

**Values** 1 to 1200

## down

**Syntax** **down ip** *seconds* [**init-only**]  
**no up ip**  
**up ipv6** *seconds* [**init-only**]  
**no up ipv6**

**Context** config>service>vprn>if>hold-time  
 config>service>vprn>nw-if>hold-time  
 config>service>vprn>sub-if>hold-time  
 config>service>vprn>red-if>hold-time

**Description** This command will cause a delay in the activation of the associated IP interface by the specified number of seconds. The delay is invoked whenever the system attempts to bring the associated IP interface up, unless the **init-only** option is configured. If the **init-only** option is configured, the delay is only applied when the IP interface is first configured or after a system reboot.

The **no** form of the command removes the command from the active configuration and removes the delay in activating the associated IP interface. If the configuration is removed during a delay period, the currently running delay will continue until it completes.

**Parameters** *seconds* — the time delay, in seconds, to make the interface operational

**Values** 1 to 1200

**init-only** — specifies that the **down** delay is only applied when the interface is configured or after a reboot

**Values** 1 to 1200

### 3.9.2.17 Interface ICMP Commands

#### icmp

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>icmp</b>                                                                                    |
| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>sub-if>grp-if<br>config>service>vprn>nw-if       |
| <b>Description</b> | This command configures Internet Control Message Protocol (ICMP) parameters on a VPRN service. |

#### mask-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] mask-reply</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>if>icmp<br>config>service>vprn>sub-if>grp-if>icmp<br>config>service>vprn>nw-if>icmp                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables responses to Internet Control Message Protocol (ICMP) mask requests on the router interface.</p> <p>If a local node sends an ICMP mask request to the router interface, the <b>mask-reply</b> command configures the router interface to reply to the request.</p> <p>By default, the router instance will reply to mask requests.</p> <p>The <b>no</b> form of this command disables replies to ICMP mask requests on the router interface.</p> |
| <b>Default</b>     | mask-reply — specifies to reply to ICMP mask requests                                                                                                                                                                                                                                                                                                                                                                                                                    |

#### redirects

|                    |                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>redirects</b> <i>[number seconds]</i><br><b>no redirects</b>                                                                 |
| <b>Context</b>     | config>service>vprn>if>icmp<br>config>service>vprn>sub-if>grp-if>icmp<br>config>service>vprn>nw-if>icmp                         |
| <b>Description</b> | This command configures the rate for Internet Control Message Protocol (ICMP) redirect messages issued on the router interface. |

When routes are not optimal on this router and another router on the same subnetwork has a better route, the router can issue an ICMP redirect to alert the sending node that a better route is available.

The **redirects** command enables the generation of ICMP redirects on the router interface. The rate at which ICMP redirects is issued can be controlled with the optional *number* and *seconds* parameters by indicating the maximum number of redirect messages that can be issued on the interface for a given time interval.

By default, generation of ICMP redirect messages is enabled at a maximum rate of 100 per 10 second time interval.

The **no** form of this command disables the generation of icmp redirects on the router interface.

|                   |                                                                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | redirects 100 10 — maximum of 100 redirect messages in 10 seconds                                                                         |
| <b>Parameters</b> | <i>number</i> — The maximum number of ICMP redirect messages to send. This parameter must be specified with the <i>seconds</i> parameter. |
| <b>Values</b>     | 10 to 1000                                                                                                                                |
|                   | <i>seconds</i> — the time frame in seconds used to limit the <i>seconds</i> of ICMP redirect messages that can be issued                  |
| <b>Values</b>     | 1 to 60                                                                                                                                   |

| <b>Description</b> | <p>This command enables and configures the rate for ICMP host and network destination unreachable messages issued on the router interface.</p> <p>The <b>unreachables</b> command enables the generation of ICMP destination unreachables on the router interface. The rate at which ICMP unreachables is issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of destination unreachable messages which can be issued on the interface for a given time interval.</p> <p>By default, generation of ICMP destination unreachable messages is enabled at a maximum rate of 10 per 10 second time interval.</p> <p>The <b>no</b> form of this command disables the generation of icmp destination unreachable messages on the router interface.</p> |
| <b>Default</b>     | unreachables 100 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <p><i>number</i> — The maximum number of ICMP unreachable messages to send. This parameter must be specified with the <i>seconds</i> parameter.</p> <p><b>Values</b> 10 to 1000</p> <p><i>seconds</i> — the time frame in seconds used to limit the <i>number</i> of ICMP unreachable messages that can be issued</p> <p><b>Values</b> 1 to 60</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## ip-mtu

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ip-mtu</b> <i>octets</i><br><b>no ip-mtu</b>                                                       |
| <b>Context</b>     | config>service>vprn>nw-if                                                                             |
| <b>Description</b> | This command configures the IP maximum transmit unit (packet) for the associated router IP interface. |

The configured IP-MTU cannot be larger then the calculated IP MTU based on the port MTU configuration.

The MTU that is advertised from the IES size is:

MINIMUM((SdpOperPathMtu - EtherHeaderSize), (Configured ip-mtu))

The **no** form of the command returns the associated IP interfaces MTU to its default value, which is calculated based on the port MTU setting. For Ethernet ports this will typically be 1554.

**Default** no ip-mtu

**Parameters** *octets* — specifies the octets

**Values** 512 to 9000

lag

**Syntax** **lag** *lag-id[:encap-val]*  
**no lag**

**Context** config>service>vprn>nw-if

**Description** This command binds the interface to a Link Aggregation Group (LAG)

The **no** form of the command removes the LAG id from the configuration.

**Parameters** *lag-id[:encap-val]* — specifies the LAG ID

**Values**

|           |                       |
|-----------|-----------------------|
| lag-id    | 1 to 800              |
| encap-val | 0 (for null)          |
|           | 0 to 4094 (for dot1q) |

lag-per-link-hash

**Syntax** **lag-per-link-hash** class {1 | 2 | 3} weight [1 to 1024]  
**no per-link-hash**

**Context** config>service>vprn>nw-if

**Description** This command configures weight and class to this SAP to be used on LAG egress when the LAG uses weighted per-link-hash.

The **no** form of this command restores the default configuration.

**Default** no lag-per-link-hash (equivalent to weight 1 class 1)

### 3.9.2.18 Interface SAP ATM Commands

#### atm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>atm</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enables the context to configure ATM-related attributes. This command can only be used when a given context (for example, a channel or SAP) supporting ATM functionality such as:</p> <ul style="list-style-type: none"><li>• Configuring ATM port or ATM port-related functionality on MDAs supporting ATM functionality.</li><li>• Configuring ATM-related configuration for ATM-based SAPs that exist on MDAs supporting ATM functionality.</li></ul> <p>If ATM functionality is not supported for a given context, the command returns an error.</p> |

#### egress

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                               |
| <b>Context</b>     | config>service>vprn>if>sap>atm<br>config>service>vprn>sub-if>grp-if>sap>atm |
| <b>Description</b> | This command configures egress ATM attributes for the SAP.                  |

#### encapsulation

|                    |                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>encapsulation</b> <i>atm-encap-type</i>                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>if>sap>atm<br>config>service>vprn>sub-if>grp-if>sap>atm                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command configures RFC 2684, <i>Multiprotocol Encapsulation over ATM AAL5</i>, encapsulation for an ATM PVCC delimited SAP. This command specifies the data encapsulation for an ATM PVCC delimited SAP. The definition also references the ATM Forum LAN Emulation specification.</p> <p>Ingress traffic that does not match the configured encapsulation will be dropped.</p> |
| <b>Default</b>     | <p>The encapsulation is driven by the services for which the SAP is configured.</p> <p>For VPRN service SAPs, the default is <b>aal5snap-routed</b>.</p>                                                                                                                                                                                                                                |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>atm-encap-type</i> — specifies the encapsulation type                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Values</b>     | <p><b>aal5snap-routed</b> — Routed encapsulation for LLC encapsulated circuit (LLC/SNAP precedes protocol datagram) as defined in RFC 2684.</p> <p><b>aal5mux-ip</b> — Routed IP encapsulation for VC multiplexed circuit as defined in RFC 2684.</p> <p><b>aal5snap-bridged</b> — Bridged encapsulation for LLC encapsulated circuit (LLC/SNAP precedes protocol datagram) as defined in RFC 2684.</p> <p><b>aal5mux-bridged-eth-nofcs</b> — Bridged IP encapsulation for VC multiplexed circuit as defined in RFC 2684.</p> |

## ingress

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ingress</b>                                                                                                       |
| <b>Context</b>     | <pre>config&gt;service&gt;vprn&gt;if&gt;sap&gt;atm config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;sap&gt;atm</pre> |
| <b>Description</b> | This command configures ingress ATM attributes for the SAP.                                                          |

## traffic-desc

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>traffic-desc</b> <i>traffic-desc-profile-id</i><br><b>no traffic-desc</b>                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | <pre>config&gt;service&gt;vprn&gt;if&gt;sap&gt;atm&gt;egress config&gt;service&gt;vprn&gt;if&gt;sap&gt;atm&gt;ingress config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;sap&gt;atm&gt;egress config&gt;service&gt;vprn&gt;sub-if&gt;grp-if&gt;sap&gt;atm&gt;ingress</pre>                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command assigns an ATM traffic descriptor profile to a given context (for example, a SAP). When configured under the ingress context, the specified traffic descriptor profile defines the traffic contract in the forward direction. When configured under the egress context, the specified traffic descriptor profile defines the traffic contract in the backward direction.</p> <p>The <b>no</b> form of the command reverts the traffic descriptor to the default traffic descriptor profile.</p> |
| <b>Default</b>     | The default traffic descriptor (trafficDescProfileId. = 1) is associated with newly created PVCC-delimited SAPs.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>traffic-desc-profile-id</i> — specifies a defined traffic descriptor profile (see the QoS atm-td-profile command)                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.</p> <p>When alarm-cells functionality is enabled, a PVCC's operational status is affected when a PVCC goes into an AIS or RDI state because of an AIS/RDI processing (assuming nothing else affects PVCC's operational status, for example, if the PVCC goes DOWN, or enters a fault state and comes back UP, or exits that fault state). RDI cells are generated when PVCC is operationally DOWN. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).</p> <p>The <b>no</b> command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, a PVCC's operational status is no longer affected by a PVCC's OAM state changes due to AIS/RDI processing (when alarm-cells is disabled, a PVCC will change operational status to UP due to alarm-cell processing) and RDI cells are not generated as result of the PVCC going into AIS or RDI state. The PVCC's OAM status, however, will record OAM faults as described above.</p> |
| <b>Default</b>     | enabled for PVCCs delimiting VPRN SAPs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Syntax</b>      | <b>[no] periodic-loopback</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>if >sap>atm>oam<br>config>service>vprn>sub-if>grp-if>sap>atm                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables periodic OAM loopbacks on this SAP. This command is only configurable on VPRN SAPs. When enabled, an ATM OAM loopback cell is transmitted every period as configured in the config&gt;system&gt;atm&gt;oam&gt;loopback-period <i>period</i> context.</p> <p>If a response is not received and consecutive retry-down retries also result in failure, the endpoint will transition to an alarm indication signal/loss of clock state. Then, an ATM OAM loopback cell will be transmitted every period as configured in the loopback-period <i>period</i>. If a response is received for the periodic loopback and consecutive retry-up retries also each receive a response, the endpoint will transition back to the up state.</p> <p>The <b>no</b> form of the command sets the value back to the default.</p> |
| <b>Default</b>     | no periodic-loopback                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

### 3.9.2.19 Interface Anti-Spoofing Commands

## anti-spoof

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the interface.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (<b>ip</b>, <b>mac</b>, <b>ip-mac</b>, <b>nh-mac</b>) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The <b>no</b> form of the command disables anti-spoof filtering on the SAP.</p> |
| <b>Default</b>     | Filter type default types: <ul style="list-style-type: none"><li>• Non-Ethernet encapsulation default anti-spoof filter type — When enabled on a non-Ethernet encapsulated SAP, the anti-spoof filter default type is <b>ip</b>.</li><li>• Ethernet encapsulated default anti-spoof filter type — When enabled on an Ethernet encapsulated SAP, the anti-spoof default type is <b>ip-mac</b>.</li></ul>                                                                                                                                                      |

- Default anti-spoof filter state — Anti-spoof filtering is disabled by default on the SAP.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>ip</b> — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type <b>ip</b> command will fail.                                                                                                                                                                                                                                                                                              |
|                   | <b>mac</b> — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. Setting the anti-spoof filter type to <b>mac</b> is not allowed on non-Ethernet encapsulated SAPs. If a static host exists on the SAP without a specified MAC address, the anti-spoof type <b>mac</b> command will fail. The anti-spoof type <b>mac</b> command will also fail if the SAP does not support Ethernet encapsulation.                                                                              |
|                   | <b>ip-mac</b> — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the anti-spoof type <b>ip-mac</b> command will fail. This is also true if the default anti-spoof filter type of the SAP is <b>ip-mac</b> and the default is not overridden. The anti-spoof type <b>ip-mac</b> command will also fail if the SAP does not support Ethernet encapsulation. |
|                   | <b>nh-mac</b> — Indicates that the ingress anti-spoof is based on the source MAC address and the egress anti-spoof is based on the nh-ip-address.                                                                                                                                                                                                                                                                                                                                                                  |

## app-profile

|                    |                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                                                                               |
| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                               |
| <b>Description</b> | This command configures the application profile name.                                                                                             |
| <b>Parameters</b>  | <i>app-profile-name</i> — specifies an existing application profile name configured in the <b>config&gt;app-assure&gt;group&gt;policy</b> context |

## arp-limit

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-limit</b> <i>limit</i> [ <b>log-only</b> ] [ <b>threshold</b> <i>percent</i> ]<br><b>no arp-limit</b>                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>interface                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command configures the maximum amount of dynamic IPv4 ARP entries that can be learned on an IP interface.</p> <p>When the number of dynamic ARP entries reaches the configured percentage of this limit, an SNMP trap is sent. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations will be dropped. Entries that have already been learned will be refreshed.</p> |

The **no** form of the command removes the **arp-limit**.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 90 percent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b> | <p><b>log-only</b> — Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit will be learned.</p> <p><i>percent</i> — The threshold value (as a percentage) that triggers a warning message to be sent.</p> <p><b>Values</b>      0 — 100</p> <p><i>limit</i> — The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic ARP learning is disabled and no dynamic ARP entries are learned.</p> <p><b>Values</b>      0 — 524288</p> |

| <b>Syntax</b>      | <b>[no] arp-populate</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>if<br>config>service>vprn>sub-if>subscriber-interface<br>config>service>vprn>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables populating static and dynamic hosts into the system ARP cache. When enabled, the host's IP address and MAC address are placed in the system ARP cache as a managed entry. Static hosts must be defined on the interface using the <b>host</b> command. Dynamic hosts are enabled on the system through enabling lease-populate in the IP interface DHCP context. In the event that both a static host and a dynamic host share the same IP and MAC address, the system's ARP cache retains the host information until both the static and dynamic information are removed. Both static and dynamic hosts override static ARP entries. Static ARP entries are marked as inactive when they conflict with static or dynamic hosts and will be repopulated once all static and dynamic host information for the IP address are removed. Since static ARP entries are not possible when static subscriber hosts are defined or when DHCP lease state table population is enabled, conflict between static ARP entries and the arp-populate function is not an issue.</p> <p>The <b>arp-populate</b> command will fail if an existing static subscriber host on the SAP does not have both MAC and IP addresses specified.</p> <p>Once <b>arp-populate</b> is enabled, creating a static subscriber host on the SAP without both an IP address and MAC address will fail.</p> <p><b>arp-populate</b> can only be enabled on VPRN interfaces supporting Ethernet encapsulation.</p> |

Use the **no** form of the command to disable ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information in the systems ARP cache will be removed. Any existing static ARP entries previously inactive due to static or dynamic hosts will be populated in the system ARP cache.

When **arp-populate** is enabled, the system will not send out ARP Requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with arp-populate enabled.

**Default** not enabled

## arp-retry-timer

**Syntax** **arp-retry-timer** *timer-multiple*  
**no arp-retry-timer**

**Context** config>service>vprn>if  
config>service>vprn>network-interface

**Description** This command allows the arp retry timer to be configured to a specific value.

The timer value is entered as a multiple of 100 ms. So a timer value of 1, means the ARP timer will be set to 100 ms.

The **no** form of this command removes the command from the active configuration and returns the ARP retry timer to its default value of 5 s.

**Default** 5 seconds

**Parameters** *timer-multiple* — specifies the multiple of 100 ms that the ARP retry timer will be configured as.

**Values** 1 to 300 (equally a timer range of 100 ms to 30 000 ms)

## arp-timeout

**Syntax** **arp-timeout** *seconds*  
**no arp-timeout**

**Context** config>service>vprn>if  
config>service>vprn>sub-if>grp-if

**Description** This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If **arp-timeout** is set to a value of zero seconds, ARP aging is disabled.

The **no** form of this command restores **arp-timeout** to the default value.

|                   |                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | 14400 seconds                                                                                                                                                                                                                         |
| <b>Parameters</b> | <i>seconds</i> — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged. |
| <b>Values</b>     | 0 to 65535                                                                                                                                                                                                                            |

## authentication-policy

|                    |                                                                                                                                                                                   |

| <b>Description</b> | <p>This command creates a static host for the SAP. Applications within the system that make use of static host entries include anti-spoof, and source MAC population into the VPLS forwarding database.</p> <p>Multiple static hosts can be defined on the SAP. Each host is identified by a source IP address, a source MAC address, or both a source IP and source MAC address. When anti-spoof is enabled on the SAP, the host information will be populated into the SAP's anti-spoof table, allowing ingress packets matching the entry access to the SAP. When the MAC address exists in the host definition, the MAC address is populated into the VPLS forwarding database and associates it with the SAP. The static host definition overrides any static MAC entries using the same MAC and prevents dynamic learning of the MAC on another interface.</p> <p>Defining a static host identical to an existing static host has no effect and will not generate a log or error message.</p> <p>Every static host definition must have at least one address defined, IP or MAC.</p> <p>Static hosts may exist on the SAP even with anti-spoof and <b>arp-populate</b> (VPRN) features disabled. When enabled, each feature has different requirements for static hosts.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>     | There are no default static entries.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><b>anti-spoof</b> — When enabled, this feature uses static and dynamic host information to populate entries into an anti-spoof filter table. The anti-spoof filter entries generated will be of the same type as specified in the anti-spoof type parameter. If the SAP anti-spoof filter is defined as mac, each static host definition must specify a MAC address. If the SAP anti-spoof filter is defined as ip, each static host definition must specify an IP address. If the SAP anti-spoof filter is defined as ip-mac, each static host definition must specify both an IP address and MAC address. If definition of a static host is attempted without the appropriate addresses specified for the enabled anti-spoof filter, the static host definition will fail.</p> <p><b>arp-populate</b> — When enabled, this feature uses static and dynamic host information to populate entries into the system's ARP cache. This is only available on the VPRN service SAPs. Both a MAC address and IP address are required to populate an ARP entry in the system. If definition of a static host is attempted without both a MAC and IP address specified when arp -populate is enabled, the static host definition will fail.</p> <p><b>fdb-populate</b> — This is an implicit feature that uses the static host definition as a static MAC in the VPLS forwarding database. It cannot be enabled or disabled and has no effect on the ability to create static hosts without a MAC address specified. When a MAC address is specified for a static host, it will automatically be populated into the VPLS forwarding database associated with the SAP on which the host is created. The static host MAC address will override any static MAC entries using the same MAC and prevent dynamic learning of the MAC on another interface. Existing static MAC entries with the same MAC address as a static host are marked as inactive but not deleted. If all static hosts are removed from the SAP, the static MAC may be populated. New static MAC definitions for the VPLS instance may be created while a static host exists associated with the static MAC address.</p> |

The **no** form of the command removes a static entry from the system. The specified **ip address** and **mac address** must match the host's exact IP and MAC addresses as defined when it was created. When a static host is removed from the SAP, the affect of its removal on the anti-spoof filter, ARP cache or the VPLS forwarding database is also evaluated.

**ip ip-address** — Specifies this optional parameter when defining a static host. The IP address must be specified for **anti-spoof ip** and **anti-spoof ip-mac** commands. Only one static host can be configured on the SAP with a given IP address.

The following rules apply to configure static hosts using an IP address:

- Only one static host can be defined using a specific IP address.
- Defining a static host with the same IP address as a previous static host overwrites the previous static host.
- If a static host has an IP address assigned, the MAC address for the host is optional (depending on the features enabled on the SAP).

**mac mac-address** — Specifies this optional parameter when defining a static host. The MAC address must be specified for **anti-spoof mac**, and **anti-spoof ip-mac**. Multiple static hosts may be configured with the same MAC address given that each definition is distinguished by a unique IP address. The following rules apply to configuring static hosts using a MAC address:

- Multiple static hosts may share the same MAC address.
- Executing the host command with the same MAC address but a different IP address as an existing static host will create a new static host.
- If a static host has a MAC address assigned, the IP address for the host is optional (depending on the features enabled on the SAP).

**Values**      8k static and dynamic hosts per 10G forwarding complex.  
64k8k per system.

**subscriber sub-ident-string** — This optional parameter specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the **config>subscr-mgmt>sub-ident-policy** context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.

- For VPRN SAPs with **arp-reply-agent** enabled with the optional **sub-ident** parameter, the static subscriber host's sub-ident-string is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.

If the static subscriber host's **sub-ident** string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.

If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.

If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.

ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.

**sub-profile** *sub-profile-name* — Specifies this optional parameter to specify an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.

**sla-profile** *sla-profile-name* — Specifies this optional parameter to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.

## frame-relay

| <b>Context</b>     | config>service>vprn>if>sap>frame-relay>frf.12                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables interleaving of high priority frames and low-priority frame fragments within a FR SAP using FRF.12 end-to-end fragmentation.</p> <p>When this option is enabled, only frames of the FR SAP non expedited forwarding class queues are subject to fragmentation. The frames of the FR SAP expedited queues are interleaved, with no fragmentation header, among the fragmented frames. In effect, this provides a behavior like in MLPPP Link Fragment Interleaving (LFI).</p> <p>When this option is disabled, frames of all the FR SAP forwarding class queues are subject to fragmentation. The fragmentation header is however not included when the frame size is smaller than the user configured fragmentation size. In this mode, the SAP transmits all fragments of a frame before sending the next full or fragmented frame.</p> <p>The receive direction of the FR SAP supports both modes of operation concurrently, with and without fragment interleaving.</p> <p>The <b>no</b> form of this command restores the default mode of operation.</p> |
| <b>Default</b>     | no interleave                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## scheduling-class

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|

| <b>Syntax</b>      | <b>ip-tunnel</b> <i>name</i> [create]<br><b>no ip-tunnel</b> <i>name</i>                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>if>sap                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command is used to configure an IP-GRE or IP-IP tunnel and associate it with a private tunnel SAP within an IES or VPRN service.<br><br>The no form of the command deletes the specified IP/GRE or IP-IP tunnel from the configuration. The tunnel must be administratively shutdown before issuing the no ip-tunnel command. |
| <b>Default</b>     | No IP tunnels are defined.                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>ip-tunnel-name</i> — Specifies the name of the IP tunnel. Tunnel names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.                                                                                  |

## backup-remote-ip

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service>interface>vprn>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command sets the source IPv4 address of GRE encapsulated packets associated with a particular GRE tunnel. It must be an address in the subnet of the associated public tunnel SAP interface. The GRE tunnel does not come up until a valid source address is configured.</p> <p>The <b>no</b> form of the command deletes the source address from the GRE tunnel configuration. The tunnel must be administratively shutdown before issuing the <b>no source</b> command.</p> |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the source IPv4 address of the GRE tunnel                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Values</b>      | 1.0.0.0 to 223.255.255.255                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**remote-ip**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>remote-ip</b> <i>ip-address</i><br><b>no remote-ip</b>                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>interface>vprn>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command sets the primary destination IPv4 address of GRE encapsulated packets associated with a particular GRE tunnel. If this address is reachable in the delivery service (there is a route) then this is the destination IPv4 address of GRE encapsulated packets sent by the delivery service.</p> <p>The <b>no</b> form of the command deletes the destination address from the GRE tunnel configuration.</p> |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the destination IPv4 address of the GRE tunnel                                                                                                                                                                                                                                                                                                                                               |
| <b>Values</b>      | 1.0.0.0 to 223.255.255.255                                                                                                                                                                                                                                                                                                                                                                                                 |

### 3.9.2.20 Interface SAP Filter and QoS Policy Commands

**egress**

|                |                                                                     |
|----------------|---------------------------------------------------------------------|
| <b>Syntax</b>  | <b>egress</b>                                                       |
| <b>Context</b> | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap |

**Description** This command enables the context to configure egress SAP Quality of Service (QoS) policies and filter policies.

If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing. If no egress filter is defined, no filtering is performed.

## ingress

**Syntax** **ingress**

**Context** config>service>vprn>if>sap  
config>service>vprn>sub-if>grp-if>sap

**Description** This command enables the context to configure ingress SAP Quality of Service (QoS) policies and filter policies.

If no sap-ingress QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing. If no ingress filter is defined, no filtering is performed.

## agg-rate

**Syntax** **[no] agg-rate**

**Context** config>service>vprn>if>sap>egress  
config>service>vprn>sub-if>grp-if>sap>egress

**Description** This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: **rate**, **limit-unused-bandwidth**, and **queue-frame-based-accounting**.

## limit-unused-bandwidth

**Syntax** **[no] limit-unused-bandwidth**

**Context** config>service>vprn>if>sap>egress>agg-rate  
config>service>vprn>sub-if>grp-if>sap>egress

**Description** This command is used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

## queue-frame-based-accounting

**Syntax** **[no] queue-frame-based-accounting**

**Context** config>service>vprn>if>sap>egress>agg-rate

```
config>service>vprn>sub-if>grp-if>sap>egress
```

**Description** This command is used to enabled (or disable) frame based accounting on all policers and queues associated with the agg-rate context. Only supported on Ethernet ports. Not supported on HSMDA Ethernet ports. Packet byte offset settings are not included in the applied rate when queue frame-based accounting is configured; the offsets are applied to the statistics.

## rate

**Syntax** **rate {max | rate}**  
**no rate**

**Context** config>service>vprn>if>sap>egress>agg-rate  
config>service>vprn>sub-if>grp-if>sap>egress

**Description** This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered to be active on the context's object (SAP, subscriber, VPORT etc.).

## agg-rate-limit

**Syntax** **agg-rate-limit agg-rate [queue-frame-based-accounting]**  
**no agg-rate-limit**

**Context** config>service>vprn>sub-if>grp-if>wlan-gw>egress

**Description** This command defines a maximum total rate for all egress queues on a service SAP or multi-service site. The **agg-rate-limit** command is mutually exclusive with the egress scheduler policy. When an egress scheduler policy is defined, the **agg-rate-limit** command will fail. If the **agg-rate-limit** command is specified, an attempt to bind a **scheduler-policy** to the SAP or multi-service site will fail.

A multi-service site must have a port scope defined that ensures all queues associated with the site are on the same port or channel. If the scope is not set to a port, the agg-rate-limit command will fail. Once an agg-rate-limit has been assigned to a multi-service site, the scope cannot be changed to card level.

A port scheduler policy must be applied on the egress port or channel the SAP or multi-service site is bound to in order for the defined agg-rate-limit to take effect. The egress port scheduler enforces the aggregate queue rate as it distributes its bandwidth at the various port priority levels. The port scheduler stops offering bandwidth to member queues once it has detected that the aggregate rate limit has been reached.

If a port scheduler is not defined on the egress port, the queues are allowed to operate based on their own bandwidth parameters.

The **no** form of the command removes the aggregate rate limit from the SAP or multi-service site.

**Parameters** *agg-rate* — defines the rate, in kilobits-per-second, that the maximum aggregate rate that the queues on the SAP or multi-service site can operate

**Values** 1 to 40000000, max

**queue-frame-based-accounting** — This keyword enables frame based accounting on all queues associated with the SAP or Multi-Service Site. If frame based accounting is required when an aggregate limit is not necessary, the max keyword should precede the queue-frame-based-accounting keyword. If frame based accounting must be disabled, execute *agg-rate-limit* without the queue-frame-based-accounting keyword present.

**Default** Frame based accounting is disabled by default.

## filter

**Syntax** **filter ip** *ip-filter-id*  
**no filter**

**Context** config>service>vprn>if>sap>egress  
config>service>vprn>if>sap>ingress  
config>service>vprn>sub-if>grp-if>sap>egress

**Description** This command associates an IP filter policy with an ingress or egress Service Access Point (SAP) or IP interface. Filter policies control the forwarding and dropping of packets based on IP matching criteria.

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress SAP. The *ip-filter-id* must already be defined before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

**Parameters** **ip** *ip-filter-id* — Specifies IP filter policy. The filter ID must already exist within the created IP filters.

**Values** 1 to 65535

## policer-control-policy

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>policer-control-policy</b> <i>policy-name</i><br><b>no policer-control-policy</b>        |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap>egress                                                |
| <b>Description</b> | This command is used to specify a policer control policy to apply to SAP egress.            |
| <b>Default</b>     | N/A                                                                                         |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies the name of a policer control policy. 32 characters maximum. |

## hsmda-queue-override

|                    |                                                                      |
|--------------------|----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] hsmda-queue-override</b>                                     |
| <b>Context</b>     | config>service>vprn>if>sap>egress                                    |
| <b>Description</b> | This command enables the context to configure HSMDA queue overrides. |

## queue

|                    |                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>queue</b> <i>queue-id</i> [ <b>create</b> ]<br><b>no queue</b> <i>queue-id</i>                                                                                     |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider                                                                                                                |
| <b>Description</b> | This command configures overrides for a HSMDA queue. The actual valid values are those defined in the given SAP QoS policy.                                           |
| <b>Parameters</b>  | <i>queue-id</i> — specifies the queue ID to override<br><br><b>Values</b> 1 to 8<br><br><b>create</b> — This keyword is mandatory when creating a new queue override. |

## packet-byte-offset

|                |                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>packet-byte-offset</b> { <b>add</b> <i>add-bytes</i>   <b>subtract</b> <i>sub-bytes</i> }<br><b>no packet-byte-offset</b> |
| <b>Context</b> | config>service>vprn>if>sap>egress>hsmda-queue-overider                                                                       |

**Description** This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSMDA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4 byte CRC (everything except the preamble and inter-frame gap). As an example, the packet-byte-offset command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions.

The accounting functions affected include:

- Offered High Priority / In-Profile Octet Counter
- Offered Low Priority / Out-of-Profile Octet Counter
- Discarded High Priority / In-Profile Octet Counter
- Discarded Low Priority / Out-of-Profile Octet Counter
- Forwarded In-Profile Octet Counter
- Forwarded Out-of-Profile Octet Counter
- Peak Information Rate (PIR) Leaky Bucket Updates
- Committed Information Rate (CIR) Leaky Bucket Updates
- Queue Group Aggregate Rate Limit Leaky Bucket Updates

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. Up to 31 bytes may be added to the packet and up to 32 bytes may be removed from the packet. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As inferred above, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. The packet-byte-offset, when set, applies to all queues in the queue group. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscriber's packets on an Ethernet aggregation network.

The packet-byte-offset value may be overridden at the queue-group level.

**Parameters** **add** *add-bytes* — Indicates that the byte value should be added to the packet for queue and queue group level accounting functions. Either the **add** or **subtract** keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command. The **add** keyword is mutually exclusive with the **subtract** keyword.

**Values** 0 to 31

**subtract** *sub-bytes* — Indicates that the byte value should be subtracted from the packet for queue and queue group level accounting functions. The **subtract** keyword is mutually exclusive with the **add** keyword. Either the **add** or **subtract** keyword must be specified. The corresponding byte value must be specified when executing the packet-byte-offset command.

**Values** 1 to 64

## slope-policy

| <b>Description</b> | This command assigns the weight value to the HSMDA queue.<br><br>The <b>no</b> form of the command returns the weight value for the queue to the default value. |
| <b>Parameters</b>  | <i>percentage</i> — specifies the weight for the HSMDA queue<br><br><b>Values</b> 1 to 32                                                                       |

## wrr-policy

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>wrr-policy</b> <i>hsmda-wrr-policy-name</i><br><b>no wrr-policy</b>                                          |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider                                                          |
| <b>Description</b> | This command associates an existing HSMDA weighted-round-robin (WRR) scheduling loop policy to the HSMDA queue. |
| <b>Parameters</b>  | <i>hsmda-wrr-policy-name</i> — specifies the existing HSMDA WRR policy name to associate to the queue           |

## secondary-shaper

|                    |                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary-shaper</b> <i>secondary-shaper-name</i><br><b>no secondary-shaper</b>                           |
| <b>Context</b>     | config>service>vprn>if>sap>egress>hsmda-queue-overider                                                       |
| <b>Description</b> | This command configures an HSMDA secondary shaper. A shaper override can only be configured on an HSMDA SAP. |
| <b>Parameters</b>  | <i>secondary-shaper-name</i> — specifies a secondary shaper name up to 32 characters in length               |

## policer-override

|                    |                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] policer-override</b>                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>if>sap>egress<br>config>service>vprn>if>sap>ingress                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command, within the SAP ingress or egress contexts, is used to create a CLI node for specific overrides to one or more policers created on the SAP through the sap-ingress or sap-egress QoS policies.</p> <p>The <b>no</b> form of the command is used to remove any existing policer overrides.</p> |
| <b>Default</b>     | no policer-override                                                                                                                                                                                                                                                                                           |

## policer

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>policer</b> <i>policer-id</i> <b>[create]</b><br><b>no policer</b> <i>policer-id</i>                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>if>sap>egress>policer-override<br>config>service>vprn>if>sap>ingress>policer-override                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command, within the SAP ingress or egress contexts, is used to create a CLI node for specific overrides to a specific policer created on the SAP through a sap-ingress or sap-egress QoS policy.</p> <p>The <b>no</b> form of the command is used to remove any existing overrides for the specified policer-id.</p>                                                                                                                                    |
| <b>Parameters</b>  | <i>policer-id</i> — This parameter is required when executing the policer command within the policer-override context. The specified <i>policer-id</i> must exist within the sap-ingress or sap-egress QoS policy applied to the SAP. If the policer is not currently used by any forwarding class or forwarding type mappings, the policer will not actually exist on the SAP. This does not preclude creating an override context for the <i>policer-id</i> . |

**create** — The create keyword is required when a policer override node is being created and the system is configured to expect explicit confirmation that a new object is being created. When the system is not configured to expect explicit configuration, the **create** keyword is not required.

## match-qinq-dot1p

|                    |                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>match-qinq-dot1p {top   bottom}</b><br><b>no match-qinq-dot1p</b>                                                                          |
| <b>Context</b>     | config>service>vprn>if>sap>ingress<br>config>service>vprn>sub-if>grp-if>sap>ingress                                                           |
| <b>Description</b> | This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification. |

The **match-qinq-dot1p** command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The **top** and **bottom** keywords specify which position should be evaluated for QinQ encapsulated packets.

The **no** form of the command restores the default dot1p evaluation behavior for the SAP.

By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. [Table 40](#) defines the default behavior for Dot1P evaluation when the **match-qinq-dot1p** command is not executed.

**Table 40** Dot1P Default Behavior

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| null            | none                          | none                 |
| null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| null            | —                             | Dot1Q PBits          |
| null            | TopQ BottomQ                  | TopQ PBits           |
| null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | none (Default SAP)            | none                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

- Default** no match-qinq-dot1p - No filtering based on p-bits.
- top or bottom must be specified to override the default Qinq dot1p behavior.
- Parameters** **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 41](#) defines the dot1p evaluation behavior when the top parameter is specified.

**Table 41** Dot1P Evaluation Behavior

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| null            | none                          | none                 |
| null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| null            | Dot1Q                         | Dot1Q PBits          |
| null            | TopQ BottomQ                  | TopQ PBits           |
| null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | none (Default SAP)            | none                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| Qinq / TopQ     | TopQ                          | TopQ PBits           |
| Qinq / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| Qinq / TopQ     | TopQ BottomQ                  | TopQ PBits           |

**bottom** — The bottom parameter is mutually exclusive to the top parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. The following tables define the bottom position Qinq and TopQ SAP dot1p evaluation and the default dot1p explicit marking actions.

**Table 42** Bottom Position Qinq and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags | PBits Used for Match |
|-----------------|----------------------|----------------------|
| null            | none                 | none                 |
| null            | Dot1P (VLAN-ID 0)    | Dot1P PBits          |
| null            | Dot1Q                | Dot1Q PBits          |
| null            | TopQ BottomQ         | BottomQ PBits        |
| null            | TopQ (No BottomQ)    | TopQ PBits           |

**Table 42** Bottom Position QinQ and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|

| <b>Description</b> | When enabled (the encapsulation type of the access port where this SAP is defined as qinq), the <b>qinq-mark-top-only</b> command specifies which P-bits/DEI bit to mark during packet egress. When disabled, both set of P-bits/DEI bit are marked. When the enabled, only the P-bits/DEI bit in the top Q-tag are marked. |
| <b>Default</b>     | no qinq-mark-top-only                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command associates a Quality of Service (QoS) policy with an ingress or egress Service Access Point (SAP).</p> <p>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP or IP interface. If the policy- id does not exist, an error will be returned.</p> <p>The qos command is used to associate both ingress and egress QoS policies. The qos command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>By default, no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.</p> <p>The <b>no</b> form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>policy-id</i> — The ingress/egress policy ID to associate with SAP or IP interface on ingress/egress. The policy ID must already exist.</p> <p><b>Values</b> 1 to 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

*port-redirect-group* — This keyword associates a SAP egress with an instance of a named queue group template on the egress port of a given IOM/IMM/XMA. The queue-group-name and instance instance-id are mandatory parameters when executing the command.

*queue-group-name* — Specifies the name of the egress port queue group of the IOM/IMM/XMA, up to 32 characters in length. The queue-group-name must correspond to a valid egress queue group, created under config>port>ethernet>access>egress.

**instance** *instance-id* — specifies the instance of the named egress port queue group on the IOM/IMM/XMA

**Values** 1 to 40960

**Default** 1

| <b>Description</b> | <p>This command associates a Quality of Service (QoS) policy with an ingress Service Access Point (SAP).</p> <p>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the policy- id does not exist, an error will be returned.</p> <p>The qos command is used to associate both ingress and egress QoS policies. The qos command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>By default, no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.</p> <p>The no form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>policy-id</i> — The ingress/egress policy ID to associate with SAP or IP interface on ingress/egress. The policy ID must already exist.</p> <p><b>Values</b> 1 to 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**shared-queuing** — Specifies the ingress shared queue policy used by this SAP. When the value of this object is null it means that the SAP will use individual ingress QoS queues instead of the shared ones.

**multipoint-shared** — Specifies that this *queue-id* is for multipoint forwarded traffic only. This *queue-id* can only be explicitly mapped to the forwarding class multicast, broadcast, or unknown unicast ingress traffic. Attempting to map forwarding class unicast traffic to a multipoint queue generates an error; no changes are made to the current unicast traffic queue mapping.

A queue must be created as multipoint. The **multipoint** designator cannot be defined after the queue is created. If an attempt is made to modify the command to include the **multipoint** keyword, an error is generated and the command will not execute.

The **multipoint** keyword can be entered in the command line on a pre-existing multipoint queue to edit *queue-id* parameters.

**Default** Present (the queue is created as non-multipoint).

**Values** Multipoint or not present.

**fp-redirect-group** — Creates an instance of a named queue group template on the ingress forwarding plane of a given IOM/IMM/XMA. The queue-group-name and instance-id are mandatory parameters when executing the command. The named queue group template can contain only policers. If it contains queues, then the command will fail.

*queue-group-name* — Specifies the name of the queue group template to be instantiated on the forwarding plane of the IOM/IMM/XMA, up to 32 characters in length. The queue-group-name must correspond to a valid ingress queue group template name, configured under *config>qos>queue-group-templates*.

*instance-id* — specifies the instance of the named queue group to be created on the IOM/IMM/XMA ingress forwarding plane

## scheduler-policy

| <b>Context</b>     | config>service>vprn>if>sap>ingress<br>config>service>vprn>if>sap>egress<br>config>service>vprn>sub-if>grp-if>sap>egress<br>config>service>vprn>sub-if>grp-if>sap>ingress                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP policers and queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created once the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the <b>config&gt;qos&gt;scheduler-policy</b> <i>scheduler-policy-name</i> context. |

The **no** form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the SAP policers and queues associated with the customer site. Policers and queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have policers and queues that rely on the removed schedulers enter into an operational state depicting the orphaned status of one or more policers and queues. When the **no scheduler-policy** command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.

**Parameters**    *scheduler-policy-name*: — The *scheduler-policy-name* parameter applies an existing scheduler policy that was created in the **config>qos>scheduler-policy scheduler-policy-name** context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues created on associated SAPs.

**Values**        any existing valid scheduler policy name

ipsec-gw

**Syntax**        **ipsec-gw** *name*  
                  **no ipsec-gw**

**Context**        config>service>vprn>if>sap

**Description**    This command configures the IPSec gateway.

**Parameters**    *name* — specifies the IPSec gateway name up to 32 characters in length

cert

**Syntax**        **cert**

**Context**        config>service>vprn>if>sap>ipsec-gw

**Description**    This command enables the context to configure certificate parameters.

cert

**Syntax**        **cert** *filename*  
                  **no cert**

**Context**        config>service>vprn>if>sap>ipsec-gw>cert

**Description**    This command configures the cert with local file URL.

**Default**        n/a

| <b>Syntax</b>      | <b>cert-profile</b> <i>profile-name</i><br><b>no cert-profile</b>                                                                                                       |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw>cert<br>config>service>vprn>if>sap>ipsec-tun>dyn>cert                                                                               |
| <b>Description</b> | This command specifies the cert-profile for the ipsec-tunnel or ipsec-gw. This command will override “cert” and “key” configuration under the ipsec-tunnel or ipsec-gw. |
| <b>Default</b>     | n/a                                                                                                                                                                     |
| <b>Parameters</b>  | <i>profile-name</i> — specifies the name of cert-profile                                                                                                                |

## key

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>key</b> <i>filename</i><br><b>no key</b>                                                                           |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw>cert                                                                              |
| <b>Description</b> | This command configures the key-pair file to be used for X.509 certificate authentication with this SAP IPSec tunnel. |
| <b>Default</b>     | n/a                                                                                                                   |
| <b>Parameters</b>  | <i>filename</i> — specifies a key with the CA profile                                                                 |

## trust-anchor

|                    |                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>trust-anchor</b> <i>ca-profile-name</i><br><b>no trust-anchor</b>                                              |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw>cert                                                                          |
| <b>Description</b> | This command configures the Certificate-Authority Profile name associated with this SAP IPSec tunnel certificate. |
| <b>Default</b>     | n/a                                                                                                               |
| <b>Parameters</b>  | <i>ca-profile-name</i> — specifies a CA profile name up to 32 characters in length                                |

## default-secure-service

|                    |                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-secure-service</b> <i>service-id</i> <b>interface</b> <i>ip-int-name</i><br><b>no default-secure-service</b>                                                                                            |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw                                                                                                                                                                                |
| <b>Description</b> | This command specifies a service ID or service name of the default security service used by this SAP IPsec gateway.                                                                                                |
| <b>Parameters</b>  | <i>service-id</i> — specifies a default secure service<br><br><div> <b>Values</b> <i>service-id</i>: 1 to 2147483648<br/> <i>svc-name</i>: specifies an existing service name up to 64 characters in length </div> |

## default-tunnel-template

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-tunnel-template</b> <i>ipsec template identifier</i><br><b>no default-tunnel-template</b> |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw                                                                  |
| <b>Description</b> | This command configures the default tunnel policy template for the gateway.                          |
| <b>Parameters</b>  | <i>ipsec template id*</i> — [1 to 2048]                                                              |

## ike-policy

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ike-policy</b> <i>ike-policy-id</i><br><b>no ike-policy</b>                                 |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw<br>config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying  |
| <b>Description</b> | This command configures the IKE policy for the gateway.                                        |
| <b>Parameters</b>  | <i>ike-policy-id</i> — specifies the IKE policy ID<br><br><div> <b>Values</b> 1 to 2048 </div> |

## local-gateway-address

|                |                                                                                   |
|----------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>local-gateway-address</b> <i>ip-address</i><br><b>no local-gateway-address</b> |
| <b>Context</b> | config>service>vprn>if>sap>ipsec-gw                                               |

---

|                    |                                                          |
|--------------------|----------------------------------------------------------|
| <b>Description</b> | This command configures the ipsec-gateway local address. |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP unicast address     |

## local-id

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-id type {ipv4   fqdn} [value [value]]</b><br><b>no local-id</b>                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command specifies the local ID of the router used for IDi or IDr for IKEv2 tunnels. The local-id can only be changed or removed when tunnel or gateway is shutdown.<br><br>Default: Depends on local-auth-method such as: <ul style="list-style-type: none"> <li>• Psk: local tunnel ip address</li> <li>• Cert-auth: subject of the local certificate</li> </ul>                                                                                                                      |
| <b>Parameters</b>  | <b>type</b> — specifies the type of local ID payload, it could be ipv4 address/FQDN domain name/distinguish name of subject in X.509 certificate.<br><br><b>Values</b> <ul style="list-style-type: none"> <li>ipv4 — Use ipv4 as the local ID type, the default value is the local tunnel end-point address.</li> <li>fqdn — Use FQDN as the local ID type, the value must be configured.</li> <li>dn — Use the subject of the certificate configured for the tunnel or gateway.</li> </ul> |

## pre-shared-key

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pre-shared-key key</b><br><b>no pre-shared-key</b>                                         |
| <b>Context</b>     | config>service>vprn>if>sap>ipsec-gw<br>config>service>vprn>if>sap>ipsec-tunnel>dynamic-keying |
| <b>Description</b> | This command specifies the shared secret between the two peers forming the tunnel.            |
| <b>Parameters</b>  | <i>key</i> — specifies a pre-shared-key for dynamic-keying                                    |

## radius-accounting-policy

|                |                                                                                   |
|----------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>radius-accounting-policy policy-name</b><br><b>no radius-accounting-policy</b> |
| <b>Context</b> | config>service>vprn>if>sap>ipsec-gw                                               |

```
config>service>vprn>l2tp
config>service>vprn>l2tp>group
config>service>vprn>l2tp>group>tunnel
```

**Description** This command configures the radius-accounting-policy.

**Parameters** *policy-name* — 32 characters maximum

## radius-authentication-policy

**Syntax** **radius-authentication-policy** *name*  
**no radius-authentication-policy**

**Context** config>service>vprn>if>sap>ipsec-gw

**Description** This command configures the radius-authentication-policy.

**Parameters** *name* — 32 characters maximum

## lag-link-map-profile

**Syntax** **lag-link-map-profile** *link-map-profile-id*  
**no lag-link-map-profile**

**Context** config>service>vprn>if>sap  
config>service>vprn> sub-if>grp-if >sap

**Description** This command assigns a pre-configured lag link map profile to a SAP/network interface configured on a LAG or a PW port that exists on a LAG. Once assigned/de-assigned, the SAP/network interface egress traffic will be re-hashed over LAG as required by the new configuration.

The **no** form of this command reverts the SAP/network interface to use per-flow, service or link hash as configured for the service/LAG.

**Default** **no lag-link-map-profile**

**Parameters** *link-map-profile-id* — an integer from 1 to 64 that defines a unique lag link map profile on which the LAG the SAP/network interface exist

## multi-service-site

**Syntax** **multi-service-site** *customer-site-name*  
**no multi-service-site** *customer-site-name*

**Context** config>service>vprn>if>sap  
config>service>vprn>sub-if>grp-if>sap

**Description** This command creates a new customer site or edits an existing customer site with the *customer-site-name* parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. When a site is created, it must be assigned to a chassis slot or port on the 7750 SR. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).

The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object will generate a log message indicating that the association was deleted due to scheduler policy removal.

When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at any time.

**Default** n/a — Each customer site must be explicitly created.

**Parameters** *customer-site-name* — Each customer site must have a unique name within the context of the customer. If *customer-site-name* already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site will affect all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing policers and queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing policers and queues relying on that scheduler to be orphaned.

If the *customer-site-name* does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:

- The maximum number of customer sites defined for the chassis slot has not been met.
- The *customer-site-name* is valid.
- The **create** keyword is included in the command line syntax (if the system requires it).

When the maximum number of customer sites has been exceeded a configuration error occurs; the command will not execute and the CLI context will not change.

If the *customer-site-name* is invalid, a syntax error occurs; the command will not execute and the CLI context will not change.

**Values** Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes.

## static-host

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn>if>sap<br>config>service>vprn>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command configures a static host on this SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><b>ip</b> <i>ip-address</i> — specifies the IPv4 unicast address</p> <p><b>mac</b> <i>ieee-address</i> — Specifies this optional parameter when defining a static host. Every static host definition must have at least one address defined, IP or MAC.</p> <p><b>force</b> — specifies the forced removal of the static host addresses</p> <p><b>sla-profile</b> <i>sla-profile-name</i></p> <p>This optional parameter is used to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> |

## ancp-string

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancp-string</b> <i>ancp-string</i><br><b>no ancp-string</b>                              |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host |
| <b>Description</b> | This command specifies the ANCP string associated to this SAP host.                         |
| <b>Parameters</b>  | <b>ancp-string</b> — specifies the ANCP string up to 63 characters in length                |

## app-profile

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                            |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host    |
| <b>Description</b> | This command specifies an application profile name.                                            |
| <b>Parameters</b>  | <b>app-profile-name</b> — specifies the application profile name up to 32 characters in length |

## inter-dest-id

|                    |                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inter-dest-id</b> <i>intermediate-destination-id</i><br><b>no inter-dest-id</b>                |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host       |
| <b>Description</b> | This command specifies to which intermediate destination (for example a DSLAM) this host belongs. |
| <b>Parameters</b>  | <i>intermediate-destination-id</i> — specifies the intermediate destination ID                    |

## managed-routes

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>managed-routes</b>                                            |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap>static-host>managed-routes |
| <b>Description</b> | This command configures managed routes.                          |

## route

|                    |                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>route</b> { <i>ip-prefix/length</i>   <i>ip-prefix netmask</i> } [ <b>create</b> ]<br><b>no route</b> { <i>ip-prefix/length</i>   <i>ip-prefix netmask</i> }                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap>static-host>managed-routes                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command assigns managed-route to a given subscriber-host. As a consequence, a static route pointing subscriber-host ip address as a next hop will be installed in FIB. Up to 16 managed routes per subscriber-host can be configured.</p> <p>The <b>no</b> form of the command removes the respective route. Per default, there are no managed-routes configured.</p> |

## sla-profile

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sla-profile</b> <i>sla-profile-name</i><br><b>no sla-profile</b>                                                                                                                             |
| <b>Context</b>     | config>service>vprn>if>sap>static-host<br>config>service>vprn>sub-if>grp-if>sap>static-host                                                                                                     |
| <b>Description</b> | This command specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |

---

**Parameters**     *sla-profile-name* — specifies the SLA profile name

## sub-profile

**Syntax**     **sub-profile** *sub-profile-name*  
**no sub-profile**

**Context**     config>service>vprn>if>sap>static-host  
                  config>service>vprn>sub-if>grp-if>sap>static-host

**Description**     This command specifies an existing subscriber profile name to be associated with the static subscriber host.

**Parameters**     *sub-profile-name* — specifies the sub-profile name

## subscriber

**Syntax**     **subscriber** *sub-ident*  
**no subscriber**

**Context**     config>service>vprn>if>sap>static-host  
                  config>service>vprn>sub-if>grp-if>sap>static-host

**Description**     This command specifies an existing subscriber identification profile to be associated with the static subscriber host.

**Parameters**     *sub-ident* — specifies the subscriber identification

## subscriber-sap-id

**Syntax**     **[no] subscriber-sap-id**

**Context**     config>service>vprn>if>sap>static-host  
                  config>service>vprn>sub-if>grp-if>sap>static-host

**Description**     This command enables using the SAP ID as subscriber id.

**Parameters**     **subscriber-sap-id** — specifies to use the sap-id as the subscriber-id

## queue-override

**Syntax**     **[no] queue-override**

**Context**     config>service>vprn>if>sap>egress  
                  config>service>vprn>if>sap>ingress

**Description** This command enables the context to configure override values for the specified SAP egress or ingress QoS queue. These values override the corresponding ones specified in the associated SAP egress or ingress QoS policy.

## queue

**Syntax** `[no] queue queue-id`

**Context** `config>service>vprn>if>sap>egress>queue-override`  
`config>service>vprn>if>sap>ingress>queue-override`

**Description** This command specifies the ID of the queue whose parameters are to be overridden.

**Parameters** *queue-id* — the queue ID whose parameters are to be overridden

**Values** 1 to 32

## adaptation-rule

**Syntax** `adaptation-rule [pir adaptation-rule] [cir adaptation-rule]`  
`no adaptation-rule`

**Context** `config>service>vprn>if>sap>egress>queue-override>queue`  
`config>service>vprn>if>sap>ingress>queue-override>queue`

**Description** This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.

The **no** form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific **adaptation-rule** is removed, the default constraints for **rate** and **cir** apply.

**Default** no adaptation-rule

**Parameters** *pir* — The **pir** parameter defines the constraints enforced when adapting the PIR rate defined within the **queue queue-id rate** command. The **pir** parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the **rate** command is not specified, the default applies.

*cir* — The **cir** parameter defines the constraints enforced when adapting the CIR rate defined within the **queue queue-id rate** command. The **cir** parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the **cir** parameter is not specified, the default constraint applies.

*adaptation-rule* — specifies the criteria to use to compute the operational CIR and PIR values for this queue, while maintaining a minimum offset

**Values**

**max** — The **max** (maximum) keyword is mutually exclusive with the **min** and **closest** options. When **max** is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the **rate** command.

**min** — The **min** (minimum) keyword is mutually exclusive with the **max** and **closest** options. When **min** is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the **rate** command.

**closest** — The **closest** parameter is mutually exclusive with the **min** and **max** parameter. When **closest** is defined, the operational PIR for the queue will be the rate closest to the rate specified using the **rate** command.

## avg-frame-overhead

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Context</b>     | config>service>vprn>if>sap>egress>queue-override>queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for Inter-Frame Gap). |

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be 10000 x 0.1 or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be 50 x 20 or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be  $1000 / 10000$  or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be  $500 \times 1.1$  or 550 octets.
- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be  $7500 \times 1.1$  or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

**Port scheduler operation using frame transformed rates** — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

SAP and subscriber SLA-profile average frame overhead override — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

**Default** 0

**Parameters** *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

**Values** 0 to 100

## cbs

**Syntax** *cbs size-in-kbytes*  
**no cbs**

**Context** config>service>vprn>if>sap>egress>queue-override>queue  
config>service>vprn>if>sap>ingress>queue-override>queue

**Description** This command can be used to override specific attributes of the specified queue's CBS parameters.

It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS setting into the defined reserved total.

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.

If the CBS value is larger than the MBS value, an error will occur, preventing the CBS change.

The **no** form of this command returns the CBS size to the default value.

**Default** no cbs

|                   |                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>size-in-kbytes</i> — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes). |
| <b>Values</b>     | 0 to 131072 or default                                                                                                                                                                                                                                                                                                          |

## high-prio-only

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's high-prio-only parameters. The <b>high-prio-only</b> command configures the percentage of buffer space for the queue, used exclusively by high priority packets.</p> <p>The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The <b>high-prio-only</b> parameter is used to override the default value derived from the <b>network-queue</b> command.</p> <p>The defined <b>high-prio-only</b> value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the <b>high-prio-only</b> value larger than the current MBS size will also result in an error and fail execution.</p> <p>The <b>no</b> form of this command restores the default high priority reserved size.</p> |
| <b>Parameters</b>  | <p><i>percent</i> — The <i>percent</i> parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.</p> <p><b>Values</b> 0 to 100   default</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## mbs

|                    |                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mbs</b> { <i>size-in-kbytes</i>   <b>default</b> }<br><b>no mbs</b>                                                                                                       |
| <b>Context</b>     | config>service>vprn>if>sap>egress>queue-override>queue<br>config>service>vprn>if>sap>egress>hsmda-queue-override>queue                                                       |
| <b>Description</b> | This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue. |

The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.

If the CBS value is larger than the MBS value, an error will occur, preventing the MBS change.

The **no** form of this command returns the MBS size assigned to the queue.

| <b>Context</b>     | config>service>vprn>if>sap>ingress>queue-override>queue                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS value is used by a queue to determine whether it has exhausted all of its buffers while enqueueing packets. Once the queue has exceeded the amount of buffers allowed by MBS, all packets are discarded until packets have been drained from the queue.</p> <p>The sum of the MBS for all queues on an ingress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> |

If the CBS value is larger than the MBS value, an error will occur, preventing the MBS change.

The defined high-prio-only value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the high-prio-only value larger than the current MBS size will also result in an error and fail execution.

The **no** form of this command returns the MBS size assigned to the queue to the value.

**Default** mbs default

**Parameters** *size-in-kbytes* — The size parameter is an integer expression of the maximum number of kilobytes of buffering allowed for the queue. For a value of 100 kbps, enter the value 100. A value of 0 causes the queue to discard all packets.

**Values** 0 to 131072 or default

## parent

**Syntax** **parent** [*weight weight*] [*cir-weight cir-weight*]  
**no parent**

**Context** config>service>vprn>if>sap>egress>queue-override>queue

**Description** This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non default weightings for fostered schedulers.

The **no** form of the command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

**Default** no parent

**Parameters** **weight** *weight* — **Weight** defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict **level** defined by the level parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the queue or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

**Values** 0 to 100

**Default** 1

**cir-weight** *cir-weight* — The **cir-weight** keyword defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue, or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict *cir-level*.

**Values** 0 to 100

**Default** 1

percent-rate

| <b>Description</b> | <p>The <b>percent-rate</b> command supports a queue's shaping rate and CIR rate as a percentage of the egress port's line rate. When the rates are expressed as a percentage within the template, the actual rate used per instance of the queue group <i>queue-id</i> will vary based on the port speed. For example, when the same template is used to create a queue group on a 1-Gigabit and a 10-Gigabit Ethernet port, the queue's rates will be 10 times greater on the 10 Gigabit port due to the difference in port speeds. This enables the same template to be used on multiple ports without needing to use port based queue overrides to modify a queue's rate to get the same relative performance from the queue.</p> <p>If the port's speed changes after the queue is created, the queue's shaping and CIR rates will be recalculated based on the defined percentage value.</p> <p>The rate and percent-rate commands override one another. If the current rate for a queue is defined using the percent-rate command and the rate command is executed, the percent-rate values are deleted. In a similar fashion, the percent-rate command causes any rate command values to be deleted. A queue's rate may dynamically be changed back and forth from a percentage to an explicit rate at anytime.</p> <p>An egress port queue group queue rate override may be expressed as either a percentage or an explicit rate independent on how the queue's template rate is expressed.</p> |

The **no** form of this command returns the queue to its default shaping rate and cir rate. When **no percent-rate** is defined within a port egress queue group queue override, the queue reverts to the defined shaping and CIR rates within the egress queue group template associated with the queue.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Parameters</b> | <p><i>pir-percent</i> — Specifies the queue’s shaping rate as a percentage of line rate. The line rate associated with the queue’s port may dynamically change due to configuration or auto-negotiation. The line rate may also be affected by an egress port scheduler defined max-rate.</p> <p><b>Values</b>      0.01 to 100.00</p> <p><b>Default</b>      100.00</p> <p><i>cir-percent</i> — Specifies the queue’s committed scheduling rate as a percentage of line rate. The line rate associated with the queue’s port may dynamically change due to configuration or auto-negotiation. The line rate may also be affected by an egress port scheduler defined max-rate.</p> <p><b>Values</b>      0.00 to 100.00</p> <p><b>Default</b>      100.00</p> |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue’s Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters. The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.</p> <p>The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.</p> <p>The CIR can be used by the queue’s parent commands <i>cir-level</i> and <i>cir-weight</i> parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.</p> <p>The <b>rate</b> command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the <i>queue-id</i>.</p> |

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

**Default**      **rate max cir 0** - The **max** default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The **max** value is mutually exclusive to the **pir-rate** value.

**Parameters**      *pir-rate* — Defines the administrative PIR rate, in kilobits, for the queue. When the **rate** command is executed, a valid PIR setting must be explicitly defined. When the **rate** command has not been executed, the default PIR of **max** is assumed.

Fractional values are not allowed and must be given as a positive integer.

The actual PIR rate is dependent on the queue's **adaptation-rule** parameters and the actual hardware where the queue is provisioned.

**Values**          1 to 2000000000, **max**

**Default**          max

*cir-rate* — The **cir** parameter overrides the default administrative CIR used by the queue. When the **rate** command is executed, a CIR setting is optional. When the **rate** command has not been executed or the **cir** parameter is not explicitly specified, the default CIR (0) is assumed.

Fractional values are not allowed and must be given as a positive integer. The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.

**Values**          0 to 2000000000, **max**

**Default**          0

rate

**Syntax**          **rate pir-rate**  
**no rate**

**Context**          config>service>vprn>if>sap>egress>hsmda-queue-override>queue

**Description**      This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR). The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.

The **rate** command can be executed at any time, altering the PIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR parameters (**max**, 0).

| <b>Syntax</b>      | <b>scheduler</b> <i>scheduler-name</i><br><b>no scheduler</b> <i>scheduler-name</i>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>if>sap>egress>sched-override<br>config>service>vprn>if>sap>ingress>sched-override                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified scheduler name.</p> <p>A scheduler defines a bandwidth controls that limit each child (other schedulers, policers, and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have policers, queues, or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier, except for schedulers created in tier 1). A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers.</p> <p>Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If <i>scheduler-name</i> already exists within the policy tier level (regardless of the inclusion of the keyword create), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause queues or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).</p> |

If the *scheduler-name* exists within the policy on a different tier (regardless of the inclusion of the keyword **create**), an error occurs and the current CLI context will not change.

If the *scheduler-name* does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:

- Step 1. The maximum number of schedulers has not been configured.
- Step 2. The provided *scheduler-name* is valid.
- Step 3. The **create** keyword is entered with the command if the system is configured to require it (enabled in the **environment create** command).

When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.

If the provided scheduler-name is invalid according to the criteria below, a name syntax error will occur, the command will not execute, and the CLI context will not change.

|            |                                                                                                                                                                                                                                      |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Parameters | <i>scheduler-name</i> — the name of the scheduler                                                                                                                                                                                    |
| Values     | Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes. |
| Default    | n/a. Each scheduler must be explicitly created.                                                                                                                                                                                      |

*create* — This optional keyword explicitly specifies that it is acceptable to create a scheduler with the given *scheduler-name*. If the **create** keyword is omitted, **scheduler-name** is not created when the system environment variable **create** is set to true. This safeguard is meant to avoid accidental creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists.

| Description | This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site. |

The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non default weightings for fostered schedulers.

The no form of the command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy.

**Default** no parent

**Parameters** **weight** *weight* — **Weight** defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict **level** defined by the **level** parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the policer, queue, or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.

A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.

**Values** 0 to 100

**Default** 1

**cir-weight** *cir-weight* — The **cir-weight** keyword defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same *cir-level* defined by the **cir-level** parameter in the applied scheduler policy. Within the strict **cir-level**, all **cir-weight** values from active children at that level are summed and the ratio of each active child's **cir-weight** to the total is used to distribute the available bandwidth at that level. A **cir-weight** is considered to be active when the policer, queue, or scheduler that the **cir-weight** pertains to has not reached the CIR and still has packets to transmit.

A 0 (zero) **cir-weight** value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict cir-level.

**Values** 0 to 100

**Default** 1

rate

**Syntax** **rate** *pir-rate* [**cir** *cir-rate*]  
**no rate**

**Context** config>service>vprn>if>sap>egress>sched-override>scheduler  
config>service>vprn>if>sap>ingress>sched-override

**Description** This command can be used to override specific attributes of the specified scheduler rate. The **rate** command defines the maximum bandwidth that the scheduler can offer its child queues or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler's 'within CIR' distribution phase.

The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler's parent scheduler may not have the available bandwidth to meet the scheduler's needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child policers and queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.

When a scheduler is defined without specifying a rate, the default rate is **max**. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child queues and schedulers to operate at their maximum rates.

The **no** form of this command returns all queues created with this *queue-id* by association with the QoS policy to the default PIR and CIR parameters.

**Parameters** *pir-rate* — The **pir** parameter accepts a value of 1 to 3200000000, or the **max** keyword. Any other value will result in an error without modifying the current PIR rate.

**Values** 1 to 3200000000, **max**

**Default** max

*cir-rate* — The **cir** parameter accepts a value of 0 to 3200000000, or the **max** or **sum** keywords. Any other value will result in an error without modifying the current CIR rate.

If the **cir** is set to **max**, then the CIR rate is set to infinity, but is limited by the *pir-rate*.

If the **cir** is set to **sum**, then the CIR rate is set to the summed CIR values of the children schedulers, policers, or queues.

**Values** 0 to 3200000000, **max**, **sum**

**Default** sum

### 3.9.2.21 Interface VRRP Commands

vrrp

**Syntax** **vrrp** *virtual-router-id* [**owner**] [**passive**]  
**no vrrp** *virtual-router-id*

| <b>Description</b>   | <p>This command creates or edits a Virtual Router ID (VRID) on the service IP interface. A VRID is internally represented in conjunction with the IP interface name. This allows the VRID to be used on multiple IP interfaces while representing different virtual router instances.</p> <p>Two VRRP nodes can be defined on an IP interface. One, both, or none may be defined as owner. The nodal context of <b>vrrp</b> <i>virtual-router-id</i> is used to define the configuration parameters for the VRID.</p> <p>The <b>no</b> form of this command removes the specified VRID from the IP interface. This terminates VRRP participation for the virtual router and deletes all references to the VRID. The VRID does not need to be shutdown in order to remove the virtual router instance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Default</b>       | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Special Cases</b> | <p><b>Virtual Router Instance Owner IP Address Conditions</b> — The virtual router instance <b>owner</b> can be created prior to assigning the parent IP interface primary or secondary IP addresses. In this case, the virtual router instance is not associated with an IP address. The operational state of the virtual router instance is down.</p> <p><b>VRRP Owner Command Exclusions</b> — By specifying the VRRP <i>vrid</i> as <b>owner</b>, the following commands are no longer available:</p> <ul style="list-style-type: none"> <li>• <b>vrrp priority</b> — The virtual router instance <b>owner</b> is hard-coded with a <b>priority</b> value of 255 and cannot be changed.</li> <li>• <b>vrrp master-int-inherit</b> — Owner virtual router instances do not accept VRRP advertisement messages; the advertisement interval field is not evaluated and cannot be inherited.</li> <li>• <b>ping-reply</b>, <b>telnet-reply</b> and <b>ssh-reply</b> — The <b>owner</b> virtual router instance always allows Ping, Telnet and SSH if the management and security parameters are configured to accept them on the parent IP interface.</li> <li>• <b>vrrp shutdown</b> — The <b>owner</b> virtual router instance cannot be shut down on the <b>vrrp</b> node. If this was allowed, VRRP messages would not be sent, but the parent IP interface address would continue to respond to ARPs and forward IP packets. Another virtual router instance may detect the missing master due to the termination of VRRP advertisement messages and become master. This would result in two routers responding to ARP requests for the same IP addresses. To shut down the <b>owner</b> virtual router instance, use the <b>shutdown</b> command in the parent IP interface context. This will prevent VRRP participation, IP ARP reply and IP forwarding. To continue parent IP interface ARP reply and forwarding without VRRP participation, remove the <b>vrrp vrid</b> instance.</li> <li>• <b>traceroute-reply</b></li> </ul> <p><b>VRRP Passive Command Exclusions</b> — By specifying the VRRP <i>vrid</i> as <b>passive</b>, the following commands related to the master election and processing of VRRP advertisement messages are no longer available:</p> <ul style="list-style-type: none"> <li>• <b>vrrp priority</b></li> <li>• <b>policy</b></li> </ul> |

- **preempt**
- **master-int-inherit**
- **standby-forwarding**
- **int-delay**
- **message-interval**
- **authentication-key**
- **bfd-enable**

**Parameters** *virtual-router-id* — The *virtual-router-id* parameter specifies a new virtual router ID or one that can be modified on the IP interface.

**Values** 1 to 255

**owner** — Identifies this virtual router instance as owning the virtual router IP addresses. If the **owner** keyword is not specified at the time of *vrid* creation, the **vrrp backup** commands must be specified to define the virtual router IP addresses. The **owner** keyword is not required when entering the *vrid* for editing purposes. Once created as **owner**, a *vrid* on an IP interface cannot have the **owner** parameter removed. The *vrid* must be deleted, and then recreated without the **owner** keyword, to remove ownership.

**passive** — Identifies this virtual router instance as **passive**, and therefore, owning the virtual router IP addresses. A **passive vrid** does not send or receive VRRP advertisement messages, and is always in either the **master** state (if the interface is operational-up), or the **init** state (if the interface is operational-down). The **passive** keyword is not required when entering the *vrid* for editing purposes. Once a *vrid* on an IP interface is created as **passive**, the parameter cannot be removed from the *vrid*. The *vrid* must be deleted, and then recreated without the **passive** keyword, to remove parameter.

## authentication-key

**Syntax** **authentication-key** [*authentication-key* | *hash-key*] [**hash** | **hash2**]  
**no authentication-key**

**Context** config>service>vprn>if>vrrp

**Description** The **authentication-key** command, within the **vrrp** *virtual-router-id* context, is used to assign a simple text password authentication key to generate master VRRP advertisement messages and validate received VRRP advertisement messages.

The **authentication-key** command is one of the few commands not affected by the presence of the **owner** keyword. If simple text password authentication is not required, this command is not required. If the command is re-executed with a different password key defined, the new key will be used immediately. If a **no authentication-key** command is executed, the password authentication key is restored to the default value. The **authentication-key** command may be executed at any time.

To change the current in-use password key on multiple virtual router instances:

- Identify the current master
- Shutdown the virtual router instance on all backups
- Execute the authentication-key command on the master to change the password key
- Execute the authentication-key command and no shutdown command on each backup key

The **no** form of this command restores the default null string to the value of key.

**Default** n/a. The authentication data field contains the value 0 in all 16 octets.

**Parameters** *authentication-key* — The *key* parameter identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *key* parameter is expressed as a string consisting of up to eight alpha-numeric characters. Spaces must be contained in quotation marks ( " " ). The quotation marks are not considered part of the string.

The string is case sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

**Values** Any 7-bit printable ASCII character.

|             |                  |          |
|-------------|------------------|----------|
| Exceptions: | Double quote (") | ASCII 34 |
|             | Carriage Return  | ASCII 13 |
|             | Line Feed        | ASCII 10 |
|             | Tab              | ASCII 9  |
|             | Backspace        | ASCII 8  |

*hash-key* — The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks ( " " )

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

**hash** — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

**hash2** — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

| Description | <p>This commands assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session. If the interface used is configured with centralized BFD, the BFD transmit and receive intervals need to be set to at least 300 ms.</p> <p>BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface. The specified interface may not be configured with BFD; when it is, the virtual router will then initiate the BFD session.</p> <p>The <b>no</b> form of this command removes BFD from the configuration.</p> |             |                 |           |                                                                  |  |                                             |
| Default     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |             |                 |           |                                                                  |  |                                             |

| <b>Description</b> | <p>This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers participating as a virtual router. Any VRRP advertisement message received with an Advertisement Interval field different than the virtual router instance configured message-interval value will be silently discarded.</p> <p>The message-interval command is available in both non-owner and owner <b>vrrp</b> <i>virtual-router-id</i> nodal contexts. If the message-interval command is not executed, the default message interval of 1 second will be used.</p> <p>The <b>no</b> form of this command restores the default message interval value of 1 second to the virtual router instance.</p> |
| <b>Parameters</b>  | <p><b>seconds</b> — the number of seconds that will transpire before the advertisement timer expires</p> <p><b>Values</b> 1 to 255</p> <p><b>Default</b> 1</p> <p><b>milliseconds milliseconds</b> — Specifies the milliseconds time interval between sending advertisement messages. This parameter is not supported on single-slot chassis.</p> <p><b>Values</b> 100 to 900</p>                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Context</b>     | config>service>vprn>if>vrrp<br>config>service>vprn>if>ipv6>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command enables the non-owner master to reply to ICMP Echo Requests directed at the virtual router instances IP addresses. The ping request can be received on any routed interface.</p> <p>Ping must not have been disabled at the management security level (either on the parental IP interface or based on the Ping source host address). When ping-reply is not enabled, ICMP Echo Requests to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to ICMP Echo Requests regardless of the setting of ping-reply configuration.</p> |

The ping-reply command is only available in non-owner **vrrp** *virtual-router-id* nodal context. If the ping-reply command is not executed, ICMP Echo Requests to the virtual router instance IP addresses will be silently discarded.

The **no** form of this command restores the default operation of discarding all ICMP Echo Request messages destined to the non-owner virtual router instance IP addresses.

**Default** no ping-reply

## policy

**Syntax** **policy** *vrrp-policy-id*  
**no policy**

**Context** config>service>vprn>if>vrrp  
config>service>vprn>if>ipv6>vrrp

**Description** This command associates a VRRP priority control policy with the virtual router instance (non-owner context only).

**Parameters** *vrrp-policy-id* — specifies a VRRP priority control policy

**Values** 1 to 9999

## preempt

**Syntax** [**no**] **preempt**

**Context** config>service>vprn>if  
config>service>vprn>if>ipv6>vrrp

**Description** The preempt mode value controls whether a specific backup virtual router preempts a lower priority master.

When preempt is enabled, the virtual router instance overrides any non-owner master with an “in use” message priority value less than the virtual router instance in-use priority value. If preempt is disabled, the virtual router only becomes master if the master down timer expires before a VRRP advertisement message is received from another virtual router.

The IP address owner will always become master when available. Preempt mode cannot be disabled on the owner virtual router.

The default value for preempt mode is enabled.

**Default** preempt

| <b>Description</b> | <p>The priority command provides the ability to configure a specific priority value to the virtual router instance. In conjunction with an optional policy command, the base-priority is used to derive the in-use priority of the virtual router instance.</p> <p>The priority command is only available in the non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed. For non-owner virtual router instances, if the priority command is not executed, the base-priority will be set to 100.</p> <p>The <b>no</b> form of this command restores the default value of 100 to base-priority.</p> |               |          |                |     |
| <b>Parameters</b>  | <p><i>base-priority</i> — The base-priority parameter configures the base priority used by the virtual router instance. If a VRRP priority control policy is not also defined, the base-priority will be the in-use priority for the virtual router instance.</p> <table><tr><td><b>Values</b></td><td>1 to 254</td></tr><tr><td><b>Default</b></td><td>100</td></tr></table>                                                                                                                                                                                                                                                                                                                           | <b>Values</b> | 1 to 254 | <b>Default</b> | 100 |

| <b>Description</b> | <p>This command enables the non-owner master to reply to SSH Requests directed at the virtual router instance's IP addresses. The SSH request can be received on any routed interface. SSH must not have been disabled at the management security level (either on the parental IP interface or based on the SSH source host address). Proper login and CLI command authentication is still enforced.</p> <p>When ssh-reply is not enabled, SSH packets to non-owner master virtual IP addresses are silently discarded. Non-owner backup virtual routers never respond to SSH regardless of the ssh-reply configuration.</p> <p>The ssh-reply command is only available in non-owner <b>vrrp</b> <i>virtual-router-id</i> nodal context. If the ssh-reply command is not executed, SSH packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all SSH packets destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no ssh-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## standby-forwarding

|                    |                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] standby-forwarding</b>                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>if>vrrp<br>config>service>vprn>if>ipv6>vrrp                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command allows the forwarding of packets by a standby router.</p> <p>The <b>no</b> form of the command specifies that a standby router should not forward traffic sent to virtual router's MAC address. However, the standby router should forward traffic sent to the standby router's real MAC address.</p> |
| <b>Default</b>     | no standby-forwarding                                                                                                                                                                                                                                                                                                 |

## telnet-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Context</b>     | config>service>vprn>if>vrrp<br>config>service>vprn>if>ipv6>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command enables the non-owner master to reply to TCP port 23 Telnet Requests directed at the virtual router instance's IP addresses. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parental IP interface or based on the Telnet source host address). Proper login and CLI command authentication is still enforced.</p> <p>When telnet-reply is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to Telnet Requests regardless of the telnet-reply configuration.</p> <p>The telnet-reply command is only available in non-owner <b>VRRP</b> nodal context. If the telnet-reply command is not executed, Telnet packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all Telnet packets destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no telnet-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## traceroute-reply

|                |                              |
|----------------|------------------------------|
| <b>Syntax</b>  | <b>[no] traceroute-reply</b> |
| <b>Context</b> | config>service>vprn>if>vrrp  |

```
config>service>vprn>if>ipv6>vrrp
```

**Description** This command is valid only if the VRRP virtual router instance associated with this entry is a non-owner.

When this command is enabled, a non-owner master can reply to traceroute requests directed to the virtual router instance IP addresses.

A non-owner backup virtual router never responds to such traceroute requests regardless of the **trace-route-reply** status.

**Default** no traceroute-reply

### 3.9.2.22 Interface SAP Commands

#### sap

**Syntax** **sap** *sap-id* [**create**]  
**no sap** *sap-id*

**Context** config>service>vprn>if  
config>service>vprn>sub-if>grp-if  
config>service>vprn>if>sap

**Description** This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the router. Each SAP must be unique.

All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object. Enter an existing SAP without the **create** keyword to edit SAP parameters. The SAP is owned by the service in which it was created.

A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the **config interface port-type port-id mode access** command. Channelized TDM ports are always access ports.

If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.

The **no** form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. The **no** form of the command causes the ptp-h-assist to be disabled.

**Default** No SAPs are defined.

**Special Cases** **VPRN** — A VPRN SAP must be defined on an Ethernet interface.

**sap ipsec-id.private | public:tag** — This parameter associates an IPSec group SAP with this interface. This is the public side for an IPSec tunnel. Tunnels referencing this IPSec group in the private side may be created if their local IP is in the subnet of the interface subnet and the routing context specified matches with the one of the interface.

This context will provide a SAP to the tunnel. The operator may associate an ingress and egress QoS policies as well as filters and virtual scheduling contexts. Internally this creates an Ethernet SAP that will be used to send and receive encrypted traffic to and from the MDA. Multiple tunnels can be associated with this SAP. The “tag” will be a dot1q value. The operator may see it as an identifier. The range is limited to 1 to 4094.

- Parameters
- sap-id — specifies the physical port identifier portion of the SAP definition

port-id — specifies the physical port ID

If the card in the slot has Media Dependent Adapters (MDAs) installed, the *port-id* must be in the slot\_number/MDA\_number/port\_number format. For example 6/2/3 specifies port 3 on MDA 2 in slot 6.

The *port-id* must reference a valid port type. When the *port-id* parameter represents SONET/SDH and TDM channels the port ID must include the channel ID. A period “.” separates the physical port from the *channel-id*. The port must be configured as an access port.

If the SONET/SDH port is configured as clear-channel then only the port is specified.

|            |                          |         |         |

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command associates an AARP instance with a multi-homed SAP or spoke SDP. This instance uses the same AARP ID in the same node or in a peer node (pre-configured) to provide traffic flow and packet asymmetry removal for a multi-homed SAP or spoke SDP.</p> <p>The type specifies the role of this service point in the AARP: either, primary (dual-homed) or secondary (dual-homed-secondary). The AA service attributes (app-profile and transit-policy) of the primary are inherited by the secondary endpoints. All endpoints within an AARP must be of the same type (SAP or spoke), and all endpoints with an AARP must be within the same service.</p> <p>The no form of the command removes the association between an AARP instance and a multi-homed SAP or spoke SDP.</p> |
| <b>Default</b>     | no aarp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>aarpId</i> — specifies the AARP instance associated with this SAP. If not configured, no AARP instance is associated with this SAP.</p> <p><b>Values</b> 1 to 65535</p> <p><b>type</b> — specifies the role of the SAP referenced by the AARP instance</p> <p><b>Values</b> <b>dual-homed</b> — the primary dual-homed AA subscriber side service-point of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.<br/><b>dual-homed-secondary</b> — one of the secondary dual-homed AA subscriber side service-points of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.</p>                                                                                                                                                          |

## bfd-enable

|                    |                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bfd-enable</b><br><b>no bfd-enable</b>                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>if>spoke-sdp                                                                                                                                                                                                                     |
| <b>Description</b> | This command enables VCCV BFD on the PW associated with the VLL, BGP VPWS, or VPLS service. The parameters for the BFD session are derived from the named BFD template, which must have been first configured using the <b>bfd-template</b> command. |

## bfd-template

|                    |                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bfd-template</b> <i>name</i><br><b>no bfd-template</b>                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>if>spoke-sdp                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures a named BFD template to be used by VCCV BFD on PWs belonging to the VLL, BGP VPWS, or VPLS service. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, to be used by the BFD session. Template parameters are configured under the <b>config&gt;router&gt;bfd</b> context. |
| <b>Default</b>     | no bfd-template                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>name</i> — a text string name for the template of up to 32 characters in printable 7-bit ASCII, enclosed in double quotes                                                                                                                                                                                                                                |

## collect-stats

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command enables accounting and statistical data collection for either an interface SAP or interface SAP spoke SDP, or network port. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file.</p> <p>When the <b>no collect-stats</b> command is issued the statistics are still accumulated by the IOM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent <b>collect-stats</b> command is issued then the counters written to the billing file include all the traffic while the <b>no collect-stats</b> command was in effect.</p> |
| <b>Default</b>     | no collect-stats                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command assigns an existing CPU protection policy to the associated group interface. The CPU protection policies are configured in the <b>config&gt;sys&gt;security&gt;cpu-protection&gt;policy</b> <i>cpu-protection-policy-id</i> context.</p> <p>If no CPU-Protection policy is assigned to a group interface SAP, then the default policy is used to limit the overall-rate. The default policy is policy number 254 for access interfaces and 255 for network interfaces.</p> <p>The no form of the command removes the association of the CPU protection policy from the associated interface and reverts to the default policy values.</p> |
| <b>Default</b>     | <p>cpu-protection 254 (for access interfaces); cpu-protection 255 (for network interfaces)</p> <p>The configuration of no cpu-protection returns the interface/SAP to the default policies as shown above.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>policy-id</i> — specifies an existing CPU protection policy.</p> <p><b>Values</b> 1 to 255</p> <p><b>mac-monitoring</b> — enables MAC monitoring</p> <p><b>eth-cfm-monitoring</b> — <i>enables Ethernet Connectivity Fault Management monitoring</i></p> <p><b>aggregate</b> — <i>applies the rate limit to the sum of the per peer packet rates</i></p> <p><b>car</b> — (Committed Access Rate) <i>causes Eth-CFM packets to be ignored when enforcing the overall-rate</i></p>                                                                                                                                                                    |

## dist-cpu-protection

|                    |                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dist-cpu-protection</b> <i>policy-name</i><br><b>no dist-cpu-protection</b>                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap<br>config>service>>vprn>if>sap                                                                                                                                                       |
| <b>Description</b> | This command assigns a Distributed CPU Protection (DCP) policy to the SAP. Only a valid created DCP policy can be assigned to a SAP or a network interface (This rule does not apply to templates such as an msap-policy). |
| <b>Default</b>     | no dist-cpu-protection                                                                                                                                                                                                     |

| <b>Context</b>     | config>service>ies>if>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the source IPv4 or IPv6 address to use for an IP tunnel. This configuration applies to the outer IP header of the encapsulated packets. The IPv4 or IPv6 address must belong to the one of the IP subnets associated with the public SAP interface of the tunnel-group. The <b>source</b> address, <b>remote-ip</b> address and <b>backup-remote-ip</b> address of a tunnel must all belong to the same address family (IPv4 or IPv6). When the source address contains an IPv6 address it must be a global unicast address. |
| <b>Default</b>     | no source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>ip-address</i> — an IPv4 address or an IPv6 address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Context</b>     | config>service>ies>if>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the alternate destination IPv4 or IPv6 address to use for an IP tunnel. This destination address is used only if the primary destination configured with the <b>remote-ip</b> command is unreachable in the delivery service. The <b>source</b> address, <b>remote-ip</b> address and <b>backup-remote-ip</b> address of a tunnel must all belong to the same address family (IPv4 or IPv6). When the backup-remote-ip address contains an IPv6 address it must be a global unicast address. |
| <b>Default</b>     | no remote-ip                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>ip-address</i> — an IPv4 address or an IPv6 address                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 3.9.2.23 Routed VPLS Commands

## vpls

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Syntax</b>      | <b>vpls service-name</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service<br>config>service>vprn>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>The <b>vpls</b> command, within the IP interface context, is used to bind the IP interface to the specified service name.</p> <p>The system does not attempt to resolve the service name provided until the IP interface is placed into the administratively up state (<b>no shutdown</b>). Once the IP interface is administratively up, the system will scan the available VPLS services that have the <b>allow-ip-int-bind</b> flag set for a VPLS service associated with the name. If the service name is bound to the service name when the IP interface is already in the administratively up state, the system will immediately attempt to resolve the given name.</p> <p>If a VPLS service is found associated with the name and with the allow-ip-int-bind flag set, the IP interface will be attached to the VPLS service allowing routing to and from the service virtual ports once the IP interface is operational.</p> |

A VPLS service associated with the specified name that does not have the allow-ip-int-bind flag set or a non-VPLS service associated with the name will be ignored and will not be attached to the IP interface.

If the service name is applied to a VPLS service after the service name is bound to an IP interface and the VPLS service allow-ip-int-bind flag is set at the time the name is applied, the VPLS service will be automatically resolved to the IP interface if the interface is administratively up or when the interface is placed in the administratively up state.

If the service name is applied to a VPLS service without the allow-ip-int-bind flag set, the system will not attempt to resolve the applied service name to an existing IP interface bound to the name. To rectify this condition, the flag must first be set and then the IP interface must enter or reenter the administratively up state.

While the specified service name may be assigned to only one service context in the system, it is possible to bind the same service name to more than one IP interface. If two or more IP interfaces are bound to the same service name, the first IP interface to enter the administratively up state (if currently administratively down) or to reenter the administratively up state (if currently administratively up) when a VPLS service is configured with the name and has the allow-ip-int-bind flag set will be attached to the VPLS service. Only one IP interface is allowed to attach to a VPLS service context. No error is generated for the remaining non-attached IP interfaces using the service name.

Once an IP interface is attached to a VPLS service, the name associated with the service cannot be removed or changed until the IP interface name binding is removed. Also, the allow-ip-int-bind flag cannot be removed until the attached IP interface is unbound from the service name.

Unbinding the service name from the IP interface causes the IP interface to detach from the VPLS service context. The IP interface may then be bound to another service name or a SAP or SDP binding may be created for the interface using the **sap** or **spoke-sdp** commands on the interface.

### **IES Chassis Mode Dependency**

An IES IP interface cannot be bound to a service name unless the system is configured in chassis mode D. Once an IES interface is bound to a service name, the chassis mode of the system cannot be changed to B or C.

### **VPRN Hardware Dependency**

When a service name is bound to a VPRN IP interface, all SAPs associated with the VPRN service must be on hardware based on the FlexPath forwarding plane. Currently, these include the IOM3-XP, the various IMM modules and the SR7710c12. If any SAPs are associated with the wrong hardware type, the service name binding to the VPRN IP interface will fail. Once an IP interface within the VPRN service is bound to a service name, attempting to create a SAP on excluded hardware will fail.

### **Route Export and Import between Routing Contexts**

The IES chassis mode dependency and the VPRN hardware dependency each are designed to prevent a condition where an ingress routing decision on hardware that does not support the mixed Layer 2 and Layer 3 behavior of routed VPLS is asked to route to a VPLS based next-hop.

Even with these restrictions, it is still possible using route leaking or import/export routing policies to create a condition where a FlexPath forwarding plane resolves a route to a VPLS next-hop. In this case, the forwarding plane handles the resolved next-hop as if it points to a null IP interface. Packets associated with a null next-hop egress IP interface will be discarded and an ICPM unreachable message will be generated when enabled.

### IP Interface MTU and Fragmentation

A VPLS service is affected by two MTU values; port MTUs and the VPLS service MTU. The MTU on each physical port defines the largest Layer 2 packet (including all DLC headers and CRC) that may be transmitted out a port. The VPLS itself has a service level MTU that defines the largest packet supported by the service. This MTU does not include the local encapsulation overhead for each port (QinQ, Dot1Q, TopQ or SDP service delineation fields and headers) but does include the remainder of the packet. As virtual ports are created in the system, the virtual port cannot become operational unless the configured port MTU minus the virtual port service delineation overhead is greater than or equal to the configured VPLS service MTU. Thus, an operational virtual port is ensured to support the largest packet traversing the VPLS service. The service delineation overhead on each Layer 2 packet is removed before forwarding into a VPLS service. VPLS services do not support fragmentation and must discard any Layer 2 packet larger than the service MTU after the service delineation overhead is removed.

IP interfaces have a configurable up MTU that defines the largest packet that may egress the IP interface without being fragmented. This MTU encompasses the IP portion of the packet and does not include any of the egress DLC header or CRC. This MTU does not affect the size of the largest ingress packet on the IP interface. If the egress IP portion of the packet is larger than the IP interface MTU and the IP header do not fragment flag is not set, the packet is fragmented into smaller packets that will not exceed the configured MTU size. If the do not fragment bit is set, the packet is silently discarded at egress when it exceeds the IP MTU.

When the IP interface is bound to a VPLS service, the IP MTU must be at least 18 bytes less than the VPLS service MTU. This allows for the addition of the minimal Ethernet encapsulation overhead; 6 bytes for the DA, 6 bytes for the SA, 2 bytes for the Etype and 4 bytes for the trailing CRC. Any remaining egress virtual port overhead (Dot1P, Dot1Q, QinQ, TopQ or SDP) required above the minimum is known to be less than the egress ports MTU since the virtual port would not be operational otherwise.

If the IP interface IP MTU value is too large based on the VPLS service MTU, the IP interface will enter the operationally down state until either the IP MTU is adequately lowered or the VPLS service MTU is sufficiently increased.

The **no** form of the command on the IP interface is used to remove the service name binding from the IP interface. If the service name has been resolved to a VPLS service context and the IP interface has been attached to the VPLS service, the IP interface will also be detached from the VPLS service.

| <b>Parameters</b> | <i>service-name</i> — The service-name parameter is required when using the IP interface vpls command and specifies the service name that the system will attempt to resolve to an allow-ip-int-bind enabled VPLS service associated with the name. The specified name is expressed as an ASCII string comprised of up to 32 characters. It does not need to already be associated with a service and the system does not check to ensure that multiple IP interfaces are not bound to the same name. |

## ingress

|                    |                                                                                                                               |

| <b>Description</b> | <p>The v4-routed-override-filter command is used to specify an IPv4 filter ID that will be applied to all ingress packets entering the VPLS service. The filter overrides any existing ingress IPv4 filter applied to SAPs or SDP bindings for packets associated with the routing IP interface. The override filter is optional and when it is not defined or it is removed, the IPv4 routed packets will use the any existing ingress IPv4 filter on the VPLS virtual port.</p> <p>The <b>no</b> form of the command is used to remove the IPv4 routed override filter from the ingress IP interface. When removed, the IPv4 ingress routed packets within a VPLS service attached to the IP interface will use the IPv4 ingress filter applied to the packets virtual port when defined.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>ipv4-filter-id</i> — The ipv4-filter-id parameter is required when executing the v4-routed-override-filter command. The specified filter ID must exist as an IPv4 filter within the system or the override command will fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>service>vprn>if>vpls>egress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>The reclassify-using-qos command is used to specify a sap-egress QoS policy that will be used to reclassify the forwarding class and profile of egress routed packets on the VPLS service. When routed packets associated with the IP interface egress a VPLS SAP, the reclassification rules within the sap-egress QoS policy applied to the SAP are always ignored (even when reclassify-using-qos is not defined).</p> <p>Any queues or policers defined within the specified QoS policy are ignored and are not created on the VPLS egress SAPs. Instead, the routed packets continue to use the forwarding class mappings, queues and policers from the sap-egress QoS policy applied to the egress VPLS SAP.</p> |

While the specified sap-egress policy ID is applied to an IP interface it cannot be deleted from the system.

The **no** form of the command removes the sap-egress QoS policy used for reclassification from the egress IP interface. When removed, IP routed packets will not be reclassified on the egress SAPs of the VPLS service attached to the IP interface.

**Parameters** *sap-egress-qos-id* — The sap-egress-qos-id parameter is required when executing the reclassify-using-qos command. The specified SAP egress QoS ID must exist within the system or the command will fail.

## allow-ip-int-bind

**Syntax** **[no] allow-ip-int-bind**

**Context** config>service>vpls

**Description** This command sets a flag on the VPLS service that enables the ability to attach an IES or VPRN IP interface to the VPLS service in order to make the VPLS service routable. When the allow-ip-int-bind command is not enabled, the VPLS service cannot be attached to an IP interface.

### VPLS Configuration Constraints for Enabling allow-ip-int-bind

When attempting to set the allow-ip-int-bind VPLS flag, the system first checks to see if the correct configuration constraints exist for the VPLS service and the network ports. The following VPLS features must be disabled or not configured for the allow-ip-int-bind flag to set:

- SAP ingress QoS policies applied to the VPLS SAPs cannot have MAC match criteria defined
- SDPs used in spoke or mesh SDP bindings cannot be configured as GRE
- The VPLS service type cannot be B-VPLS or M-VPLS and it cannot be an I-VPLS service bound to a B-VPLS context
- MVR from Routed VPLS and to another SAP is not supported
- Enhanced and Basic Subscriber Management features
- Network Domain on SDP bindings

Once the VPLS allow-ip-int-bind flag is set on a VPLS service, the above features cannot be enabled on the VPLS service.

### Network Port Hardware Constraints

The system also checks to ensure that all ports configured in network mode are associated with FlexPath forwarding planes. If a port is currently in network mode and the port is associated with a FlexPath forwarding plane, the allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is set on any VPLS service, attempting to enable network mode on a port associated with a FlexPath forwarding plane will fail.

**VPLS SAP Hardware Constraints**

Besides VPLS configuration and network port hardware association, the system also checks to that all SAPs within the VPLS are created on Ethernet ports and the ports are associated with FlexPath forwarding planes. Certain Ethernet ports and virtual Ethernet ports are not supported which include HSMDA ports and CCAG virtual ports (VSM based). If a SAP in the VPLS exists on an unsupported port type or is associated with a FlexPath forwarding plane, the allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is set on the VPLS service, attempting to create a VPLS SAP on the wrong port type or associated with a FlexPath forwarding plane will fail.

**VPLS Service Name Bound to IP Interface without allow-ip-int-bind flag Set**

In the event that a service name is applied to a VPLS service and that service name is also bound to an IP interface but the allow-ip-int-bind flag has not been set on the VPLS service context, the system attempt to resolve the service name between the VPLS service and the IP interface will fail. After the allow-ip-int-bind flag is successfully set on the VPLS service, either the service name on the VPLS service must be removed and reapplied or the IP interface must be re-initialized using the shutdown / no shutdown commands. This will cause the system to reattempt the name resolution process between the IP interface and the VPLS service.

The **no** form of the command resets the allow-ip-int-bind flag on the VPLS service. If the VPLS service currently has an IP interface from an IES or VPRN service attached, the no allow-ip-int-bind command will fail. Once the allow-ip-int-bind flag is reset on the VPLS service, the configuration and hardware restrictions associated with setting the flag are removed. The port network mode hardware restrictions are also removed.

**3.9.2.24 Network Ingress Commands**

network

|                    |                                                                                        |

| <b>Context</b>     | config>service>vprn>network                                                                    |
| <b>Description</b> | This command enables the context to configure network ingress parameters for the VPRN service. |

## qos

|                    |                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>qos</b> <i>network-policy-id</i> <b>fp-redirect-group</b> <i>queue-group-name</i> <i>instance</i> <i>instance-id</i><br><b>no qos</b>                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>network>ingress                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command is used to redirect unicast packets arriving on an automatically (using the <b>auto-bind</b> command) or manually configured (using a <b>spoke-sdp</b> command, but not the <b>spoke-sdp</b> command under the VPRN IP interface) binding in a VPRN to a policer in an ingress forwarding plane queue-group for the purpose of rate-limiting. |

For the policer to be used, the following must be true:

- Step 1.** The configured queue group template name must be applied to the forwarding plane on which the ingress traffic arrives using the instance id specified.
- Step 2.** The policer referenced in the FC-to-policer mappings in the ingress context of a network QoS policy must be present in the specified queue group template.

The command will fail if the queue group template name does not exist or if the policer specified in the network QoS policy does not exist in the queue group template. If the queue group template name with the specified instance is not applied to the forwarding plane on which the VPRN binding unicast traffic arrives then this traffic will use the ingress network queues related to the network interface, however, the ingress classification is still based on the applied network QoS policy.

The unicast traffic can be redirected to a policer under the forwarding class **fp-redirect-group** command in the ingress section of a network QoS policy; any **fp-redirect-group multicast-policer**, **broadcast-policer** or **unknown-policer** commands are ignored for this traffic. Multicast traffic would use the ingress network queues or queue group related to the network interface.

Ingress classification is based on the configuration of the ingress section of the specified network QoS policy, noting that the dot1p and exp classification is based on the outer Ethernet header and MPLS label whereas the DSCP applies to the outer IP header if the tunnel encapsulation is GRE, or the DSCP in the first IP header in the payload if **ler-use-dscp** is enabled in the ingress section of the referenced network QoS policy.

When this command is applied, it overrides the QoS applied to the related network interfaces for unicast traffic arriving on bindings in that VPRN.

The **no** version of this command removes the redirection of VPRN binding traffic to the queue-group policers.

|                   |                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>network-policy-id</i> — Specifies the network policy identification. The value uniquely identifies the policy on the system. |
| <b>Values</b>     | 1 to 65535                                                                                                                      |
|                   | <b>fp-redirect-group</b> <i>queue-group-name</i> — specifies the name of the queue group template up to 32 characters in length |

**instance** *instance-id* — specifies the identification of a specific instance of the queue-group

**Values** 1 to 65535

### 3.9.2.25 SAP Subscriber Management Commands

#### sub-sla-mgmt

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sub-sla-mgmt</b>                                                                     |
| <b>Context</b>     | config>service>vprn>sub-if>grp-if>sap                                                        |
| <b>Description</b> | This command enables the context to configure subscriber management parameters for this SAP. |
| <b>Default</b>     | no sub-sla-mgmt                                                                              |

#### def-sla-profile

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sla-profile</b> context.</p> <p>An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts. SLA profiles are maintained in two locations, the subscriber identification policy and the subscriber profile templates. After a subscriber host is associated with an SLA profile name, either the subscriber identification policy used to identify the subscriber or the subscriber profile associated with the subscriber host must contain an SLA profile with that name. If both the subscriber identification policy and the subscriber profile contain the SLA profile name, the SLA profile in the subscriber profile is used.</p> <p>The <b>no</b> form of the command removes the default SLA profile from the SAP configuration.</p> |
| <b>Default</b>     | no def-sla-profile                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <i>config&gt;subscriber-mgmt&gt;sub-profile</i> context.</p> <p>A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.</p> <p>The <b>no</b> form of the command removes the default SLA profile from the SAP configuration.</p> |
| <b>Parameters</b>  | <i>default-sub-profile</i> — Specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sub-profile</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Description</b> | <p>This command configures non-subscriber traffic profiles. It is used in conjunction with the <b>profiled-traffic-only</b> command on single subscriber SAPs and creates a subscriber host which is used to forward non-IP traffic through the single subscriber SAP without the need for SAP queues.</p> <p>The <b>no</b> form of the command removes the profiles and disables the feature.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><b>sub-profile</b> <i>sub-profile-name</i> — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the <b>config&gt;subscr-mgmt&gt;sub-profile</b> context.</p> <p><b>sla-profile</b> <i>sla-profile-name</i> — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context.</p> <p><b>subscriber</b> <i>sub-ident-string</i> — Specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.</p> <ul style="list-style-type: none"> <li>For VPRN SAPs with <b>arp-reply-agent</b> enabled with the optional <i>sub-ident</i> parameter, the static subscriber host's <i>sub-ident-string</i> is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.</li> </ul> <p>If the static subscriber host's <i>sub-ident</i> string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.</p> <p>If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.</p> <p>If <i>sub-ident</i> is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.</p> <p>ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.</p> |

| <b>Description</b> | This command enables profiled traffic only for this SAP. The profiled traffic refers to single subscriber traffic on a dedicated SAP (in the VLAN-per-subscriber model). When enabled, subscriber queues are instantiated through the QOS policy defined in the sla-profile and the associated SAP queues are deleted. This can increase subscriber scaling by reducing the number of queues instantiated per subscriber (in the VLAN-per-subscriber model). In order for this to be achieved, any configured multi-sub-sap limit must be removed (leaving the default of 1). |

The **no** form of the command disables the command.

## sub-ident-policy

| <b>Description</b> | <p>This command associates a subscriber identification policy to this SAP. The subscriber identification policy must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sub-ident-policy</b> context.</p> <p>Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host.</p> <p>For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet string. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.</p> <p>When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.</p> <p>The <b>no</b> form of the command removes the default subscriber identification policy from the SAP configuration.</p> |
| <b>Default</b>     | no sub-ident-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>sub-ident-policy-name</i> — Specifies a subscriber identification policy for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscriber-mgmt&gt;sub-ident-policy</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command creates an SRRP instance on a group IP interface. An SRRP instance manages all subscriber subnets within the group interfaces subscriber IP interface or other subscriber IP interfaces that are associated through a wholesale/retail relationship. Only one unique SRRP instance can be configured per group interface.</p> <p>The <b>no</b> form of the command removes an SRRP instance from a group IP interface. Once removed, the group interface ignores ARP requests for the SRRP gateway IP addresses that may exist on subscriber subnets associated with the group IP interface. Then the group interface stops routing using the redundant IP interface associated with the group IP interface and will stop routing with the SRRP gateway MAC address. Ingress packets destined to the SRRP gateway MAC will also be silently discarded. This is the same behavior as a group IP interface that is disabled (shutdown).</p> |
| <b>Default</b>     | no srrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>srrp-id</i> — Specifies a 32 bit instance ID that must be unique to the system. The instance ID must also match the instance ID used by the remote router that is participating in the same SRRP context. SRRP is intended to perform a function similar to VRRP where adjacent IP hosts within local subnets use a default gateway to access IP hosts on other subnets.</p> <p><b>Values</b> 1 to 4294967295</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.</p> <p>One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.</p> <p>The <b>no</b> form of the command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.</p> |

|                   |                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>mac-address</i> — specifies a MAC address that is used to override the default SRRP base MAC address                                                                                                                          |
| <b>Values</b>     | Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address. |
| <b>Default</b>    | If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.                                                                          |

| <b>Description</b> | <p>This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.</p> <p>When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.</p> <p>The keep-alive-interval may be changed at anytime, but will have no effect until the SRRP instance is in the master state.</p> <p>The <b>no</b> form of the command restores the default interval.</p> |
| <b>Parameters</b>  | <i>interval</i> — specifies the interval, in ms, between SRRP advertisement messages sent when operating in the master state                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Values</b>      | 1 to 100                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## message-path

|                |                                                             |
|----------------|-------------------------------------------------------------|
| <b>Syntax</b>  | <b>message-path</b> <i>sap-id</i><br><b>no message-path</b> |
| <b>Context</b> | config>service>vpn>sub-if>grp-if>srrp                       |

**Description** This command defines a specific SAP for SRRP in-band messaging. A message-path SAP must be defined prior to activating the SRRP instance. The defined SAP must exist on the SRRP instances group IP interface for the command to succeed and cannot currently be associated with any dynamic or static subscriber hosts. Once a group IP interface SAP has been defined as the transmission path for SRRP Advertisement messages, it cannot be administratively shutdown, will not support static or dynamic subscriber hosts and cannot be removed from the group IP interface.

The SRRP instance message-path command may be executed at anytime on the SRRP instance. Changing the message SAP will fail if a dynamic or static subscriber host is associated with the new SAP. Once successfully changed, the SRRP instance will immediately disable anti-spoof on the SAP and start sending SRRP Advertisement messages if the SRRP instance is activated.

Changing the current SRRP message SAP on an active pair of routers should be done in the following manner:

1. Shutdown the backup SRRP instance.
2. Change the message SAP on the shutdown node.
3. Change the message SAP on the active master node.
4. Re-activate the shutdown SRRP instance.

Shutting down the backup SRRP instance prevents the SRRP instances from becoming master due to temporarily using differing message path SAPs.

If an MCS peering is operational between the redundant nodes and the SRRP instance has been associated with the peering, the designated message path SAP will be sent from each member.

The **no** form of the command can only be executed when the SRRP instance is shutdown. Executing no message-path allows the existing SAP to be used for subscriber management functions. A new message-path SAP must be defined prior to activating the SRRP instance.

**Parameters** *sap-id* — specifies the physical port identifier portion of the SAP definition

## policy

**Syntax** **[no] policy** *vrp-policy-id*

**Context** config>service>vprn>sub-if>grp-if>srrp

**Description** This command associates one or more VRRP policies with the SRRP instance. A VRRP policy is a collection of connectivity and verification tests used to manipulate the in-use priorities of VRRP and SRRP instances. A VRRP policy can test the link state of ports, ping IP hosts, discover the existence of routes in the routing table or the ability to reach Layer 2 hosts. When one or more of these tests fail, the VRRP policy has the option of decrementing or setting an explicit value for the in-use priority of an SRRP instance.

More than one VRRP policy may be associated with an SRRP instance. When more than one VRRP policy is associated with an SRRP instance the delta decrement of the in-use priority is cumulative unless one or more test fail that have explicit priority values. When one or more explicit tests fail, the lowest priority value event takes effect for the SRRP instance. When the highest delta-in-use-limit is used to manage the lowest delta derived in-use priority for the SRRP instance.

VRRP policy associations may be added and removed at anytime. A maximum of two VRRP policies can be associated with a single SRRP instance.

The **no** form of the command removes the association with vrrp-policy-id from the SRRP instance.

Parameters

vrrp-policy-id — specifies one or more VRRP policies with the SRRP instance

Values1 to 9999

| Description | <p>This command overrides the default base priority for the SRRP instance. The SRRP instance priority is advertised by the SRRP instance to its neighbor router and is compared to the priority received from the neighbor router. The router with the best (highest) priority enters the master state while the other router enters the backup state. If the priority of each router is the same, the router with the lowest source IP address in the SRRP advertisement message assumes the master state.</p> <p>The base priority of an SRRP instance can be managed by VRRP policies. A VRRP policy defines a set of connectivity or verification tests which, when they fail, may lower an SRRP instances base priority (creating an in-use priority for the instance). Every time an SRRP instances in-use priority changes when in master state, it sends an SRRP advertisement message with the new priority. If the dynamic priority drops to zero or receives an SRRP Advertisement message with a better priority, the SRRP instance transitions to the <i>becoming backup</i> state.</p> <p>When the priority command is not specified, or the no priority command is executed, the system uses a default base priority of 100. The priority command may be executed at anytime.</p> <p>The <b>no</b> form of the command restores the default base priority to the SRRP instance. If a VRRP policy is associated with the SRRP instance, it will use the default base priority as the basis for any modifications to the SRRP instances in-use priority.</p> |

|                   |                                                                                           |
|-------------------|-------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>priority</i> — specifies a base priority for the SRRP instance to override the default |
| <b>Values</b>     | 1 to 254                                                                                  |
| <b>Default</b>    | 100                                                                                       |

## send-fib-population-packets

|                    |                                                                                                                                          |

| <b>Default</b>     | no send-fib-population-packets                                                                                                                   |

### 3.9.2.26 BGP Commands

## bgp

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] bgp</b>                                              |
| <b>Context</b>     | service>vprn                                                 |
| <b>Description</b> | This command enables the BGP protocol with the VPRN service. |

The **no** form of the command disables the BGP protocol from the given VPRN service.

**Default**    no bgp

## bgp-shared-queue

|                    |                                                                                                                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bgp-shared-queue</b> [ <i>cir rate</i> ] [ <i>pir rate</i> ]<br><b>no bgp-shared-queue</b>                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command enables all BGP peers within a VPRN instance to share a single CPM queue. This command takes affect on new BGP connections established; already established BGP peers continue to use their own CPM queue. Any changes to PIR/CIR of the shared queue takes effect only after BGP connections are re-established. |
| <b>Parameters</b>  | <b>cir rate</b> — specifies the CIR rate for the shared queue<br><b>pir rate</b> — specifies the PIR rate for the shared queue                                                                                                                                                                                                 |

## advertise-inactive

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command enables or disables the advertising of inactive BGP routers to other BGP peers.</p> <p>By default, BGP only advertises BGP routes to other BGP peers if a given BGP route is chosen by the route table manager as the most preferred route within the system and is active in the forwarding plane. This command allows system administrators to advertise a BGP route even though it is not the most preferred route within the system for a given destination.</p> |
| <b>Default</b>     | no advertise-inactive                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command configures the comparison of BGP routes based on the MED attribute. The default behavior of SR-OS (equivalent to the <b>no</b> form of the command) is to only compare two routes on the basis of MED if they have the same neighbor AS (the first non-confed AS in the received AS_PATH attribute). Also by default, a route without a MED attribute is handled the same as though it had a MED attribute with the value 0. The <b>always-compare-med</b> command without the <b>strict-as</b> keyword allows MED to be compared even if the paths have a different neighbor AS; in this case, if neither <b>zero</b> or <b>infinity</b> is specified, the <b>zero</b> option is inferred, meaning a route without a MED is handled the same as though it had a MED attribute with the value 0. When the <b>strict-as</b> keyword is present, MED is only compared between paths from the same neighbor AS, and in this case, <b>zero</b> or <b>infinity</b> is mandatory and tells BGP how to interpret paths without a MED attribute.</p> |
| <b>Default</b>     | <b>no always-compare-med</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <b>zero</b> — Specifies that for routes learned without a MED attribute that a zero (0) value is used in the MED comparison. The routes with the lowest metric are the most preferred.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**infinity** — Specifies for routes learned without a MED attribute that a value of infinity ( $2^{32}-1$ ) is used in the MED comparison. This in effect makes these routes the least desirable.

**strike-as** — specifies BGP paths to be compared even with different neighbor AS

## as-path-ignore

| <b>Description</b> | <p>This command controls how the BGP decision process compares routes on the basis of MED. When <b>deterministic-med</b> is configured, BGP groups paths that are equal up to the MED comparison step based on neighbor AS, and then compares the best path from each group to arrive at the overall best path. This change to the BGP decision process makes best path selection completely deterministic in all cases. Without <b>deterministic-med</b>, the overall best path selection is sometimes dependent on the order of the route arrival because of the rule that MED cannot be compared in routes from different neighbor AS.</p> |
| <b>Default</b>     | no deterministic-med                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command instructs the BGP decision process to ignore the difference between EBGp and IBGP routes in selecting the best path and eligible multipaths (if multipath and ECMP are enabled). The result is a form of EIBGP load-balancing in a multipath scenario.</p> <p>By default (with the <b>no</b> form of the command), the BGP decision process prefers an EBGp learned route over an IBGP learned route.</p> <p>The behavior can be applied selectively to only certain types of routes by specifying one or more address family names in the command. If no families are specified, the command applies to IPv4 and IPv6 routes, and VPN-IPv4 and VPN-IPv6 routes.</p> |
| <b>Default</b>     | no ebgp-ibg-equal                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><b>ipv4</b> — Specifies that the command should be applied to unlabeled unicast IPv4 routes.</p> <p><b>ipv6</b> — Specifies that the command should be applied to unlabeled unicast IPv6 routes.</p> <p><b>label-ipv4</b> — Specifies that the command should be applied to labeled IPv4 routes.</p>                                                                                                                                                                                                                                                                                                                                                                              |

## as-override

|                    |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] as-override</b>                                                                                                                                                                                       |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                       |
| <b>Description</b> | <p>This command replaces all instances of the peer's AS number with the local AS number in a BGP route's AS_PATH.</p> <p>This command breaks BGP's loop detection mechanism. It should be used carefully.</p> |
| <b>Default</b>     | as-override is not enabled by default.                                                                                                                                                                        |

## authentication-key

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-key</b> [authentication-key   hash-key] [hash   hash2]<br><b>no authentication-key</b> |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor       |
| <b>Description</b> | This command configures the BGP authentication key.                                                      |

Authentication is performed between neighboring routers before setting up the BGP session by verifying the password. Authentication is performed using the MD-5 message-based digest. The authentication key can be any combination of letters or numbers from 1 to 16.

The no form of the command removes the authentication password from the configuration and effectively disables authentication.

**Default** Authentication is disabled and the authentication password is empty.

**Parameters** *authentication-key* — The authentication key. The key can be any combination of ASCII characters up to 255 characters in length (unencrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

*hash-key* — The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

**hash** — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

**hash2** — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

## auth-keychain

**Syntax** **auth-keychain** *name*

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description** This command configures the BGP authentication key for all peers.

The keychain allows the rollover of authentication keys during the lifetime of a session.

**Default** no auth-keychain

**Parameters** *name* — specifies the name of an existing keychain, up to 32 characters, to use for the specified TCP session or sessions

## best-path-selection

|                    |                                                    |
|--------------------|----------------------------------------------------|
| <b>Syntax</b>      | <b>best-path-selection</b>                         |
| <b>Context</b>     | config>service>vprn>bgp                            |
| <b>Description</b> | This command enables path selection configuration. |

## ignore-nh-metric

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>router>bgp>best-path-selection<br>config>service>vprn<br>config>service>vprn>bgp>best-path-selection                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command instructs BGP to disregard the resolved distance to the BGP next-hop in its decision process for selecting the best route to a destination. When configured in the config&gt;router&gt;bgp&gt;best-path-selection context, this command applies to the comparison of two BGP routes with the same NLRI learned from base router BGP peers. When configured in the config&gt;service&gt;vprn context, this command applies to the comparison of two BGP-VPN routes for the same IP prefix imported into the VPRN from the base router BGP instance. When configured in the config&gt;service&gt;vprn&gt;bgp&gt;best-path-selection context, this command applies to the comparison of two BGP routes for the same IP prefix learned from VPRN BGP peers.</p> <p>The no form of the command (no ignore-nh-metric) restores the default behavior whereby BGP factors distance to the next-hop into its decision process.</p> |
| <b>Default</b>     | no ignore-nh-metric                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command enables the use of bi-directional forwarding (BFD) to control the state of the associated protocol interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface.</p> <p>The <b>no</b> form of this command removes BFD from the associated BGP protocol peering.</p> |
| <b>Default</b>     | no bfd-enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Syntax</b>      | <b>cluster <i>cluster-id</i></b><br><b>no cluster</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | <p>This command configures the cluster ID for a route reflector server.</p> <p>Route reflectors are used to reduce the number of IBGP sessions required within an AS. Normally, all BGP speakers within an AS must have a BGP peering with every other BGP speaker in an AS. A route reflector and its clients form a cluster. Peers that are not part of the cluster are considered to be non-clients.</p> <p>When a route reflector receives a route, first it must select the best path from all the paths received. If the route was received from a non-client peer, then the route reflector sends the route to all clients in the cluster. If the route came from a client peer, the route reflector sends the route to all non-client peers and to all client peers except the originator.</p> <p>For redundancy, a cluster can have multiple route reflectors.</p> <p>Confederations can also be used to remove the full IBGP mesh requirement within an AS.</p> <p>The <b>no</b> form of the command deletes the cluster ID and effectively disables the Route Reflection for the given group.</p> |
| <b>Default</b>     | no cluster — No cluster ID is defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

---

**Parameters** *cluster-id* — The route reflector cluster ID is expressed in dot decimal notation.

**Values** Any 32 bit number in dot decimal notation. (0.0.0.1 to 255.255.255.255)

## connect-retry

**Syntax** **connect-retry** *seconds*  
**no connect-retry**

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description** This command configures the BGP connect retry timer value in seconds.

When this timer expires, BGP tries to reconnect to the configured peer. This configuration parameter can be set at three levels: global level (applies to all peers), peer-group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of the command used at the global level reverts to the default value.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Default** 120 seconds

**Parameters** *seconds* — the BGP Connect Retry timer value in seconds, expressed as a decimal integer

**Values** 1 to 65535

## damp-peer-oscillations

**Syntax** **damp-peer-oscillations** [*idle-hold-time initial-wait second-wait max-wait*] [*error-interval minutes*]

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command controls how long a BGP peer session remains in the idle-state after some type of error causes the session to reset. In the idle state, BGP does not initiate or respond to attempts to establish a new session. Repeated errors that occur a short while after each session reset cause longer and longer hold times in the idle state. This command supports the DampPeerOscillations FSM behavior described in section 8.1 of RFC 4271, <i>A Border Gateway Protocol 4 (BGP-4)</i>.</p> <p>The default behavior, which applies when no damp-peer-oscillations is configured, is to immediately transition out of the idle-state after every reset.</p>                                                                                                                                                                                                                                        |
| <b>Default</b>     | no damp-peer-oscillations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>initial-wait</i> — the amount of time, in minutes, that a session remains in the idle-state after it has been stable for a while</p> <p><b>Values</b> 0 to 2048</p> <p><b>Default</b> 0</p> <p><i>second-wait</i> — a period of time, in minutes, that is doubled after each repeated session failure that occurs within a relatively short span of time</p> <p><b>Values</b> 0 to 2048</p> <p><b>Default</b> 5</p> <p><i>max-wait</i> — the maximum amount of time, in minutes, that a session remains in the idle-state after it has experienced repeated instability</p> <p><b>Values</b> 0 to 2048</p> <p><b>Default</b> 60</p> <p><i>minutes</i> — the interval of time, in minutes after a session reset, during which the session must be error-free in order to reset the penalty counter and return to idle-hold-time to initial-wait</p> <p><b>Values</b> 0 to 2048</p> <p><b>Default</b> 30</p> |

|                    |                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] damping                                                                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command enables BGP route damping for learned routes which are defined within the route policy. Use damping to reduce the number of update messages sent between BGP peers and reduce the load on peers without affecting the route convergence time for stable routes. Damping parameters are set via route policy definition.</p> |

The **no** form of the command used at the global level disables route damping.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

When damping is enabled and the route policy does not specify a damping profile, the default damping profile is used. This profile is always present and consists of the following parameters:

Half-life: 15 minutes

Max-suppress: 60 minutes

Suppress-threshold: 3000

Reuse-threshold: 750

**Default** no damping — Learned route damping is disabled.

| <b>Description</b> | <p>This command disables the use of 4-byte ASNs. It can be configured at all 3 level of the hierarchy so it can be specified down to the per peer basis.</p> <p>If this command is enabled 4-byte ASN support should not be negotiated with the associated remote peer(s).</p> <p>The <b>no</b> form of the command resets the behavior to the default which is to enable the use of 4-byte ASN.</p> |

## disable-capability-negotiation

|                    |                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] disable-capability-negotiation</b>                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                       |
| <b>Description</b> | <p>This command disables the exchange of capabilities. When command is enabled and after the peering is flapped, any new capabilities are not negotiated and will strictly support IPv4 routing exchanges with that peer.</p> |

The **no** form of the command removes this command from the configuration and restores the normal behavior.

**Default** no disable-capability-negotiation

## disable-client-reflect

**Syntax** [no] disable-client-reflect

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description** This command disables the reflection of routes by the route reflector to the group or neighbor. This only disables the reflection of routes from other client peers. Routes learned from non-client peers are still reflected to all clients.

The **no** form re-enables client reflection of routes.

**Default** no disable-client-reflect — Client routes are reflected to all client peers.

## disable-communities

**Syntax** disable-communities [standard] [extended]  
no disable-communities

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description** This command configures BGP to disable sending communities.

**Parameters** **standard** — specifies standard communities that existed before VPRNs or 2547  
**extended** — specifies BGP communities used were expanded after the concept of 2547 was introduced, to include handling the VRF target

## disable-fast-external-failover

**Syntax** [no] disable-fast-external-failover

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description** This command configures BGP fast external failover.

## dynamic-neighbor-limit

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | This command enables BGP peer tracking.                                                                                                     |
| <b>Default</b>     | no enable-peer-tracking                                                                                                                     |

## graceful-restart

|                    |                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] graceful-restart</b>                                                                                                                |
| <b>Context</b>     | <pre>config&gt;service&gt;vprn&gt;bgp config&gt;service&gt;vprn&gt;bgp&gt;group config&gt;service&gt;vprn&gt;bgp&gt;group&gt;neighbor</pre> |
| <b>Description</b> | This command enables or disables graceful-restart for all VPRN BGP peers.                                                                   |

## enable-notification

|               |                            |
|---------------|----------------------------|
| <b>Syntax</b> | <b>enable-notification</b> |
|---------------|----------------------------|

**no enable-notification**

|                    |                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>bgp>graceful-restart<br>config>service>vprn>bgp>group>graceful-restart<br>config>service>vprn>bgp>group>neighbor>graceful-restart                                                                                                                                                                                       |
| <b>Description</b> | When this command is present, the graceful restart capability sent by this router indicates support for NOTIFICATION messages. If the peer also supports this capability then the session can be restarted gracefully (while preserving forwarding) if either peer needs to send a NOTIFICATION message due to some type of event or error. |
| <b>Default</b>     | no enable-notification                                                                                                                                                                                                                                                                                                                      |

**restart-time**

|                    |                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>restart-time</b> <i>seconds</i><br><b>no restart-time</b>                                                                                                           |
| <b>Context</b>     | config>service>vprn>bgp>graceful-restart<br>config>service>vprn>bgp>group>graceful-restart<br>config>service>vprn>bgp>group>neighbor>graceful-restart                  |
| <b>Description</b> | This command sets the value of the restart-time that is advertised in the router's graceful-restart capability. If this command is not configured, the default is 300. |
| <b>Default</b>     | no restart time                                                                                                                                                        |
| <b>Parameters</b>  | <i>seconds</i> — the restart-time that is advertised in the router's graceful-restart capability<br><b>Values</b> 0 to 4095 seconds<br><b>Default</b> 300              |

**stale-routes-time**

|                    |                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] stale-routes-time</b> <i>time</i>                                                                                                             |
| <b>Context</b>     | config>service>vprn>bgp>graceful-restart<br>config>service>vprn>bgp>group>graceful-restart<br>config>service>vprn>bgp>group>neighbor>graceful-restart |
| <b>Description</b> | This command configures the time period to keep stale routes before the END-OF-RIB message is received from the restarting router.                    |
| <b>Default</b>     | 360 seconds                                                                                                                                           |
| <b>Parameters</b>  | <i>time</i> — [1 to 3600 seconds]                                                                                                                     |

## error-handling

|                    |                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>error-handling</b>                                                                                                               |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                  |
| <b>Description</b> | This command specifies whether the error handling mechanism for optional transitive path attributes is enabled for this peer group. |

## update-fault-tolerance

|                    |                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] update-fault-tolerance</b>                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>bgp>error-handling<br>config>service>vprn>bgp>group>error-handling<br>config>service>vprn>bgp>group>neighbor>error-handling                                                                                                                       |
| <b>Description</b> | This command enables <b>treat-as-withdraw</b> and other similarly non-disruptive approaches for handling a wide range of UPDATE message errors, as long as there are no length errors that prevent all of the NLRI fields from being correctly identified and parsed. |
| <b>Default</b>     | no fault-tolerance                                                                                                                                                                                                                                                    |

## export

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command is used to specify route policies that control how outbound routes transmitted to certain peers are handled. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context.</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in a peer-group) or neighbor level (only applies to the specified peer). The most specific level is used.</p> <p>The <b>export</b> command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.</p> |

Only one of the 15 objects referenced by the **export** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.

When multiple **export** commands are issued, the last command entered overrides the previous command.

When an export policy is not specified, BGP-learned routes are advertised by default; non-BGP routes are not advertised.

The **no** form of this command removes the policy association.

| <b>Description</b> | <p>This command enables/disables validation of received flowspec routes. A flow route with a destination prefix subcomponent received from a particular peer is considered valid if and only if that peer also advertised the best unicast route to the destination prefix and any of its more-specific components. If validation is enabled and a flowspec route is not valid, it is not eligible for import into the RIB, it is not used for filtering, and it is not propagated to other flowspec peers.</p> <p>The <b>no</b> form of the command disables the validation procedure.</p> |
| <b>Default</b>     | no flowspec-validate                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command creates a BGP peer/neighbor instance within the context of the BGP group.</p> <p>This command can be issued repeatedly to create multiple peers and their associated configuration.</p> <p>The <b>no</b> form of the command is used to remove the specified neighbor and the entire configuration associated with the neighbor. The neighbor must be administratively <b>shutdown</b> before attempting to delete it. If the neighbor is not shutdown, the command will not result in any action except a warning message on the console indicating that neighbor is still administratively up.</p> |
| <b>Default</b>     | n/a — No neighbors are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | <p>This command specifies the address family or families to be supported over BGP peerings in the base router. This command is additive so issuing the <b>family</b> command adds the specified address family to the list.</p> <p>The <b>no</b> form of the command removes the specified address family from the associated BGP peerings. If an address family is not specified, then reset the supported address family back to the default.</p> |

| <b>Description</b> | <p>This command configures the BGP hold time, expressed in seconds.</p> <p>The BGP hold time specifies the maximum time BGP waits between successive messages (either keepalive or update) from its peer, before closing the connection. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>Even though the router OS implementation allows setting the <a href="#">keepalive</a> time separately, the configured <a href="#">keepalive</a> timer is overridden by the <a href="#">hold-time</a> value under the following circumstances:</p> <ol style="list-style-type: none"> <li>1. If the specified hold-time is less than the configured <a href="#">keepalive</a> time, then the operational <a href="#">keepalive</a> time is set to a third of the <a href="#">hold-time</a>; the configured <a href="#">keepalive</a> time is not changed.</li> <li>2. If the <a href="#">hold-time</a> is set to zero, then the operational value of the <a href="#">keepalive</a> time is set to zero; the configured <a href="#">keepalive</a> time is not changed. This means that the connection with the peer is up permanently and no <a href="#">keepalive</a> packets are sent to the peer.</li> </ol> <p>The <b>no</b> form of the command used at the global level reverts to the default value.</p> <p>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | 90 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — The hold-time, in seconds, expressed as a decimal integer. A value of 0 indicates the connection to the peer is up permanently.<br><b>Values</b> 0, 3 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

*seconds2* — The minimum hold-time that will be accepted for the session. If the peer proposes a hold-time lower than this value the session attempt will be rejected.

| <b>Description</b> | <p>This command is used to specify route policies that control the handling of inbound routes received from certain peers. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context.</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in a peer-group) or neighbor level (only applies to the specified peer). The most specific level is used.</p> <p>The <b>import</b> command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine the modifications of each route and the final action to accept or reject the route.</p> <p>Only one of the 15 objects referenced by the <b>import</b> command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.</p> <p>When multiple <b>import</b> commands are issued, the last command entered overrides the previous command.</p> <p>When an import policy is not specified, BGP routes are accepted by default.</p> <p>The <b>no</b> form of this command removes the policy association.</p> |

| <b>Description</b> | <p>This command configures the BGP keepalive timer. A keepalive message is sent every time this timer expires. The <b>seconds</b> parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>The <b>keepalive</b> value is generally one-third of the <b>hold-time</b> interval. Even though the OS implementation allows the <b>keepalive</b> value and the <b>hold-time</b> interval to be independently set, under the following circumstances, the configured <b>keepalive</b> value is overridden by the <b>hold-time</b> value:</p> <p>If the specified <b>keepalive</b> value is greater than the configured <b>hold-time</b>, then the specified value is ignored, and the <b>keepalive</b> is set to one third of the current <b>hold-time</b> value.</p> <p>If the specified <b>hold-time</b> interval is less than the configured <b>keepalive</b> value, then the <b>keepalive</b> value is reset to one third of the specified <b>hold-time</b> interval.</p> <p>If the <b>hold-time</b> interval is set to zero, then the configured value of the <b>keepalive</b> value is ignored. This means that the connection with the peer is up permanently and no <b>keepalive</b> packets are sent to the peer.</p> <p>The <b>no</b> form of the command used at the global level reverts to the default value.</p> <p>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | 30 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## local-address

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-address</b> <i>ip-address</i><br><b>no local-address</b>                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                       |
| <b>Description</b> | <p>Configures the local IP address used by the group or neighbor when communicating with BGP peers.</p> <p>Outgoing connections use the <b>local-address</b> as the source of the TCP connection when initiating connections with a peer.</p> |

When a local address is not specified, the OS uses the system IP address when communicating with IBGP peers and uses the interface address for directly connected EBGp peers. This command is used at the neighbor level to revert to the value defined under the group level.

The **no** form of the command removes the configured local-address for BGP.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Parameters**    **no local-address** — the router ID is used when communicating with IBGP peers and the interface address is used for directly connected EBGp peers

*ip-address* — The local address expressed in dotted decimal notation. Allowed values are a valid routable IP address on the router, either an interface or system IP address.

## local-as

**Syntax**    **local-as** *as-number* [**private**] [**no-prepend-global-as**]  
**no local-as**

**Context**    config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description**    This command configures a BGP virtual autonomous system (AS) number.

In addition to the global AS number configured for BGP in the config>router>autonomous-system context, a virtual (local) AS number can be configured to support various AS number migration scenarios. The local AS number is added to the beginning of the as-path attribute ahead of the router's AS number.

This configuration parameter can be set at three levels: global level (applies to all EBGp peers), group level (applies to all EBGp peers in peer-group) or neighbor level (only applies to EBGp specified peer). Thus, by specifying this at each neighbor level, it is possible to have a separate local-as per EBGp session. The local-as command is not supported for IBGP sessions. When the optional **private** keyword is specified in the command the local-as number is not added to inbound routes from the EBGp peer that has **local-as** in effect.

When a command is entered multiple times for the same AS, the last command entered is used in the configuration. The **private** attribute can be added or removed dynamically by reissuing the command.

Changing the local AS at the global level in an active BGP instance causes the BGP instance to restart with the new local AS number. Changing the local AS at the global level in an active BGP instance causes BGP to re-establish the peer relationships with all peers in the group with the new local AS number. Changing the local AS at the neighbor level in an active BGP instance causes BGP to re-establish the peer relationship with the new local AS number.

This is an optional command and can be used in the following circumstance:

Provider router P is moved from AS1 to AS2. The customer router that is connected to P, however, is configured to belong to AS1. To avoid reconfiguring the customer router, the **local-as** value on router P can be set to AS1. Thus, router P adds AS1 to the as-path message for routes it advertises to the customer router.

The **no** form of the command used at the global level will remove any virtual AS number configured.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

|                   |                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no local-as                                                                                              |
| <b>Parameters</b> | <i>as-number</i> — the virtual autonomous system number, expressed as a decimal integer                  |
| <b>Values</b>     | 1 to 65535                                                                                               |
|                   | <b>private</b> — specifies the local-as is hidden in paths learned from the peering                      |
|                   | <b>no-prepend-global-as</b> — specifies that the global-as is hidden in paths announced to the EBGp peer |

## local-preference

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command enables setting the BGP local-preference attribute in incoming routes if not specified and configures the default value for the attribute. This value is used if the BGP route arrives from a BGP peer without the <b>local-preference</b> integer set.</p> <p>The specified value can be overridden by any value set via a route policy. This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> |

The **no** form of the command at the global level specifies that incoming routes with local-preference set are not overridden and routes arriving without local-preference set are interpreted as if the route had local-preference value of 100.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no local-preference - Does not override the local-preference value set in arriving routes and analyze routes without local preference with value of 100. |
| <b>Parameters</b> | <i>local-preference</i> — the local preference value to be used as the override value, expressed as a decimal integer                                    |
| <b>Values</b>     | 0 to 4294967295                                                                                                                                          |

| <b>Description</b> | <p>This command enables advertising the Multi-Exit Discriminator (MED) and assigns the value used for the path attribute for the MED advertised to BGP peers if the MED is not already set.</p> <p>The specified value can be overridden by any value set via a route policy.</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> <p>The <b>no</b> form of the command used at the global level reverts to default where the MED is not advertised.</p> <p>The <b>no</b> form of the command used at the group level reverts to the value defined at the global level.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Default</b>     | no med-out                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <p><i>number</i> — the MED path attribute value, expressed as a decimal integer</p> <p><b>Values</b>      0 to 4294967295</p> <p><b>igp-cost</b> — the MED is set to the IGP cost of the given IP prefix</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## min-route-advertisement

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-route-advertisement seconds</b><br><b>no min-route-advertisement</b>                              |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor       |
| <b>Description</b> | This command configures the minimum interval, in seconds, at which a prefix can be advertised to a peer. |

This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.

The **no** form of the command reverts to default values.

| <b>Context</b>     | config>service>vprn>bgp                                                                                                                                                                                    |
| <b>Description</b> | This command enables BGP multipath for the IPv4 and IPv6 address families.                                                                                                                                 |

When multipath is enabled, traffic to the destination is load-shared across a set of paths (BGP routes) that the BGP decision process considers 'equal' to the best path. The actual distribution of traffic over the multiple paths may be equal or unequal (that is, based on weights derived from the Link Bandwidth extended community).

To qualify as a multipath, a non-best route must meet the following criteria (some criteria are controlled by this command):

- must be the same type of route as the best path (same AFI/SAFI and, in some cases, same next-hop resolution method)
- must be tied with the best path for all criteria of equal or higher importance than IGP cost to reach the BGP next-hop, except for criteria that are configured to be ignored
- must not have the same BGP next-hop as the best path or any other multipath
- must not cause the ECMP limit of the routing instance to be exceeded (configurable using the **ecmp** command to a value in the range 1-64)
- must not cause the configured *max-paths* limit of the BGP instance to be exceeded  
If the best path is an EBGp learned route and the **ebgp** option is present, the *ebgp-max-paths* limit overrides the *max-paths* limit. If the best path is an IBGP learned route and the **ibgp** option is present, the *ibgp-max-paths* limit overrides the *max-paths* limit.  
All path limits are configurable up to a maximum of 64. Multipath is effectively disabled if a value is set to one
- must have the same neighbor AS in its AS path as the best path if the **restrict same-neighbor-as** option is configured  
By default, any path with the same AS path length as the best path (regardless of neighbor AS) is eligible for multipath.
- must have the exact same AS path as the best path if the **restrict exact-as-path** option is configured  
By default, any path with the same AS path length as the best path (regardless of the actual AS numbers) is eligible for multipath.

The **no** form of the command disables BGP multipath (equivalent to multipath 1).

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Default</b>    | no multipath                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b> | <p><i>max-paths</i> — the maximum number of multipaths per prefix/NLRI if <i>ebgp-max-paths</i> or <i>ibgp-max-paths</i> does not apply</p> <p><b>Values</b> 1 to 64</p> <p><i>ebgp-max-paths</i> — the maximum number of multipaths per prefix/NLRI when the best path is an EBGp-learned route</p> <p><b>Values</b> 1 to 64</p> <p><i>ibgp-max-paths</i> — the maximum number of multipaths per prefix/NLRI when the best path is an IBGP-learned route</p> <p><b>Values</b> 1 to 64</p> <p><b>same-neighbor-as</b> — the non-best path must have the same neighbor AS in its AS path as the best path</p> |

**exact-as-path-as** — the non best path must have the exact same AS path as the best path

## next-hop-resolution

|                    |                                                                               |
|--------------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>next-hop-resolution</b>                                                    |
| <b>Context</b>     | config>service>vprn>bgp                                                       |
| <b>Description</b> | This command enables the context to configure next-hop resolution parameters. |

## next-hop-self

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] next-hop-self</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command configures the group or neighbor to always set the NEXTHop path attribute to its own physical interface when advertising to a peer.</p> <p>This is primarily used to avoid third-party route advertisements when connected to a multi-access network.</p> <p>The <b>no</b> form of the command used at the group level allows third-party route advertisements in a multi-access network.</p> <p>The <b>no</b> form of the command used at the neighbor level reverts to the value defined at the group level.</p> |
| <b>Parameters</b>  | <b>no next-hop-self</b> — third-party route advertisements are allowed                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## passive

|                    |                                                                                                                                                                                                                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] passive</b>                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables passive mode for the BGP group or neighbor.</p> <p>When in passive mode, BGP will not attempt to actively connect to the configured BGP peers but responds only when it receives a connect open request from the peer.</p> <p>The <b>no</b> form of the command used at the group level disables passive mode where BGP actively attempts to connect to its peers.</p> |

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

**Parameters**    **no passive** — BGP will actively try to connect to all the configured peers

## peer-as

**Syntax**    **peer-as** *as-number*

**Context**    config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description**    This command configures the autonomous system number for the remote peer. The peer AS number must be configured for each configured peer.

For EBGp peers, the peer AS number configured must be different from the autonomous system number configured for this router under the global level since the peer will be in a different autonomous system than this router

For IBGP peers, the peer AS number must be the same as the autonomous system number of this router configured under the global level.

This is a required command for each configured peer. This may be configured under the group level for all neighbors in a particular group.

**Default**    No AS numbers are defined.

**Parameters**    *as-number* — the autonomous system number, expressed as a decimal integer

**Values**    1 to 65535

## policy

**Syntax**    **policy** *policy-name*  
**no policy**

**Context**    config>service>vprn>bgp>next-hop-res

**Description**    This command specifies the name of a policy statement to use with the BGP next-hop resolution process. The policy controls which IP routes in RTM are eligible to resolve the BGP next-hop addresses of IPv4 and IPv6 routes. The policy has no effect on the resolution of BGP next-hops to MPLS tunnels. If a BGP next-hop of an IPv4 or IPv6 route R is resolved in RTM and the longest matching route for the next-hop address is an IP route N that is rejected by the policy then route R is unresolved; if the route N is accepted by the policy then it becomes the resolving route for R.

The default next-hop resolution policy (when the **no policy** command is configured) is to use the longest matching active route in RTM that is not a BGP route (unless **use-bgp-routes** is configured), an aggregate route or a subscriber management route.

---

| <b>Description</b> | <p>This command specifies the name of a policy statement to use with the BGP peer-tracking function on the BGP sessions where this is enabled. The policy controls which IP routes in RTM are eligible to indicate reachability of IPv4 and IPv6 BGP neighbor addresses. If the longest matching route in RTM for a BGP neighbor address is an IP route that is rejected by the policy, or it is a BGP route accepted by the policy, or if there is no matching route, the neighbor is considered unreachable and BGP tears down the peering session and holds it in the idle state until a valid route is once again available and accepted by the policy.</p> <p>The default peer-tracking policy (when the no peer-tracking-policy command is configured) is to use the longest matching active route in RTM that is not an LDP shortcut route or an aggregate route.</p> |
| <b>Default</b>     | no peer-tracking-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>policy-name</i> — The route policy name. Allowed values are any string up to 64 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed between double quotes. Route policies are configured in the <b>config&gt;router&gt;policy-options</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## preference

|                    |                                                                                                                                                                                                                                                                                                                                                |

| <b>Syntax</b>      | <b>[no] preference preference</b>                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>vprn>bgp<br>config>service>vprn>bgp>group                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command configures the route preference for routes learned from the configured peer(s).</p> <p>This configuration parameter can be set at three levels: global level (applies to all peers), group level (applies to all peers in peer-group) or neighbor level (only applies to specified peer). The most specific value is used.</p> |

The lower the preference the higher the chance of the route being the active route. The OS assigns BGP routes highest default preference compared to routes that are direct, static or learned via MPLS or OSPF.

The **no** form of the command used at the global level reverts to default value.

The **no** form of the command used at the group level reverts to the value defined at the global level.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

| <b>Description</b> | <p>This command configures the maximum number of BGP routes that can be received from a peer before administrative action is taken. The administrative action can be the generation of a log event or taking down the session. If a session is taken down, then it can be brought back up automatically after an idle-timeout period, or else it can be configured to stay down ('forever') until the operator performs a reset.</p> <p>The <b>prefix-limit</b> command allows each address family to have its own limit; a set of address family limits can be applied to one neighbor or to all neighbors in a group.</p> <p>The <b>no</b> form of the command removes the <b>prefix-limit</b>.</p> |
| <b>Default</b>     | No prefix limits for any address family.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>percent</i> — the threshold value (as a percentage) that triggers a warning message to be sent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|                    | <b>Values</b> 1 to 100                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|                    | <b>Values</b> ipv4, label-ipv4, ipv6, mcast-ipv4, flow-ipv4, flow-ipv6, mcast-ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

*limit* — the number of routes that can be learned from a peer expressed as a decimal integer

**Values** 1 to 4294967295

*minutes* — specifies duration in minutes before automatically re-establishing a session

**Values** 1 to 1024

**forever** — specifies that the session is reestablished only after **clear router bgp** command is executed

**log-only** — Enables the warning message to be sent at the specified threshold percentage, and also when the limit is reached. However, the BGP session is not taken down.

**post-import** — specifies that the limit should be applied only to the number of routes that are accepted by import policies

## rapid-withdrawal

**Syntax** [no] **rapid-withdrawal**

**Context** config>service>vprn>bgp

**Description** This command disables the delay (Minimum Route Advertisement) on sending BGP withdrawals. Normal route withdrawals may be delayed up to the minimum route advertisement to allow for efficient packing of BGP updates.

The **no** form of the command removes this command from the configuration and returns withdrawal processing to the normal behavior.

**Default** no rapid-withdrawal

## remove-private

**Syntax** **remove-private** [limited] [skip-peer-as]  
**no remove-private**

**Context** config>service>vprn>bgp  
config>service>vprn>bgp>group  
config>service>vprn>bgp>group>neighbor

**Description** This command allows private AS numbers to be removed from the AS path before advertising them to BGP peers.

When the **remove-private** parameter is set at the global level, it applies to all peers regardless of group or neighbor configuration. When the parameter is set at the group level, it applies to all peers in the group regardless of the neighbor configuration.

The OS software recognizes the set of AS numbers that are defined by IANA as private. These are AS numbers in the range 64512 through 65535, inclusive.

The **no** form of the command used at the global level reverts to default value. The **no** form of the command used at the group level reverts to the value defined at the global level. The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

|                   |                                                                                                                                                                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no remove-private - Private AS numbers will be included in the AS path attribute.                                                                                                                                                                                                                           |
| <b>Parameters</b> | <i>limited</i> — This optional keyword removes private ASNs up to the first public ASN encountered. It then stops removing private ASNs.<br><i>skip-peer-as</i> — This optional keyword causes this command to not remove a private ASN from the AS-Path if that ASN is the same as the BGP peer AS number. |

## rib-management

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rib-management</b>                                                    |
| <b>Context</b>     | config>service>vprn>bgp                                                  |
| <b>Description</b> | This command enables the context to configure RIB management parameters. |
| <b>Default</b>     | N/A                                                                      |

## leak-import

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command is used to specify route policies that control the importation of leak-eligible routes from the BGP RIB of another routing instance into the unlabeled-IPv4, unlabeled-IPv6, or labeled-IPv4 RIB of the base router. To leak a route from one routing instance to another, the origin and destination RIB types must be the same; for example, it is not possible to leak a route from an unlabeled-IPv4 RIB of a VPRN into the labeled-IPv4 RIB of the base router.</p> <p>The <b>leak-import</b> command can reference up to 15 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine final action to accept or reject the route.</p> <p>Only one of the 15 objects referenced by the <b>leak-import</b> command is allowed to be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 15 objects has a maximum length of 255 characters while the remaining 14 objects have a maximum length of 64 characters each.</p> |

When multiple **leak-import** commands are issued, the last command entered overrides the previous command.

When a **leak-import** policy is not specified, no BGP routes from other routing instances are leaked into the VPRN BGP RIB.

The **no** form of the command removes the policy association.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command specifies the name of a route policy to control the importation of active routes from the IP route table into one of the BGP RIBs.</p> <p>If the <b>route-table-import</b> command is not configured, or if the command refers to an empty policy, all non-BGP routes from the IP route table are imported into the applicable RIB.</p> <p>If the <b>route-table-import</b> command is configured, then routes dropped or rejected by the configured policy are not installed in the associated RIB. Rejected routes cannot be advertised to BGP peers associated with the RIB, but they can still be used to resolve BGP next-hops of routes in that RIB. If the active route for a prefix is rejected by the <b>route-table-import</b> policy, then the best BGP route for that prefix in the BGP RIB can be advertised to peers as though it is used.</p> <p>Aggregate routes are always imported into each RIB, independent of the <b>route-table-import</b> policy.</p> <p>Route modifications specified in the actions of a <b>route-table-import</b> policy are ignored and have no effect on the imported routes.</p> |
| <b>Default</b>     | no route-table-import                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies the name of a policy-statement (up to 64 characters).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command enables the use of split-horizon. When applied globally, to a group, or a specific peer, split-horizon prevents routes from being reflected back to a peer that sends the best route. It applies to routes of all address families and to any type of sending peer; confed-EBGP, EBGP and IBGP.</p> <p>The configuration default is <b>no split-horizon</b>, meaning that no effort is taken to prevent a best route from being reflected back to the sending peer.</p> |

**Caution:** Use of the **split-horizon** command may have a detrimental impact on peer and route scaling and therefore operators are encouraged to use it only when absolutely needed.

The **no** form of the command disables split horizon command which allows the lower level to inherit the setting from an upper level.

**Default** no split-horizon

| <b>Description</b> | <p>Use this command to enable the router to send third-party next-hop to EBGp peers in the same subnet as the source peer, as described in RFC 4271. If enabled when an IPv4 or IPv6 route is received from one EBGp peer and advertised to another EBGp peer in the same IP subnet, the BGP next-hop is left unchanged. Third-party next-hop is not done if the address family of the transport does not match the address family of the route.</p> <p>The <b>no</b> form of the command prevents BGP from performing any third party next-hop processing toward any single-hop EBGp peers within the scope of the command. No third-party next-hop means the next-hop will always carry the IP address of the interface used to establish the TCP connection to the peer.</p> |
| <b>Default</b>     | no third-party-nexthop                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Context</b>     | config>service>vprn>bgp>group<br>config>service>vprn>bgp>group>neighbor                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command designates the BGP peer as type internal or external.</p> <p>The type of <b>internal</b> indicates the peer is an IBGP peer while the type of external indicates that the peer is an EBGp peer.</p> <p>By default, the OS derives the type of neighbor based on the local AS specified. If the local AS specified is the same as the AS of the router, the peer is considered <b>internal</b>. If the local AS is different, then the peer is considered <b>external</b>.</p> |

The **no** form of the command used at the group level reverts to the default value.

The **no** form of the command used at the neighbor level reverts to the value defined at the group level.

| <b>Description</b> | <p>This command enables the collection of statistics on the SAP or MPLS SDP binding on which the ETH- LMM test is configured. The collection of LMM statistics must be enabled if a MEP is launching or responding to ETH-LMM packets. If LMM statistics collection is not enabled, the counters in the LMM and LMR PDU do not represent accurate measurements and all measurements should be ignored. The <b>show sap-using eth-cfm collect-lmm-stats</b> command and the <b>show sdp-using eth-cfm collect-lmm-stats</b> command can be used to display which entities are collecting stats.</p> <p>The <b>no</b> form of the command disables and deletes the counters for this SAP or MPLS SDP binding.</p> |
| <b>Default</b>     | <b>no collect-lmm-stats</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Context</b>     | config>service>vprn>sap>eth-cfm>mep>ais-enable<br>config>service>vprn>spoke-sdp>eth-cfm>mep>ais-enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command enables the AIS function to consider the operational state of the entity on which it is configured. With this command, ETH-AIS on DOWN MEPs will be triggered and cleared based on the operational status of the entity on which it is configured. If CCM is also enabled then transmission of the AIS PDU will be based on either the non operational state of the entity or on ANY CCM defect condition. AIS generation will cease if BOTH operational state is UP and CCM has no defect conditions. If the MEP is not CCM enabled then the operational state of the entity is the only consideration assuming this command is present for the MEP. |
| <b>Default</b>     | <b>no interface-support-enabled</b> (AIS will not be generated or stopped based on the state of the entity on) which the DOWN MEP is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command enables eth-test functionality on MEP. For this test to work, operators need to configure ETH-test parameters on both sender and receiver nodes. The ETH-test then can be done using the following OAM commands:</p> <pre>oam eth-cfm eth-test <i>mac-address</i> mep <i>mep-id</i> domain <i>md-index</i> association <i>ma-index</i> [priority <i>priority</i>] [data-length <i>data-length</i>]</pre> <p>A check is done for both the provisioning and test to ensure the MEP is an Y.1731 MEP (MEP provisioned with domain format none, association format icc-based). If not, the operation fails. An error message in the CLI and SNMP will indicate the problem.</p> |

## test-pattern

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>test-pattern</b> { <b>all-zeros</b>   <b>all-ones</b> } [ <b>crc-enable</b> ]<br><b>no test-pattern</b>                                                                              |

| <b>Description</b> | <p>This command defines the levels of the ETH-CFM PDUs that will silently be discarded on ingress into the SAP or SDP Binding from the wire. All ETH-CFM PDUs inbound to the SAP or SDP binding will be dropped that match the configured levels without regard for any other ETH-CFM criteria. No statistical information or drop count will be available for any ETH-PDU that is silently discarded by this option. The operator must configure a complete contiguous list of md-levels up to the highest level that will be dropped. The command must be retyped in complete form to modify a previous configuration, if the operator does not want to delete it first.</p> <p>The <b>no</b> form of the command removes the silent discarding of previously matching ETH-CFM PDUs.</p> |
| <b>Default</b>     | no squelch-ingress-levels                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>md-level</i> — identifies the level                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>Allows the individual service SAPs to react to changes in the tunnel MEP state. When tunnel-fault accept is configured at the service level, the SAP will react according to the service type, Epipe will set the operational flag and VPLS, IES and VPRN SAP operational state will become down on failure or up on clear. This command triggers the OAM mapping functions to mate SAPs and bindings in an Epipe service as well as setting the operational flag. If AIS generation is the requirement for the Epipe services this command is not required. See the command ais-enable under epipe&gt;sap&gt;eth-cfm&gt;ais-enable for more details. This works in</p> |

conjunction with the tunnel-fault accept on the individual SAPs. Both must be set to accept to react to the tunnel MEP state. By default the service level command is “ignore” and the sap level command is “accept”. This means simply changing the service level command to “accept” will enable the feature for all SAPs. This is not required for Epipe services that only wish to generate AIS on failure.

|                   |                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | <b>ignore</b> (Service Level)<br><br><b>accept</b> (SAP Level for Epipe and VPLS)                                         |
| <b>Parameters</b> | <i>accept</i> — share fate with the facility tunnel MEP<br><i>ignore</i> — do not share fate with the facility tunnel MEP |

### fault-propagation-enable

|                    |                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fault-propagation-enable {use-if-tlv   suspend-ccm}</b><br><b>no fault-propagation-enable</b>                                        |
| <b>Context</b>     | config>service>vprn>if>sap>eth-cfm>mep<br>config>service>vprn>if>spoke-sdp>eth-cfm>mep<br>config>service>vprn>sub-if>grp-if>sap>eth-cfm |
| <b>Description</b> | This command configures the fault propagation for the MEP.                                                                              |
| <b>Parameters</b>  | <b>use-if-tlv</b> — specifies to use the interface TLV<br><b>suspend-ccm</b> — specifies to suspend the continuity check messages       |

### low-priority-defect

|                    |                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>low-priority-defect {allDef   macRemErrXcon   remErrXcon   errXcon   xcon   noXcon}</b>                                              |

| <b>Syntax</b>      | <b>[no] area-id</b> <i>area-address</i>                                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>isis                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures the area ID portion of NSAP addresses for the VPRN instance. This identifies a point of connection to the network, such as a router interface, and is called a Network Service Access Point (NSAP). Addresses in the IS-IS protocol are based on the ISO NSAP addresses and Network Entity Titles (NETs), not IP addresses. |

A maximum of 3 **area addresses** can be configured for the VPRN instance.

NSAP addresses are divided into three parts. Only the area ID portion is configurable.

- Area ID — A variable length field between 1 and 13 bytes long. This includes the Authority and Format Identifier (AFI) as the most significant byte and the area ID.
- System ID — A six-byte system identification. This value is not configurable. The system ID is derived from the system or router ID.
- Selector ID — A one-byte selector identification that must contain zeros when configuring a NET. This value is not configurable. The selector ID is always 00.

The NET is constructed like an NSAP but the selector byte contains a 00 value. NET addresses are exchanged in hello and LSP PDUs. All net addresses configured on the node are advertised to its neighbors.

For Level 1 interfaces, neighbors can have different area IDs, but, they must have at least one area ID (AFI + area) in common. Sharing a common area ID, they become neighbors and area merging between the potentially different areas can occur.

For Level 2 (only) interfaces, neighbors can have different area IDs. However, if they have no area IDs in common, they become only Level 2 neighbors and Level 2 LSPs are exchanged.

For Level 1 and Level 2 interfaces, neighbors can have different area IDs. If they have at least one area ID (AFI + area) in common, they become neighbors. In addition to exchanging Level 2 LSPs, area merging between potentially different areas can occur.

If multiple **area-id** commands are entered, the system ID of all subsequent entries must match the first **area** address.

The **no** form of the command removes the area address.

## auth-keychain

|                    |                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>auth-keychain</b> <i>name</i>                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>isis><br>config>service>vprn>isis>level                                                                                                                                           |
| <b>Description</b> | This command configures an authentication keychain to use for the protocol interface for the VPRN instance. The keychain allows the rollover of authentication keys during the lifetime of a session. |
| <b>Default</b>     | no auth-keychain                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>name</i> — specifies the name of the keychain, up to 32 characters, to use for the specified protocol session or sessions                                                                          |

## authentication-check

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>This command sets an authentication check to reject PDUs that do not match the type or key requirements for the VPRN instance.</p> <p>The default behavior when authentication is configured is to reject all IS-IS protocol PDUs that have a mismatch in either the authentication type or authentication key.</p> <p>When <b>no authentication-check</b> is configured, authentication PDUs are generated and IS-IS PDUs are authenticated on receipt. However, mismatches cause an event to be generated and will not be rejected.</p> <p>The <b>no</b> form of this command allows authentication mismatches to be accepted and generate a log event.</p> |
| <b>Default</b>     | authentication-check — rejects authentication mismatches                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## authentication-key

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service>vprn>isis<br>config>service>vprn>isis>level                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command sets the authentication key used to verify PDUs sent by neighboring routers on the interface for the VPRN instance.</p> <p>Neighboring routers use passwords to authenticate PDUs sent from an interface. For authentication to work, both the authentication <i>key</i> and the authentication <i>type</i> on a segment must match. The <a href="#">OSPF Commands</a> statement must also be included.</p> <p>To configure authentication on the global level, configure this command in the <b>config&gt;router&gt;isis</b> context. When this parameter is configured on the global level, all PDUs are authenticated including the hello PDU.</p> <p>To override the global setting for a specific level, configure the <b>authentication-key</b> command in the <b>config&gt;router&gt;isis&gt;level</b> context. When configured within the specific level, hello PDUs are not authenticated.</p> <p>The <b>no</b> form of the command removes the authentication key.</p> |
| <b>Default</b>     | no authentication-key — No authentication key is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>authentication-key</i> — The authentication key. The key can be any combination of ASCII characters up to 255 characters in length (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").                                                                                                                                                                                                                                      |
|                   | <i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").<br><br>This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.                                                                                                               |
|                   | <b>hash</b> — Specifies the key is entered in an encrypted form. If the <b>hash</b> or <b>hash2</b> parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> or <b>hash2</b> parameter specified                                                                                                                                                   |
|                   | <b>hash2</b> — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the <b>hash2</b> encrypted variable cannot be copied and pasted. If the <b>hash</b> or <b>hash2</b> parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> or <b>hash2</b> parameter specified. |

## authentication-type

|                    |                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-type {password   message-digest}</b><br><b>no authentication</b>                                                              |
| <b>Context</b>     | config>service>vprn>isis<br>config>service>vprn>isis>level                                                                                      |
| <b>Description</b> | This command enables either simple password or message digest authentication or must go in either the global IS-IS or IS-IS level context.      |
|                    | Both the authentication key and the authentication type on a segment must match. The <b>authentication-key</b> statement must also be included. |
|                    | Configure the authentication type on the global level in the <b>config&gt;router&gt;isis</b> context.                                           |
|                    | Configure or override the global setting by configuring the authentication type in the <b>config&gt;router&gt;isis&gt;level</b> context.        |
| <b>Default</b>     | The <b>no</b> form of the command disables authentication.                                                                                      |
|                    | <b>no authentication-type</b> — No authentication type is configured and authentication is disabled.                                            |
| <b>Parameters</b>  | <b>password</b> — specifies that simple password (plain text) authentication is required.                                                       |
|                    | <b>message-digest</b> — specifies that MD5 authentication in accordance with RFC2104 is required.                                               |

## csnp-authentication

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] csnp-authentication</b>                                                                                                    |
| <b>Context</b>     | config>service>vprn>isis<br>config>service>vprn>isis>level                                                                         |
| <b>Description</b> | This command enables authentication of individual ISIS packets of complete sequence number PDUs (CSNP) type for the VPRN instance. |

## default-route-tag

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-route-tag tag</b><br><b>no default-route-tag</b>                             |
| <b>Context</b>     | config>service>vprn>isis                                                                |
| <b>Description</b> | This command configures the route tag for default route for the router or VPRN service. |
| <b>Parameters</b>  | <i>tag</i> — assigns a default tag<br><b>Values</b> 1 — 4294967295                      |

## export

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>vprn>isis                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command configures export routing policies that determine the routes exported from the routing table to IS-IS.</p> <p>If no export policy is defined, non IS-IS routes are not exported from the routing table manager to IS-IS.</p> <p>If multiple policy names are specified, the policies are evaluated in the order they are specified. The first policy that matches is applied. If multiple export commands are issued, the last command entered overrides the previous command. A maximum of five policy names can be specified.</p> <p>If an <b>aggregate</b> command is also configured in the <b>config&gt;router</b> context, then the aggregation is applied before the export policy is applied.</p> <p>Routing policies are created in the <b>config&gt;router&gt;policy-options</b> context.</p> <p>The <b>no</b> form of the command removes the specified <i>policy-name</i> or all policies from the configuration if no <i>policy-name</i> is specified.</p> |
| <b>Default</b>     | no export — No export policy name is specified.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Parameters** *policy-name* — The export policy name. Up to five *policy-name* arguments can be specified.

## export-limit

**Syntax** **export-limit** *number* [**log** *percentage*]  
**no export-limit**

**Context** config>service>vpn>isis

**Description** This command configures the maximum number of routes (prefixes) that can be exported into IS-IS from the route table for the VPRN instance.

The **no** form of the command removes the parameters from the configuration.

**Default** no export-limit - The export limit for routes or prefixes is disabled.

**Parameters** *number* — specifies the maximum number of routes (prefixes) that can be exported into RIP from the route table

**Values** 1 to 4294967295

**log** *percentage* — specifies the percentage of the export-limit, at which a warning log message and SNMP notification would be sent

**Values** 1 to 100

## graceful-restart

**Syntax** [**no**] graceful-restart

**Context** config>service>vpn>isis

**Description** This command enables IS-IS graceful restart (GR) to minimize service interruption. When the control plane of a GR-capable router fails or restarts, the neighboring routers (GR helpers) temporarily preserve IS-IS forwarding information. Traffic continues to be forwarded to the restarting router using the last known forwarding tables. If the control plane of the restarting router becomes operationally and administratively up within the grace period, the restarting router resumes normal IS-IS operation. If the grace period expires, then the restarting router is presumed inactive and the IS-IS topology is recalculated to route traffic around the failure.

The **no** form of the command disables graceful restart and removes the graceful restart configuration from the IS-IS instance.

**Default** no graceful-restart

## helper-disable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command disables helper support for IS-IS graceful restart (GR).</p> <p>When <b>graceful-restart</b> is enabled, the router can be a helper (meaning that the router is helping a neighbor to restart), a restarting router, or both. The router only supports helper mode. It will not act as a restarting router, because the high availability feature set already preserves IS-IS forwarding information such that this functionality is not needed. This command is a historical command and should not be disabled. Configuring <b>helper-disable</b> has the effect of disabling graceful restart, because the router only supports helper mode.</p> <p>The <b>no helper-disable</b> command enables helper support and is the default when graceful restart is enabled.</p> |
| <b>Default</b>     | no helper-disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>vprn>isis                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command specifies that for this VPRN instance, ISIS will ignore LSP packets with errors. When enabled, IS-IS LSP errors will be ignored and the associated record will not be purged.</p> <p>This command enables ISIS to ignore the ATT bit and therefore suppress the installation of default routes.</p> <p>The <b>no</b> form of the command specifies that ISIS will not ignore LSP errors.</p> |

| <b>Description</b> | <p>This command enables IS-IS multi-instance (MI) as described in draft-ietf-isis-mi-02. Multiple instances allow instance-specific adjacencies to be formed that support multiple network topologies on the same physical interfaces. Each instance has an LSDB, and each PDU contains a TLV identifying the instance and the topology to which the PDU belongs.</p> <p>The <b>iid-tlv-enable</b> (based on draft-ietf-isis-mi-02) and <b>standard-multi-instance</b> (based on draft-ginsberg-isis-mi-bis-01) commands cannot be configured in the same instance, because the MAC addresses and PDUs in each standard are incompatible.</p> |
| <b>Default</b>     | no iid-tlv-enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn>isis                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command creates the context to configure an IS-IS interface.</p> <p>When an area is defined, the interfaces belong to that area. Interfaces cannot belong to separate areas.</p> <p>When the interface is a POS channel, the OSINCP is enabled when the interface is created and removed when the interface is deleted.</p> <p>The <b>no</b> form of the command removes IS-IS from the interface.</p> <p>The <b>shutdown</b> command in the <b>config&gt;router&gt;isis&gt;interface</b> context administratively disables IS-IS on the interface without affecting the IS-IS configuration.</p> |
| <b>Default</b>     | no interface — No IS-IS interfaces are defined.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>ip-int-name</i> — Identify the IP interface name created in the <b>config&gt;router&gt;interface</b> context. The IP interface name must already exist.                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## bfd-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] bfd-enable {ipv4   ipv6} [include-bfd-tlv]                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>interface                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command enables the use of bi-directional forwarding (BFD) to control IPv4 adjacencies. By enabling BFD on an IPv4 or IPv6 protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set by the BFD command under the IP interface. This command must be given separately to enable/disable BFD for both IPv4 and IPv6.</p> |

The **no** form of this command removes BFD from the associated adjacency.

**Default** no bfd-enable ipv4

## csnp-interval

**Syntax** **csnp-interval** *seconds*  
**no csnp-interval**

**Context** config>service>vprn>isis>interface

**Description** This command configures the time interval, in seconds, to send complete sequence number (CSN) PDUs from the interface. IS-IS must send CSN PDUs periodically.

The **no** form of the command reverts to the default value.

**Default** csnp-interval 10 — CSN PDUs are sent every 10 seconds for LAN interfaces.  
csnp-interval 5 — CSN PDUs are sent every 5 seconds for point-to-point interfaces.

**Parameters** *seconds* — the time interval, in seconds between successive CSN PDUs sent from this interface expressed as a decimal integer  
1 to 65535

## default-instance

**Syntax** [**no**] **default-instance**

**Context** config>service>vprn>isis>interface

**Description** This command enables a non-MI capable router to establish an adjacency and operate with an SR OS in a non-zero instance. If the router does not receive IID-TLVs, it will establish an adjacency in a single instance. Instead of establishing an adjacency in the standard instance 0, the router will establish an adjacency in the configured non-zero instance. The router will then operate in the configured non-zero instance so that it appears to be in the standard instance 0 to its neighbor. This feature is supported on point-to-point interfaces, broadcast interfaces are not supported.

The **no** form of the command disables the functionality so that the router can only establish adjacencies in the standard instance 0.

**Default** no default-instance

## hello-auth-keychain

**Syntax** **hello-auth-keychain** *name*

---

| <b>Context</b>     | config>service>vprn>isis>interface<br>config>service>vprn>isis>interface>level                                                                                                  |
| <b>Description</b> | This command configures an authentication keychain to use for the protocol interface. The keychain allows the rollover of authentication keys during the lifetime of a session. |
| <b>Default</b>     | no hello-auth-keychain                                                                                                                                                          |
| <b>Parameters</b>  | <i>name</i> — specifies the name of the keychain, up to 32 characters, to use for the specified protocol session or sessions                                                    |

## hello-authentication-key

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>vprn>isis>interface<br>config>service>vprn>isis>interface>level                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures the authentication key (password) for hello PDUs. Neighboring routers use the password to verify the authenticity of hello PDUs sent from this interface. Both the hello authentication key and the hello authentication type on a segment must match. The <b>hello-authentication-type</b> must be specified.</p> <p>To configure the hello authentication key in the interface context use the <b>hello-authentication-key</b> in the <b>config&gt;router&gt;isis&gt;interface</b> context.</p> <p>To configure or override the hello authentication key for a specific level, configure the <b>hello-authentication-key</b> in the <b>config&gt;router&gt;isis&gt;interface&gt;level</b> context.</p> <p>If both IS-IS and hello-authentication are configured, Hello messages are validated using hello authentication. If only IS-IS authentication is configured, it will be used to authenticate all IS-IS (including hello) protocol PDUs.</p> <p>When the hello authentication key is configured in the <b>config&gt;router&gt;isis&gt;interface</b> context, it applies to all levels configured for the interface.</p> <p>The <b>no</b> form of the command removes the authentication-key from the configuration.</p> |
| <b>Default</b>     | no hello-authentication-key — No hello authentication key is configured.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>authentication-key</i> — The hello authentication key (password). The key can be any combination of ASCII characters up to 254 characters in length (un-encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p><i>hash-key</i> — The hash key. The key can be any combination of ASCII characters up to 342 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").</p> <p>This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**hash** — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified

**hash2** — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

## hello-authentication-type

| <b>Description</b> | <p>This command enables hello authentication at either the interface or level context. Both the hello authentication key and the hello authentication type on a segment must match. The hello <b>authentication-key</b> statement must also be included.</p> <p>To configure the hello authentication type at the interface context, use <b>hello-authentication-type</b> in the <b>config&gt;router&gt;isis&gt;interface</b> context.</p> <p>To configure or override the hello authentication setting for a given level, configure the <b>hello-authentication-type</b> in the <b>config&gt;router&gt;isis&gt;interface&gt;level</b> context.</p> <p>The <b>no</b> form of the command disables hello authentication.</p> |
| <b>Default</b>     | no hello-authentication-type — hello authentication is disabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><b>password</b> — specifies simple password (plain text) authentication is required</p> <p><b>message-digest</b> — specifies MD5 authentication in accordance with RFC2104 (HMAC: Keyed-Hashing for Message Authentication) is required</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## interface-type

|                    |                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>interface-type</b> {broadcast   point-to-point}<br><b>no interface-type</b>                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>vprn>isis>interface                                                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command configures the IS-IS interface type as either broadcast or point-to-point.</p> <p>Use this command to set the interface type of an Ethernet link to point-to-point to avoid having to carry the designated IS-IS overhead if the link is used as a point-to-point.</p> |

If the interface type is not known at the time the interface is added to IS-IS and subsequently the IP interface is bound (or moved) to a different interface type, then this command must be entered manually.

The **no** form of the command reverts to the default value.

|                      |                                                                                                              |
|----------------------|--------------------------------------------------------------------------------------------------------------|
| <b>Default</b>       | point-to-point — For IP interfaces on SONET channels.                                                        |
|                      | broadcast — For IP interfaces on Ethernet or unknown type physical interfaces.                               |
| <b>Special Cases</b> | <b>SONET</b> — Interfaces on SONET channels default to the point-to-point type.                              |
|                      | <b>Ethernet or Unknown</b> — Physical interfaces that are Ethernet or unknown default to the broadcast type. |
| <b>Parameters</b>    | <b>broadcast</b> — configures the interface to maintain this link as a broadcast network                     |
|                      | <b>point-to-point</b> — configures the interface to maintain this link as a point-to-point link              |

## ipv4-multicast-disable

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv4-multicast-disable</b>                                      |
| <b>Context</b>     | config>service>vprn>isis>interface                                      |
| <b>Description</b> | This command administratively disables/enables ISIS operation for IPv4. |
| <b>Default</b>     | no ipv4-multicast-disable                                               |

## ipv6-unicast-disable

|                    |                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6-unicast-disable</b>                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>router>isis>if<br>config>service>vprn>isis>interface                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command disables IS-IS IPv6 unicast routing for the interface.</p> <p>By default IPv6 unicast on all interfaces is enabled. However, IPv6 unicast routing on IS-IS is in effect when the <b>config&gt;router&gt;isis&gt;ipv6-routing mt</b> command is configured.</p> <p>The <b>no</b> form of the command enables IS-IS IPv6 unicast routing for the interface.</p> |

## hello-interval

|               |                                                                  |
|---------------|------------------------------------------------------------------|
| <b>Syntax</b> | <b>hello-interval</b> <i>seconds</i><br><b>no hello-interval</b> |
|---------------|------------------------------------------------------------------|

---

|                    |                                                                                                                                                                                          |

| <b>Context</b>     | config>service>vprn>isis>interface<br>config>service>vprn>isis>interface>level                                                                                                                                                                                                           |
| <b>Description</b> | This command adds the passive attribute which causes the interface to be advertised as an IS-IS interface without running the IS-IS protocol. Normally, only interface addresses that are configured for IS-IS are advertised as IS-IS interfaces at the level that they are configured. |

When the passive mode is enabled, the interface or the interface at the level ignores ingress IS-IS protocol PDUs and will not transmit IS-IS protocol PDUs.

The **no** form of the command removes the passive attribute.

|                      |                                                                                                                                                                                                                               |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>       | <b>passive</b> — Service interfaces are passive.<br><b>no passive</b> — All other interfaces are not passive.                                                                                                                 |
| <b>Special Cases</b> | <b>Service Interfaces</b> — service interfaces (defined using the service-prefix command in <b>config&gt;router</b> ) are passive by default<br><b>All other Interfaces</b> — all other interfaces are not passive by default |

| <b>Context</b>     | config>service>vprn>isis>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command applies a route next-hop policy template to the IS-IS interface for the VPRN instance.</p> <p>When a route next-hop policy template is applied to an interface in IS-IS, it is applied in both level 1 and level 2. When a route next-hop policy template is applied to an interface in OSPF, it is applied in all areas. However, the command in an OSPF interface context can only be executed under the area in which the specified interface is primary and then applied in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command will fail.</p> <p>If the user excluded the interface from LFA using the command <b>loopfree-alternate-exclude</b>, the LFA policy, if applied to the interface, has no effect.</p> |

Finally, if the user applied a route next-hop policy template to a loopback interface or to the system interface, the command will not be rejected, but it will result in no action being taken.

The **no** form deletes the mapping of a route next-hop policy template to an OSPF or IS-IS interface.

**Parameters**    *template-name* — specifies the name of the template, up to 32 characters

## loopfree-alternate-exclude

**Syntax**    **[no] loopfree-alternate-exclude**

**Context**    config>service>vprn>isis>interface  
config>service>vprn>isis>level

**Description**    This command instructs IGP to not include a specific interface or all interfaces participating in a specific IS-IS level or OSPF area in the SPF LFA computation. This provides a way of reducing the LFA SPF calculation where it is not needed.

When an interface is excluded from the LFA SPF in IS-IS, it is excluded in both level 1 and level 2. When it is excluded from the LFA SPF in OSPF, it is excluded in all areas. However, the above OSPF command can only be executed under the area in which the specified interface is primary and once enabled, the interface is excluded in that area and in all other areas where the interface is secondary. If the user attempts to apply it to an area where the interface is secondary, the command will fail.

The **no** form of this command re-instates the default value for this command.

**Default**    no loopfree-alternate-exclude

## load-balancing-weight

**Syntax**    **load-balancing-weight** *weight*  
**no load-balancing-weight**

**Context**    config>service>vprn>isis>interface

**Description**    This command configures the weighted ECMP load-balancing weight for an IS-IS interface of the VPRN. If the interface becomes an ECMP next-hop for IPv4 or IPv6 route and all the other ECMP next-hops are interfaces with configured (non-zero) load-balancing weights, then the traffic distribution over the ECMP interfaces is proportional to the weights. In other words, the interface with the largest load-balancing-weight should receive the most forwarded traffic if weighted ECMP is applicable.

The **no** form of this command disables weighted ECMP for the interface and, therefore, effectively disables weighted ECMP for any IP prefix that has this interface as a next-hop.

**Default**    no load-balancing-weight

| <b>Context</b>     | config>service>vprn>isis>interface                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command configures the interval during which LSPs are sent from the interface.</p> <p>To avoid overwhelming neighbors that have less CPU processing power with LSPs, the pacing interval can be configured to limit how many LSPs are sent during an interval. LSPs may be sent in bursts during the interval up to the configured limit. If a value of 0 is configured, no LSPs are sent from the interface.</p> <p>The <b>no</b> form of the command reverts to the default value.</p> |
| <b>Default</b>     | 100 — LSPs are sent in 100 millisecond intervals.                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>milli-seconds</i> — the interval in milliseconds during which IS-IS LSPs are sent from the interface expressed as a decimal integer                                                                                                                                                                                                                                                                                                                                                           |
| <b>Values</b>      | 0 to 65535                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## mesh-group

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command assigns an interface to a mesh group. Mesh groups limit the amount of flooding that occurs when a new or changed LSP is advertised throughout an area.</p> <p>All routers in a mesh group should be fully meshed. When LSPs need to be flooded, only a single copy is received rather than a copy per neighbor.</p> <p>To create a mesh group, configure the same mesh group value for each interface that is part of the mesh group. All routers must have the same mesh group value configured for all interfaces that are part of the mesh group.</p> <p>To prevent an interface from flooding LSPs, the optional <b>blocked</b> parameter can be specified. Configure mesh groups carefully. It is easy to create isolated islands that do not receive updates as (other) links fail.</p> <p>The <b>no</b> form of the command removes the interface from the mesh group.</p> |

---

|                   |                                                                                                                                                                  |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no mesh-group — the interface does not belong to a mesh group                                                                                                    |
| <b>Parameters</b> | <i>value</i> — the unique decimal integer value distinguishes this mesh group from other mesh groups on this or any other router that is part of this mesh group |
| <b>Values</b>     | 1 to 2000000000                                                                                                                                                  |
|                   | <b>blocked</b> — prevents an interface from flooding LSPs                                                                                                        |

## retransmit-interval

|                    |                                                                                                                                                                                |

| <b>Context</b>     | config>service>vprn>isis>interface                                                                                                                                             |
| <b>Description</b> | This command configures the minimum time between LSP PDU retransmissions on a point-to-point interface.<br><br>The <b>no</b> form of the command reverts to the default value. |
| <b>Default</b>     | 100                                                                                                                                                                            |
| <b>Parameters</b>  | <i>seconds</i> — the interval in seconds that IS-IS LSPs can be sent on the interface<br>1 to 65535                                                                            |

## tag

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tag</b> <i>tag</i><br><b>no tag</b>                                           |
| <b>Context</b>     | config>service>vprn>isis>interface                                               |
| <b>Description</b> | This command configures a route tag to the specified IP address of an interface. |
| <b>Parameters</b>  | <i>tag</i> — [1 - 4294967295]                                                    |

## ipv4-multicast-routing

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipv4-multicast-routing</b> { <b>native</b>   <b>mt</b> }<br><b>[no] ipv4-multicast-routing</b>                                                    |
| <b>Context</b>     | config>service>vprn>isis                                                                                                                             |
| <b>Description</b> | The multicast RTM is used for Reverse Path Forwarding checks. This command controls which IS-IS topology is used to populate the IPv4 multicast RTM. |

The **no** ipv4-multicast-routing form of the command results in none of the IS-IS routes being populated in the IPv4 multicast RTM and would be used if multicast is configured to use the unicast RTM for the RPF check.

|                   |                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | ipv4-multicast-routing native                                                                                                                                                                                               |
| <b>Parameters</b> | <p><b>native</b> — causes IPv4 routes from the MT0 topology to be added to the multicast RTM for RPF checks</p> <p><b>mt</b> — causes IPv4 routes from the MT3 topology to be added to the multicast RTM for RPF checks</p> |

## ipv4-routing

|                    |                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv4-routing</b>                                                                                                                               |
| <b>Context</b>     | config>service>vprn>isis                                                                                                                               |
| <b>Description</b> | <p>This command specifies whether this IS-IS instance supports IPv4.</p> <p>The <b>no</b> form of the command disables IPv4 on the IS-IS instance.</p> |
| <b>Default</b>     | ipv4-routing                                                                                                                                           |

## ipv6-routing

|                    |                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6-routing {native   mt}</b>                                                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>isis                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables IPv6 routing.</p> <p>The <b>no</b> form of the command disables support for IS-IS IPv6 TLVs for IPv6 routing.</p>                                                                                                                       |
| <b>Default</b>     | disabled                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><b>native</b> — enables IS-IS IPv6 TLVs for IPv6 routing and enables support for native IPv6 TLVs</p> <p><b>mt</b> — Enables IS-IS multi-topology TLVs for IPv6 routing. When this parameter is specified, the support for native IPv6 TLVs is disabled.</p> |

## level

|                |                                                                                                    |

| <b>Description</b>   | <p>This command creates the context to configure IS-IS Level 1 or Level 2 area attributes.</p> <p>A router can be configured as a Level 1, Level 2, or Level 1-2 system. A Level 1 adjacency can be established if there is at least one area address shared by this router and a neighbor. A Level 2 adjacency cannot be established over this interface.</p> <p>Level 1/2 adjacency is created if the neighbor is also configured as Level 1/2 router and has at least one area address in common. A Level 2 adjacency is established if there are no common area IDs.</p> <p>A Level 2 adjacency is established if another router is configured as Level 2 or a Level 1/2 router with interfaces configured as Level 1/2 or Level 2. Level 1 adjacencies will not be established over this interface.</p> <p>To reset global and/or interface level parameters to the default, the following commands must be entered independently:</p> <pre>level&gt; no hello-authentication-key level&gt; no hello-authentication-type level&gt; no hello-interval level&gt; no hello-multiplier level&gt; no metric level&gt; no passive level&gt; no priority</pre> |
| <b>Default</b>       | level 1 or level 2                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Special Cases</b> | <p><b>Global IS-IS Level</b> — The <code>config&gt;router&gt;isis</code> context configures default global parameters for both Level 1 and Level 2 interfaces.</p> <p><b>IS-IS Interface Level</b> — The <code>config&gt;router&gt;isis&gt;interface</code> context configures IS-IS operational characteristics of the interface at Level 1 and/or Level 2. A logical interface can be configured on one Level 1 and one Level 2. In this case, each level can be configured independently and parameters must be removed independently. By default an interface operates in both Level 1 and Level 2 modes.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>    | <p><i>level-number</i> — the IS-IS level number</p> <p><b>Values</b> 1, 2</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## default-ipv4-multicast-metric

|                    |                                                                                                                     |

| <b>Description</b> | <p>This command configures the external route preference for the IS-IS level.</p> <p>The <b>external-preference</b> command configures the preference level of either IS-IS level 1 or IS-IS level 2 external routes. By default, the preferences are as listed in the table below.</p> <p>A route can be learned by the router by different protocols, in which case, the costs are not comparable. When this occurs, the preference decides the route to use.</p> <p>Different protocols should not be configured with the same preference, if this occurs the tiebreaker is dependent on the default preference table. If multiple routes are learned with an identical preference using the same protocol, the lowest cost route is used. If multiple routes are learned with an identical preference using the same protocol and the costs (metrics) are equal, then the decision of the route to use is determined by the configuration of the <b>ecmp</b> in the <b>config&gt;router</b> context.</p> |
| <b>Default</b>     | Default preferences are listed in <a href="#">Table 44</a> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 44** Default Preferences

| Route Type             | Preference | Configurable     |
|------------------------|------------|------------------|
| Direct attached        | 0          | No               |
| Static route           | 5          | Yes              |
| MPLS                   | 7          | —                |
| OSPF internal routes   | 10         | No               |
| IS-IS Level 1 internal | 15         | Yes <sup>1</sup> |
| IS-IS Level 2 internal | 18         | Yes <sup>1</sup> |
| OSPF external          | 150        | Yes              |

**Table 44** Default Preferences (Continued)

| Route Type             | Preference | Configurable |
|------------------------|------------|--------------|
| IS-IS Level 1 external | 160        | Yes          |
| IS-IS Level 2 external | 165        | Yes          |
| TMS                    | 167        | No           |
| BGP                    | 170        | Yes          |
| BGP                    | 170        | Yes          |

**Note:**

- Internal preferences are changed using the **preference** command in the `config>router>isis>level level-number` context

**Parameters** *preference* — the preference for external routes at this level as expressed

**Values** 1 to 255

## preference

**Syntax** **preference** *preference*  
**no preference**

**Context** `cconfig>service>vpn>isis>level`

**Description** This command configures the preference level of either IS-IS Level 1 or IS-IS Level 2 internal routes. By default, the preferences are listed in the table below.

A route can be learned by the router by different protocols, in which case, the costs are not comparable. When this occurs, the preference is used to decide to which route will be used.

Different protocols should not be configured with the same preference, if this occurs the tiebreaker is per the default preference table as defined in the table below. If multiple routes are learned with an identical preference using the same protocol, the lowest cost route is used. If multiple routes are learned with an identical preference using the same protocol and the costs (metrics) are equal, then the decision what route to use is determined by the configuration of the **ecmp** in the `config>router` context.

**Default** Default preferences are listed in [Table 45](#)

**Table 45** Default Preferences

| Route Type      | Preference | Configurable |
|-----------------|------------|--------------|
| Direct attached | 0          | No           |

**Table 45** Default Preferences (Continued)

| Route Type             | Preference | Configurable     |
|------------------------|------------|------------------|
| Static route           | 5          | Yes              |
| MPLS                   | 7          | —                |
| OSPF internal routes   | 10         | No               |
| IS-IS level 1 internal | 15         | Yes              |
| IS-IS level 2 internal | 18         | Yes              |
| OSPF external          | 150        | Yes              |
| IS-IS level 1 external | 160        | Yes <sup>1</sup> |
| IS-IS level 2 external | 165        | Yes <sup>1</sup> |
| BGP                    | 170        | Yes              |

**Note:**

1. External preferences are changed using the **external-preference** command in the `config>router>isis>level level-number` context.

**Parameters** *preference* — the preference for external routes at this level expressed as a decimal integer

**Values** 1 to 255

## wide-metrics-only

**Syntax** `[no] wide-metrics-only`

**Context** `config>service>vpn>isis>level`

**Description** This command enables the exclusive use of wide metrics in the LSPs for the level number. Narrow metrics can have values between 1 and 63. IS-IS can generate two TLVs, one for the adjacency and one for the IP prefix. In order to support traffic engineering, wider metrics are required. When wide metrics are used, a second pair of TLVs are added, again, one for the adjacency and one for the IP prefix.

By default, both sets of TLVs are generated. When wide-metrics-only is configured, IS-IS only generates the pair of TLVs with wide metrics for that level.

The **no** form of the command reverts to the default value.

## level-capability

- Syntax** `level-capability {level-1 | level-2 | level-1/2}`  
**no level-capability**
- Context** `config>service>vprn>isis`  
`config>service>vprn>isis>interface`
- Description** This command configures the routing level for an instance of the IS-IS routing process.
- An IS-IS router and an IS-IS interface can operate at Level 1, Level 2 or both Level 1 *and* 2.
- [Table 46](#) displays configuration combinations and the potential adjacencies that can be formed.

**Table 46** Potential Adjacency Capabilities

| Global Level | Interface Level | Potential Adjacency    |
|--------------|-----------------|------------------------|
| L 1/2        | L 1/2           | Level 1 and/or Level 2 |
| L 1/2        | L 1             | Level 1 only           |
| L 1/2        | L 2             | Level 2 only           |
| L 2          | L 1/2           | Level 2 only           |
| L 2          | L 2             | Level 2 only           |
| L 2          | L 1             | none                   |
| L 1          | L 1/2           | Level 1 only           |
| L 1          | L 2             | none                   |
| L 1          | L 1             | Level 1 only           |

The **no** form of the command removes the level capability from the configuration.

- Default** level-1/2
- Special Cases** **IS-IS Router** — In the `config>router>isis` context, changing the **level-capability** performs a restart on the IS-IS protocol instance.
- IS-IS Interface** — In the `config>router>isis>interface` context, changing the **level-capability** performs a restart of IS-IS on the interface.
- Parameters** **level-1** — specifies the router/interface can operate at Level 1 only
- level-2** — specifies the router/interface can operate at Level 2 only
- level-1/2** — specifies the router/interface can operate at both Level 1 and Level 2

---

## link-group

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] link-group</b> <i>link-group-name</i>                                                                                                    |
| <b>Context</b>     | config>service>vprn>isis                                                                                                                         |
| <b>Description</b> | This command configures a link-group for the router or VPRN instance.<br><br>The <b>no</b> form of the command removes the specified link-group. |
| <b>Parameters</b>  | <i>link-group-name</i> — name of the link-group to be added or removed from the router or VPRN service                                           |

## description

|                    |                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>description</b> <i>string</i><br><b>no description</b>                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>isis>link-group                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command adds a description string to the associated link-group. The string can be up to 256 characters long and can only contain printable characters. If the command is issued in the context of a link-group that already contains a description then the previous description string is replaced.<br><br>The <b>no</b> form of the command removes the description from the associated link-group. |
| <b>Default</b>     | revert-members <i>oper-members</i>                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>string</i> — character string to be associated with the associated link-group                                                                                                                                                                                                                                                                                                                           |

## ipv4-multicast-metric-offset

|                    |                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ipv4-multicast-metric-offset</b> <i>offset-value</i><br><b>no ipv4-multicast-metric-offset</b>                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>isis>link-group>level                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command sets the offset value for the IPv4 multicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric for the IPv4 multicast topology.<br><br>The <b>no</b> form of the command reverts the offset value to 0. |
| <b>Default</b>     | no ipv4-multicast-metric-offset                                                                                                                                                                                                                                                                                        |

**Parameters** *offset-value* — specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold

**Values** 0 to 6777215

## ipv4-unicast-metric-offset

**Syntax** **ipv4-unicast-metric-offset** *offset-value*  
**no ipv4-unicast-metric-offset**

**Context** config>service>vprn>isis>link-group>level

**Description** This command sets the offset value for the IPv4 unicast address family. If the number of operational links drops below the oper-members threshold, the configured offset is applied to the interface metric.

The **no** form of the command reverts the offset value to 0.

**Default** no ipv4-unicast-metric-offset

**Parameters** *offset-value* — specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold

**Values** 0 to 6777215

## ipv6-unicast-metric-offset

**Syntax** **ipv6-unicast-metric-offset** *offset-value*  
**no ipv6-unicast-metric-offset**

**Context** config>service>vprn>isis>link-group>level

**Description** This command sets the offset value for the IPv6 unicast address family. If the number of operational links drops below the **oper-members** threshold, the configured offset is applied to the interface metric for the IPv6 topology.

The **no** form of the command reverts the offset value to 0.

**Default** no ipv6-unicast-metric-offset

**Parameters** *offset-value* — specifies the amount the interface metric for the associated address family is to be increased if the number of operational members in the associated link-group drops below the oper-members threshold

**Values** 0 to 6777215

| <b>Description</b> | <p>This command excludes from LFA SPF calculation prefixes that match a prefix entry or a tag entry in a prefix policy.</p> <p>The implementation already allows the user to exclude an interface in IS-IS or OSPF, an OSPF area, or an IS-IS level from the LFA SPF.</p> <p>If a prefix is excluded from LFA, then it will not be included in LFA calculation regardless of its priority. The prefix tag will, however, be used in the main SPF. Prefix tags are defined for the IS-IS protocol but not for the OSPF protocol.</p> <p>The default action of the <b>loopfree-alternate-exclude</b> command, when not explicitly specified by the user in the prefix policy, is a “reject”. Thus, regardless if the user did or did not explicitly add the statement “default-action reject” to the prefix policy, a prefix that did not match any entry in the policy will be accepted into LFA SPF.</p> <p>The <b>no</b> form deletes the exclude prefix policy.</p> |
| <b>Parameters</b>  | <i>prefix-policy prefix-policy</i> — specifies the name of the prefix policy, up to 32 characters.<br>The specified name must have been already defined                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Isp-lifetime

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command sets the time, in seconds, the router wants the LSPs it originates to be considered valid by other routers in the domain.</p> <p>Each LSP received is maintained in an LSP database until the <b>Isp-lifetime</b> expires unless the originating router refreshes the LSP. By default, each router refreshes its LSPs every 20 minutes (1200 seconds) so other routers will not age out the LSP.</p> <p>The LSP refresh timer is derived from this formula: Isp-lifetime/2</p> <p>The <b>no</b> form of the command reverts to the default value.</p> |
| <b>Default</b>     | 1200 — LSPs originated by the router should be valid for 1200 seconds (20 minutes).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — the time, in seconds, that the router wants the LSPs it originates to be considered valid by other routers in the domain                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command configures the LSP MTU size. If the <i>size</i> value is changed from the default using CLI or SNMP, then ISIS must be restarted for the change to take effect. This can be done by performing a <b>shutdown</b> command and then a <b>no shutdown</b> command in the <b>config&gt;router&gt;isis</b> context.</p> <div><b>Note:</b> Using the <b>exec</b> command to execute a configuration file to change the LSP MTU size from its default value will automatically restart IS-IS for the change to take effect.</div> <p>The <b>no</b> form of the command reverts to the default value.</p> |
| <b>Default</b>     | 1492                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command configures the IS-IS LSP refresh timer interval for the VPRN instance. When configuring the LSP refresh interval, the value that is specified for <b>lsp-lifetime</b> must also be considered. The LSP refresh interval cannot be greater than 90% of the LSP lifetime.</p> <p>The no form of the command reverts to the default (600 seconds), unless this value is greater than 90% of the LSP lifetime. For example, if the LSP lifetime is 400, then the no lsp-refresh-interval command will be rejected.</p> |
