1	Getting Started.....	11
1.1	About This Guide.....	11
1.1.1	Audience.....	12
2	Internet Enhanced Service.....	13
2.1	In This Chapter.....	13
2.2	IES Service Overview.....	14
2.3	IES Features.....	15
2.3.1	IP Interfaces.....	15
2.3.1.1	QoS Policy Propagation Using BGP (QPPB).....	15
2.3.1.2	QPPB.....	17
2.3.1.3	QPPB and GRT Lookup.....	22
2.3.1.4	Object Grouping and State Monitoring.....	25
2.3.2	Subscriber Interfaces.....	27
2.3.2.1	IPv6 Enhanced Subscriber Management (ESM).....	27
2.3.2.2	RADIUS Accounting.....	28
2.3.3	SAPs.....	30
2.3.3.1	Encapsulations.....	30
2.3.3.2	ATM SAP Encapsulations for IES.....	31
2.3.3.3	Pseudowire SAPs.....	31
2.3.3.4	Encapsulation.....	32
2.3.3.5	Pseudowire SAP Configuration.....	33
2.3.3.6	QoS for Pseudowire Ports and Pseudowire SAPs.....	34
2.3.3.7	Shaping and Bandwidth Control.....	35
2.3.3.8	Lag Considerations.....	37
2.3.3.9	Last Mile Packet Size Adjustment.....	37
2.3.3.10	Redundancy with Pseudowire SAPs.....	38
2.3.3.11	Operational Group Support for PW Ports.....	40
2.3.4	Routing Protocols.....	41
2.3.4.1	CPE Connectivity Check.....	41
2.3.5	QoS Policies.....	42
2.3.6	Filter Policies.....	42
2.3.7	MPLS Entropy Label and Hash Label.....	42
2.3.8	Spoke SDPs.....	42
2.3.9	SRRP.....	44
2.3.9.1	SRRP Messaging.....	49
2.3.9.2	SRRP and Multi-Chassis Synchronization.....	51
2.3.9.3	SRRP Instance.....	51
2.3.9.4	Subscriber Subnet Owned IP Address Connectivity.....	55
2.3.9.5	Subscriber Subnet SRRP Gateway IP Address Connectivity.....	55
2.3.9.6	Receive SRRP Advertisement SAP and Anti-Spoof.....	55
2.3.9.7	BFD with SRRP/VRRP.....	56
2.4	Configuring an IES Service with CLI.....	57
2.4.1	Basic Configuration.....	57
2.4.2	Common Configuration Tasks.....	58

2.4.3	Configuring IES Components	58
2.4.3.1	Configuring an IES Service	59
2.4.3.2	Configuring IES Subscriber Interface Parameters	59
2.4.3.3	Configuring IES Interface Parameters	60
2.4.3.4	Configuring Spoke-SDP Parameters	61
2.4.3.5	Configuring SAP Parameters	61
2.4.3.6	Configuring IES SAP ATM Parameters	62
2.4.3.7	Configuring VRRP	63
2.4.3.8	Configuring IPsec Parameters	64
2.4.3.9	IGMP Host Tracking	64
2.4.4	Service Management Tasks	65
2.4.4.1	Modifying IES Service Parameters	65
2.4.4.2	Deleting a Spoke-SDP	66
2.4.4.3	Deleting an IES Service	66
2.4.4.4	Disabling an IES Service	67
2.4.4.5	Re-Enabling an IES Service	67
2.5	IES Services Command Reference	69
2.5.1	Command Hierarchies	69
2.5.1.1	IES Service Configuration Commands	70
2.5.1.2	Routed VPLS Commands	74
2.5.1.3	Redundant Interface Commands	75
2.5.1.4	Interface SAP Commands	75
2.5.1.5	Interface SAP Tunnel Commands	80
2.5.1.6	VRRP Commands	85
2.5.1.7	Spoke SDP Commands	86
2.5.1.8	Subscriber Interface Commands	87
2.5.1.9	Threat Management Service Interface Commands	94
2.5.2	Command Descriptions	95
2.5.2.1	Generic Commands	95
2.5.2.2	IES Global Commands	96
2.5.2.3	Redundant Interface Commands	101
2.5.2.4	IES Subscriber Interface Commands	101
2.5.2.5	IES Interface Commands	108
2.5.2.6	IES Interface DHCP Commands	157
2.5.2.7	PPPoE Commands	166
2.5.2.8	IES Interface ICMP Commands	168
2.5.2.9	IES Interface IPv6 Commands	174
2.5.2.10	IES Spoke SDP Commands	191
2.5.2.11	IES SAP Commands	204
2.5.2.12	SAP Subscriber Management Commands	220
2.5.2.13	ETH-CFM Service Commands	226
2.5.2.14	IES Filter and QoS Policy Commands	232
2.5.2.15	ATM Commands	261
2.5.2.16	IES Interface VRRP Commands	265
2.5.2.17	IPsec Gateway Commands	275
2.5.2.18	Threat Management Service Interface Commands	279
2.6	IES Show, Clear, and Debug Command Reference	283
2.6.1	Command Hierarchies	283
2.6.1.1	Show Commands	283

2.6.1.2	Clear Commands.....	284
2.6.1.3	Debug Commands.....	285
2.6.1.4	Monitor Commands	286
2.6.2	Command Descriptions	287
2.6.2.1	IES Show Commands	287
2.6.2.2	IES Clear Commands.....	353
2.6.2.3	IES Debug Commands.....	358
2.6.2.4	IES Monitor Commands	360
3	Virtual Private Routed Network Service	361
3.1	In This Chapter	361
3.2	VPRN Service Overview.....	363
3.2.1	Routing Prerequisites	364
3.2.2	Core MP-BGP Support.....	364
3.2.3	Route Distinguishers	365
3.2.3.1	eiBGP Load Balancing	366
3.2.4	Route Reflector.....	367
3.2.5	CE to PE Route Exchange	367
3.2.5.1	Route Redistribution.....	368
3.2.5.2	CPE Connectivity Check	368

3.2.6.1	Constrained VPN Route Distribution Based on Route Targets	370
3.2.6.2	Configuring the Route Target Address Family	370
3.2.6.3	Originating RT Constraint Routes.....	371
3.2.6.4	Receiving and Re-Advertising RT Constraint Routes.....	371
3.2.6.5	Using RT Constraint Routes.....	373
3.2.7	BGP Fast Reroute in a VPRN	375
3.2.7.1	BGP Fast Reroute in a VPRN Configuration	376
3.2.8	BGP Best-External in a VPRN Context	377
3.3	VPRN Features	378
3.3.1	IP Interfaces	378
3.3.1.1	QoS Policy Propagation Using BGP (QPPB)	379
3.3.1.2	QPPB Applications	379
3.3.1.3	Inter-AS Coordination of QoS Policies	379
3.3.1.4	Traffic Differentiation Based on Route Characteristics	380
3.3.1.5	QPPB.....	381
3.3.1.6	Associating an FC and Priority with a Route	381
3.3.1.7	Displaying QoS Information Associated with Routes	383
3.3.1.8	Enabling QPPB on an IP interface	384
3.3.1.9	QPPB When Next-Hops are Resolved by QPPB Routes.....	385
3.3.1.10	QPPB and Multiple Paths to a Destination	385
3.3.1.11	QPPB and Policy-Based Routing	386
3.3.1.12	QPPB and GRT Lookup	386
3.3.1.13	QPPB Interaction with SAP Ingress QoS Policy.....	386
3.3.1.14	Object Grouping and State Monitoring	389
3.3.1.15	VPRN IP Interface Applicability	389
3.3.2	Subscriber Interfaces.....	391
3.3.3	SAPs.....	391
3.3.3.1	Encapsulations	391

3.3.3.2	ATM SAP Encapsulations for VPRN Services	392
3.3.3.3	Pseudowire SAPs	392
3.3.4	QoS Policies	392
3.3.5	Filter Policies	392
3.3.6	DSCP Marking	393
3.3.6.1	Default DSCP Mapping Table	394
3.3.7	Configuration of TTL Propagation for VPRN Routes	395
3.3.8	CE to PE Routing Protocols	396
3.3.8.1	PE to PE Tunneling Mechanisms	397
3.3.8.2	Per VRF Route Limiting	397
3.3.9	Spoke SDPs	397
3.3.9.1	T-LDP Status Signaling for Spoke-SDPs Terminating on IES/VPRN	398
3.3.9.2	Spoke SDP Redundancy into IES/VPRN	399
3.3.10	IP-VPNs	400
3.3.10.1	Using OSPF in IP-VPNs	400
3.3.11	IPCP Subnet Negotiation	401
3.3.12	Cflowd for IP-VPNs	401
3.3.13	Inter-AS VPRNs	402
3.3.14	Carrier Supporting Carrier (CsC)	404
3.3.14.1	Terminology	405
3.3.14.2	CSC Connectivity Models	406
3.3.14.3	CSC-PE Configuration and Operation	406
3.3.14.4	CSC Interface	406
3.3.14.5	QoS	408
3.3.14.6	MPLS	409
3.3.14.7	CSC VPRN Service Configuration	410
3.3.15	Traffic Leaking to GRT	410
3.3.16	Traffic Leaking from VPRN to GRT for IPv6	412
3.3.17	RIP Metric Propagation in VPRNs	412
3.3.18	NTP Within a VPRN Service	413
3.3.19	PTP Within a VPRN Service	413
3.3.20	VPN Route Label Allocation	413
3.3.20.1	Configuring the Service Label Mode	415
3.3.20.2	Restrictions and Usage Notes	415
3.3.21	VPRN Support for BGP Flowspec	416
3.3.22	MPLS Entropy Label and Hash Label	417
3.4	QoS on Ingress Bindings	417
3.5	Multicast in IP-VPN Applications	418
3.5.1	Use of Data MDTs	420
3.5.2	Multicast Protocols Supported in the Provider Network	421
3.5.3	MVPN Membership Auto-discovery using BGP	422
3.5.4	PE-PE Transmission of C-Multicast Routing using BGP	424
3.5.5	VRF Route Import Extended Community	424
3.5.6	Provider Tunnel Support	425
3.5.6.1	Point-to-Multipoint Inclusive (I-PMSI) and Selective (S-PMSI) Provider Multicast Service Interface	425
3.5.6.2	P2MP RSVP-TE I-PMSI and S-PMSI	426
3.5.6.3	P2MP LDP I-PMSI and S-PMSI	426

3.5.6.4	Wildcard (C-*, C-*) P2MP LSP S-PMSI	426
3.5.6.5	P2MP LSP S-PMSI	429
3.5.6.6	Dynamic Multicast Signaling over P2MP LDP in VRF	430
3.5.6.7	MVPN Sender-only/Receiver-only	432
3.5.6.8	S-PMSI Trigger Thresholds	434
3.5.6.9	Migration from Existing Rosen Implementation	435
3.5.6.10	Policy-based S-PMSI	435
3.5.7	MVPN (NG-MVPN) Upstream Multicast Hop Fast Failover	438
3.5.8	Multicast VPN Extranet	439
3.5.8.1	Multicast Extranet for Rosen MVPN for PIM SSM	439
3.5.8.2	Multicast Extranet for NG-MVPN for PIM SSM	441
3.5.8.3	Multicast Extranet with Per-group Mapping for PIM SSM	441
3.5.8.4	Multicast GRT-source/VRF-receiver Extranet with Per Group Mapping for PIM SSM	444
3.5.8.5	Multicast Extranet with Per-group Mapping for PIM ASM	445
3.5.9	Non-Congruent Unicast and Multicast Topologies for Multicast VPN	446
3.5.10	Automatic Discovery of Group-to-RP Mappings (Auto-RP)	447
3.5.11	IPv6 MVPN Support	448
3.5.12	Multicast Core Diversity for Rosen MDT_SAFI MVPNs	450
3.5.13	NG-MVPN Multicast Source Geo-Redundancy	452
3.5.14	Multicast Core Diversity for Rosen MDT SAFI MVPNs	455
3.5.15	Inter-AS MVPN	457
3.5.15.1	BGP Connector Attribute	458
3.5.15.2	PIM RPF Vector	458
3.5.15.3	Inter-AS MVPN Option B	459
3.5.15.4	Inter-AS MVPN Option C	460
3.5.15.5	NG-MVPN Non-segmented Inter-AS Solution	462
3.6	VPRN Off-Ramp	472
3.6.1	DDoS Off-Ramping Through Flowspec	473
3.7	FIB Prioritization	473
3.8	Configuring a VPRN Service with CLI	475
3.8.1	Basic Configuration	475

1 Getting Started

1.1 About This Guide

This guide describes Layer 3 service functionality provided by Nokia's family of routers and presents examples to configure and implement various protocols and services.

This guide is organized into functional chapters and provides concepts and descriptions of the implementation flow, as well as Command Line Interface (CLI) syntax and command usage.

The topics and commands described in this document apply to the:

- 7450 ESS
- 7750 SR
- 7950 XRS

[Table 1](#) lists the available chassis types for each SR OS router.

Table 1 Supported SR OS Router Chassis Types

7450 ESS	7750 SR	7950 XRS
• 7450 ESS-6/6v • 7450 ESS-7/12 running in standard mode (not mixed-mode)	• 7450 ESS-7/12 running in mixed-mode (not standard mode) • 7750 SR-a4/a8 • 7750 SR-c4/c12 • 7750 SR-1e/2e/3e • 7750 SR-7/12 • 7750 SR-12e	• 7950 XRS-16c • 7950 XRS-20/40

For a list of unsupported features by platform and chassis, refer to the *SR OS R14.0.Rx Software Release Notes*, part number 3HE10818 000x TQZZA.

Command outputs shown in this guide are examples only; actual displays may differ depending on supported functionality and user configuration.

Note: This guide generically covers Release 14.0 content and may contain some content that will be released in later maintenance loads. Please refer to the *SR OS R14.0.Rx Software Release Notes*, part number 3HE10818 000x TQZZA, for information on features supported in each load of the Release 14.0 software.

1.1.1 Audience

This guide is intended for network administrators who are responsible for configuring routers. It is assumed that the network administrators have an understanding of networking principles and configurations. Concepts described in this guide include the following:

- Internet Enhanced Services (IES)
- Virtual Private Routed Network (VPRN) services

2 Internet Enhanced Service

2.1 In This Chapter

This chapter provides information about Internet Enhanced Service (IES), process overview, and implementation notes.

Topics in this chapter include:

- [IES Service Overview](#)
- [IES Features](#)
 - [IP Interfaces](#)
 - [QoS Policy Propagation Using BGP \(QPPB\)](#)
 - [Object Grouping and State Monitoring](#)
 - [Subscriber Interfaces](#)
 - [IPv6 Enhanced Subscriber Management \(ESM\)](#)
 - [RADIUS Accounting](#)
 - [SAPs](#)
 - [Routing Protocols](#)
 - [QoS Policies](#)
 - [Filter Policies](#)
 - [MPLS Entropy Label and Hash Label](#)
 - [Spoke SDPs](#)
 - [SRRP](#)
- [Configuring an IES Service with CLI](#)
- [Basic Configuration](#)
- [Common Configuration Tasks](#)
- [Service Management Tasks](#)

2.2 IES Service Overview

Internet Enhanced Service (IES) is a routed connectivity service where the subscriber communicates with an IP router interface to send and receive Internet traffic. An IES has one or more logical IP routing interfaces each with a SAP which acts as the access point to the subscriber's network. IES allows customer-facing IP interfaces to participate in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber be unique between other provider addressing schemes and potentially the entire Internet.

While IES is part of the routing domain, the usable IP address space may be limited. This allows a portion of the service provider address space to be reserved for service IP provisioning, and be administered by a separate but subordinate address authority.

IP interfaces defined within the context of an IES service must have a SAP associated as the uplink access point to the subscriber network. Multiple IES services are created to segregate subscriber-owned IP interfaces.

Figure 1 Internet Enhanced Service

OSSG023

The IES service provides Internet connectivity. Other features include:

- multiple IES services are created to separate customer-owned IP interfaces
 - more than one IES service can be created for a single customer ID
 - more than one IP interface can be created within a single IES service ID
- All IP interfaces created within an IES service ID belong to the same customer.

These features apply to the 7750 SR and 7450 ESS.

Refer to the 7450 ESS and 7750 SR Triple Play Guide for information about how subscriber group-interfaces function in the Routed Central Office model.

2.3 IES Features

This section describes the 7450 ESS and 7750 SR service features and any special capabilities or considerations as they relate to IES services.

2.3.1 IP Interfaces

IES customer IP interfaces can be configured with most of the same options found on the core IP interfaces. The advanced configuration options supported are:

- QoS Policy Propagation Using BGP (QPPB)
- VRRP - for IES services with more than one IP interface
- Cflowd
- Secondary IP addresses
- ICMP Options

Configuration options found on core IP interfaces not supported on IES IP interfaces are:

- MPLS forwarding
- NTP broadcast receipt

2.3.1.1 QoS Policy Propagation Using BGP (QPPB)

This section discusses QPPB as it applies to VPRN, IES, and router interfaces. Refer to the [Internet Enhanced Service](#) section and the IP Router Configuration section in the 7750 SR OS Configuration Guide.

QoS policy propagation using BGP (QPPB) is a feature that allows a route to be installed in the routing table with a forwarding-class and priority so that packets matching the route can receive the associated QoS. The forwarding-class and priority associated with a BGP route are set using BGP import route policies. In the industry this feature is called QPPB, and even though the feature name refers to BGP specifically. On SR OS, QPPB is supported for BGP (IPv4, IPv6, VPN-IPv4, VPN-IPv6), RIP and static routes.

While SAP ingress and network QoS policies can achieve the same end result as QPPB, assigning a packet arriving on a particular IP interface to a specific forwarding-class and priority/profile based on the source IP address or destination IP address of the packet, the effort involved in creating the QoS policies, keeping them up-to-date, and applying them across many nodes is much greater than with QPPB. In a typical application of QPPB, a BGP route is advertised with a BGP community attribute that conveys a particular QoS. Routers that receive the advertisement accept the route into their routing table and set the forwarding-class and priority of the route from the community attribute.

2.3.1.1.1 QPPB Applications

There are two typical applications of QPPB:

1. coordination of QoS policies between different administrative domains
2. traffic differentiation within a single domain, based on route characteristics

2.3.1.1.2 Inter-AS Coordination of QoS Policies

The operator of an administrative domain A can use QPPB to signal to a peer administrative domain B that traffic sent to certain prefixes advertised by domain A should receive a particular QoS treatment in domain B. More specifically, an ASBR of domain A can advertise a prefix XYZ to domain B and include a BGP community attribute with the route. The community value implies a particular QoS treatment, as agreed by the two domains (in their peering agreement or service level agreement, for example). When the ASBR and other routers in domain B accept and install the route for XYZ into their routing table, they apply a QoS policy on selected interfaces that classifies traffic towards network XYZ into the QoS class implied by the BGP community value.

QPPB may also be used to request that traffic sourced from certain networks receive appropriate QoS handling in downstream nodes that may span different administrative domains. This can be achieved by advertising the source prefix with a BGP community, as discussed above. However, in this case other approaches are equally valid, such as marking the DSCP or other CoS fields based on source IP address so that downstream domains can take action based on a common understanding of the QoS treatment implied by different DSCP values.

In the above examples, coordination of QoS policies using QPPB could be between a business customer and its IP VPN service provider, or between one service provider and another.

2.3.1.1.3 Traffic Differentiation Based on Route Characteristics

There may be times when a network operator wants to provide differentiated service to certain traffic flows within its network, and these traffic flows can be identified with known routes. For example, the operator of an ISP network may want to give priority to traffic originating in a particular ASN (the ASN of a content provider offering over-the-top services to the ISP's customers), following a certain AS_PATH, or destined for a particular next-hop (remaining on-net vs. off-net).

Figure 2 shows an example of an ISP that has an agreement with the content provider managing AS300 to provide traffic sourced and terminating within AS300 with differentiated service appropriate to the content being transported. In this example we presume that ASBR1 and ASBR2 mark the DSCP of packets terminating and sourced, respectively, in AS300 so that other nodes within the ISP's network do not need to rely on QPPB to determine the correct forwarding-class to use for the traffic. The DSCP or other COS markings could be left unchanged in the ISP's network and QPPB used on every node.

Figure 2 Use of QPPB to Differentiate Traffic in an ISP Network

2.3.1.2 QPPB

There are two main aspects of the QPPB feature:

- the ability to associate a forwarding-class and priority with certain routes in the routing table; and
- The ability to classify an IP packet arriving on a particular IP interface to the forwarding-class and priority associated with the route that best matches the packet.

2.3.1.2.1 Associating an FC and Priority with a Route

This feature uses a command in the route-policy hierarchy to set the forwarding class and optionally the priority associated with routes accepted by a route-policy entry. The command has the following structure:

fc *fc-name* [**priority** {**low** | **high**}]

The use of this command is illustrated by the following example:

```
config>router>policy-options
begin
community gold members 300:100
policy-statement qppb_policy
entry 10
from
protocol bgp
community gold
exit
action accept
fc hl priority high
exit
exit
exit
commit
```

The **fc** command is supported with all existing from and to match conditions in a route policy entry and with any action other than reject, it is supported with next-entry, next-policy and accept actions. If a next-entry or next-policy action results in multiple matching entries then the last entry with a QPPB action determines the forwarding class and priority.

A route policy that includes the **fc** command in one or more entries can be used in any import or export policy but the **fc** command has no effect except in the following types of policies:

- VRF import policies:
 - config>service>vprn>vrf-import
- BGP import policies:
 - config>router>bgp>import
 - config>router>bgp>group>import
 - config>router>bgp>group>neighbor>import
 - config>service>vprn>bgp>import
 - config>service>vprn>bgp>group>import
 - config>service>vprn>bgp>group>neighbor>import
- RIP import policies:

- config>router>rip>import
- config>router>rip>group>import
- config>router>rip>group>neighbor>import
- config>service>vpn>rip>import
- config>service>vpn>rip>group>import
- config>service>vpn>rip>group>neighbor>import

As evident from above, QPPB route policies support routes learned from RIP and BGP neighbors of a VPRN as well as for routes learned from RIP and BGP neighbors of the base/global routing instance.

QPPB is supported for BGP routes belonging to any of the address families listed below:

- IPv4 (AFI=1, SAFI=1)
- IPv6 (AFI=2, SAFI=1)
- VPN-IPv4 (AFI=1, SAFI=128)
- VPN-IPv6 (AFI=2, SAFI=128)

A VPN-IP route may match both a VRF import policy entry and a BGP import policy entry (if vpn-apply-import is configured in the base router BGP instance). In this case the VRF import policy is applied first and then the BGP import policy, so the QPPB QoS is based on the BGP import policy entry.

This feature also introduces the ability to associate a forwarding-class and optionally priority with IPv4 and IPv6 static routes. This is achieved by specifying the forwarding-class within the static-route-entry next-hop or indirect context.

Priority is optional when specifying the forwarding class of a static route, but once configured it can only be deleted and returned to unspecified by deleting the entire static route.

2.3.1.2.2 Displaying QoS Information Associated with Routes

The following commands are enhanced to show the forwarding-class and priority associated with the displayed routes:

- **show router route-table**
- **show router fib**
- **show router bgp routes**
- **show router rip database**

- **show router static-route**

This feature uses a **qos** keyword to the **show>router>route-table** command. When this option is specified the output includes an additional line per route entry that displays the forwarding class and priority of the route. If a route has no fc and priority information then the third line is blank. The following CLI shows an example:

**show router route-table [family] [ip-prefix[/prefix-length]] [longer | exact]
[protocol protocol-name] qos**

An example output of this command is shown below:

```
A:Dut-A# show router route-table 10.1.5.0/24 qos
=====
Route Table (Router: Base)
=====
Dest Prefix                                Type    Proto    Age          Pref
      Next Hop[Interface Name]              Metric
      QoS
-----
10.1.5.0/24                                Remote   BGP      15h32m52s    0
      PE1_to_PE2
      h1, high
-----
No. of Routes: 1
=====
A:Dut-A#
```

2.3.1.2.3 Enabling QPPB on an IP Interface

To enable QoS classification of ingress IP packets on an interface based on the QoS information associated with the routes that best match the packets the **qos-route-lookup** command is necessary in the configuration of the IP interface. The **qos-route-lookup** command has parameters to indicate whether the QoS result is based on lookup of the source or destination IP address in every packet. There are separate **qos-route-lookup** commands for the IPv4 and IPv6 packets on an interface, which allows QPPB to be enabled for IPv4 only, IPv6 only, or both IPv4 and IPv6. The current QPPB based on a source IP address is not supported for IPv6 packets nor is it supported for ingress subscriber management traffic on a group interface.

The **qos-route-lookup** command is supported on the following types of IP interfaces:

- base router network interfaces (config>router>interface)
- VPRN SAP and spoke SDP interfaces (config>service>vprn>interface)
- VPRN group-interfaces (config>service>vprn>sub-if>grp-if)
- IES SAP and spoke SDP interfaces (config>service>ies>interface)

- IES group-interfaces (config>service>ies>sub-if>grp-if)

When the **qos-route-lookup** command with the destination parameter is applied to an IP interface and the destination address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the sap-ingress or network qos policy associated with the IP interface. If the destination address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the sap-ingress or network qos policy.

Similarly, when the **qos-route-lookup** command with the source parameter is applied to an IP interface and the source address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the sap-ingress or network qos policy associated with the IP interface. If the source address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the sap-ingress or network qos policy.

Currently, QPPB is not supported for ingress MPLS traffic on network interfaces or on CsC PE'-CE' interfaces (config>service>vpn>nw-if).

Note: QPPB based on a source IP address is not supported for ingress subscriber management traffic on a group interface.

2.3.1.2.4 QPPB When Next-Hops are Resolved by QPPB Routes

In some circumstances (IP VPN inter-AS model C, Carrier Supporting Carrier, indirect static routes, etc.) an IPv4 or IPv6 packet may arrive on a QPPB-enabled interface and match a route A1 whose next-hop N1 is resolved by a route A2 with next-hop N2 and perhaps N2 is resolved by a route A3 with next-hop N3, etc. The QPPB result is based only on the forwarding-class and priority of route A1. If A1 does not have a forwarding-class and priority association then the QoS classification is not based on QPPB, even if routes A2, A3, etc. have forwarding-class and priority associations.

2.3.1.2.5 QPPB and Multiple Paths to a Destination

When ECMP is enabled some routes may have multiple equal-cost next-hops in the forwarding table. When an IP packet matches such a route the next-hop selection is typically based on a hash algorithm that tries to load balance traffic across all the next-hops while keeping all packets of a given flow on the same path. The QPPB configuration model described in [Associating an FC and Priority with a Route](#) allows different QoS information to be associated with the different ECMP next-hops of a route. The forwarding-class and priority of a packet matching an ECMP route is based on the particular next-hop used to forward the packet.

When BGP fast reroute [1] is enabled some BGP routes may have a backup next-hop in the forwarding table in addition to the one or more primary next-hops representing the equal-cost best paths allowed by the ECMP/multipath configuration. When an IP packet matches such a route a reachable primary next-hop is selected (based on the hash result) but if all the primary next-hops are unreachable then the backup next-hop is used. The QPPB configuration model described in [Associating an FC and Priority with a Route](#) allows the forwarding-class and priority associated with the backup path to be different from the QoS characteristics of the equal-cost best paths. The forwarding class and priority of a packet forwarded on the backup path is based on the **fc** and priority of the backup route.

2.3.1.2.6 QPPB and Policy-Based Routing

When an IPv4 or IPv6 packet with destination address X arrives on an interface with both QPPB and policy-based-routing enabled:

- There is no QPPB classification if the IP filter action redirects the packet to a directly connected interface, even if X is matched by a route with a forwarding-class and priority
- QPPB classification is based on the forwarding-class and priority of the route matching IP address Y if the IP filter action redirects the packet to the indirect next-hop IP address Y, even if X is matched by a route with a forwarding-class and priority

2.3.1.3 QPPB and GRT Lookup

Source-address based QPPB is not supported on any SAP or spoke SDP interface of a VPRN configured with the **grt-lookup** command.

2.3.1.3.1 QPPB Interaction with SAP Ingress QoS Policy

When QPPB is enabled on a SAP IP interface the forwarding class of a packet may change from **fc1**, the original **fc** determined by the SAP ingress QoS policy to **fc2**, the new **fc** determined by QPPB. In the ingress datapath SAP ingress QoS policies are applied in the first P chip and route lookup/QPPB occurs in the second P chip. This has the implications listed below:

- Ingress remarking (based on profile state) is always based on the original **fc** (**fc1**) and sub-class (if defined)
- The profile state of a SAP ingress packet that matches a QPPB route depends on the configuration of **fc2** only. If the de-1-out-profile flag is enabled in **fc2** and **fc2** is not mapped to a priority mode queue then the packet will be marked out of profile if its DE bit = 1. If the profile state of **fc2** is explicitly configured (in or out) and **fc2** is not mapped to a priority mode queue then the packet is assigned this profile state. In both cases there is no consideration of whether or not **fc1** was mapped to a priority mode queue.
- The priority of a SAP ingress packet that matches a QPPB route depends on several factors. If the de-1-out-profile flag is enabled in **fc2** and the DE bit is set in the packet then priority will be low regardless of the QPPB priority or **fc2** mapping to profile mode queue, priority mode queue or policer. If **fc2** is associated with a profile mode queue then the packet priority will be based on the explicitly configured profile state of **fc2** (in profile = high, out profile = low, undefined = high), regardless of the QPPB priority or **fc1** configuration. If **fc2** is associated with a priority mode queue or policer then the packet priority will be based on QPPB (unless DE=1), but if no priority information is associated with the route then the packet priority will be based on the configuration of **fc1** (if **fc1** mapped to a priority mode queue then it is based on DSCP/IP prec/802.1p and if **fc1** mapped to a profile mode queue then it is based on the profile state of **fc1**).

Table 2 summarizes the interactions.

Table 2 QPPB Interactions with SAP Ingress QoS

Original FC object mapping	New FC object mapping	Profile	Priority (drop preference)	DE=1 override	In/out of profile marking
Profile mode queue	Profile mode queue	From new base FC unless overridden by DE=1	From QPPB, unless packet is marked in or out of profile in which case follows profile. Default is high priority	From new base FC	From original FC and sub-class

Table 2 QPPB Interactions with SAP Ingress QoS (Continued)

Original FC object mapping	New FC object mapping	Profile	Priority (drop preference)	DE=1 override	In/out of profile marking
Priority mode queue	Priority mode queue	Ignored	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Policer	Policer	From new base FC unless overridden by DE=1	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Priority mode queue	Policer	From new base FC unless overridden by DE=1	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Policer	Priority mode queue	Ignored	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Profile mode queue	Priority mode queue	Ignored	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then follows original FC's profile mode rules.	From new base FC	From original FC and sub-class
Priority mode queue	Profile mode queue	From new base FC unless overridden by DE=1	From QPPB, unless packet is marked in or out of profile in which case follows profile. Default is high priority	From new base FC	From original FC and sub-class

Table 2 QPPB Interactions with SAP Ingress QoS (Continued)

Original FC object mapping	New FC object mapping	Profile	Priority (drop preference)	DE=1 override	In/out of profile marking
Profile mode queue	Policer	From new base FC unless overridden by DE=1	If DE=1 override, then low otherwise from QPPB. If no DEI or QPPB overrides, then follows original FC's profile mode rules.	From new base FC	From original FC and sub-class
Policer	Profile mode queue	From new base FC unless overridden by DE=1	From QPPB, unless packet is marked in or out of profile in which case follows profile. Default is high priority	From new base FC	From original FC and sub-class

2.3.1.4 Object Grouping and State Monitoring

This feature introduces a generic operational group object which associates different service endpoints (pseudowires and SAPs) located in the same or in different service instances. The operational group status is derived from the status of the individual components using certain rules specific to the application using the concept. A number of other service entities, the monitoring objects, can be configured to monitor the operational group status and to perform certain actions as a result of status transitions. For example, if the operational group goes down, the monitoring objects will be brought down.

2.3.1.4.1 IES IP Interface Applicability

This concept is used by an IPv4 IES interface to affect the operational state of the IP interface monitoring the operational group. Individual SAP and spoke SDPs are supported as monitoring objects.

The following rules apply:

- an object can only belong to one group at a time
- an object that is part of a group cannot monitor the status of a group
- an object that monitors the status of a group cannot be part of a group
- an operational group may contain any combination of member types: SAP or Spoke-SDPs

- an operational group may contain members from different VPLS service instances
- objects from different services may monitor the oper-group

There are two steps involved in enabling the functionality:

1. Identify a set of objects whose forwarding state should be considered as a whole group then group them under an operational group using the **oper-group** command.
2. Associate the IP interface to the oper-group using the **monitor-group** command.

The status of the operational group (oper-group) is dictated by the status of one or more members according to the following rules:

- The oper-group goes down if all the objects in the oper-group go down. The oper-group comes up if at least one component is up.
- An object in the group is considered down if it is not forwarding traffic in at least one direction. That could be because the operational state is down or the direction is blocked through some validation mechanism.
- If a group is configured but no members are specified yet then its status is considered up.
- As soon as the first object is configured the status of the operational group is dictated by the status of the provisioned member(s).

The following configuration shows the oper-group g1, the VPLS SAP that is mapped to it and the IP interfaces in IES service 2001 monitoring the oper-group g1. This example uses an R-VPLS context. The VPLS instance includes the **allow-ip-int-binding** and the **service-name v1**. The IES interface links to the VPLS using the **vpls v1** option. All commands are under the configuration service hierarchy.

To further explain the configuration. Oper-group g1 has a single SAP (1/1/1:2001) mapped to it and the IP interfaces in the IES service 2001 will derive its state from the state of oper-group g1.

```
oper-group g1 create

vpls 1 customer 1 create
    allow-ip-int-binding
    stp
        shutdown
    exit
    service-name "v1"
    sap 1/1/1:2001 create
        oper-group g1
        eth-cfm
            mep domain 1 association 1 direction down
ccm-enable
```

```
no shutdown
    exit
exit
sap 1/1/2:2001 create
exit
sap 1/1/3:2001 create
exit
no shutdown

ies 2001 customer 1 create
    interface "i2001" create
        address 21.1.1.1/24
        monitor-oper-group "g1"
        vpls "v1"
    exit
no shutdown
exit
```

2.3.2 Subscriber Interfaces

Subscriber interfaces are composed of a combination of two key technologies, subscriber interfaces and group interfaces. While the subscriber interface defines the subscriber subnets, the group interfaces are responsible for aggregating the SAPs. Subscriber Interfaces apply to the 7450 ESS and 7750 SR only.

- Subscriber interface — An interface that allows the sharing of a subnet among one or many group interfaces in the routed CO model.
- Group interface — Aggregates multiple SAPs on the same port.
- Redundant interfaces — A special spoke-terminated Layer 3 interface. It is used in a Layer 3 routed CO dual-homing configuration to shunt downstream (network to subscriber) to the active node for a given subscriber. Redundant interfaces apply to the 7750 SR only.

2.3.2.1 IPv6 Enhanced Subscriber Management (ESM)

All IPv6 ESM services require either Routed CO (IES), or Routed CO for VPRN as a supporting service construct. Because of the complexities of the IPv6 link-model, there is currently no support for IPv6 ESM in a VPLS. There is also currently no support for IPv6 in combination with Basic Subscriber Management (BSM). This feature applies to the 7450 ESS and 7750 SR only.

2.3.2.2 RADIUS Accounting

In the 7750 SR OS, the accounting paradigm is based on sla-profile instances, yet this is at odds with traditional RADIUS authentication and accounting which is host-centric. In previous OS releases, it was possible to have many hosts sharing a common sla-profile instance, and thus accounting and QoS parameters.

Complications would arise with RADIUS accounting because Accounting-Start and Accounting-Stop are a function of sla-profile instance and not the hosts – this meant that some host-specific parameters (like Framed-Ip-Address) would not be consistently included in RADIUS accounting.

Dual-stack subscribers are now two different hosts sharing a single sla-profile instance. A new RADIUS accounting mode has been introduced to support multiple-host environments.

A new command, **host-accounting**, is introduced under **accounting-policy**, which allows configurable behavior.

No host-accounting:

When **no host-accounting** is configured, accounting behavior is as follows:

- A RADIUS accounting start message is sent when the SLA-profile instance is created. It contains accounting (octets/packets) and the Framed-Ip-Address of the host which caused the sla-profile instance to be created.
- Additional hosts may bind to the sla-profile instance at any time, but no additional accounting messages are sent during these events.
- If the original host disconnects, then future accounting messages will use an IP address of one of the remaining hosts.
- When the final host associated with an sla-profile instance disconnects, an accounting stop message will be sent.

Host-accounting enabled:

When **host-accounting** is configured, additional RADIUS accounting messages are created for host activity in addition to messages for common queue accounting. The behavior is as follows:

- A RADIUS accounting start message is sent each time a host is authenticated. It contains the Framed-Ip-Address among other things. It does not contain any octet or packet counts.
- A RADIUS accounting start message is sent each time a sla-profile instance is created.
- Whenever a host disconnects a RADIUS, accounting stop message is sent for that host.

- If all host associated with an sla-profile instance disconnect, a RADIUS accounting stop message is sent for that instance.

This behavior means certain AVP may be in either host, sla-profile instance, or both accounting records. See [Table 3](#).

Note: Interim-Acct records are not sent for hosts, only the start- and stop-accounting messages.

Table 3 RADIUS Accounting Table

RADIUS Accounting AVP	Host Accounting	SLA-Profile Accounting
User-Name	Yes	No
NAS-Identifier	Yes	Yes
NAS-IP-Address	Yes	Yes
Nas-Port-Id	Yes	No

Alc-Subscriber-Profile-String	Yes	Yes
Alc-Sla-Profile-String	Yes	Yes

2.3.3 SAPs

2.3.3.1 Encapsulations

The following SAP encapsulations are supported on the IES services:

- Ethernet null
- Ethernet dot1q
- SONET/SDH IPCP
- SONET/SDH BCP-null
- SONET/SDH BCP-dot1q
- SONET/SDH ATM

- ATM - LLC SNAP or VC-MUX

2.3.3.2 ATM SAP Encapsulations for IES

The 7750 SR series supports ATM PVC service encapsulation for IES SAPs. Both UNI and NNI cell formats are supported. The format is configurable on a SONET/SDH path basis. A path maps to an ATM VC. All VCs on a path must use the same cell format.

The following ATM encapsulation and transport modes are supported:

- RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*:
 - AAL5 LLC/SNAP IPv4 routed
 - AAL5 VC mux IPv4 routed
 - AAL5 LLC/SNAP IPv4 bridged
 - AAL5 VC mux IPv4 bridged

2.3.3.3 Pseudowire SAPs

This feature allows customers of an IES, VPRN, or Epipe VLL service and connected to an Ethernet SAP on an Access PE to be backhauled through an Ethernet aggregation network using MPLS pseudowires terminating directly on a Converged PE hosting the IES, VPRN, or Epipe VLL service. If Enhanced Subscriber Management over PW is also used, then the converged PE may also act as a BNG. This service is different from VLL Spoke-SDP termination on an IES or VPRN because access QoS policies can be applied directly at a centralized PE hosting the IES or VPRN instance. This feature uses the same concepts of pseudowire ports and pseudowire SAPs that are used for ESM over MPLS pseudowires, described in the SR OS Triple Play Service Delivery Architecture user guide.

The MPLS pseudowire originates from the first hop aggregation PE (referred to as access PE) upstream of the Access-Node (or directly from a multi-service AN), and terminates on the Converged PE. Multiple customers from a given access-port on the Access-PE can be backhauled over a single MPLS pseudowire towards the Converged PE. This capability allows the network to scale and does not require an MPLS pseudowire per customer between the Access-PE and the Converged PE. The access-port on the Access-PE can be dot1q, q-in-q or NULL encapsulated. The Converged PE terminates the MPLS pseudowire, decapsulates the received frames, and provides access QoS functions including HQoS, without requiring an internal or

external loopback. Each MPLS pseudowire is represented on the BNG as a “PW-port” for which SAPs are created. These SAPs are termed “PW SAPs”, and must be statically configured on IES or VPRN interfaces (unlike the ESM case where a capture SAP can be configured). The underlying Ethernet port must be in hybrid mode. Pseudowire SAPs are supported on Ethernet MDAs and on the HSMDAv2.

Figure 3 illustrates the architecture of an aggregation network that uses pseudowire SAPs.

Figure 3 Network Architecture using Pseudowire SAPs

2.3.3.4 Encapsulation

The packet is encapsulated on an Ethernet pseudowire, which is associated with a pseudowire port on the Converged PE, and a Spoke-SDP on the access PE. The optional control word is not supported. The SDP could use an LDP LSP, RSVP LSP, BGP RFC3107 tunnel, or LDP over RSVP tunnel. Hash labels are not supported. The SDP may be bound to a port or a LAG, although shaping vports for pseudowire ports on LAGs in distributed mode is not supported. If an SDP is rerouted, then the corresponding pseudowire ports are brought operationally down. Pseudowire ports are associated with an SDP by configuration.

2.3.3.5 Pseudowire SAP Configuration

The following steps are required at the access PE:

1. Configure an Epipe VLL service.
2. Configure a NULL, 1q or q-in-q SAP on the Epipe service.

The following steps are used to configure a pseudowire SAP on the IES or VPRN service at the Layer 3 PE:

Step 1. Define a pseudowire port.

```
pw-port 1 create
exit
pw-port 2 create
exit
```

Step 2. Bind a physical port or LAG, in hybrid mode, with the pseudowire port.

```
service customer 1 create
    multi-service-site "abc" create
        assignment port pw-1
        egress
        policer-control-policy "abc"
        exit
    exit description "Default customer"
    exit
sdp 1 mpls create
    far-end 10.1.1.2
    ldp
    path-mtu 1514
    keep-alive
    shutdown
    exit
binding
    port lag-1
    pw-port 1 vc-id 1 create
        no shutdown
        exit
    pw-port 2 vc-id 2 create
```

```

        no shutdown
        exit
    exit
no shutdown
exit

```

Step 3. Perform one of the following steps:

Step 4. For a PW SAP on an IES/VRN, configure a SAP on the IES or VRN interface, with a SAP ID that uses the form **pw-id**.

```

ies 1 customer 1 create
interface "ies if" create
address 30.1.1.1/24
mac 00:00:00:00:00:ff
static-arp 30.1.1.2 00:00:00:00:00:aa
sap pw-1:1 create
    exit
exit
no shutdown
exit

```

Step 5. For a PW SAP on an Epipe VLL, configure a SAP on the service, with a SAP ID that uses the form **pw-id**.

```

epipe 1 customer 1 create
sap pw-1:1 create
    exit
exit
no shutdown
exit

```

The PW SAP may be mated to an Ethernet SAP or an Ethernet Spoke-SDP in the Epipe VLL service

2.3.3.6 QoS for Pseudowire Ports and Pseudowire SAPs

Pseudowire SAPs support the QoS models allowed for regular VLL, IES or VRN SAPs. These include:

- Per-service HQoS.

- This allows shaping of the total traffic per access node (and total traffic per class per AN), assuming one pseudowire per AN from the A-PE.
- SAP QoS support as available on the IOM3-XP, including
 - H-QoS (service scheduler child to port scheduler parent)
 - SAP queues attached to H-QoS scheduler by 'parent' statement
 - Scheduler attached to Port Scheduler by 'port-parent' statement
 - Direct service queue to port scheduler mapping
 - Aggregate-rate-limit
- Support for the redirection of SAP egress queues to an access queue group instance. It is possible to redirect SAP queues of a pseudowire SAP using the SAP based redirection for the IOM3 with Ethernet MDA or HSMDAv2, and policy based redirection for the IOM3 with Ethernet MDA, as applicable.
- Policing and H-POL

2.3.3.7 Shaping and Bandwidth Control

Pseudowire SAPs can be shaped on egress by a vport on a physical port. The pseudowire SAP egress cannot explicitly declare which vport to use, but they will inherit the vport used by the pw-port egress shaping.

The vport is represented by a secondary shaper on an HSMDAv2. The intermediate destination identifier, used for ESM on MPLS pseudowires, is not applicable to VLL, IES and VPRN pseudowire SAPs.

If a pseudowire port is configured on a LAG, then vport shaping is only supported if the LAG is in link mode.

Per-access node shaping is configured as follows:

1. Configure a vport(s) per AN under the port (or LAG) to which the SDP corresponding to the pseudowire SAP is bound. The vport would be configured with **aggregate rate-limit**. (`config>port>ethernet>access>egress>vport vport-name create`).
2. Explicitly assign (via static configuration) a pseudowire port to a vport. For limiting the total traffic to an AN, all pseudowire ports for an AN-port would refer to the same vport.

As in the ESM on pseudowire case, vport scheduling on the HSMDAv2 is implemented using an **exp-secondary-shaper**. This is referred to as a **pw-sap-secondary-shaper** in the new CLI below. If an **hsmda-queue-override secondary-shape** is defined for the pw-sap, then the system will use the override, else:

- If a named **pw-sap-secondary-shaper** is defined for the pw-port, then that is used,
- Else, the default **exp-secondary-shaper** for the port is used.

For bandwidth control per pseudowire, the following configuration steps are used:

1. Create multiple vports under the port to which SDP is bound. Each vport can be configured with **agg-rate rate**, a scheduler or port-scheduler.
2. Assign each pseudowire to an AN to a unique vport shaper (regular IOM/MDA) or secondary shaper (on HSMDAv2).

To make use of the **agg-rate rate** or **port-scheduler** under a VPORT, PW SAP queues and schedulers must be configured with the **port-parent** command. To make use of a scheduler under a VPORT, PW SAP schedulers must be configured with a **parent** command and the **parent-location vport** under the tier 1 of the scheduler policy. The egress hierarchical parenting relationship options are shown in Figure 4. See the SR OS Quality of Service guide for more details.

Figure 4 PW SAP Egress Scheduling Hierarchy Options

al_0376

2.3.3.8 Lag Considerations

PW Ports may be bound to VPORT Schedulers bound to a LAG. However, if the LAG is configured in distributed mode, then bandwidth is shared according to the active LAG members across a single IOM. If the LAG spans multiple IOMs, then it effectively operates in link mode across the IOMs. That is, the full LAG bandwidth is allocated to the LAG members on each IOM. Therefore the use of a vport on a distributed mode LAG with a port scheduler on the port or vport and PW SAPs is explicitly not supported and is not a recommended configuration. It is recommended that port-fair mode is used instead.

2.3.3.9 Last Mile Packet Size Adjustment

In the application where pseudowire SAPs are used to apply access QoS for services aggregated from an Ethernet access network, MPLS labels may not be present on the last-mile and link from an access node. In these cases, policers, queues and H-QoS schedulers should account for packets without MPLS overhead, modeled as “encaps-offset”. Vport and port schedulers behave as per the table below. In the data-path, the actual pseudowire encap overhead (taking into account the MPLS labels) added to the packet is tracked, and may be applied to the scheduler calculations via the configured packet-byte-offset.

The exp-secondary-shaper used on the HSMDAv2 always assumes MPLS overhead and does not account for the packet-byte-offset. In all other cases, the rate limit configured for the pseudowire SAP accounts for subscriber or service frame wire rate: without MPLS overhead and including the last mile overhead (unless a packet-byte-offset is configured).

[Table 4](#) summarizes the default packet sizes used at each of the schedulers on the IOM/Ethernet MDA and HSMDAv2, assuming a 1000byte customer packet.

Table 4 Packet Sizes Used for Pseudowire SAPs

Type	Size
exp-secondary-shaper	20B preamble + 26 MPLS + 1000B pkt
queue/policer rate on hsmдав2	1000B customer pkt
port-scheduler rate	20B preamble + 1000B pkt
regular queue/policer rate	1000B pkt
vport agg-limit-rate	20B preamble + 1000B pkt
vport port-scheduler rate	20B preamble + 1000B pkt

Table 4 Packet Sizes Used for Pseudowire SAPs (Continued)

Type	Size
vport scheduler rate	1000B pkt
vport scheduler to port-scheduler rates	20B preamble + 1000B pkt

2.3.3.10 Redundancy with Pseudowire SAPs

Within a chassis, IOM and port based redundancy is based on active/backup LAG. The topology for the base MPLS LSP used by the SDP could be constrained such that it could get re-routed in the aggregation network, but would always appear on the LAG ports on the Layer 3 PE. In the case that the tunnel is re-routed to a different port, the MPLS pseudowire SAPs would be brought down.

In order to provide Layer 3 PE redundancy, dual homing of the access PE into separate Layer 3 PEs using active/standby pseudowire status is supported. This is shown in [Figure 5](#).

Figure 5 Dual Homing into Multiple Layer 3 PEs

Dual homing operates in a similar manner to Spoke-SDP termination on IES/VP RN. [Figure 5](#) displays the access PE is dual-homed to the Layer 3 PEs using two spoke-SDPs. The endpoint in the access PE is configured to be the master from a pseudowire redundancy perspective using the **standby-signaling-master** command. The access PE picks one of the Spoke-SDPs to make active, and one to make standby, based on the local configuration of primary or Spoke SDP precedence.

The pseudowire port at the Layer 3 PE behaves as a slave from the perspective of pseudowire status signaling. That is, if its peer signals “PW FWD standby (0x20)” status bit for the given Spoke-SDP and the local configuration does not allow this bit to be ignored, the PE will take the pseudowire port to a local operationally down state. This is consistent with the Spoke-SDP behavior for the case of Spoke-SDP termination on IES/VRPN.

As a consequence, all of the pseudowire SAPs bound to the pseudowire port are taken down, which causes the corresponding IES or VRPN interface to go to a local operationally down state and thus will stop forwarding packets towards this pseudowire port.

Conversely, the formerly standby pseudowire is made active and then the corresponding pseudowire port on the second Layer 3 PE is taken locally operationally up. Therefore, all of the pseudowire SAPs bound to the pseudowire port are brought up, which causes the corresponding IES or VRPN interface to go to a local operationally up state allowing forwarding of packets towards this pseudowire port.

For VLLs, a PW Port always behaves as a slave from the perspective of PW redundancy. This is because the PW Port is taken locally operationally down if any non-zero PW status (including a PW Preferential Forwarding status of 'standby') is received. Support for existing master-slave PW redundancy mechanisms for dual homing of the access PE into separate converged PEs using active/standby PW status is required as shown in [Figure 6](#).

Figure 6 Master-Slave PW Redundancy

As in the existing implementation, standby-signaling-master is configured on the Spoke-SDP at the access PE. However explicit configuration of standby-signaling-slave on the PW Port is not required, as this is the default behavior.

The forwarding behavior is the same as when standby-signaling-slave for Epipe Spoke-SDPs. That is, when enabled, if a PW Forwarding Standby (0x20) LDP status message is received for the PW, then the transmit direction is blocked for the PW Port. All PW SAPs bound to the corresponding PW Port are treated from a SAP OAM perspective in the same manner as a fault on the service e.g. an SDP-binding down or remote SAP down.

PW redundancy with multiple active/standby PW Ports or PW SAPs bound to the same Ethernet SAP in the Converged PE is not supported. The Independent Mode of operation for PW Redundancy is not also supported for a PW Port.

2.3.3.11 Operational Group Support for PW Ports

A PW Port state may be linked to the state of an oper-group, such that if the oper-group goes down, the SDP binding for the PW Port will also go operationally down, and thus the corresponding PW status bit signaled (0x00000001 - Pseudowire Not Forwarding). If a status of 0x00000001 is signaled for a currently active PW, and active/standby dual homing is in use then the access PE will fail over to the standby PW to the standby Converged PE.

This is achieved by linking an SDP binding to an operational group for PW SAPs belonging to any supported service types (including those with group interfaces) bound to that PW Port i.e. IES, VPRN, or Epipe VLL. The association to an operational group is configured under the PW port config at the SDP binding level, as follows:

```
config
  service
    sdp
      binding
        [no] pw-port <pw-port-id> [vc-id <vc-id>] [create]
        monitor-oper-group <group-name>
```

The **monitor-oper-group** command specifies the operational group to be monitored by the PW-Port under which it is configured. The oper-group name must be already configured under the **config>service** context before its name is referenced in this command.

The following illustrates how a PW Port can track the status of VPRN uplinks using monitor-oper-group.

Uplinks in a VPRN may be monitored using a BFD session on the network facing IP interfaces in a VPRN or on the network IP interfaces supporting the uplinks.

Oper-groups monitor the state of these BFD sessions inside the VPRN as follows:

```
config>service>  
  oper-group "test-oper-grp" create  
    bfd-enable interface "vprn-if" dest-ip 10.0.0.20 service 105
```

Alternatively, the state of network interfaces can be monitored as follows:

```
config>service>  
  oper-group "test-oper-grp" create  
    bfd-enable interface "network-if" dest-ip 10.0.1.20
```

The PW Port is then configured with monitor-oper-group as follows:

```
config>service>sdp>binding  
  pw-port 100 vc-id 25  
  monitor-oper-group "test-oper-group"
```

2.3.4 Routing Protocols

The IES IP interfaces are restricted as to the routing protocols that can be defined on the interface based on the fact that the customer has a different routing domain for this service. The IES IP interfaces support the following routing protocols:

- RIP
- OSPF
- IS-IS
- BGP
- IGMP
- PIM

Note: The SAP for the IES IP interface is created at the IES service level, but the routing protocols for the IES IP interface are configured at the routing protocol level for the main router instance.

2.3.4.1 CPE Connectivity Check

Static routes are used within many IES services. Unlike dynamic routing protocols, there is no way to change the state of routes based on availability information for the associated CPE. CPE connectivity check adds flexibility so that unavailable destinations will be removed from the service provider's routing tables dynamically and minimize wasted bandwidth.

The availability of the far-end static route is monitored through periodic polling. The polling period is configured. If the poll fails a specified number of sequential polls, the static route is marked as inactive.

An ICPM ping mechanism is used to test the connectivity.

If the connectivity check fails and the static route is deactivated, the router will continue to send polls and re-activate any routes that are restored.

2.3.5 QoS Policies

When applied to IES services, service ingress QoS policies only create the unicast queues defined in the policy. The multipoint queues are not created on the service. With IES services, service egress QoS policies function as with other services where the class-based queues are created as defined in the policy. Both Layer 2 or Layer 3 criteria can be used in the QoS policies for traffic classification in an IES.

2.3.6 Filter Policies

Only IP filter policies can be applied to IES services.

2.3.7 MPLS Entropy Label and Hash Label

The router supports both the MPLS entropy label (RFC 6790) and the Flow Aware Transport label, known as the hash label (RFC 6391). These labels allow LSR nodes in a network to load-balance labeled packets in a much more granular fashion than allowed by simply hashing on the standard label stack. See the *MPLS Guide* for further information.

2.3.8 Spoke SDPs

Distributed services use service distribution points (SDPs) to direct traffic to another router through service tunnels. SDPs are created on each participating router and then bound to a specific service. SDP can be created as either GRE or MPLS. Refer to the *7450 ESS*, *7750 SR*, and *7950 XRS Services Overview Guide* for information about configuring SDPs.

This feature provides the ability to cross-connect traffic entering on a spoke SDP, used for Layer 2 services (VLLs or VPLS), on to an IES or VPRN service. From a logical point of view, the spoke SDP entering on a network port is cross-connected to the Layer 3 service as if it entered by a service SAP. The main exception to this is traffic entering the Layer 3 service by a spoke SDP is handled with network QoS policies not access QoS policies.

This feature applies to the 7450 ESS and 7750 SR only.

[Figure 7](#) depicts traffic terminating on a specific IES or VPRN service that is identified by the SDP-ID and VC label present in the service packet.

Figure 7 SDP-ID and VC Label Service Identifiers

al_0163

Figure 8 IES Spoke-SDP Termination

OSSG188

[Figure 8](#) depicts a spoke-SDP terminating directly into a Layer 3 service interface (IES or VPRN) at one end, and a Layer 2 service (Epipe, lpipe, or VPLS) at the other. There is no special configuration required on the Layer 2 service.

If the terminating Layer 2 service is an Ipipe, then on the IES/VP RN interface end, the spoke-SDP must be created with the vc-type ipipe option. Spoke-SDPs created with vc-type ether (the default) are compatible with Epipe and VPLS services, as well as with other IES/VP RN interfaces.

If the MPLS network uses LDP signaling, then in order for a spoke-SDP to function, the LDP binding MTUs at each end must match. For a Layer 2 service, the MTU of the local binding is 14 octets less than the configured service-mtu (such as, binding MTU = service-mtu - 14). For an IES or VP RN interface, the binding MTU is equal to either the configured ip-mtu of the interface, or the SDP's path-mtu minus 14, whichever is lower. The local and remote MTUs of all bindings can be found using the CLI command **show router ldp bindings**.

All routing protocols that are supported by IES/VP RN are supported for spoke-SDP termination.

2.3.9 SRRP

Subscriber Router Redundancy Protocol (SRRP) is used on the 7750 SR and 7450 ESS and is closely tied to the multi-chassis synchronization (MCS) protocol used to synchronize information between redundant nodes. An MCS peer must be configured and operational when subscriber hosts have a redundant connection to two nodes. Subscriber hosts are identified by the ingress SAP, the host's IP and MAC addresses. Once a host is identified on one node, the MCS peering is used to inform the other node that the host exists and conveys the dynamic DHCP lease state information of the host. MCS creates a common association between the virtual ports (SAPs) shared by a subscriber. This association is configured at the MCS peering level by defining a tag for a port and range of SAPs. The same tag is defined on the other nodes peering context for another port (does not need to be the same port-ID) with the same SAP range. In this manner, a subscriber host and Dot1Q tag sent across the peering with the appropriate tag is mapped to the redundant SAP on the other node.

SRRP can only be configured on group interfaces. Once SRRP is active on a group IP interface, the SRRP instance attempts to communicate through in-band (over the group IP interfaces SAPs) and out-of-band (over the group IP interfaces redundant IP interface) messages to a remote router. If the remote router is also running SRRP with the same SRRP instance ID, one router enters a master state while the other router enters a backup state. Since both routers are sharing a common SRRP gateway MAC address that is used for the SRRP gateway IP addresses and for proxy ARP functions, either node may act as the default gateway for the attached subscriber hosts.

For proper operation, each subscriber subnet associated with the SRRP instance must have a gw-address defined. The SRRP instance cannot be activated (no shutdown) unless each subscriber subnet associated with the group IP interface has an SRRP gateway IP address. Once the SRRP instance is activated, new subscriber subnets cannot be added without a corresponding SRRP gateway IP address. [Table 5](#) describes how the SRRP instance state is used to manage access to subscriber hosts associated with the group IP interface.

SRRP instances are created in the disabled state (shutdown). To activate SRRP the **no shutdown** command in the SRRP context must be executed.

Before activating an SRRP instance on a group IP interface, the following actions are required:

- Add a SRRP gateway IP addresses to all subscriber subnets associated with the group IP interface, including subnets on subscriber IP interfaces associated as retail routing contexts (at least one subnet must be on the subscriber IP interface containing the group IP interface and its SRRP instance).
- Create a redundant IP interface and associate it with the SRRP instances group IP interface for shunting traffic to the remote router when master.
- Specify the group IP interface SAP used for SRRP advertisement and Information messaging.

Before activating an SRRP instance on a group IP interface, the following actions should be considered:

- Associate the SRRP instance to a Multi-Chassis Synchronization (MCS) peering terminating on the neighboring router (the MCS peering should exist as the peering is required for redundant subscriber host management).
- Define a description string for the SRRP instance.
- Specify the SRRP gateway MAC address used by the SRRP instance (must be the same on both the local and remote SRRP instance participating in the same SRRP context).
- Change the base priority for the SRRP instance.
- Specify one or more VRRP policies to dynamically manage the SRRP instance base priority.
- Specify a new keep alive interval for the SRRP instance.

[Table 5](#) lists the SRRP's state effect on subscriber hosts associated with group IP interfaces.

Table 5 SRRP State Effect on Subscriber Hosts Associated with Group IP Interface

SRRP State	ARP	Local Proxy ARP Enabled	Remote Proxy ARP Enabled	Subscriber Host Routing
Disabled	- Responds to ARP for all owned subscriber subnet IP addresses. - Will not respond to ARP for subscriber subnet SRRP gateway IP addresses. - All ARP responses will contain the native MAC of the group IP interface (not the SRRP gateway MAC).	- Responds to ARP for all subscriber hosts on the subscriber subnet.	- Responds to ARP for all reachable remote IP hosts.	- All routing out the group IP interface will use the native group IP interface MAC address. - The group IP interface redundant IP interface will not be used. - Will not accept packets destined to the SRRP gateway MAC received on the group IP interface.
Becoming Master (In order to enter becoming master state, a master must currently exist)	- Responds to ARP for all owned subscriber subnet IP addresses (hardware address and source MAC = group IP interface native MAC). - Responds to ARP for subscriber subnet SRRP gateway IP addresses (hardware address = SRRP gateway IP address, source MAC = group IP interface native MAC).	- Responds to ARP for all subscriber hosts on the subscriber subnet (hardware address = SRRP gateway MAC address, source MAC = group IP interface native MAC).	- Responds to ARP for all reachable remote IP hosts (hardware address = SRRP gateway MAC address, source MAC = group IP interface native MAC).	- All routing out the group IP interface use the native group IP interface MAC address. - Subscriber hosts mapped to the redundant IP interface are remapped to the group IP interface. - Will not accept packets destined to the SRRP gateway MAC received on the group IP interface.

Table 5 SRRP State Effect on Subscriber Hosts Associated with Group IP Interface

SRRP State	ARP	Local Proxy ARP Enabled	Remote Proxy ARP Enabled	Subscriber Host Routing
Master	- Responds to ARP for all owned subscriber subnet IP addresses (hardware address and source MAC = group IP interface native MAC). - Responds to ARP for subscriber subnet SRRP gateway IP addresses (hardware address = SRRP gateway IP address, source MAC = group IP interface native MAC).	- Responds to ARP for all subscriber hosts on the subscriber subnet (hardware address = SRRP gateway MAC address, source MAC = group IP interface native MAC).	- Responds to ARP for all reachable remote IP hosts (hardware address = SRRP gateway MAC address, source MAC = group IP interface native MAC).	- All routing out the group IP interface will use the SRRP gateway MAC address. - Subscriber hosts mapped to the redundant IP interface are remapped to the group IP interface. - Will accept packets destined to the SRRP gateway MAC received on the group IP interface.
Becoming Backup (redundant IP interface operational)	- Responds to ARP for all owned subscriber subnet IP addresses (hardware address and source MAC = group IP interface native MAC). - Will not respond to ARP for subscriber subnet SRRP gateway IP addresses	- Will not respond to ARP for any subscriber hosts on the subscriber subnet.	- Will not respond to ARP for any remote IP hosts.	- Will not route out the group IP interface for subscriber hosts associated with the subscriber subnet. - Will accept packets destined to the SRRP gateway MAC received on the group IP interface. - Subscriber hosts mapped to the group IP interface are remapped to the redundant IP interface.

Table 5 SRRP State Effect on Subscriber Hosts Associated with Group IP Interface

SRRP State	ARP	Local Proxy ARP Enabled	Remote Proxy ARP Enabled	Subscriber Host Routing
Becoming Backup (redundant IP interface not available)	- Responds to ARP for all owned subscriber subnet IP addresses (hardware address and source MAC = group IP interface native MAC). - Will not respond to ARP for subscriber subnet SRRP gateway IP addresses.	- Will not respond to ARP for any subscriber hosts on the subscriber subnet.	- Will not respond to ARP for any remote IP hosts.	- Will route out the group IP interface for subscriber hosts associated with the subscriber subnet using the group IP interface native MAC address. - Subscriber hosts mapped to the redundant IP interface are remapped to the group IP interface. - Will accept packets destined to the SRRP gateway MAC received on the group IP interface
Backup (redundant IP interface operational)	- Responds to ARP for all owned subscriber subnet IP addresses (hardware address and source MAC = group IP interface native MAC). - Will not respond to ARP for subscriber subnet SRRP gateway IP addresses.	- Will not respond to ARP for any subscriber hosts on the subscriber subnet	- Will not respond to ARP for any remote IP hosts	- Will not route out the group IP interface for subscriber hosts associated with the subscriber subnet. - Subscriber hosts mapped to the group IP interface are remapped to the redundant IP interface. - Will not accept packets destined to the SRRP gateway MAC received on the group IP interface.

Table 5 SRRP State Effect on Subscriber Hosts Associated with Group IP Interface

SRRP State	ARP	Local Proxy ARP Enabled	Remote Proxy ARP Enabled	Subscriber Host Routing
Backup (redundant IP interface not available)	- Responds to ARP for all owned subscriber subnet IP addresses (hardware address and source MAC = group IP interface native MAC). - Will not respond to ARP for subscriber subnet SRRP gateway IP addresses.	- Will not respond to ARP for any subscriber hosts on the subscriber subnet.	- Will not respond to ARP for any remote IP hosts.	- Will route out the group IP interface for subscriber hosts associated with the subscriber subnet using the group IP interface native MAC address. - Subscriber hosts mapped to the redundant IP interface are remapped to the group IP interface. - Will not accept packets destined to the SRRP gateway MAC received on the group IP interface.

2.3.9.1 SRRP Messaging

SRRP uses the same messaging format as VRRP with slight modifications. The source IP address is derived from the system IP address assigned to the local router. The destination IP address and IP protocol are the same as VRRP (224.0.0.18 and 112, respectively).

The message type field is set to 1 (advertisement) and the protocol version is set to 8 to differentiate SRRP message processing from VRRP message processing.

The vr-id field supports an SRRP instance ID of 32 bits.

Due to the large number of subnets backed up by SRRP, only one message every minute carries the gateway IP addresses associated with the SRRP instance. These gateway addresses are stored by the local SRRP instance and are compared with the gateway addresses associated with the local subscriber IP interface.

Unlike VRRP, only two nodes may participate in an SRRP instance due to the explicit association between the SRRP instance group IP interface, the associated redundant IP interface and the multi-chassis synchronization (MCS) peering. Since only two nodes are participating, the VRRP skew timer is not utilized when waiting to enter the master state. Also, SRRP always preempts when the local priority is better than the current master and the backup SRRP instance always inherits the master's advertisement interval from the SRRP advertisement messaging.

SRRP advertisement messages carry a *becoming-master* indicator flag. The *becoming-master* flag is set by a node that is attempting to usurp the master state from an existing SRRP master router. When receiving an SRRP advertisement message with a better priority and with the *becoming-master* flag set, the local master initiates its *becoming-backup* state, stops routing with the SRRP gateway MAC and sends an SRRP advertisement message with a priority set to zero. The new master continues to send SRRP advertisement messages with the *becoming-master* flag set until it either receives a return priority zero SRRP advertisement message from the previous master or its *becoming-master* state timer expires. The new backup node continues to send zero priority SRRP advertisement messages every time it receives an SRRP advertisement message with the *becoming-master* flag set. After the new master either receives the old master's priority zero SRRP advertisement message or the *become-master* state timer expires, it enters the *master* state. The *become-master* state timer is set to 10 seconds upon entering the *become-master* state.

The SRRP advertisement message is always evaluated to see if it has a higher priority than the SRRP advertisement that would be sent by the local node. If the advertised priority is equal to the current local priority, the source IP address of the received SRRP advertisement is used as a tie breaker. The node with the lowest IP address is considered to have the highest priority. SRRP will not preempt when priorities are equal. Preemption occurs only when priorities are specified. The lower IP address is only used as a tie-breaker when there is no master in the network. In other words, when both routers are changing from the "init" state, the lower IP will be used to choose the master. If a master already exists, despite having the lower IP address, the system will not preempt the current master.

The SRRP instance maintains the source IP address of the current master. If an advertisement is received with the current master's source IP address and the local priority is higher than the master's advertised priority, the local node immediately enters the *becoming-master* state unless the advertised priority is zero. If the advertised priority is zero, the local node bypasses the *becoming-master* state and immediately enters the *master* state. Priority zero is a special case and is sent when an SRRP instance is relinquishing the master state.

2.3.9.2 SRRP and Multi-Chassis Synchronization

In order to take full advantage of SRRP resiliency and diagnostic capabilities, the SRRP instance should be tied to a MCS peering that terminates on the redundant node. The SRRP instance is tied to the peering using the **srrp srrp-id** command within the appropriate MCS peering configuration. Once the peering is associated with the SRRP instance, MCS will synchronize the local information about the SRRP instance with the neighbor router. MCS automatically derives the MCS key for the SRRP instance based on the SRRP instance ID. For example, an SRRP instance ID of 1 would appear in the MCS peering database with a MCS-key srrp-0000000001.

The SRRP instance information stored and sent to the neighbor router consists of:

- The SRRP instance MCS key
- Containing service type and ID
- Containing subscriber IP interface name
- Subscriber subnet information
- Containing group IP interface information
- The SRRP group IP interface redundant IP interface name, IP address and mask
- The SRRP advertisement message SAP
- The local system IP address (SRRP advertisement message source IP address)
- The Group IP interface MAC address
- The SRRP gateway MAC address
- The SRRP instance administration state (up / down)
- The SRRP instance operational state (disabled / becoming-backup / backup / becoming-master / master)
- The current SRRP priority
- Remote redundant IP interface availability (available / unavailable)
- Local receive SRRP advertisement SAP availability (available / unavailable)

2.3.9.3 SRRP Instance

The SRRP instance uses the received information to verify provisioning and obtain operational status of the SRRP instance on the neighboring router.

2.3.9.3.1 SRRP Instance MCS Key

The SRRP instance MCS key ties the received MCS information to the local SRRP instance with the same MCS key. If the received key does not match an existing SRRP instance, the MCS information associated with the key is ignored. Once an SRRP instance is created and mapped to an MCS peering, the SRRP instance evaluates received information with the same MCS key to verify it corresponds to the same peering. If the received MCS key is on a different peering than the local MCS key an SRRP peering mismatch event is generated detailing the SRRP instance ID, the IP address of the peering the MCS key is received on and the IP address to which the local MCS key is mapped. If the peering association mismatch is corrected, an SRRP peering mismatch clear event is generated.

2.3.9.3.2 Containing Service Type and ID

The Containing Service Type is the service type (IES or VPRN) that contains the local SRRP instance. The Containing Service ID is the service ID of that service. This information is supplied for troubleshooting purposes only and is not required to be the same on both nodes.

2.3.9.3.3 Containing Subscriber IP Interface Name

The containing subscriber IP interface name is the subscriber IP interface name that contains the SRRP instance and its group IP interface. This information is supplied for troubleshooting purposes only and is not required to be the same on both nodes.

2.3.9.3.4 Subscriber Subnet Information

The subscriber subnet information includes all subscriber subnets backed up by the SRRP instance. The information for each subnet includes the Owned IP address, the mask and the gateway IP address. If the received subscriber subnet information does not match the local subscriber subnet information, an SRRP Subscriber Subnet Mismatch event is generated describing the SRRP instance ID and the local and remote node IP addresses. Once the subscriber subnet information matches, an SRRP Subscriber Subnet Mismatch Clear event is generated.

2.3.9.3.5 Containing Group IP Interface Information

The containing group IP interface information is the information about the group IP interface that contains the SRRP instance. The information includes the name of the group IP interface, the list of all SAPs created on the group IP interface, the administrative and operational state of each SAP and the MCS key and the peering destination IP address associated with each SAP. To obtain the MCS information, the SRRP instance queries MCS to determine the peering association of the SRRP instance and then queries MCS for each SAP on the group IP interface. If the local SRRP instance is associated with a different MCS peering than any of the SAPs or if one or more SAPs are not tied to an MCS peering, an SRRP group interface SAP peering mismatch event is generated detailing the SRRP instance ID, and the group IP interface name.

When receiving the remote containing group IP interface information, the local node compares the received SAP information with the local group IP interface SAP information. If a local SAP is not included in the SAP information or a remote SAP is not included in the local group IP interface, an SRRP Remote SAP mismatch event is generated detailing the SRRP instance ID and the local and remote group IP interface names. If a received SAP's MCS key does not match a local SAP's MCS Key, an SRRP SAP MCS key mismatch event is generated detailing the SRRP instance ID, the local and remote group IP interface names, the SAP-ID and the local and remote MCS keys.

2.3.9.3.6 Remote Redundant IP Interface Mismatch

If the group IP remote redundant IP interface address space does not exist, is not within the local routing context for the SRRP instances group IP interface or is not on a redundant IP interface, the local node sends redundant IP interface unavailable to prevent the remote neighbor from using its redundant IP interface. An SRRP redundant IP interface mismatch event is generated for the SRRP instance detailing the SRRP instance, the local and remote system IP addresses, the local and remote group IP interface names and the local and remote redundant IP interface names and IP addresses and masks. The local redundant IP interface may still be used if the remote node is not sending redundant IP interface unavailable.

2.3.9.3.7 Remote Sending Redundant IP Interface Unavailable

If the remote node is sending redundant IP interface unavailable, the local node will treat the local redundant IP interface associated with the SRRP instances group IP interface as down. A Local Redundant IP Interface Unavailable event is generated detailing the SRRP instance ID, the local and remote system IP addresses, the local group IP interface name, the local redundant IP interface name and the redundant IP interface IP address and mask.

2.3.9.3.8 Remote SRRP Advertisement SAP Non-existent

If the remote node's SRRP advertisement SAP does not exist on the local SRRP instances group IP interface, the local node sends local receive SRRP advertisement SAP unavailable to the remote node. An SRRP receive advertisement SAP non-existent event is generated detailing the SRRP instance ID, the local and remote system IP addresses, the local group IP interface name and the received remote SRRP advertisement SAP. Since SRRP advertisement messages cannot be received, the local node will immediately become master if it has the lower system IP address.

2.3.9.3.9 Remote Sending Local Receive SRRP Advertisement SAP Unavailable

If the local node is receiving local receive SRRP advertisement SAP unavailable from the remote node, an SRRP Remote Receive advertisement SAP Unavailable event will be generated detailing the SRRP instance ID, the local and remote system IP addresses, the remote group IP interface name and the local SRRP advertisement SAP. Since the remote node cannot receive SRRP advertisement messages, the local node will immediately become master if it has the lower system IP address.

2.3.9.3.10 Local and Remote Dual Master Detected

If the local SRRP state is master and the remote SRRP state is master, an SRRP dual master event is generated detailing the SRRP instance ID and the local, remote system IP addresses and the local and remote group IP interface names and port numbers.

2.3.9.4 Subscriber Subnet Owned IP Address Connectivity

In order for the network to reliably reach the owned IP addresses on a subscriber subnet, it is not necessary for the owning node to advertise the IP addresses as /32 host routes into the core. Network reachability to the subscriber subnet is advertised into the IGP core by both of the dual homing nodes. The shortest path to the subscriber may not always traverse the active path for a subscriber. In this case, the path traverses the non-active/primary node for the subscriber and the traffic will be redirected through the redundant interface to the other node through the redundant interface to the active path. This ensures that all downstream traffic to a given subscriber will always flow through one node.

2.3.9.5 Subscriber Subnet SRRP Gateway IP Address Connectivity

The SRRP gateway IP addresses on the subscriber subnets cannot be advertised as /32 host routes since they may be active (master) on multiple group IP interfaces on multiple SRRP routers. Without a /32 host route path, the network will forward any packet destined to an SRRP gateway IP address to the closest router advertising the subscriber subnet. While a case may be made that only a node that is currently forwarding for the gateway IP address in a master state should respond to ping or other diagnostic messages, the distribution of the subnet and the case of multiple masters make any resulting response or non-response inconclusive at best. To provide some ability to ping the SRRP gateway address from the network side reliably, any node receiving the ICMP ping request responds if the gateway IP address is defined on its subscriber subnet.

2.3.9.6 Receive SRRP Advertisement SAP and Anti-Spoof

The group IP interface SAPs are designed to support subscriber hosts and perform an ingress anti-spoof function that ensures that any IP packet received on the group IP interface is coming in the correct SAP with the correct MAC address. If the IP and MAC are not registered as valid subscriber hosts on the SAP, the packet is silently discarded. Since the SRRP advertisement source IP addresses are not subscriber hosts, an anti-spoof entry will not exist and SRRP advertisement messages would normally be silently discarded. To avoid this issue, when a group IP interface SAP is configured to send and receive SRRP advertisement messages, anti-spoof processing on the SAP is disabled. This precludes subscriber host management on the SRRP messaging SAP.

2.3.9.7 BFD with SRRP/VRRP

BFD with SRRP is supported. This allows the use of longer timers inside SRRP resulting in more SRRP instances while still retaining fast failure detection with BFD.

2.4 Configuring an IES Service with CLI

This section provides information to configure IES services using the command line interface.

Topics in this section include:

- [Basic Configuration](#)
- [Common Configuration Tasks](#)
 - [Configuring IES Components](#)
 - [Configuring an IES Service](#)
 - [Configuring IES Subscriber Interface Parameters](#)
 - [Configuring IES Interface Parameters](#)
 - [Configuring Spoke-SDP Parameters](#)
 - [Configuring SAP Parameters](#)
 - [Configuring IPSec Parameters](#)
 - [Configuring VRRP](#)
- [Service Management Tasks](#)
 - [Modifying IES Service Parameters](#)
 - [Deleting an IES Service](#)
 - [Disabling an IES Service](#)
 - [Re-Enabling an IES Service](#)

2.4.1 Basic Configuration

The most basic IES service configuration has the following entities:

- customer ID (refer to the *7450 ESS, 7750 SR, and 7950 XRS Services Overview Guide* for more information)
- an interface to create and maintain IP routing interfaces within IES service ID
- a SAP on the interface specifying the access port and encapsulation values

The following is a sample configuration of an IES service on ALA-48:

```
*A:ALA-48>config>service# info
-----
ies 1000 customer 50 vpn 1000 create
    description "to internet"
    interface "to-web" create
```

```
        address 10.1.1.1/24
        sap 1/1/5:0.* create
        exit
    exit
    no shutdown
-----
*A:ALA-48>config>service#
```

2.4.2 Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed to configure IES services and provides the CLI commands.

- Step 1.** Associate an IES service with a customer ID.
- Step 2.** Associate customer ID with the service.
- Step 3.** Assign an IP address.
- Step 4.** Create a subscriber interface (for 7450 ESS and 7750 SR only and optional).
- Step 5.** Create an interface.
- Step 6.** Define SAP parameters on the interface
 - Select node(s) and port(s).
 - Optional — select QoS policies other than the default (configured in the **config>qos** context); for 7450 ESS and 7750 SR only.
 - Optional — select filter policies (configured in the **config>filter** context).
 - Optional — select accounting policy (configured in the **config>log** context); for 7450 ESS and 7750 SR only.
- Step 7.** Enable service.

2.4.3 Configuring IES Components

Use the CLI syntax to configure the following entities:

- [Configuring an IES Service](#)
- [Configuring IES Interface Parameters](#)
 - [Configuring IES Subscriber Interface Parameters](#)
 - [Configuring Spoke-SDP Parameters](#)
 - [Configuring SAP Parameters](#)

– [Configuring VRRP](#)

2.4.3.1 Configuring an IES Service

Use the following CLI syntax to create an IES service:

The following example displays a basic IES service configuration for the 7450 ESS and 7750 SR:

```
A:ALA-48>config>service#
-----
...
ies 1001 customer 1730 vpn 1001 create
        description "to-internet"
        no shutdown
exit
-----
A:ALA-48>config>service#
```

The following example displays a basic IES service configuration for the 7950 XRS:

```
A:ALA-48>config>service#
-----
...
ies 1001 customer 1730 create
        description "to-internet"
        no shutdown
exit
-----
A:ALA-48>config>service#
```

2.4.3.2 Configuring IES Subscriber Interface Parameters

Note: This section applies only to the 7750 SR only.

Subscriber interfaces operate only with basic (or enhanced) subscriber management. At the very least, a host, either statically configured or dynamically learned by DHCP must be present in order for the interface to be useful.

Refer to [IES Services Command Reference](#) for CLI syntax to configure IES subscriber interface parameters.

The following example displays a subscriber interface configuration for the 7750 SR:

```

A:ALA-48>config>service>ies>sub-if# info
-----
        address 143.144.140.1/24
        group-interface "abc-if" create
            sap 1/1/19:0 create
                ingress
                    qos 2
                    filter ip 10
                exit
            static-host ip 143.144.145.100 mac 00:01:00:00:00:01 create
            exit
        exit
    exit
-----
A:ALA-48>config>service>ies>sub-if#

```

2.4.3.3 Configuring IES Interface Parameters

The following example displays an IES configuration with interface parameters for the 7450 ESS and 7750 SR:

```

A:ALA-48>config>service>ies>if# info
-----
        address 10.1.1.1/24
        sap 1/1/10:0.* create
            ingress
                qos 100
            exit
            egress
                scheduler-policy "SLA1"
            exit
        exit
    vrrp 1 owner
    authentication-key "3WErEDozxyQ" hash
    exit
-----
A:ALA-48>config>service>ies>if#

```

The following example displays an IES configuration with interface parameters for the 7950 XRS:

```

A:ALA-48>config>service>ies>if# info
-----
        address 10.1.1.1/24
        sap 1/1/10:0.* create
    exit
-----
A:ALA-48>config>service>ies>if#

```

2.4.3.4 Configuring Spoke-SDP Parameters

The following example displays a spoke SDP configuration for the 7450 ESS and 7750 SR:

```
A:ALA-48>config>service>ies# info
-----
description "to internet"
interface "spokeSDP-test" create
  spoke-sdp 2:100 create
    egress
      filter ip 10
    exit
  exit
exit
no shutdown
-----
A:ALA-48>config>service>ies#
```

2.4.3.5 Configuring SAP Parameters

A SAP is a combination of a port and encapsulation parameters which identifies the service access point on the interface and within the router. Each SAP must be unique within a router.

When configuring IES SAP parameters on a 7450 ESS or 7750 SR, a default QoS policy is applied to each ingress and egress SAP. Additional QoS policies and scheduler policies must be configured in the **config>qos** context. Filter policies are configured in the **config>filter** context and must be explicitly applied to a SAP. There are no default filter policies.

IES interface ATM SAP parameters can only be configured on ATM-type MDAs and ATM-configured ports of the 7750 SR. See the Basic System Configuration Guide.

Refer to [IES Services Command Reference](#) for CLI syntax.

This example displays an IES SAP configuration for the 7450 ESS and 7750 SR:

```
*A:ALA-A>config>service>ies>if# info
-----
address 10.10.36.2/24
sap 5/1/3.1:0 create
  ingress
    qos 101
  exit
  egress
    scheduler-policy "alpha"
    qos 1010
  exit
exit
```

```
-----
*A:ALA-A>config>service>ies>if#
```

This example displays an IES SAP configuration for the 7950 XRS:

```
*A:ALA-A>config>service>ies>if# info
-----
                        address 10.10.36.2/24
exit
-----
*A:ALA-A>config>service>ies>if#
```

2.4.3.6 Configuring IES SAP ATM Parameters

Note: This section applies only to the 7750 SR only.

The following example displays the command usage to create Apipe SAPs:

PE router 1 (A:ALA-41):

Example:

```
A:ALA-41>config>service# ies 5
A:ALA-41>config>service>ies# sap 1/1/1:0/32 create
A:ALA-41>config>service>ies>sap# ingress
A:ALA-41>config>service>ies>sap>ingress# qos 102
A:ALA-41>config>service>ies>sap>ingress# exit
A:ALA-41>config>service>ies>sap# egress
A:ALA-41>config>service>ies>sap>egress# qos 103
A:ALA-41>config>service>ies>sap>egress# exit
A:ALA-41>config>service>ies>sap# no shutdown
A:ALA-41>config>service>ies>sap# exit
A:ALA-41>config>service>ies#
```

PE router 2 (A:ALA-42):

Example:

```
A:ALA-42>config>service# ies 5
A:ALA-42>config>service>ies# sap 2/2/2:0/32 create
A:ALA-42>config>service>ies>sap# ingress
A:ALA-42>config>service>ies>sap>ingress# qos 102
A:ALA-42>config>service>ies>sap>ingress# exit
A:ALA-42>config>service>ies>sap# egress
A:ALA-42>config>service>ies>sap>egress# qos 103
A:ALA-42>config>service>ies>sap>egress# exit
A:ALA-42>config>service>ies>sap# no shutdown
A:ALA-42>config>service>ies>sap# exit
```

```
A:ALA-42>config>service>ies#
```

The following output displays the IES SAP configuration.

PE Router 1 (ALA-41):

```
A:ALA-41>config>service# info
-----
...
    ies 5 customer 1 create
        description "apipe test"
        service-mtu 1400
        sap 1/1/1:0/32 create
            ingress
                qos 102
            exit
            egress
                qos 103
            exit
        exit
        no shutdown
    exit
...
-----
A:ALA-41>config>service#
```

2.4.3.7 Configuring VRRP

Configuring VRRP parameters on an IES interface is optional and applies only to the 7450 ESS and 7750 SR. VRRP can be configured in either an owner or non-owner mode. The owner is the VRRP router whose virtual router IP address is the same as the real interface IP address. This is the router that responds to packets addressed to one of the IP addresses for ICMP pings, TCP connections, etc. All other virtual router instances participating in this message domain must have the same VRID configured and cannot be configured as owner.

For further information about VRRP CLI syntax and command descriptions refer to the *Router Configuration Guide*.

The following example displays the IES configuration:

```
*A:ALA-A>config>service>ies>if# info
-----
        address 10.10.36.2/24
        vrrp 2 owner
            backup 10.10.36.2
        authentication-key "3WErEDozxyQ" hash
        exit
-----
*A:ALA-A>config>service#
```

2.4.3.8 Configuring IPSec Parameters

The following output displays an IES service with IPSec parameters configured for the 7750 SR:

```
*A:ALA-49>config# info
-----
...
  service
    ies 100 customer 1 create
      interface "ipsec-public" create
        address 10.10.10.1/24
        sap ipsec-1.public:1 create
        exit
      exit
      no shutdown
    exit
  exit
...
-----
*A:ALA-49>config#
```

2.4.3.9 IGMP Host Tracking

The following output displays an IES service with IGMP host tracking parameters configured.

```
*A:ALA-49>config>service# info
-----
...
  ies 25 customer 1 create
    interface "ip_if_4" create
      loopback
      delayed-enable 1200
      address 64.64.64.64/24
      sap lag-64:64 create
        no shutdown
      exit
      allow-directed-broadcasts
      host-connectivity-verify
      ip-mtu 9000
      local-dhcp-server "server 1"
      local-proxy-arp
      proxy-arp-policy tree-trace-1
      remote-proxy-arp
      secondary 2.3.4.5 255.255.255.0
      secondary 2.3.4.5/24
      tos-marking-state trusted
      tos-marking-state untrusted
      urpf-check
      exit
    exit
  igmp-host-tracking
```

```
        expiry-time 65535
        no shutdown
    exit
...
-----
*A:ALA-49>config>service#
```

2.4.4 Service Management Tasks

This section discusses the following service management tasks:

- [Modifying IES Service Parameters](#)
- [Deleting a Spoke-SDP](#)
- [Deleting an IES Service](#)

2.4.4.1 Modifying IES Service Parameters

Existing IES service parameters in the CLI or NMS can be modified, added, removed, enabled or disabled. The changes are applied immediately to all services when the changes are applied.

To display a list of customer IDs, use the **show service customer** command. Enter the parameter(s) (such as description, SAP information and SDP information) and then enter the new information.

The following example displays the modified service for 7450 ESS and 7750 SR:

```
*A:ALA-A>config>service>ies# info
-----
ies 1000 customer 50 vpn 1000 create
    description "This is a new description"
    interface "to-web" create
        address 10.1.1.1/24
        mac 00:dc:98:1d:00:00
        allow-directed-broadcast
        sap 22/1/50:0 create
    exit
    exit
    no shutdown
exit
-----
*A:ALA-A>config>service#
```

The following example displays the modified service for the 7950 XRS:

```
*A:ALA-A>config>service>ies# info
```

```

-----
ies 1000 customer 50 vpn 1000 create
    description "This is a new description"
    interface "to-web" create
        address 10.1.1.1/24
        mac 00:dc:98:1d:00:00
        allow-directed-broadcast
    exit
    exit
    no shutdown
exit
-----
*A:ALA-A>config>service#

```

2.4.4.2 Deleting a Spoke-SDP

To delete the spoke SDP from the service interface must be shut down. This cleans up the associated VC labels.

Use the following CLI syntax to delete a spoke SDP from an interface for the 7450 ESS and 7750 SR:

CLI Syntax:

```

config>service# ies service-id [customer customer-id]
                    [vpn vpn-id]
                    interface ip-int-name
                        [no] spoke-sdp sdp-id:vc-id
                        shutdown

```

The following example displays the spoke SDP configuration for the 7450 ESS and 7750 SR:

```

A:ALA-48>config>service>ies# info
-----
    description "to internet"
    interface "spokeSDP-test" create
    exit
    no shutdown
-----
A:ALA-48>config>service>ies#

```

2.4.4.3 Deleting an IES Service

An IES service cannot be deleted until SAPs and interfaces are shut down *and* deleted and the service is shutdown on the service level.

Use the following CLI syntax to delete an IES service:

CLI Syntax:

```
config>service#
[no] ies service-id
shutdown
[no] interface ip-int-name
shutdown
[no] sap sap-id
shutdown
```

2.4.4.4 Disabling an IES Service

An IES service can be shut down without deleting the service parameters.

CLI Syntax:

```
config>service> ies service-id
shutdown
```

2.4.4.5 Re-Enabling an IES Service

To re-enable an IES service that was shut down.

CLI Syntax:

```
config>service> ies service-id
[no] shutdown
```

Example:

```
config>service# ies 2000
config>service>ies# no shutdown
config>service>ies# exit
```

2.5 IES Services Command Reference

2.5.1 Command Hierarchies

- [IES Service Configuration Commands](#)
- [Routed VPLS Commands](#)
- [Redundant Interface Commands](#)
- [Interface SAP Commands](#)
- [Interface SAP Tunnel Commands](#)
- [VRRP Commands](#)
- [Spoke SDP Commands](#)
- [Subscriber Interface Commands](#)
- [Threat Management Service Interface Commands](#)

2.5.1.1 IES Service Configuration Commands

2.5.1.1.1 Global Commands

```

config
— service
— ies service-id [customer customer-id] [vpn vpn-id] [create]
— no ies service-id
— description description-string
— no description
— igmp-host-tracking
— expiry-time expiry-time
— no expiry-time
— [no] shutdown
— service-name service-name
— no service-name
— [no] shutdown

```

2.5.1.1.2 Interface Commands

```

config
— service
— ies service-id [customer customer-id] [vpn vpn-id]
— interface ip-int-name [create] [tunnel]
— no interface ip-int-name
— address {ip-address/mask | ip-address netmask} [broadcast [all-ones
| host-ones]][track-srrp srrp-instance]
— no address [ip-address/mask | ip-address netmask]
— [no] allow-directed-broadcasts
— arp-limit limit [log-only] [threshold percent]
— no arp-limit
— arp-retry-timer timer-multiple
— no arp-retry-timer
— [no] arp-timeout
— arp-timeout seconds
— no arp-timeout
— authentication-policy name
— no authentication-policy name
— bfd transmit-interval [receive receive-interval] [multiplier
multiplier][echo-receive echo-interval] [type cpm-np]

## 2.5.1.6 VRRP Commands

```

config
 — service
 — ies service-id [customer customer-id] [vpn vpn-id]
 — [no] interface ip-int-name
 — [no] ipv6
 — vrrp virtual-router-id [owner] [passive]
 — no vrrp virtual-router-id
 — [no] backup ip-address
 — [no] bfd-enable service-id interface interface-name dst-
 ip ip-address
 — [no] bfd-enable interface interface-name dst-ip ip-
 address
 — init-delay seconds
 — no init-delay
 — mac mac-address
 — no mac
 — [no] master-int-inherit
 — message-interval {[seconds] [milliseconds
 milliseconds]}
 — no message-interval
 — [no] ping-reply
 — policy vrrp-policy-id
 — no policy
 — [no] preempt
 — priority base-priority
 — no priority
 — [no] shutdown
 — [no] standby-forwarding
 — [no] telnet-reply
 — [no] traceroute-reply
 — vrrp virtual-router-id [owner] [passive]
 — no vrrp virtual-router-id
 — authentication-key {authentication-key | hash-key} [hash |
 hash2]
 — no authentication-key
 — [no] backup ip-address
 — [no] bfd-enable [service-id] interface interface-name dst-ip ip-
 address
 — init-delay seconds
 — no init-delay
 — mac ieee-address
 — no mac
 — [no] master-int-inherit
 — message-interval {[seconds] [milliseconds milliseconds]}
 — no message-interval
 — [no] ping-reply
 — policy vrrp-policy-id
 — no policy
 — [no] preempt
 — priority priority
 — no priority

```

- [no] **shutdown**
- [no] **ssh-reply**
- [no] **standby-forwarding**
- [no] **telnet-reply**
- [no] **traceroute-reply**

### 2.5.1.7 Spoke SDP Commands

```

config
 — service

| <b>Syntax</b>        | <b>[no] shutdown</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>       | <pre> config&gt;service&gt;ies config&gt;service&gt;ies&gt;if&gt;sap&gt;eth-cfm config&gt;service&gt;ies&gt;sub-if config&gt;service&gt;ies&gt;sub-if&gt;grp-if config&gt;service&gt;ies&gt;sub-if&gt;grp-if&gt;dhcp config&gt;service&gt;ies&gt;sub-if&gt;grp-if&gt;sap config&gt;service&gt;ies&gt;sub-if&gt;grp-if&gt;sap&gt;sub-sla-mgmt config&gt;service&gt;ies&gt;sub-if&gt;grp-if&gt;srrp config&gt;service&gt;ies&gt;if config&gt;service&gt;ies&gt;sub-if&gt;grp-if&gt;ipv6&gt;dhcp6&gt;proxy-server config&gt;service&gt;ies&gt;if&gt;vrrp config&gt;service&gt;ies&gt;if&gt;dhcp config&gt;service&gt;ies&gt;if&gt;dhcp&gt;proxy-server config&gt;service&gt;ies&gt;if&gt;sap&gt;static-host config&gt;service&gt;ies&gt;redundant-interface config&gt;service&gt;ies&gt;sub-if&gt;grp-if&gt;pppoe </pre> |
| <b>Description</b>   | <p>This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics. The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.</p> <p>Services are created in the administratively down (<b>shutdown</b>) state. When a <b>no shutdown</b> command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities is described below in Special Cases.</p> <p>The <b>no</b> form of this command places the entity into an administratively enabled state.</p>                                      |
| <b>Special Cases</b> | <p><b>IES</b> — The default administrative status of an IES service is down. While the service is down, all its associated virtual router interfaces will be operationally down. The administrative state of the service is not reflected in the administrative state of the virtual router interface.</p> <p>For example if:</p> <ol style="list-style-type: none"> <li>1) An IES service is operational and an associated interface is shut down.</li> <li>2) The IES service is administratively shutdown and brought back up.</li> <li>3) The interface shutdown will remain in administrative shutdown state.</li> </ol>                                                                                                                                                                                         |

A service is regarded as operational provided that one IP Interface is operational. Shutting down a subscriber interface will operationally shut down all child group interfaces and SAPs. Shutting down a group interface will operationally shut down all SAPs that are part of that group-interface.

**IES IP Interfaces** — When the IP interface is shutdown, it enters the administratively and operationally down states. For a SAP bound to the IP interface, no packets are transmitted out the SAP and all packets received on the SAP will be dropped while incrementing the packet discard counter.

| <b>Description</b> | <p>This command creates or edits an IES service instance.</p> <p>The <b>ies</b> command is used to create or maintain an Internet Enhanced Service (IES). If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>IES services allow the creation of customer facing IP interfaces in the same routing instance used for service network core routing connectivity. IES services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.</p> <p>While IES is part of the routing domain, the usable IP address space may be limited. This allows a portion of the service provider address space to be set aside for service IP provisioning, becoming administered by a separate but subordinate address authority. This feature is defined using the <b>config router service-prefix</b> command.</p> <p>IP interfaces defined within the context of an IES service ID must have a SAP created as the access point to the subscriber network. This allows a combination of bridging and IP routing for redundancy purposes.</p> <p>When a service is created, the <b>customer</b> keyword and <i>customer-id</i> must be specified and associates the service with a customer. The <i>customer-id</i> must already exist having been created using the <b>customer</b> command in the service context. Once a service has been created with a customer association, it is not possible to edit the customer association. The service must be deleted and recreated with a new customer association.</p> <p>Once a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional for navigating into the service configuration context. Attempting to edit a service with the incorrect <i>customer-id</i> specified will result in an error.</p> <p>Multiple IES services are created to separate customer owned IP interfaces. More than one IES service may be created for a single customer ID. More than one IP interface may be created within a single IES service ID. All IP interfaces created within an IES service ID belongs to the same customer.</p> <p>By default, no IES service instances exist until they are explicitly created.</p> <p>The <b>no</b> form of this command deletes the IES service instance with the specified <i>service-id</i>. The service cannot be deleted until all the IP interfaces defined within the service ID have been shutdown and deleted.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — The unique service identification number or string identifying the service in the service domain. This ID must be unique to this service and may not be used for any other service of any type. The <i>service-id</i> must be the same number used for every SR OS on which this service is defined.</p> <p><b>Values</b>     <i>service-id</i>:1 to 2147483648<br/>              <i>svc-name</i>:64 characters maximum</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**customer** *customer-id* — Specifies the customer ID number to be associated with the service. This parameter is required on service creation and optional for service editing or deleting.

**Values** 1 to 2147483647

**vpn** *vpn-id* — specifies the VPN ID number which allows you to identify virtual private networks (VPNs) by a VPN identification number

**Values** 1 to 2147483647

**Default** null (0)

## igmp-host-tracking

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>igmp-host-tracking</b>                                                    |
| <b>Context</b>     | config>service>ies<br>config>service>ies>sub-if>grp-if>sap                   |
| <b>Description</b> | This command enables the context to configure IGMP host tracking parameters. |

## disable-router-alert-check

|                    |                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] disable-router-alert-check</b>                                                                                             |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>igmp-host-tracking                                                                            |
| <b>Description</b> | This command enables the IGMP router alert check option.<br><br>The <b>no</b> form of the command disables the router alert check. |

## expiry-time

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>expiry-time</b> <i>expiry-time</i><br><b>no expiry-time</b>                                                                                                          |
| <b>Context</b>     | config>service>ies>igmp-host-tracking<br>config>service>ies>sub-if>grp-if>sap>igmp-host-tracking                                                                        |
| <b>Description</b> | This command configures the time that the system continues to track inactive hosts.<br><br>The <b>no</b> form of the command removes the values from the configuration. |
| <b>Default</b>     | no expiry-time                                                                                                                                                          |

---

|                   |                                                                                                           |
|-------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>expiry-time</i> — specifies the time, in seconds, that this system continues to track an inactive host |
| <b>Values</b>     | 1 to 65535                                                                                                |

## max-num-group

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-num-groups</b> <i>max-num-groups</i><br><b>no max-num-groups</b>                                                                            |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>igmp-host-tracking                                                                                            |
| <b>Description</b> | This command configures the maximum number of multicast groups allowed to be tracked.<br><br>The <b>no</b> form of the command disables the check. |
| <b>Default</b>     | no max-num-groups                                                                                                                                  |
| <b>Parameters</b>  | <i>max-num-groups</i> — specifies the maximum number of multicast groups allowed to be tracked                                                     |
| <b>Values</b>      | 1 to 196607                                                                                                                                        |

## max-num-sources

|                    |                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-num-sources</b> <i>max-num-sources</i><br><b>no max-num-sources</b>                                                                                                   |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>igmp-host-tracking                                                                                                                      |
| <b>Description</b> | This command configures the maximum number of multicast sources allowed to be tracked per group.<br><br>The no form of the command removes the value from the configuration. |
| <b>Parameters</b>  | <i>max-num-sources</i> — specifies the maximum number of multicast sources allowed to be tracked per group                                                                   |
| <b>Values</b>      | 1 to 1000                                                                                                                                                                    |

## max-num-grp-sources

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-num-grp-sources</b> <i>max-num-sources</i><br><b>no max-num-grp-sources</b> |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>igmp-host-tracking                            |
| <b>Description</b> | This command configures the max number of multicast (S,G)s allowed to be tracked.  |

The **no** form of this command disables the check.

|                   |                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------|

| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>igmp-host-tracking                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command specifies the import routing policy to be used for IGMP packets to be used on this SAP. Only a single policy can be imported on a single SAP at any time.<br><br>The <b>no</b> form of the command removes the policy association from the SAP.                                                                                                                                                    |
| <b>Default</b>     | no import — No import policy is specified.                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>policy-name</i> — The import policy name. Values can be string up to 32 characters long of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. These policies are configured in the <b>config&gt;router&gt; policy-options</b> context The router policy must be defined before it can be imported. |

## service-name

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>service-name</b> <i>service-name</i><br><b>no service-name</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures an optional service name, up to 64 characters in length, which adds a name identifier to a given service to then use that service name in configuration references as well as display and use service names in show commands throughout the system. This helps the service provider/administrator to identify and manage services within the SR OS platforms.<br><br>All services are required to assign a service ID to initially create a service. However, either the service ID or the service name can be used to identify and reference a given service once it is initially created. |
| <b>Parameters</b>  | <i>service-name</i> — Specifies a unique service name to identify the service. Service names may not begin with an integer (0-9).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

### 2.5.2.3 Redundant Interface Commands

#### redundant-interface

|                    |                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] redundant-interface</b> <i>ip-int-name</i>                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>ies                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures a redundant interface.                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>ip-int-name</i> — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. |

#### address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>address</b> { <i>ip-address/mask</i>   <i>ip-address netmask</i> } [ <b>remote-ip</b> <i>ip-address</i> ]<br><b>no address</b>                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies>redundant-interface                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command assigns an IP address mask or netmask and a remote IP address to the interface.                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>ip-address/mask</i> — assigns an IP address/IP subnet format to the interface<br><i>ip-address netmask</i> — specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains<br>assigns an IP address netmask to the interface<br><b>remote-ip</b> <i>ip-address</i> — assigns a remote IP to the interface |

### 2.5.2.4 IES Subscriber Interface Commands

#### subscriber-interface

|                    |                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] subscriber-interface</b> <i>ip-int-name</i>                                                                                                                                                                                                                                                                                             |
| <b>Context</b>     | config>service>ies                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command allows the operator to create special subscriber-based interfaces. It is used to contain multiple group interfaces. Multiple subnets associated with the subscriber interface can be applied to any of the contained group interfaces in any combination. The subscriber interface allows subnet sharing between group interfaces. |

Use the **no** form of the command to remove the subscriber interface.

**Parameters** *ip-int-name* — Specifies the name of the IP interface. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

## group-interface

**Syntax** **group-interface** *ip-int-name* [**create**]  
**group-interface** *ip-int-name* [**create**] **lns**  
**group-interface** *ip-int-name* [**create**] **wlangw**  
**no group-interface** *ip-int-name* [**create**]

**Context** config>service>ies>subscriber-interface

**Description** This command creates a group interface. This interface is designed for triple-play services where multiple SAPs are part of the same subnet. A group interface may contain one or more SAPs.

Use the **no** form of the command to remove the group interface from the subscriber interface.

**Default** no group interface

**Parameters** *ip-int-name* — Specifies the interface name of a group interface. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

**lns** — Specifies that LNS will be used

**wlangw** — Specifies that WLAN gateway interface will be used

## authentication-policy

**Syntax** **authentication-policy** *name*  
**no authentication-policy**

**Context** config>service>ies>if  
config>service>ies>sub-if>grp-if

**Description** This command assigns an authentication policy to the interface.

The **no** form of this command removes the policy name from the group interface configuration.

**Default** no authentication-policy

**Parameters** *name* — Specifies the authentication policy name. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

## oper-up-while-empty

|                    |                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command creates a Subscriber Router Redundancy Protocol (SRRP) instance on a group IP interface. An SRRP instance manages all subscriber subnets within the group interfaces subscriber IP interface or other subscriber IP interfaces that are associated through a wholesale/retail relationship. Only one unique SRRP instance can be configured per group interface.</p> <p>The <b>no</b> form of the command removes an SRRP instance from a group IP interface. Once removed, the group interface ignores ARP requests for the SRRP gateway IP addresses that may exist on subscriber subnets associated with the group IP interface. Then the group interface stops routing using the redundant IP interface associated with the group IP interface and will stop routing with the SRRP gateway MAC address. Ingress packets destined to the SRRP gateway MAC will also be silently discarded. This is the same behavior as a group IP interface that is disabled (shutdown).</p> |
| <b>Default</b>     | no srrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><b>srrp-id</b> — Specifies a 32 bit instance ID that must be unique to the system. The instance ID must also match the instance ID used by the remote router that is participating in the same SRRP context. SRRP is intended to perform a function similar to VRRP where adjacent IP hosts within local subnets use a default gateway to access IP hosts on other subnets.</p> <p><b>Values</b> 1 to 4294967295</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session. If the interface configured with BFD is using a LAG or a spoke-SDP, the BFD transmit and receive intervals need to be set to a minimum of 300 ms.</p> <p>BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface. The specified interface may not be configured with BFD; when it is, the virtual router will then initiate the BFD session.</p> <p>The no form of this command removes BFD from the configuration.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service>ies>sub-if>grp-if>srrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command overrides the default SRRP gateway MAC address used by the SRRP instance. Unless specified, the system uses the same base MAC address for all SRRP instances with the last octet overridden by the lower 8 bits of the SRRP instance ID. The same SRRP gateway MAC address should be in-use by both the local and remote routers participating in the same SRRP context.</p> <p>One reason to change the default SRRP gateway MAC address is if two SRRP instances sharing the same broadcast domain are using the same SRRP gateway MAC. The system will use the SRRP instance ID to separate the SRRP messages (by ignoring the messages that does not match the local instance ID), but a unique SRRP gateway MAC is essential to separate the routed packets for each gateway IP address.</p> |

The **no** form of the command removes the explicit SRRP gateway MAC address from the SRRP instance. The SRRP gateway MAC address can only be changed or removed when the SRRP instance is shutdown.

**Parameters** *mac-address* — specifies a MAC address that is used to override the default SRRP base MAC address

**Values** Any MAC address except all zeros, broadcast or multicast addresses. The offset is expressed in normal Ethernet MAC address notation. The defined gw-mac cannot be 00:00:00:00:00:00, ff:ff:ff:ff:ff:ff or any multicast address.  
If not specified, the system uses the default SRRP gateway MAC address with the last octet set to the 8 least significant bits of the SRRP instance ID.

## keep-alive-interval

**Syntax** **keep-alive-interval** *interval*  
**no keep-alive-interval**

**Context** config>service>ies>sub-if>grp-if>srrp

**Description** This command defines the interval between SRRP advertisement messages sent when operating in the master state. The interval is also the basis for setting the master-down timer used to determine when the master is no longer sending. The system uses three times the keep-alive interval to set the timer. Every time an SRRP advertisement is seen that is better than the local priority, the timer is reset. If the timer expires, the SRRP instance assumes that a master does not exist and initiates the attempt to become master.

When in backup state, the SRRP instance takes the keep-alive interval of the master as represented in the masters SRRP advertisement message. Once in master state, the SRRP instance uses its own configured keep-alive interval.

The keep-alive-interval may be changed at anytime, but will have no effect until the SRRP instance is in the master state.

The **no** form of the command restores the default interval.

**Parameters** *interval* — specifies the interval, in milliseconds, between SRRP advertisement messages sent when operating in the master state

**Values** 1 to 100

**Default** 10 milliseconds

## message-path

**Syntax** **message-path** *sap-id*  
**no message-path**

| <b>Description</b> | <p>This command defines a specific SAP for SRRP in-band messaging. A message-path SAP must be defined prior to activating the SRRP instance. The defined SAP must exist on the SRRP instances group IP interface for the command to succeed and cannot currently be associated with any dynamic or static subscriber hosts. Once a group IP interface SAP has been defined as the transmission path for SRRP Advertisement messages, it cannot be administratively shutdown, will not support static or dynamic subscriber hosts and cannot be removed from the group IP interface.</p> <p>The SRRP instance message-path command may be executed at anytime on the SRRP instance. Changing the message SAP will fail if a dynamic or static subscriber host is associated with the new SAP. Once successfully changed, the SRRP instance will immediately disable anti-spoof on the SAP and start sending SRRP Advertisement messages if the SRRP instance is activated.</p> <p>Changing the current SRRP message SAP on an active pair of routers should be done in the following manner:</p> <ol style="list-style-type: none"> <li>1. Shutdown the backup SRRP instance.</li> <li>2. Change the message SAP on the shutdown node.</li> <li>3. Change the message SAP on the active master node.</li> <li>4. Re-activate the shutdown SRRP instance.</li> </ol> <p>Shutting down the backup SRRP instance prevents the SRRP instances from becoming master due to temporarily using differing message path SAPs.</p> <p>If an MCS peering is operational between the redundant nodes and the SRRP instance has been associated with the peering, the designated message path SAP will be sent from each member.</p> <p>The <b>no</b> form of the command can only be executed when the SRRP instance is shutdown. Executing no message-path allows the existing SAP to be used for subscriber management functions. A new message-path SAP must be defined prior to activating the SRRP instance.</p> |
| <b>Parameters</b>  | <i>sap-id</i> — specifies the physical port identifier portion of the SAP definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Description | <p>This command associates one or more VRRP policies with the SRRP instance. A VRRP policy is a collection of connectivity and verification tests used to manipulate the in-use priorities of VRRP and SRRP instances. A VRRP policy can test the link state of ports, ping IP hosts, discover the existence of routes in the routing table or the ability to reach L2 hosts. When one or more of these tests fail, the VRRP policy has the option of decrementing or setting an explicit value for the in-use priority of an SRRP instance.</p> <p>More than one VRRP policy may be associated with an SRRP instance. When more than one VRRP policy is associated with an SRRP instance the delta decrement of the in-use priority is cumulative unless one or more test fail that have explicit priority values. When one or more explicit tests fail, the lowest priority value event takes effect for the SRRP instance. When the highest delta-in-use-limit is used to manage the lowest delta derived in-use priority for the SRRP instance.</p> <p>VRRP policy associations may be added and removed at anytime. A maximum of two VRRP policies can be associated with a single SRRP instance.</p> <p>The <b>no</b> form of the command removes the association with <i>vrrp-policy-id</i> from the SRRP instance.</p> |        |           |

| Description | <p>This command overrides the default base priority for the SRRP instance. The SRRP instance priority is advertised by the SRRP instance to its neighbor router and is compared to the priority received from the neighbor router. The router with the best (highest) priority enters the master state while the other router enters the backup state. If the priority of each router is the same, the router with the lowest source IP address in the SRRP advertisement message assumes the master state.</p> <p>The base priority of an SRRP instance can be managed by VRRP policies. A VRRP policy defines a set of connectivity or verification tests which, when they fail, may lower an SRRP instances base priority (creating an in-use priority for the instance). Every time an SRRP instances in-use priority changes when in master state, it sends an SRRP advertisement message with the new priority. If the dynamic priority drops to zero or receives an SRRP Advertisement message with a better priority, the SRRP instance transitions to the <i>becoming backup</i> state. When the priority command is not specified, or the no priority command is executed, the system uses a default base priority of 100. The priority command may be executed at anytime.</p> |

The **no** form of the command restores the default base priority to the SRRP instance. If a VRRP policy is associated with the SRRP instance, it will use the default base priority as the basis for any modifications to the SRRP instances in-use priority.

| <b>Description</b> | This command creates a logical IP routing interface for an Internet Enhanced Service (IES). Once created, attributes like an IP address and service access point (SAP) can be associated with the IP interface. |

The **interface** command, under the context of services, is used to create and maintain IP routing interfaces within IES service IDs. The **interface** command can be executed in the context of an IES service ID. The IP interface created is associated with the service core network routing instance and default routing table. The typical use for IP interfaces created in this manner is for subscriber Internet access. An IP address cannot be assigned to an IES interface. Multiple SAPs can be assigned to a single group interface.

Interface names are case sensitive and must be unique within the group of defined IP interfaces defined for **config router interface** and **config service ies interface** (that is, the network core router instance). Interface names must not be in the dotted decimal notation of an IP address. For example, the name “1.1.1.1” is not allowed, but “int-1.1.1.1” is allowed. Show commands for router interfaces use either interface names or the IP addresses. Use unique IP address values and IP address names to maintain clarity. It could be unclear to the user if the same IP address and IP address name values are used. Although not recommended, duplicate interface names can exist in different router instances.

The available IP address space for local subnets and routes is controlled with the **config router service-prefix** command. The **service-prefix** command administers the allowed subnets that can be defined on IES IP interfaces. It also controls the prefixes that may be learned or statically defined with the IES IP interface as the egress interface. This allows segmenting the IP address space into **config router** and **config service** domains.

When a new name is entered, a new logical router interface is created. When an existing interface name is entered, the user enters the router interface context for editing and configuration.

By default, there are no default IP interface names defined within the system. All IES IP interfaces must be explicitly defined. Interfaces are created in an enabled state.

The **no** form of this command removes IP the interface and all the associated configuration. The interface must be administratively shutdown before issuing the **no interface** command.

For IES services, the IP interface must be shutdown before the SAP on that interface may be removed. IES services do not have the **shutdown** command in the SAP CLI context. IES service SAPs rely on the interface status to enable and disable them.

Parameters

*ip-int-name* — Specifies the name of the IP interface. Interface names must be unique within the group of defined IP interfaces for **config router interface** and **config service ies interface** commands. An interface name cannot be in the form of an IP address. Interface names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.

If *ip-int-name* already exists within the service ID, the context will be changed to maintain that IP interface. If *ip-int-name* already exists within another service ID or is an IP interface defined within the **config router** commands, an error will occur and context will not be changed to that IP interface. If *ip-int-name* does not exist, the interface is created and context is changed to that interface for further command processing.

address

Syntax

Context

Description

**address** {*ip-address/mask* | *ip-address netmask*} [**broadcast all-ones** | **host-ones**] [**track-srrp srrp-instance**]  
**no address**[*ip-address/mask* | *ip-address netmask*]

config>service>ies>if  
config>service>ies>subscriber-interface

This command assigns an IP address, IP subnet, and broadcast address format to an IES IP router interface. Only one IP address can be associated with an IP interface. An IP address must be assigned to each IES IP interface. An IP address and a mask are used together to create a local IP prefix. The defined IP prefix must be unique within the context of the routing instance. It cannot overlap with other existing IP prefixes defined as local subnets on other IP interfaces in the same routing context within the router.

For the 7750 SR only, in the IES subscriber interface context, this command is used to assign one or more host IP addresses and subnets. This differs from a normal IES interfaces where the **secondary** command creates an additional subnet after the primary address is assigned. A user can then add or remove addresses without having to keep a primary address.

The local subnet that the **address** command defines must be part of the services address space within the routing context using the **config router service-prefix** command. The default is to disallow the complete address space to services. Once a portion of the address space is allocated as a service prefix, that portion can be made unavailable for IP interfaces defined within the **config router interface** CLI context for network core connectivity with the **exclude** option in the **config router service-prefix** command.

The IP address for the interface can be entered in either CIDR (Classless Inter-Domain Routing) or traditional dotted decimal notation. The show commands display CIDR notation and is stored in configuration files.

By default, no IP address or subnet association exists on an IP interface until it is explicitly created.

Use the **no** form of this command to remove the IP address assignment from the IP interface.

The **no** form of this command will cause ptp-hw-assist to be disabled.

**Table 6 Address Field Descriptions**

| Address    | Admin state | Oper state |
|------------|-------------|------------|
| no address | up          | down       |
| no address | down        | down       |
| 1.1.1.1    | up          | up         |
| 1.1.1.1    | down        | down       |

The operational state is a read-only variable and the only controlling variables are the address and admin states. The address and admin states are independent and can be set independently. If an interface is in an administratively up state and an address is assigned, it becomes operationally up and the protocol interfaces and the MPLS LSPs associated with that IP interface will be reinitialized.

- Parameters**
- ip-address* — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).
  - /* — The forward slash is a parameter delimiter and separates the *ip-address* portion of the IP address from the mask that defines the scope of the local subnet. No spaces are allowed between the *ip-address*, the “/” and the *mask-length* parameter. If a forward slash is not immediately following the *ip-address*, a dotted decimal mask must follow the prefix.

*mask-length* — The subnet mask length when the IP prefix is specified in CIDR notation. When the IP prefix is specified in CIDR notation, a forward slash (/) separates the *ip-address* from the *mask-length* parameter. The mask length parameter indicates the number of bits used for the network portion of the IP address; the remainder of the IP address is used to determine the host portion of the IP address. Allowed values are integers in the range 0 – 30. A mask length of 32 is reserved for system IP addresses.

*mask* — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.

*netmask* — specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains

**broadcast** — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**. The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface. (Default: *host-ones*)

**all-ones** — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

**host-ones** — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

**track-srrp** — specifies the SRRP instance ID that this interface route needs to track

## address

**Syntax**     **[no] address {*ip-address/mask* | *ip-address netmask*} [**gw-ip-address** *ip-address*]  
                  **[populate-host-routes]****

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command configures the local subscriber subnets available on a subscriber IP interface. The configured ip-address and mask define the address space associated with the subscriber subnet. Each subnet supports a locally owned IP host address within the subnet that is not expected to appear on other routers that may be servicing the same subscriber subnet. For redundancy purposes, the keyword <b>gw-address</b> defines a separate IP address within the subnet for Subscriber Routed Redundancy Protocol (SRRP) routing. This IP address must be the same on the local and remote routers participating in a common SRRP instance.</p> <p>In SRRP, a single SRRP instance is tied to a group IP interface. The group IP interface is contained directly within a subscriber IP interface context and thus directly associated with the subscriber subnets on the subscriber IP interface. The SRRP instance is also indirectly associated with any subscriber subnets tied to the subscriber interface through wholesale/retail VPN configurations. With the directly-associated and the indirectly-associated subscriber interface subnets, a single SRRP instance can manage hundreds of SRRP gateway IP addresses. This automatic subnet association to the SRRP instance is different from VRRP where the redundant IP address is defined within the VRRP context.</p> <p>Defining an SRRP gateway IP address on a subscriber subnet is not optional when the subnet is associated with a group IP interface with SRRP enabled. Enabling SRRP (<b>no shutdown</b>) will fail if one or more subscriber subnets do not have an SRRP gateway IP address defined. Creating a new subscriber subnet without an SRRP gateway IP address defined will fail when the subscriber subnet is associated with a group IP interface with an active SRRP instance. Once SRRP is enabled on a group interface, the SRRP instance will manage the ARP response and routing behavior for all subscriber hosts reachable through the group IP interface.</p> <p>The no form of the command removes the address from a subscriber subnet. The <b>address</b> command for the specific subscriber subnet must be executed without the <b>gw-address</b> parameter. To succeed, all SRRP instances associated with the subscriber subnet must be removed or shutdown.</p> |
| <b>Parameters</b>  | <p><i>ip-address/mask</i>   <i>ip-address netmask</i> — specifies the address space associated with the subscriber subnet</p> <p><b>gw-ip-address</b> <i>ip-address</i> — Specifies a separate IP address within the subnet for SRRP routing purposes. This parameter must be followed by a valid IP interface that exists within the subscriber subnet created by the address command. The defined gateway IP address cannot currently exist as a subscriber host (static or dynamic). If the defined ip-address already exists as a subscriber host address, the address command will fail. The specified ip-address must be unique within the system.</p> <p>The gw-address parameter may be specified at anytime. If the subscriber subnet was created previously, executing the address command with a gw-address parameter will simply add the SRRP gateway IP address to the existing subnet.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

If the address command is executed without the gw-address parameter when the subscriber subnet is associated with an active SRRP instance, the address will fail. If the SRRP instance is inactive or removed, executing the address command without the gw-address parameter will remove the SRRP gateway IP address from the specified subscriber subnet.

If the address command is executed with a new gw-address, all SRRP instances currently associated with the specified subscriber subnet will be updated with the new SRRP gateway IP address.

**populate-host-routes** — Indicates that all subscriber-hosts created on the interface with the ip-address falling in this subnet will have their route populated in FIB. This flag will not be set per default.

| <b>Context</b>     | config>service>ies>if                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command enables the forwarding of directed broadcasts out of the IP interface.</p> <p>A directed broadcast is a packet received on a local router interface destined for the subnet broadcast address on another IP interface. The <b>allow-directed-broadcasts</b> command on an IP interface enables or disables the transmission of packets destined to the subnet broadcast address of the egress IP interface.</p> <p>When enabled, a frame destined to the local subnet on this IP interface will be sent as a subnet broadcast out this interface. Care should be exercised when allowing directed broadcasts as it is a well-known mechanism used for denial-of-service attacks.</p> <p>When disabled, directed broadcast packets discarded at this egress IP interface will be counted in the normal discard counters for the egress SAP.</p> <p>By default, directed broadcasts are not allowed and will be discarded at this egress IP interface.</p> <p>The <b>no</b> form of this command disables the forwarding of directed broadcasts out of the IP interface.</p> |
| <b>Default</b>     | no allow-directed-broadcasts — Directed broadcasts are dropped.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the maximum amount of dynamic IPv4 ARP entries that can be learned on an IP interface.</p> <p>When the number of dynamic ARP entries reaches the configured percentage of this limit, an SNMP trap is sent. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations will be dropped. Entries that have already been learned will be refreshed.</p> <p>The <b>no</b> form of the command removes the <b>arp-limit</b>.</p>                                                                                 |
| <b>Default</b>     | 90 percent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><b>log-only</b> — Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit will be learned.</p> <p><i>percent</i> — The threshold value (as a percentage) that triggers a warning message to be sent.</p> <p><b>Values</b> 0 to 100</p> <p><i>limit</i> — The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic ARP learning is disabled and no dynamic ARP entries are learned.</p> <p><b>Values</b> 0 to 524288</p> |

## arp-retry-timer

|                    |                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-retry-timer</b> <i>timer-multiple</i><br><b>no arp-retry-timer</b>                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command allows the arp retry timer to be configured to a specific value.</p> <p>The timer value is entered as a multiple of 100 ms. So a timer value of 1, means the ARP timer will be set to 100 ms.</p> <p>The <b>no</b> form of this command removes the command from the active configuration and returns the ARP retry timer to its default value of 5 seconds.</p> |
| <b>Default</b>     | 5 seconds                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>timer-multiple</i> — specifies the multiple of 100 ms that the ARP retry timer will be configured as</p> <p><b>Values</b> 1 to 300 (equally a timer range of 100 ms to 30,000 ms)</p>                                                                                                                                                                                      |

## arp-timeout

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command configures the minimum time in seconds an ARP entry learned on the IP interface will be stored in the ARP table. ARP entries are automatically refreshed when an ARP request or gratuitous ARP is seen from an IP host, otherwise, the ARP entry is aged from the ARP table. If <b>arp-timeout</b> is set to a value of zero seconds, ARP aging is disabled.</p> <p>When the <b>arp-populate</b> and <b>lease-populate</b> commands are enabled on an IES interface, the ARP table entries will no longer be dynamically learned, but instead by snooping DHCP ACK message from a DHCP server. In this case the configured <b>arp-timeout</b> value has no effect.</p> <p>The <b>no</b> form of this command restores <b>arp-timeout</b> to the default value.</p> |
| <b>Default</b>     | 14400 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>seconds</i> — The minimum number of seconds a learned ARP entry will be stored in the ARP table, expressed as a decimal integer. A value of zero specifies that the timer is inoperative and learned ARP entries will not be aged.</p> <p><b>Values</b>      0 to 65535</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## bfd

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Description</b> | <p>This command specifies the BFD parameters for the associated IP interface. If no parameters are defined the default value are used.</p> <p>The multiplier specifies the number of consecutive BFD messages that must be missed from the peer before the BFD session state is changed to down and the upper level protocols (OSPF, IS-IS, BGP or PIM) is notified of the fault.</p> <p>The <b>no</b> form of the command removes BFD from the interface.</p> |

**Caution:** On the 7750-SR, the *transmit-interval*, **receive** *receive-interval*, and **echo-receive** *echo-interval* values can only be modified to a value less than 100 when:

1. The **type cpm-np** option is explicitly configured.
2. The service is shut down (**shutdown**)
3. The interval is specified 10 to 100000.
4. The service is re-enabled (**no shutdown**)

To remove the **type cpm-np** option, re-issue the **bfd** command without specifying the **type** parameter.

| <b>Parameters</b> | <i>transmit-interval</i> — sets the transmit interval for the BFD session                                                                                                                            |
| <b>Values</b>     | 100 to 100000<br>10 to 100000 (for the 7750 SR only; see the Caution above)                                                                                                                          |
| <b>Default</b>    | 100                                                                                                                                                                                                  |
|                   | <i>receive receive-interval</i> — sets the receive interval for the BFD session                                                                                                                      |
| <b>Values</b>     | 100 to 100000<br>10 to 100000 (for the 7750 SR only; see the Caution above)                                                                                                                          |
| <b>Default</b>    | 100                                                                                                                                                                                                  |
|                   | <i>multiplier multiplier</i> — set the multiplier for the BFD session                                                                                                                                |
| <b>Values</b>     | 3 to 20                                                                                                                                                                                              |
| <b>Default</b>    | 3                                                                                                                                                                                                    |
|                   | <i>echo-receive echo-interval</i> — sets the minimum echo receive interval, in milliseconds, for the BFD session                                                                                     |
| <b>Values</b>     | 100 to 100000<br>10 to 100000 (for the 7750 SR only; see the Caution above)                                                                                                                          |
| <b>Default</b>    | 100                                                                                                                                                                                                  |
|                   | <b>type cpm-np</b> — for the 7750 SR only, specifies that BFD sessions associated with this interface will be created on the CPM network processor to allow for fast timers down to 10ms granularity |

## cflowd-parameters

| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap                                                                                                                                                                                                                     |
| <b>Description</b> | <p>This command assigns an existing CPU protection policy to the associated group interface. The CPU protection policies are configured in the <b>config&gt;sys&gt;security&gt;cpu-protection&gt;policy</b> <i>cpu-protection-policy-id</i> context.</p> |

If no CPU-Protection policy is assigned to a group interface SAP, then the default policy is used to limit the overall-rate. The default policy is policy number 254 for access interfaces and 255 for network interfaces.

The no form of the command removes the association of the CPU protection policy from the associated interface and reverts to the default policy values.

|                   | <b>ip-src-monitoring</b> — Enables per SAP + IP source address rate limiting for DHCP packets using the per-source-rate from the associated cpu-protection policy. The ip-src-monitoring is useful in subscriber management architectures that have routers between the subscriber and the BNG (router). In Layer 3 aggregation scenarios all packets from all subscribers behind the same aggregation router will arrive with the same source MAC address and as such the mac-monitoring functionality can not differentiate traffic from different subscribers. |

| <b>Description</b> | This command creates allows access to the IPCP context within the interface configuration. Within this context, IPCP extensions can be configured to define such things as the remote IP address and DNS IP address to be signaled via IPCP on the associated PPP interface. This command is only applicable if the associated SAP/port is a PPP/MLPPP interface. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                               |

| <b>Description</b> | <p>This command defines the dns address(es) to be assigned to the far-end of the associated PPP/MLPPP link through IPCP extensions. This command is only applicable if the associated SAP/port is a PPP/MLPPP interface with an IPCP encapsulation.</p> <p>The <b>no</b> form of the command deletes either the specified primary DNS address, secondary DNS address or both addresses from the IPCP extension peer-ip-address configuration.</p> |
| <b>Default</b>     | no dns                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><i>ip-address</i> — specifies a unicast IPv4 address for the primary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions</p> <p><b>secondary ip-address</b> — specifies a unicast IPv4 address for the secondary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions</p>                                                                                     |

## peer-ip-address

|                    |                                                                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer-ip-address ip-address</b><br><b>no peer-ip-address</b>                                                                                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>ies>if>ipcp                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command defines the remote IP address to be assigned to the far-end of the associated PPP/MLPPP link via IPCP extensions. This command is only applicable if the associated SAP/port is a PPP/MLPPP interface with an IPCP encapsulation.</p> <p>The <b>no</b> form of the command deletes the IPCP extension peer-ip-address configuration.</p> |
| <b>Default</b>     | no peer-ip-address (0.0.0.0)                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><i>ip-address</i> — specifies a unicast IPv4 address to be signaled to the far-end of the associated PPP/MLPPP link by IPCP extensions</p>                                                                                                                                                                                                            |

## ipv6

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6</b>                                                       |
| <b>Context</b>     | config>service>ies>sub-if>grp-if                                       |
| <b>Description</b> | This command enables IPv6 forwarding on the specified group-interface. |

## router-advertisements

|                    |                                                                                 |
|--------------------|---------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] router-advertisements</b>                                               |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6                                           |
| <b>Description</b> | This command enables router advertisement transmission on this group interface. |
| <b>Default</b>     | router-advertisements                                                           |

## current-hop-limit

|                    |                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>current-hop-limit</b> <i>hop-count</i><br><b>no current-hop-limit</b>                         |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                  |
| <b>Description</b> | This command specifies the hop-limit advertised to hosts in router advertisements.               |
| <b>Default</b>     | 64                                                                                               |
| <b>Parameters</b>  | <i>hop-count</i> — specifies the current hop limit (decimal) inserted into router advertisements |
| <b>Values</b>      | 0 to 255                                                                                         |

## managed-configuration

|                    |                                                                                                                                                                                                                                                              |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] managed-configuration</b>                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                                                                                                                                                                              |
| <b>Description</b> | This command sets the managed address configuration flag. This flag indicates that DHCPv6 is available for address configuration in addition to any address auto-configured using stateless address auto-configuration. See RFC 3315 for additional details. |
| <b>Default</b>     | no managed-configuration                                                                                                                                                                                                                                     |

## max-advertisement-interval

|                    |                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-advertisement-interval</b> <i>seconds</i><br><b>no max-advertisement-interval</b>    |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                             |
| <b>Description</b> | This command configures the maximum interval between sending router advertisement messages. |
| <b>Default</b>     | 900                                                                                         |

---

|                   |                                                                                                          |
|-------------------|----------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — specifies the maximum interval in seconds between sending router advertisement messages |
| <b>Values</b>     | 900 to 1800                                                                                              |

## min-advertisement-interval

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-advertisement-interval</b> <i>seconds</i><br><b>no min-advertisement-interval</b>                 |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                          |
| <b>Description</b> | This command configures the minimum interval between sending router advertisement messages.              |
| <b>Default</b>     | 900                                                                                                      |
| <b>Parameters</b>  | <i>seconds</i> — specifies the minimum interval in seconds between sending router advertisement messages |
| <b>Values</b>      | 900 to 1350                                                                                              |

## mtu

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mtu</b> <i>bytes</i><br><b>no mtu</b>                                          |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                   |
| <b>Description</b> | This command configures the MTU for the nodes to use to send packets on the link. |
| <b>Default</b>     | no mtu                                                                            |
| <b>Parameters</b>  | <i>bytes</i> — specifies the MTU for the nodes to use to send packets on the link |
| <b>Values</b>      | 1280 to 9212                                                                      |

## other-stateful-configuration

|                    |                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] other-stateful-configuration</b>                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command sets the "other configuration" flag. This flag indicates that DHCPv6 is available for autoconfiguration of other (non-address) information such as DNS-related information or information on other servers in the network. See RFC 3736, <i>Stateless Dynamic Host Configuration Protocol (DHCP) for IPv6</i> . |
| <b>Default</b>     | no other-stateful-configuration                                                                                                                                                                                                                                                                                              |

## prefix-options

|                    |                                                                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] prefix-options</b>                                                                                                                                                  |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                                                                                             |
| <b>Description</b> | This command configures Router Advertisement parameters for IPv6 prefixes returned via RADIUS Framed-IPv6-Prefix. All prefixes will inherit these configuration parameters. |
| <b>Default</b>     | no prefix-options                                                                                                                                                           |

## autonomous

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] autonomous</b>                                                                     |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad>prefix-op                                  |
| <b>Description</b> | This command specifies whether the prefix can be used for stateless address configuration. |
| <b>Default</b>     | no autonomous                                                                              |

## preferred-lifetime

|                    |                                                                                                                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>preferred-lifetime</b> [ <i>seconds</i>   <i>infinite</i> ]<br><b>no preferred-lifetime</b>                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad>prefix-op                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command configures the remaining length of time in seconds that this prefix will continue to be preferred, for example, time until deprecation. The address generated from a deprecated prefix should not be used as a source address in new communications, but packets received on such an interface are processed as expected. |
| <b>Default</b>     | 3600                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds<br><b>Values</b> 0 to 4294967295<br><i>infinite</i> — specifies a 0xffffffff value, Dec = 4294967295                                                                                                                                                                     |

## valid-lifetime

|                |                                                                                        |
|----------------|----------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>valid-lifetime</b> [ <i>seconds</i>   <i>infinite</i> ]<br><b>no valid-lifetime</b> |
| <b>Context</b> | config>service>ies>sub-if>grp-if>ipv6>router-ad>prefix-op                              |

---

|                    |                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command specifies the length of time in seconds that the prefix is valid for the purpose of on-link determination. A value of all one bits (0xffffffff) represents infinity. The address generated from an invalidated prefix should not appear as the destination or source address of a packet. |
| <b>Default</b>     | 86,400                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds<br><b>Values</b> 0 to 4294967295<br><i>infinite</i> — specifies a 0xffffffff value, Dec = 4294967295                                                                                                                                     |

## reachable-time

|                    |                                                                                                                                                     |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>reachable-time</b> <i>milliseconds</i><br><b>no reachable-time</b>                                                                               |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                                                                     |
| <b>Description</b> | This command configures how long this router should be considered reachable by other nodes on the link after receiving a reachability confirmation. |
| <b>Default</b>     | no reachable-time                                                                                                                                   |
| <b>Parameters</b>  | <i>milliseconds</i> — The length of time the router should be considered reachable for default router selection.<br><b>Values</b> 0 to 3600000      |

## retransmit-time

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>retransmit-time</b> <i>milliseconds</i><br><b>no retransmit-time</b>                       |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                               |
| <b>Description</b> | This command configures the retransmission frequency of neighbor solicitation messages.       |
| <b>Default</b>     | no retransmit-time                                                                            |
| <b>Parameters</b>  | <i>milliseconds</i> — specifies how often retransmissions occur<br><b>Values</b> 0 to 1800000 |

## router-lifetime

|               |                                                                                   |
|---------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b> | <b>router-lifetime</b> <i>seconds</i><br><b>router-lifetime no-default-router</b> |
|---------------|-----------------------------------------------------------------------------------|

### **no router-lifetime**

|                    |                                                                                                                               |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>router-ad                                                                               |
| <b>Description</b> | This command sets the router lifetime. A value of zero indicates this router should not be used by hosts as a default router. |
| <b>Default</b>     | 4500                                                                                                                          |
| <b>Parameters</b>  | <i>seconds</i> — specifies how long the router is valid for default router selection                                          |
|                    | <b>Values</b> 2700 to 9000                                                                                                    |
|                    | <b>no-default-router</b> — indicates that the router is not to be used as a default router                                    |

## dhcp6

|                    |                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] dhcp6                                                                                                                                         |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6                                                                                                              |
| <b>Description</b> | This command allows access to the DHCP6 context within the group interface configuration. Within this context, DHCP6 parameters can be configured. |
| <b>Default</b>     | no dhcp6                                                                                                                                           |

## proxy-server

|                    |                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [no] proxy-server                                                                                                                                         |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>dhcp6                                                                                                               |
| <b>Description</b> | This command allows access to the DHCP6 proxy server context. Within this context, DHCP6 proxy server parameters of the group interface can be configured |
| <b>Default</b>     | no proxy-server                                                                                                                                           |

## client-applications

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>client-applications</b> [dhcp] [ppp]<br><b>no client-applications</b>                                      |
| <b>Context</b>     | config>services>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                     |
| <b>Description</b> | This command configures the client host types to which the DHCP6 proxy server is allowed to assign addresses. |
| <b>Parameters</b>  | <b>dhcp</b> — specifies IP over Ethernet hosts                                                                |

**ppp** — specifies PPP over Ethernet hosts

## preferred-lifetime

|                    |                                                                                                                                                                                |

| <b>Syntax</b>      | <b>preferred-lifetime</b> [ <i>seconds</i>   <b>infinite</b> ]<br><b>no preferred-lifetime</b>                                                                                 |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                       |
| <b>Description</b> | The preferred lifetime for the IPv6 prefix or address in the option, expressed in units of seconds. When the preferred lifetime expires, any derived addresses are deprecated. |
| <b>Default</b>     | 3600                                                                                                                                                                           |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds<br><b>Values</b> 600 to 4294967295<br><b>infinite</b> — specifies a 0xffffffff value, Dec = 4294967295           |

## rebind-timer

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rebind-timer</b> <i>seconds</i><br><b>no rebind-timer</b>                                                                                                                           |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                               |
| <b>Description</b> | This command configures the rebind-timer (T2), the time at which the client contacts any available server to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 2880                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — T2 is a time duration relative to the current time. A value of zero leaves the rebind-time at the discretion of the client.<br><b>Values</b> 0 to 1209600             |

## renew-timer

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>renew-timer</b> <i>seconds</i><br><b>no renew-timer</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server                                                                                                                                                                                 |
| <b>Description</b> | This command configures the renew-timer (T1), the time at which the client contacts the server from which the addresses in the IA_NA or IA_PD were obtained to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 1800                                                                                                                                                                                                                                     |

---

|                   |                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — Specifies the time duration relative to the current time, expressed in units of seconds. A value of zero leaves the renew-time at the discretion of the client. |
| <b>Values</b>     | 0 to 604800                                                                                                                                                                      |

## valid-lifetime

|                    |                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>valid-lifetime</b> [ <i>seconds</i>   <b>infinite</b> ]<br><b>no valid-lifetime</b>          |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>ipv6>dhcp6>proxy-server                                        |
| <b>Description</b> | The valid lifetime for the IPv6 prefix or address in the option, expressed in units of seconds. |
| <b>Default</b>     | 86,400                                                                                          |
| <b>Parameters</b>  | <i>seconds</i> — specifies a decimal time interval in seconds                                   |
| <b>Values</b>      | 600 to 4294967295                                                                               |
|                    | <b>infinite</b> — specifies a 0xffffffff value, Dec = 4294967295                                |

## load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>load-balancing</b>                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>ies>if                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command enables the load-balancing context to configure interface per-flow load balancing options that will apply to traffic entering this interface and egressing over a LAG/ECMP on system-egress. This is a per interface setting. For load balancing options that can also be enabled on the system level, the options enabled on the interface level overwrite system level configurations. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                   |

## egr-ip-load-balancing

|                    |                                                                                                                                                                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egr-ip-load-balancing</b> { <i>source</i>   <i>destination</i>   <i>inner-ip</i> }<br><b>no egr-ip-load-balancing</b>                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>ies>if>load-balancing                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command specifies whether to include the source address or destination address or both in the LAG/ECMP hash on IP interfaces. Additionally, when I4-load-balancing is enabled, the command also applies to the inclusion of source/destination port in the hash inputs.<br><br>The <b>no</b> form of this command includes both source and destination parameters. |

| <b>Context</b>     | config>service>ies>if<br>config>service>ies>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command enables local proxy ARP. When local proxy ARP is enabled on an IP interface, the system responds to all ARP requests for IP addresses belonging to the subnet with its own MAC address, and thus will become the forwarding point for all traffic between hosts in that subnet. When local-proxy-arp is enabled, ICMP redirects on the ports associated with the service are automatically blocked. |
| <b>Default</b>     | ies>if: no local-proxy-arp<br><br>ies>sub-if>grp-if: local-proxy-arp (7750 SR)                                                                                                                                                                                                                                                                                                                                   |

| <b>Context</b>     | config>service>ies>if<br>config>service>ies>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command assigns a specific MAC address to an IES IP interface.</p> <p>For Routed Central Office (CO), a group interface has no IP address explicitly configured but inherits an address from the parent subscriber interface when needed. For example, a MAC will respond to an ARP request when an ARP is requested for one of the IPs associated with the subscriber interface through the group interface.</p> <p>The <b>no</b> form of the command returns the MAC address of the IP interface to the default value.</p> |
| <b>Default</b>     | the physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system)                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command is used to enable efficient multicast replication over a spoke SDP. Multicast traffic is copied to only a subset of network interfaces that may be used as egress for a spoke SDP. A network domain is defined by associating multiple interfaces to a logical group that may participate in multicast replication for a spoke SDP.</p> <p>The <b>no</b> form of command disables efficient multicast replication to a network domain for a spoke SDP and traffic is replicated to all forwarding complexes.</p> |
| <b>Default</b>     | no multicast-network-domain                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | This command assigns a secondary IP address/IP subnet/broadcast address format to the interface.                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the <b>address</b> command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). |

*mask* — The subnet mask in dotted decimal notation. When the IP prefix is not specified in CIDR notation, a space separates the *ip-address* from a traditional dotted decimal mask. The *mask* parameter indicates the complete mask that will be used in a logical 'AND' function to derive the local subnet of the IP address. Allowed values are dotted decimal addresses in the range 128.0.0.0 – 255.255.255.252. A mask of 255.255.255.255 is reserved for system IP addresses.

*netmask* — specifies a string of 0s and 1s that mask or screen out the network part of an IP address so that only the host computer part of the address remains

**broadcast** — The optional **broadcast** parameter overrides the default broadcast address used by the IP interface when sourcing IP broadcasts on the IP interface. If no broadcast format is specified for the IP address, the default value is **host-ones** which indicates a subnet broadcast address. Use this parameter to change the broadcast address to **all-ones** or revert back to a broadcast address of **host-ones**. The broadcast format on an IP interface can be specified when the IP address is assigned or changed.

This parameter does not affect the type of broadcasts that can be received by the IP interface. A host sending either the local broadcast (**all-ones**) or the valid subnet broadcast address (**host-ones**) will be received by the IP interface. (Default: *host-ones*)

**all-ones** — The **all-ones** keyword following the **broadcast** parameter specifies the broadcast address used by the IP interface for this IP address will be 255.255.255.255, also known as the local broadcast.

**host-ones** — The **host-ones** keyword following the **broadcast** parameter specifies that the broadcast address used by the IP interface for this IP address will be the subnet broadcast address. This is an IP address that corresponds to the local subnet described by the *ip-address* and the *mask-length* or *mask* with all the host bits set to binary one. This is the default broadcast address used by an IP interface.

The **broadcast** parameter within the **address** command does not have a negate feature, which is usually used to revert a parameter to the default value. To change the **broadcast** type to **host-ones** after being changed to **all-ones**, the **address** command must be executed with the **broadcast** parameter defined.

**igp-inhibit** — The optional **igp-inhibit** parameter signals that the given secondary IP interface should not be recognized as a local interface by the running IGP. For OSPF and IS-IS, this means that the specified secondary IP interfaces will not be injected and used as passive interfaces and will not be advertised as internal IP interfaces into the IGP's link state database. For RIP, this means that these secondary IP interfaces will not source RIP updates.

## static-arp

**Syntax**     **static-arp** *ieee-mac-address* *unnumbered*  
              **no static-arp** *unnumbered*

**Context**    config>service>ies>if

|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures a static address resolution protocol (ARP) entry associating a subscriber IP address with a MAC address for the core router instance. This static ARP appears in the core routing ARP table. A static ARP can only be configured if it exists on the network attached to the IP interface.</p> <p>If an entry for a particular IP address already exists and a new MAC address is configured for the IP address, the existing MAC address will be replaced with the new MAC address.</p> <p>The <b>no</b> form of the command removes a static ARP entry.</p>                   |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>ip-address</i> — specifies the IP address for the static ARP in IP address dotted decimal notation</p> <p><i>ieee-mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.</p> <p><i>unnumbered</i> — Specifies the static ARP MAC for an unnumbered interface. Unnumbered interfaces support dynamic ARP. Once this command is configured, it overrides any dynamic ARP.</p> |

| <b>Description</b> | <p>This command specifies redundant next-hop address on public or private IPsec interface (with public or private tunnel-sap) for static IPsec tunnel. The specified next-hop address will be used by standby node to shunt traffic to master in case of it receives them.</p> <p>The next-hop address will be resolved in routing table of corresponding service.</p> <p>The no form of the command removes the address from the interface configuration.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the static ISA tunnel redundant next-hop address                                                                                                                                                                                                                                                                                                                                                                                 |

## tos-marking-state

|                |                                                                               |
|----------------|-------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>tos-marking-state</b> {trusted   untrusted}<br><b>no tos-marking-state</b> |
| <b>Context</b> | config>service>ies>if                                                         |

```
config>service>ies>sub-if>grp-if
```

**Description** This command is used to change the default trusted state to a non-trusted state. When unset or reverted to the trusted default, the ToS field will not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set, in which case the egress network interface treats all IES and network IP interface as untrusted.

When the ingress interface is set to untrusted, all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface. The egress network remarking rules also apply to the ToS field of IP packets routed using IGP shortcuts (tunneled to a remote next-hop). However, the tunnel QoS markings are always derived from the egress network QoS definitions.

Egress marking and remarking is based on the internal forwarding class and profile state of the packet once it reaches the egress interface. The forwarding class is derived from ingress classification functions. The profile of a packet is either derived from ingress classification or ingress policing.

The default marking state for network IP interfaces is trusted. This is equivalent to declaring no tos-marking-state on the network IP interface. When undefined or set to tos-marking-state trusted, the trusted state of the interface will not be displayed when using show config or show info unless the detail parameter is given. The **save config** command will not store the default tos-marking-state trusted state for network IP interfaces unless the detail parameter is also specified.

The **no** form of the command is used to restore the trusted state to a network IP interface. This is equivalent to executing the tos-marking-state trusted command.

**Default** untrusted for config>service>ies context

**Parameters** **trusted** — The default prevents the ToS field to not be remarked by egress network IP interfaces unless the egress network IP interface has the remark-trusted state set.

**untrusted** — specifies that all egress network IP interfaces will remark IP packets received on the network interface according to the egress marking definitions on each network interface

## unnumbered

**Syntax** **unnumbered** [*ip-int-name* | *ip-address*]  
**no unnumbered**

**Context** config>service>ies>if  
configure>service>ies>subscriber-interface  
configure>service>vpn>subscriber-interface

**Description** This command configures the interface as an unnumbered interface. Unnumbered IP interfaces are supported on a SONET/SDH access port with the PPP, ATM, Frame Relay, cisco-HDLC encapsulation. It is not supported on access ports that do not carry IP traffic, but are used for native TDM circuit emulation.

| <b>Description</b> | <p>This command configures the type of a Value Added Service (VAS) facing interface. To change the <b>vas-if-type</b>, the <b>shutdown</b> command is required. The <b>vas-if-type</b> and <b>loopback</b> commands are mutually exclusive.</p> <p>The <b>no</b> form of the command removes the VAS interface type configuration.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Default</b>     | no vas-if-type                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><b>to-from-access</b> — used when two separate (<b>to-from-access</b> and <b>to-from-network</b>) interfaces are used for VAS connectivity. For service chaining, traffic arriving from access interfaces (upstream) is redirected to a PBR target reachable over this interface for upstream VAS processing. Downstream traffic after VAS processing must arrive on this interface, so that the traffic is subject to regular routing but is not subject to AA divert, nor egress subscriber PBR.</p> <p><b>to-from-network</b> — used when two separate (<b>to-from-access</b> and <b>to-from-network</b>) interfaces are used for VAS connectivity. For service chaining, traffic arriving from network interfaces (downstream) is redirected to a PBR target reachable over this interface for downstream VAS processing. Upstream traffic after VAS processing must arrive on this interface, so that regular routing can be applied.</p> |

**to-from-both** — used when a single interface is used for VAS connectivity (no local-to-local traffic). For service chaining, both traffic arriving from access interfaces and from network interfaces is redirected to a PBR target reachable over this interface for upstream/downstream VAS processing. Traffic after VAS processing must arrive on this interface, so that the traffic is subject to regular routing but is not subject to AA divert, nor egress subscriber PBR.

| <b>Description</b> | The <b>vpls</b> command, within the IP interface context, is used to bind the IP interface to the specified service name (VPLS or I-VPLS).<br><br>The system does not attempt to resolve the service name provided until the IP interface is placed into the administratively up state ( <b>no shutdown</b> ). Once the IP interface is administratively up, the system will scan the available VPLS services that have the allow-ip-int-binding flag set for a VPLS service associated with the name. If the service name is bound to the service name when the IP interface is already in the administratively up state, the system will immediately attempt to resolve the given name. |

If a VPLS service is found associated with the name and with the allow-ip-int-binding flag set, the IP interface will be attached to the VPLS service allowing routing to and from the service virtual ports once the IP interface is operational.

A VPLS service associated with the specified name that does not have the allow-ip-int-binding flag set or a non-VPLS service associated with the name will be ignored and will not be attached to the IP interface.

If the service name is applied to a VPLS service after the service name is bound to an IP interface and the VPLS service allow-ip-int-binding flag is set at the time the name is applied, the VPLS service will be automatically resolved to the IP interface if the interface is administratively up or when the interface is placed in the administratively up state.

If the service name is applied to a VPLS service without the allow-ip-int-binding flag set, the system will not attempt to resolve the applied service name to an existing IP interface bound to the name. To rectify this condition, the flag must first be set and then the IP interface must enter or reenter the administratively up state.

While the specified service name may be assigned to only one service context in the system, it is possible to bind the same service name to more than one IP interface. If two or more IP interfaces are bound to the same service name, the first IP interface to enter the administratively up state (if currently administratively down) or to reenter the administratively up state (if currently administratively up) when a VPLS service is configured with the name and has the allow-ip-int-binding flag set will be attached to the VPLS service. Only one IP interface is allowed to attach to a VPLS service context. No error is generated for the remaining non-attached IP interfaces using the service name.

Once an IP interface is attached to a VPLS service, the name associated with the service cannot be removed or changed until the IP interface name binding is removed. Also, the allow-ip-int-binding flag cannot be removed until the attached IP interface is unbound from the service name.

Unbinding the service name from the IP interface causes the IP interface to detach from the VPLS service context. The IP interface may then be bound to another service name or a SAP or SDP binding may be created for the interface using the **sap** or **spoke-sdp** commands on the interface.

### **IES Chassis Mode Dependency**

An IES IP interface cannot be bound to a service name unless the system is configured in chassis mode D. Once an IES interface is bound to a service name, the chassis mode of the system cannot be changed to B or C.

### **VPRN Hardware Dependency**

When a service name is bound to a VPRN IP interface, all SAPs associated with the VPRN service must be on hardware based on the FlexPath2 forwarding plane. Currently, these include the IOM3-XP, the various IMM modules and the SR7710c12. If any SAPs are associated with the wrong hardware type, the service name binding to the VPRN IP interface will fail. Once an IP interface within the VPRN service is bound to a service name, attempting to create a SAP on excluded hardware will fail.

### Route Export and Import between Routing Contexts

The IES chassis mode dependency and the VPRN hardware dependency each are designed to prevent a condition where an ingress routing decision on hardware that does not support the mixed L2 and L3 behavior of routed VPLS is asked to route to a VPLS based next-hop.

Even with these restrictions, it is still possible using route leaking or import/export routing policies to create a condition where a FlexPath1 forwarding plane resolves a route to a VPLS next-hop. In this case, the forwarding plane handles the resolved next-hop as if it points to a null IP interface. Packets associated with a null next-hop egress IP interface will be discarded and an ICPM unreachable message will be generated when enabled.

### IP Interface MTU and Fragmentation

A VPLS service is affected by two MTU values; port MTUs and the VPLS service MTU. The MTU on each physical port defines the largest L2 packet (including all DLC headers and CRC) that may be transmitted out a port. The VPLS itself has a service level MTU that defines the largest packet supported by the service. This MTU does not include the local encapsulation overhead for each port (QinQ, Dot1Q, TopQ or SDP service delineation fields and headers) but does include the remainder of the packet. As virtual ports are created in the system, the virtual port cannot become operational unless the configured port MTU minus the virtual port service delineation overhead is greater than or equal to the configured VPLS service MTU. Thus, an operational virtual port is ensured to support the largest packet traversing the VPLS service. The service delineation overhead on each L2 packet is removed before forwarding into a VPLS service. VPLS services do not support fragmentation and must discard any L2 packet larger than the service MTU after the service delineation overhead is removed.

IP interfaces have a configurable up MTU that defines the largest packet that may egress the IP interface without being fragmented. This MTU encompasses the IP portion of the packet and does not include any of the egress DLC header or CRC. This MTU does not affect the size of the largest ingress packet on the IP interface. If the egress IP portion of the packet is larger than the IP interface MTU and the IP header do not fragment flag is not set, the packet is fragmented into smaller packets that will not exceed the configured MTU size. If the do not fragment bit is set, the packet is silently discarded at egress when it exceeds the IP MTU.

When the IP interface is bound to a VPLS service, the IP MTU must be at least 18 bytes less than the VPLS service MTU. This allows for the addition of the minimal Ethernet encapsulation overhead; 6 bytes for the DA, 6 bytes for the SA, 2 bytes for the Etype and 4 bytes for the trailing CRC. Any remaining egress virtual port overhead (Dot1P, Dot1Q, QinQ, TopQ or SDP) required above the minimum is known to be less than the egress ports MTU since the virtual port would not be operational otherwise.

If the IP interface IP MTU value is too large based on the VPLS service MTU, the IP interface will enter the operationally down state until either the IP MTU is adequately lowered or the VPLS service MTU is sufficiently increased.

The **no** form of the command on the IP interface is used to remove the service name binding from the IP interface. If the service name has been resolved to a VPLS service context and the IP interface has been attached to the VPLS service, the IP interface will also be detached from the VPLS service.

---

| <b>Parameters</b> | <i>service-name</i> — The service-name parameter is required when using the IP interface vpls command and specifies the service name that the system will attempt to resolve to an allow-ip-int-binding enabled VPLS service associated with the name. The specified name is expressed as an ASCII string comprised of up to 32 characters. It does not need to already be associated with a service and the system does not check to ensure that multiple IP interfaces are not bound to the same name. |

## ingress

|                    |                                                                                                                               |

| <b>Description</b> | <p>The v4-routed-override-filter command is used to specify an IPv4 filter ID that will be applied to all ingress packets entering the VPLS or I-VPLS service. The filter overrides any existing ingress IPv4 filter applied to SAPs or SDP bindings for packets associated with the routing IP interface. The override filter is optional and when it is not defined or it is removed, the IPv4 routed packets will use the any existing ingress IPv4 filter on the VPLS virtual port.</p> <p>The <b>no</b> form of the command is used to remove the IPv4 routed override filter from the ingress IP interface. When removed, the IPv4 ingress routed packets within a VPLS service attached to the IP interface will use the IPv4 ingress filter applied to the packets virtual port when defined.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>ipv4-filter-id</i> — The ipv4-filter-id parameter is required when executing the v4-routed-override-filter command. The specified filter ID must exist as an IPv4 filter within the system or the override command will fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>The v6-routed-override-filter command is used to specify an IPv6 filter ID that will be applied to all ingress packets entering the VPLS or I-VPLS service. The filter overrides any existing ingress IPv6 filter applied to SAPs or SDP bindings for packets associated with the routing IP interface. The override filter is optional and when it is not defined or it is removed, the IPv6 routed packets will use the any existing ingress IPv6 filter on the VPLS virtual port.</p> <p>The no v6-routed-override-filter command is used to remove the IPv6 routed override filter from the ingress IP interface. When removed, the IPv6 ingress routed packets within a VPLS service attached to the IP interface will use the IPv6 ingress filter applied to the packets virtual port when defined.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>ipv6-filter-id</i> — The ipv6-filter-id parameter is required when executing the v6-routed-override-filter command. The specified filter ID must exist as an IPv6 filter within the system or the override command will fail.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## egress

|                    |                                                                                                                                                                                                                                                                            |

| <b>Context</b>     | config>service>ies>if>vpls>egress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>The reclassify-using-qos command is used to specify a sap-egress QoS policy that will be used to reclassify the forwarding class and profile of egress routed packets on the VPLS or I-VPLS service. When routed packets associated with the IP interface egress a VPLS SAP, the reclassification rules within the sap-egress QoS policy applied to the SAP are always ignored (even when reclassify-using-qos is not defined).</p> <p>Any queues or policers defined within the specified QoS policy are ignored and are not created on the VPLS egress SAPs. Instead, the routed packets continue to use the forwarding class mappings, queues and policers from the sap-egress QoS policy applied to the egress VPLS SAP.</p> |

While the specified sap-egress policy ID is applied to an IP interface it cannot be deleted from the system.

The **no** form of the command removes the sap-egress QoS policy used for reclassification from the egress IP interface. When removed, IP routed packets will not be reclassified on the egress SAPs of the VPLS service attached to the IP interface.

**Parameters** *sap-egress-qos-id* — The sap-egress-qos-id parameter is required when executing the reclassify-using-qos command. The specified SAP egress QoS ID must exist within the system or the command will fail.

## proxy-arp-policy

**Syntax** **[no] proxy-arp** *policy-name* [*policy-name...*(up to 5 max)]

**Context** config>service>ies>if

**Description** This command configures a proxy ARP policy for the interface.

The **no** form of this command disables the proxy ARP capability.

**Default** no proxy-arp

**Parameters** *policy-name* — The export route policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. The specified name(s) must already be defined.

## ptp-hw-assist

**Syntax** **[no] ptp-hw-assist**

**Context** config>service>ies>if

**Description** This command configures the 1588 port based timestamping assist function for the interface. This capability is supported on a specific set of hardware. The command may be blocked if not all hardware has the required level of support.

Only one interface per physical port can have ptp-hw-assist enabled.

no ptp-hw-assist

## qos-route-lookup

**Syntax** **qos-route-lookup** [source | destination]  
**no qos-route-lookup**

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command enables QoS classification of the ingress IP packets on an interface based on the QoS information associated with routes in the forwarding table.</p> <p>If the optional <b>destination</b> parameter is specified and the destination address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the sap-ingress or network qos policy associated with the IP interface. If the destination address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the sap-ingress or network qos policy.</p> <p>If the optional <b>source</b> parameter is specified and the source address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the sap-ingress or network qos policy associated with the IP interface. If the source address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the sap-ingress or network qos policy.</p> <p>If neither the optional <b>source</b> or <b>destination</b> parameter is present, then the default is <b>destination</b> address matching.</p> <p>The functionality enabled by the qos-route-lookup command can be applied to IPv4 packets or IPv6 packets on an interface, depending on whether it is present at the interface context (applies to IPv4) or the interface&gt;ipv6 context (applies to IPv6). Subscriber management group interfaces also do not support the source QPPB option.</p> <p>The <b>no</b> form of the command reverts to the default.</p> |
| <b>Default</b>     | destination                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|                    |                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] allow-unsecured-msgs</b>                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>ies>if>ipv6>secure-nd                                                                                                                                                                                                            |
| <b>Description</b> | This command specifies whether unsecured messages are accepted. When Secure Neighbor Discovery (SeND) is enabled, only secure messages are accepted by default.<br><br>The <b>no</b> form of the command disables accepting unsecured messages. |

## link-local-modifier

|                    |                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>link-local-modifier</b> <i>modifier</i><br><b>[no] link-local-modifier</b>                            |
| <b>Context</b>     | config>service>ies>if>ipv6>secure-nd                                                                     |
| <b>Description</b> | This command configures the Cryptographically Generated Address (CGA) modifier for link-local addresses. |
| <b>Parameters</b>  | <i>modifier</i> — specifies the modifier in 32 hexadecimal nibbles<br><br><b>Values</b> 0x0–0xFFFFFFFF   |

## public-key-min-bits

|                    |                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>public-key-min-bits</b> <i>bits</i><br><b>[no] public-key-min-bits</b>                                                                        |
| <b>Context</b>     | config>service>ies>if>ipv6>secure-nd                                                                                                             |
| <b>Description</b> | This command configures the minimum acceptable key length for public keys used in the generation of a Cryptographically Generated Address (CGA). |
| <b>Parameters</b>  | <i>bits</i> — specifies the number of bits<br><br><b>Values</b> 512 to 1024                                                                      |

## security-parameter

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>security-parameter</b> <i>sec</i><br><b>[no] security-parameter</b>                                                |
| <b>Context</b>     | config>service>ies>if>ipv6>secure-nd                                                                                  |
| <b>Description</b> | This command configures the security parameter used in the generation of a Cryptographically Generated Address (CGA). |

---

|                   |                                               |
|-------------------|-----------------------------------------------|
| <b>Parameters</b> | <i>sec</i> — specifies the security parameter |
| <b>Values</b>     | 0–1                                           |

## shutdown

|                    |                                                                                     |
|--------------------|-------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] shutdown</b>                                                                |
| <b>Context</b>     | config>service>ies>if>ipv6>secure-nd                                                |
| <b>Description</b> | This command enables or disables Secure Neighbor Discovery (SeND) on the interface. |

## stale-time

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>stale-time</b> <i>seconds</i><br><b>no stale-time</b>                                                                                                                        |
| <b>Context</b>     | config>service>ies>ipv6<br>config>service>ies>if>ipv6                                                                                                                           |
| <b>Description</b> | This command configures the time a neighbor discovery cache entry can remain stale before being removed.<br><br>The <b>no</b> form of the command removes the stale-time value. |
| <b>Default</b>     | no stale-time                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — The allowed stale time (in seconds) before a neighbor discovery cache entry is removed.<br><br><b>Values</b> 60 - 65535                                        |

## tcp-mss

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tcp-mss</b> <i>mss-value</i><br><b>no tcp-mss</b>                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if<br>config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command statically sets the TCP maximum segment size (MSS) for TCP connections originated from the associated IP interface to the specified value.<br><br>The <b>no</b> form of the command removes the static value and allows the TCP MSS value to be calculated based on the IP MTU value by subtracting the base IP and TCP header lengths from the IP MTU value ( $\text{tcp\_mss} = \text{ip\_mtu} - 40$ ). |
| <b>Default</b>     | no tcp-mss                                                                                                                                                                                                                                                                                                                                                                                                             |

|                   |                                                                                                                                                                                                                                                       |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>mss-value</i> — The TCP MSS value that should be used in the TCP SYN packet during the three-way handshake negotiation of a TCP connection.<br><b>Note:</b> 9158 = max-IP_MTU (9198)-40<br><b>Values</b> 536 to 9158 (IPv4)<br>1220 to 9138 (IPv6) |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## remote-proxy-arp

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Syntax</b>      | <b>[no] remote-proxy-arp</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>ies>if<br>config>service>ies>sub-if>grp-if                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command enables remote proxy ARP on the interface.<br><br>Remote proxy ARP is similar to proxy ARP. It allows the router to answer an ARP request on an interface for a subnet that is not provisioned on that interface. This allows the router to forward to the other subnet on behalf of the requester. To distinguish remote proxy ARP from local proxy ARP, local proxy ARP performs a similar function but only when the requested IP is on the receiving interface. |
| <b>Default</b>     | no remote-proxy-arp                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## ipv6

|                    |                                                                             |
|--------------------|-----------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6</b>                                                            |
| <b>Context</b>     | config>services>ies>sub-if                                                  |
| <b>Description</b> | This command enables IPv6 forwarding on the specified subscriber-interface. |
| <b>Default</b>     | no ipv6                                                                     |

|                    |                                                                                                                                                                                                                                                           |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] subscriber-prefixes</b>                                                                                                                                                                                                                           |
| <b>Context</b>     | config>services>ies>sub-if>ipv6                                                                                                                                                                                                                           |
| <b>Description</b> | This command specifies aggregate off-link subscriber prefixes associated with this subscriber interface. Individual prefixes are specified under the prefix context list aggregate routes in which the next-hop is indirect via the subscriber interface. |

---

## prefix

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>prefix</b> <i>ipv6-address/prefix-length</i> [ <b>pd</b> ] [ <b>wan-host</b> ]<br><b>no prefix</b> <i>ipv6-address/prefix-length</i>                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>services>ies>sub-if>ipv6>sub-prefixes                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command allows a list of prefixes (using the prefix command multiple times) to be routed to hosts associated with this subscriber interface. Each prefix will be represented in the associated FIB with a reference to the subscriber interface. Prefixes are defined as being for prefix delegation (pd) or use on a WAN interface or host (wan-host).                                                                                                                          |
| <b>Parameters</b>  | <i>ipv6-address</i> — specifies the 128-bit IPv6 address<br><b>Values</b> 128-bit hexadecimal IPv6 address in compressed form.<br><i>prefix-length</i> — specifies the length of any associated aggregate prefix<br><b>Values</b> 32-63<br><b>pd</b> — specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation<br><b>wan-host</b> — specifies that this aggregate is used by IPv6 ESM hosts for local addressing or by a routing gateway's WAN interface |

## allow-unmatching-prefixes

|                    |                                                                                                                                                                                                                                                                          |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [ <b>no</b> ] <b>allow-unmatching-prefixes</b>                                                                                                                                                                                                                           |
| <b>Context</b>     | config>service>ies>sub-if                                                                                                                                                                                                                                                |
| <b>Description</b> | This command allows address assignment to PPPoX hosts in cases where the assigned address falls outside the range of the configured subnets below the subscriber interface. Alternatively, if the interface is configured as unnumbered, this command cannot be enabled. |
| <b>Default</b>     | no allow-unmatching-prefixes                                                                                                                                                                                                                                             |

## delegated-prefix-length

|                    |                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | [ <b>no</b> ] <b>delegated-prefix-length</b> <i>prefix-length</i>                                           |
| <b>Context</b>     | config>services>ies>sub-if>ipv6                                                                             |
| <b>Description</b> | This command defines the prefix-length used for all DHCPv6 prefix delegations on this subscriber interface. |
| <b>Default</b>     | 64                                                                                                          |

|                   |                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>prefix-length</i> — specifies the prefix length in use on this subscriber interface for DHCPv6<br>IA_PD |
| <b>Values</b>     | 48 to 64                                                                                                   |

## redundant-interface

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>redundant-interface</b> <i>red-ip-int-name</i><br><b>no redundant-interface</b> |
| <b>Context</b>     | config>service>ies<br>config>service>ies>sub-if>grp-if                             |
| <b>Description</b> | This command configures a redundant interface used for dual homing.                |
| <b>Parameters</b>  | <i>red-ip-int-name</i> — specifies the redundant IP interface name                 |

## arp-host

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>arp-host</b>                                                    |
| <b>Context</b>     | config>service>ies>sub-if>grp-if                                   |
| <b>Description</b> | This command enables the context to configure ARP host parameters. |

## host-limit

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>host-limit</b> <i>max-num-hosts</i><br><b>no host-limit</b>   |
| <b>Context</b>     | config>service>ies>sub-if>grp-if                                 |
| <b>Description</b> | This command configures the maximum number of ARP hosts.         |
| <b>Parameters</b>  | <i>max-num-hosts</i> — specifies the maximum number of ARP hosts |
| <b>Values</b>      | 1 to 32767                                                       |

## min-auth-interval

|                    |                                                                                  |
|--------------------|----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>min-auth-interval</b> <i>min-auth-interval</i><br><b>no min-auth-interval</b> |
| <b>Context</b>     | config>service>ies>sub-if>grp-if                                                 |
| <b>Description</b> | This command configures the minimum authentication interval.                     |

---

|                   |                                                                          |
|-------------------|--------------------------------------------------------------------------|
| <b>Parameters</b> | <i>min-auth-interval</i> — specifies the minimum authentication interval |
| <b>Values</b>     | 1 to 6000                                                                |

## sap-host-limit

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap-host-limit</b> <i>max-num-hosts-sap</i><br><b>no sap-host-limit</b>                                 |
| <b>Context</b>     | config>service>ies>sub-if>grp-if                                                                           |
| <b>Description</b> | This command configures the maximum number of ARP hosts per SAP.                                           |
| <b>Parameters</b>  | <i>max-num-hosts-sap</i> — specifies the maximum number of ARP hosts per SAP allowed on this IES interface |
| <b>Values</b>      | 1 to 32767                                                                                                 |

## arp-populate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>This command, when enabled, disables dynamic learning of ARP entries. Instead, the ARP table is populated with dynamic entries from the DHCP Lease State Table (enabled with <b>lease-populate</b>), and optionally with static entries entered with the <b>host</b> command.</p> <p>Enabling the <b>arp-populate</b> command will remove any dynamic ARP entries learned on this interface from the ARP cache.</p> <p>The <b>arp-populate</b> command will fail if an existing static ARP entry exists for this interface. The <b>arp-populate</b> command will fail if an existing static subscriber host on the SAP does not have both MAC and IP addresses specified.</p> <p>Once <b>arp-populate</b> is enabled, creating a static subscriber host on the SAP without both an IP address and MAC address will fail.</p> <p>When <b>arp-populate</b> is enabled, the system will not send out ARP requests for hosts that are not in the ARP cache. Only statically configured and DHCP learned hosts are reachable through an IP interface with <b>arp-populate</b> enabled. The <b>arp-populate</b> command can only be enabled on IES and VPRN interfaces supporting Ethernet encapsulation.</p> <p>Use the <b>no</b> form of the command to disable ARP cache population functions for static and dynamic hosts on the interface. All static and dynamic host information for this interface will be removed from the system's ARP cache.</p> |
| <b>Default</b>     | not enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command sets the delivery service for encapsulated packets associated with a particular tunnel. This is the IES or VPRN service where the encapsulated packets are injected and terminated. The delivery service may be the same service that owns the private tunnel SAP associated with the tunnel. The tunnel does not come up until a valid delivery service is configured.</p> <p>The <b>no</b> form of the command deletes the delivery-service from the tunnel configuration.</p> |
| <b>Parameters</b>  | <p><i>service-id</i> — Identifies the service used to originate and terminate the encapsulated packets belonging to the tunnel.</p> <p><b>Values</b> 1 to 2147483648</p> <p><i>svc-name</i> — Identifies the service used to originate and terminate the encapsulated packets belonging to the GRE tunnel.</p> <p><b>Values</b> 1 to 64 characters</p>                                                                                                                                           |

|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------|-------------------------------------|
| Description | <p>This command configures a private IPv4 or IPv6 address of the remote tunnel endpoint. A tunnel can have up to 16 <b>dest-ip</b> commands. At least one <b>dest-ip</b> address is required in the configuration of a tunnel. A tunnel does not come up operationally unless all <b>dest-ip</b> addresses are reachable (part of a local subnet).</p> <p>Unnumbered interfaces are not supported.</p> <p>The <b>no</b> form of the command deletes the destination IP of the tunnel.</p> |              |                                     |
| Default     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |              |                                     |
| Parameters  | <i>ip-address</i> — specifies the destination IPv4 or IPv6 address                                                                                                                                                                                                                                                                                                                                                                                                                        |              |                                     |
|             | Values                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |              |                                     |

| Description | This command sets the DSCP code-point in the outer IP header of encapsulated packets associated with a particular tunnel. The default, set using the no form of the command, is to copy the DSCP value from the inner IP header (after remarking by the private tunnel SAP egress qos policy) to the outer IP header.                                                                     |
| Default     | no dscp                                                                                                                                                                                                                                                                                                                                                                                   |
| Parameters  | dscp — specifies the DSCP code-point to be used                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | This command sets the maximum length, in bytes, of a fragment transmitted across a Frame Relay SAP with the FRF.12 end-to-end fragmentation enabled.<br><br>The no form of this command resets the fragment threshold back to the default value. |
| <b>Default</b>     | 128                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <i>fragment-threshold</i> — specifies the maximum fragment length, in bytes, to be transmitted across the FR SAP<br><br><b>Values</b> 128 to 512 bytes                                                                                           |

## interleave

|                    |                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>interleave</b><br><b>no interleave</b>                                                                                                         |
| <b>Context</b>     | config>service>ies>if>sap>frame-relay>frf.12                                                                                                      |
| <b>Description</b> | This command enables interleaving of high priority frames and low-priority frame fragments within a FR SAP using FRF.12 end-to-end fragmentation. |

When this option is enabled, only frames of the FR SAP non expedited forwarding class queues are subject to fragmentation. The frames of the FR SAP expedited queues are interleaved, with no fragmentation header, among the fragmented frames. In effect, this provides a behavior like in MLPPP Link Fragment Interleaving (LFI).

When this option is disabled, frames of all the FR SAP forwarding class queues are subject to fragmentation. The fragmentation header is however not included when the frame size is smaller than the user configured fragmentation size. In this mode, the SAP transmits all fragments of a frame before sending the next full or fragmented frame.

The receive direction of the FR SAP supports both modes of operation concurrently, with and without fragment interleaving.

The **no** form of this command restores the default mode of operation.

**Default** no interleave

## scheduling-class

|                    |                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command creates a static subscriber host for the SAP. Static subscriber hosts may be used by the system for various purposes. Applications within the system that make use of static host entries include anti-spoof filters and ARP cache population.</p> <p>Multiple static hosts may be defined on the SAP. Each host is identified by either a source IP address, a source MAC address or both a source IP and source MAC address. Every static host definition must have at least one address defined, IP or MAC.</p> <p>Static hosts can exist on the SAP even with anti-spoof and ARP populate features disabled. When enabled, each feature has different requirements for static hosts.</p> |

**anti-spoof** – When enabled, this feature uses static and dynamic host information to populate entries into an anti-spoof filter table. The anti-spoof filter entries generated will be of the same type as specified in the anti-spoof type parameter. If the SAP anti-spoof filter is defined as **ip**, each static host definition must specify an IP address. If the SAP anti-spoof filter is defined as **ip-mac**, each static host definition must specify both an IP address and MAC address. If definition of a static host is attempted without the appropriate addresses specified for the enabled anti-spoof filter, the static host definition will fail.

**arp-populate** – When enabled, this feature uses static and dynamic host information to populate entries in the system ARP cache.

Attempting to define a static subscriber host that conflicts with an existing DHCP Lease State Table entry will fail.

Use the **no** form of the command to remove a static entry from the system. The specified *ip-address* and *mac-address* must match the host's exact IP and MAC addresses as defined when it was created. When a static host is removed from the SAP, the corresponding anti-spoof entry and/or ARP cache entry is also removed.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Default</b>    | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b> | <p><b>ip</b> <i>ip-address</i> — Specify this optional parameter when defining a static host. The IP address must be specified for <b>anti-spoof ip</b>, <b>anti-spoof ip-mac</b> and <b>arp-populate</b>. Only one static host may be configured on the SAP with a given IP address.</p> <p><b>mac</b> <i>mac-address</i> — Specify this optional parameter when defining a static host. The MAC address must be specified for <b>anti-spoof ip-mac</b> and <b>arp-populate</b>. Multiple static hosts may be configured with the same MAC address given that each definition is distinguished by a unique IP address.</p> <p><b>subscriber</b> <i>sub-ident-string</i> — Specify this optional parameter to specify an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context. The subscriber information is used by the SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.</p> <p>For VPRN SAPs with <b>arp-reply-agent</b> enabled with the optional <i>sub-ident</i> parameter, the static subscriber host's sub-ident-string is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.</p> <p>If the static subscriber host's <i>sub-ident</i> string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.</p> <p>If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.</p> <p>If <i>sub-ident</i> is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.</p> <p>ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.</p> |

**sub-profile** *sub-profile-name* — Specify this optional parameter to specify an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.

**sla-profile** *sla-profile-name* — Specify this optional parameter to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.

**ancp-string** *ancp-string* — specifies the ASCII string of the DSLAM circuit ID name

## 2.5.2.6 IES Interface DHCP Commands

### dhcp

|                    |                                                                                        |
|--------------------|----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                                            |
| <b>Context</b>     | config>service>ies>if<br>config>service>ies>sub-if<br>config>service>ies>sub-if>grp-if |
| <b>Description</b> | This command enables the context to configure DHCP parameters.                         |

### client-applications

|                    |                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>client-applications dhcp</b><br><b>client-applications ppp</b><br><b>client-applications dhcp ppp</b><br><b>no client-applications</b>                                                                     |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>dhcp                                                                                                                                                                         |
| <b>Description</b> | This command enables the clients that will try to contact the DHCP server(s).<br><br>The <b>no</b> form of the command removes the server client type from the configuration.                                 |
| <b>Parameters</b>  | <b>dhcp</b> — specifies that the DHCP relay will forward requests to the DHCP server(s)<br><b>ppp</b> — specifies that PPPoE will attempt to request an IP address for a PPPoE client from the DHCP server(s) |

### action

|               |                                                           |
|---------------|-----------------------------------------------------------|
| <b>Syntax</b> | <b>action {replace   drop   keep}</b><br><b>no action</b> |
|---------------|-----------------------------------------------------------|

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | This command configures the Relay Agent Information Option (Option 82) processing.<br><br>The <b>no</b> form of this command returns the system to the default value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Default</b>     | no action                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><b>replace</b> — In the upstream direction (from the user), the Option 82 field from the router is inserted in the packet (overwriting any existing Option 82 field). In the downstream direction (towards the user) the Option 82 field is stripped (in accordance with RFC 3046).</p> <p><b>drop</b> — The DHCP packet is dropped if an Option 82 field is present, and a counter is incremented.</p> <p><b>keep</b> — The existing information is kept in the packet and the router does not add any additional information. In the downstream direction the Option 82 field is not stripped and is forwarded towards the client.</p> <p>The behavior is slightly different in case of Vendor Specific Options (VSOs). When the keep parameter is specified, the router will insert his own VSO into the Option 82 field. This will only be done when the incoming message has already an Option 82 field.</p> <p>If no Option 82 field is present, the router will not create the Option 82 field. In this in that case, no VSO will be added to the message.</p> |

## circuit-id

| <b>Description</b> | <p>When enabled, the router sends either an ASCII tuple, or the interface index (If Index), on the specified SAP ID in the <b>circuit-id</b> sub-option of the DHCP packet.</p> <p>If disabled, the <b>circuit-id</b> sub-option of the DHCP packet will be left empty.</p> <p>The <b>no</b> form of this command returns the system to the default.</p>                         |
| <b>Default</b>     | circuit-id ascii-tuple                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <p><b>ascii-tuple</b> — specifies that the ASCII-encoded concatenated tuple will be used which consists of the access-node-identifier, service-id, and interface-name, separated by “ ”</p> <p><b>ifindex</b> — specifies that the interface index will be used. The If Index of a router interface can be displayed using the command <b>show&gt;router&gt;if&gt;detail</b></p> |

**sap-id** — specifies that the SAP ID will be used

**vlan-ascii-tuple** — Specifies that the format will include VLAN ID, dot1p bits in addition to what is included in ascii-tuple already. The format is supported on dot1q and qinq ports only. Thus, when the Option 82 bits are stripped, dot1p bits will be copied to the Ethernet header of an outgoing packet.

| <b>Description</b> | <p>This command enables Option 82 circuit ID on relayed DHCP packet matching.</p> <p>For Routed CO, the group interface DHCP relay process is stateful. When packets are relayed to the server the virtual router ID, transaction ID, SAP ID, and client hardware MAC address of the relayed packet are tracked. When a response is received from the server the virtual router ID, transaction ID, and client HW MAC address must be matched to determine the SAP on which to send the packet out. In some cases, the virtual router ID, transaction ID, and client hardware MAC address are not guaranteed to be unique.</p> <p>When the <b>match-circuit-id</b> command is enabled, it is used as part of the key to guarantee correctness in our lookup. This is really only needed when we are dealing with an IP aware DSLAM that proxies the client HW mac address.</p> |
| <b>Default</b>     | no match-circuit-id                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|                    |                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] string text</b>                                                                                                                                                                  |
| <b>Context</b>     | config>service>ies>if>dhcp>option>vendor<br>config>service>ies>sub-if>grp-if>dhcp>option>vendor                                                                                          |
| <b>Description</b> | This command specifies the string in the vendor specific sub-option of the DHCP relay packet.<br><br>The <b>no</b> form of the command returns the default value.                        |
| <b>Parameters</b>  | <i>text</i> — The string can be any combination of ASCII characters up to 32 characters in length. If spaces are used in the string, enclose the entire string in quotation marks (" "). |

## system-id

|                    |                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] system-id</b>                                                                                   |
| <b>Context</b>     | config>service>ies>if>dhcp>option>vendor<br>config>service>ies>sub-if>grp-if>dhcp>option>vendor         |
| <b>Description</b> | This command specifies whether the system-id is encoded in the vendor specific sub-option of Option 82. |

## proxy-server

|               |                     |
|---------------|---------------------|
| <b>Syntax</b> | <b>proxy-server</b> |
|---------------|---------------------|

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Context</b>     | config>service>ies>if>dhcp<br>config>service>ies>sub-if>grp-if>dhcp |
| <b>Description</b> | This command configures the DHCP proxy server.                      |

## emulated-server

|                    |                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>emulated-server</b> <i>ip-address</i><br><b>no emulated-server</b>                                                                                                                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>ies>if>dhcp>proxy-server<br>config>service>ies>sub-if>grp-if>dhcp>proxy-server                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | <p>This command configures the IP address which will be used as the DHCP server address in the context of this SAP. Typically, the configured address should be in the context of the subnet represented by service.</p> <p>The <b>no</b> form of this command reverts to the default setting. The local proxy server will not become operational without the emulated-server address being specified.</p> |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the emulated server address                                                                                                                                                                                                                                                                                                                                                  |

## lease-time

|                    |                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lease-time</b> [ <i>days days</i> ] [ <i>hrs hours</i> ] [ <i>min minutes</i> ] [ <i>sec seconds</i> ] [ <i>radius-override</i> ]<br><b>no lease-time</b>                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>ies>if>dhcp>proxy-server<br>config>service>ies>sub-if>grp-if>dhcp>proxy-server                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | <p>This command defines the length of lease-time that will be provided to DHCP clients. By default the local-proxy-server will always make use of the lease-time information provide by either a RADIUS or DHCP server.</p> <p>The <b>no</b> form of this command disables the use of the lease-time command. The local-proxy-server will use the lease-time offered by either a RADIUS or DHCP server.</p> |
| <b>Default</b>     | 7 days 0 hours 0 seconds                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <p><b>radius-override</b> — specifies that the local-proxy-server will use the configured lease-time information to provide DHCP clients</p> <p><i>days</i> — specifies the number of days that the given IP address is valid</p> <p><b>Values</b> 0 to 3650</p> <p><i>hours</i> — specifies the number of hours that the given IP address is valid</p> <p><b>Values</b> 0 to 23</p>                        |

*minutes* — specifies the number of minutes that the given IP address is valid

**Values** 0 to 59

*seconds* — specifies the number of seconds that the given IP address is valid

**Values** 0 to 59

## python-policy

|                    |                                                                                                                                                                    |

|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>Relay unicast client DHCPv4 request (renew) messages. In the upstream direction: update the source-ip address and add the gateway IP address (gi-address) field before sending the message to the intended DHCP server (the message is not broadcasted to all configured DHCP servers). In the downstream direction: remove the gi-address and update the destination IP address to the value of the "yiaddr" (your IP address) field.</p> <p>By default, unicast DHCPv4 release messages are forwarded transparently. The optional "release-update-src-ip" flag, updates the source IP address with the value used for relayed DHCPv4 messages.</p> <p>Additionally when the optional flag "relay-unicast-msg" is enabled, then the gi-address and source IP address of relayed DHCPv4 messages can be configured to any local configured IP address in the same routing instance.</p> |
| <b>Default</b>     | no relay-unicast-msg                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <b>release-update-src-ip</b> — updates the source IP address with the value used for relayed DHCPv4 messages                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>According to RFC 3046, <i>DHCP Relay Agent Information Option</i>, a DHCP request where the gi-addr is 0.0.0.0 and which contains a Option 82 field in the packet, should be discarded, unless it arrives on a trusted circuit. If trusted mode is enabled on an IP interface, the Relay Agent (the router) will modify the request's gi-addr to be equal to the ingress interface and forward the request.</p> <p>This behavior only applies when the action in the Relay Agent Information Option is "keep". In the case where the Option 82 field is being replaced by the Relay Agent (action = replace), the original Option 82 information is lost anyway, and there is thus no reason for enabling the trusted option.</p> <p>The <b>no</b> form of this command returns the system to the default.</p> |
| <b>Default</b>     | not enabled                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## user-db

|                    |                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>user-db</b> <i>local-user-db-name</i><br><b>no user-db</b>                                                                                                        |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>dhcp                                                                                                                                |
| <b>Description</b> | <p>This command configures the local user database to use for authentication.</p> <p>The <b>no</b> form of the command removes the value from the configuration.</p> |
| <b>Default</b>     | no user-db                                                                                                                                                           |
| <b>Parameters</b>  | <i>local-user-db-name</i> — specifies the local user database to use for authentication                                                                              |

## filter

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>filter</b> <i>filter-id</i><br><b>no filter</b>                                                              |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>dhcp                                                                           |
| <b>Description</b> | This command configures the DHCP filter for this interface.                                                     |
| <b>Parameters</b>  | <i>filter-id</i> — Specifies the filter policy. The filter ID must already exist within the created IP filters. |
| <b>Values</b>      | 1 to 65535                                                                                                      |

## gi-address

|               |                                                            |

| <b>Syntax</b> | <b>gi-address</b> <i>ip-address</i> [ <i>src-ip-addr</i> ] |
|---------------|------------------------------------------------------------|

**no gi-address**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>ies>if>dhcp<br>config>service>ies>sub-if>grp-if>dhcp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Description</b> | <p>This command configures the gateway interface address for the DHCP relay. A subscriber interface can include multiple group interfaces with multiple SAPs. The GI address is needed, when the router functions as a DHCP relay, to distinguish between different interfaces.</p> <p>By default, the GI address used in the relayed DHCP packet is the primary IP address of a normal IES interface. Specifying the GI address allows the user to choose a secondary address. For group interfaces a GI address must be specified under the group interface DHCP context or subscriber-interface DHCP context in order for DHCP to function.</p> |
| <b>Default</b>     | no gi-address                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>ip-address</i> — specifies the host IP address to be used for DHCP relay packets</p> <p><i>src-ip-address</i> — specifies that this GI address is to be the source IP address for DHCP relay packets</p>                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## 2.5.2.7 PPPoE Commands

### pppoe

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] pppoe</b>                                               |
| <b>Context</b>     | config>service>ies>sub-if>grp-if                                |
| <b>Description</b> | This command enables the context to configure PPPoE parameters. |

### dhcp-client

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp-client</b>                                                       |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>pppoe                                   |
| <b>Description</b> | This command enables the context to configure the PPPoE-to-DHCP options. |

### ccag-use-origin-sap

|                |                                                    |
|----------------|----------------------------------------------------|
| <b>Syntax</b>  | <b>[no] ccag-use-origin-sap</b>                    |
| <b>Context</b> | config>service>ies>sub-if>grp-if>pppoe>dhcp-client |

---

|                    |                                                                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command enables the original VPLS SAP to be included in the circuit-id option to send to the DHCP server (in case this interface is connected to a VPLS by a CCA MDA).<br><br>The <b>no</b> form of the command disables the feature. |
| <b>Default</b>     | no ccag-use-origin-sap                                                                                                                                                                                                                     |

## pap-chap-user-db

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pap-chap-user-db</b> <i>local-user-db-name</i><br><b>no pap-chap-user-db</b>                                                                                                                                                                                                                                                                                                                                  |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>pppoe                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command configures the local user database to use for PPP Challenge-Handshake Authentication Protocol/Password Authentication Protocol (PAP/CHAP) authentication.<br><br>If an authentication policy is also configured, <b>pppoe-access-method</b> must be set to none in this authentication policy to use the local user database (in that case RADIUS authentication will not be used for PPPoE hosts). |
| <b>Parameters</b>  | <i>local-user-db-name</i> — specifies the local user database to use for authentication                                                                                                                                                                                                                                                                                                                          |

## pppoe-policy

|                    |                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pppoe-policy</b> <i>pppoe-policy-name</i><br><b>no pppoe-policy</b>                                |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>pppoe                                                                |
| <b>Description</b> | This command associates a PPPoE policy on this interface.                                             |
| <b>Default</b>     | default                                                                                               |
| <b>Parameters</b>  | <i>pppoe-policy-name</i> — specifies a a PPPoE policy up to 32 characters in length on this interface |

## sap-session-limit

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sap-session-limit</b> <i>sap-session-limit</i><br><b>no sap-session-limit</b>           |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>pppoe                                                     |
| <b>Description</b> | This command specifies the number of PPPoE hosts per SAP allowed for this group-interface. |

---

|                   |                                                                                |
|-------------------|--------------------------------------------------------------------------------|
| <b>Default</b>    | 1                                                                              |
| <b>Parameters</b> | <i>sap-session-limit</i> — specifies the number of PPPoE hosts per SAP allowed |
| <b>Values</b>     | 1 to 20000                                                                     |

## session-limit

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>session-limit</b> <i>session-limit</i><br><b>no session-limit</b>               |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>pppoe                                             |
| <b>Description</b> | This command specifies the number of PPPoE hosts allowed for this group interface. |
| <b>Default</b>     | 1                                                                                  |
| <b>Parameters</b>  | <i>session-limit</i> — specifies the number of PPPoE hosts allowed                 |
| <b>Values</b>      | 1 to 20000                                                                         |

## 2.5.2.8 IES Interface ICMP Commands

### hold-time

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command will cause a delay in the activation of the associated IP interface by the specified number of seconds. The delay is invoked whenever the system attempts to bring the associated IP interface up, unless the <b>init-only</b> option is configured. If the <b>init-only</b> option is configured, the delay is only applied when the IP interface is first configured or after a system reboot.</p> <p>The <b>no</b> form of the command removes the command from the active configuration and removes the delay in activating the associated IP interface. If the configuration is removed during a delay period, the currently running delay will continue until it completes.</p> |
| <b>Parameters</b>  | <p><i>seconds</i> — the time delay, in seconds, to make the interface operational</p> <p><b>Values</b> 1 to 1200</p> <p><b>init-only</b> — specifies that the <b>down</b> delay is only applied when the interface is configured or after a reboot</p> <p><b>Values</b> 1 to 1200</p>                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command configures the rate for Internet Control Message Protocol (ICMP) redirect messages issued on the router interface.</p> <p>When routes are not optimal on this router and another router on the same subnetwork has a better route, the router can issue an ICMP redirect to alert the sending node that a better route is available.</p> <p>The <b>redirects</b> command enables the generation of ICMP redirects on the router interface. The rate at which ICMP redirects is issued can be controlled with the optional <i>number</i> and <i>seconds</i> parameters by indicating the maximum number of redirect messages that can be issued on the interface for a given time interval.</p> <p>By default, generation of ICMP redirect messages is enabled at a maximum rate of 100 per 10 second time interval. (<i>Default: redirects 100 10</i>)</p> <p>The <b>no</b> form of this command disables the generation of icmp redirects on the router interface.</p> |
| <b>Default</b>     | redirects 100 10 — Maximum of 100 redirect messages in 10 seconds                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command configures the rate for ICMP host and network destination unreachable messages issued on the router interface.</p> <p>The <b>unreachables</b> command enables the generation of ICMP destination unreachables on the router interface. The rate at which ICMP unreachables is issued can be controlled with the optional <i>number</i> and <i>time</i> parameters by indicating the maximum number of destination unreachable messages which can be issued on the interface for a given time interval.</p> <p>By default, generation of ICMP destination unreachable messages is enabled at a maximum rate of 10 per 60 second time interval.</p> <p>The <b>no</b> form of this command disables the generation of icmp destination unreachable messages on the router interface.</p> |
| <b>Default</b>     | unreachables 100 10                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <p><i>number</i> — the maximum number of ICMP unreachable messages to send. This parameter must be specified with the <i>seconds</i> parameter</p> <p><b>Values</b> 10 to 1000</p> <p><i>seconds</i> — the time frame in seconds used to limit the <i>number</i> of ICMP unreachable messages that can be issued</p> <p><b>Values</b> 1 to 60</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>This command configures the admin group membership of an interface. The user can apply admin groups to an IES, VPRN, network IP, or MPLS interface.</p> <p>Each single operation of the <b>admin-group</b> command allows a maximum of five (5) groups to be specified at a time. However, a maximum of 32 groups can be added to a given interface through multiple operations. Once an admin group is bound to one or more interface, its value cannot be changed until all bindings are removed.</p> <p>The configured admin-group membership will be applied in all levels/areas the interface is participating in. The same interface cannot have different memberships in different levels/areas.</p> <p>Only the admin groups bound to an MPLS interface are advertised in TE link TLVs and sub-TLVs when the <b>traffic-engineering</b> option is enabled in IS-IS or OSPF. IES and VPRN interfaces do not have their attributes advertised in TE TLVs.</p> <p>The <b>no</b> form of this command deletes one or more of the admin-group memberships of an interface. The user can also delete all memberships of an interface by not specifying a group name.</p> |
| <b>Parameters</b>  | <i>group-name</i> — Specifies the name of the group with up to 32 characters. The association of group name and value should be unique within an IP/MPLS domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command configures the SRLG membership of an interface. The user can apply SRLGs to an IES, VPRN, network IP, or MPLS interface.</p> <p>An interface can belong to up to 64 SRLG groups. However, each single operation of the <b>srlg-group</b> command allows a maximum of five (5) groups to be specified at a time. Once an SRLG group is bound to one or more interface, its value cannot be changed until all bindings are removed.</p> <p>The configured SRLG membership will be applied in all levels/areas the interface is participating in. The same interface cannot have different memberships in different levels/areas.</p> <p>Only the SRLGs bound to an MPLS interface are advertised in TE link TLVs and sub-TLVs when the <b>traffic-engineering</b> option is enabled in IS-IS or OSPF. IES and VPRN interfaces do not have their attributes advertised in TE TLVs.</p> <p>The <b>no</b> form of this command deletes one or more of the SRLG memberships of an interface. The user can also delete all memberships of an interface by not specifying a group name.</p> |
| <b>Parameters</b>  | <i>group-name</i> — Specifies the name of the group, up to 32 characters. The association of group name and value should be unique within an IP/MPLS domain.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

### 2.5.2.9 IES Interface IPv6 Commands

## ipv6

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ipv6</b>                                                         |
| <b>Context</b>     | config>service>ies>if                                                    |
| <b>Description</b> | This command enables the context to configure IPv6 for an IES interface. |

## address

|                      |                                                                                                                  |
|----------------------|------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>        | <b>address</b> <i>ipv6-address/prefix-length</i> [eui-64]<br><b>no address</b> <i>ipv6-address/prefix-length</i> |
| <b>Context</b>       | config>service>ies>if>ipv6                                                                                       |
| <b>Description</b>   | This command assigns an IPv6 address to the IES interface.                                                       |
| <b>Parameters</b>    | <i>ipv6-address/prefix-length</i> — specifies the IPv6 address on the interface                                  |
| <b>Values</b>        |                                                                                                                  |
| ipv6-address/prefix: | ipv6-address      x:x:x:x:x:x:x (eight 16-bit pieces)<br>x:x:x:x:x:d.d.d.d<br>x [0 to FFFF]H<br>d [0 to 255]D    |
| prefix-length        | 1 to 128                                                                                                         |

**eui-64** — When the **eui-64** keyword is specified, a complete IPv6 address from the supplied prefix and 64-bit interface identifier is formed. The 64-bit interface identifier is derived from MAC address on Ethernet interfaces. For interfaces without a MAC address, for example ATM interfaces, the Base MAC address of the chassis is used.

## dad-disable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| <b>Context</b>     | config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Description</b> | This command disables duplicate address detection (DAD) on a per-interface basis. This prevents the router from performing a DAD check on the interface. All IPv6 addresses of an interface with DAD disabled, immediately enter a preferred state, without checking for uniqueness on the interface. This is useful for interfaces which enter a looped state during troubleshooting and operationally disable themselves when the loop is detected, requiring manual intervention to clear the DAD violation.<br><br>The <b>no</b> form of the command turns off <b>dad-disable</b> on the interface. |
| <b>Default</b>     | no dad-disable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## dhcp6-relay

|                |                                  |
|----------------|----------------------------------|
| <b>Syntax</b>  | [ <b>no</b> ] <b>dhcp6-relay</b> |
| <b>Context</b> | config>service>ies>if>ipv6       |

**Description** This command enables the context to configure DHCPv6 relay parameters for the IES interface.

The **no** form of the command disables DHCPv6 relay.

## lease-populate

**Syntax** **lease-populate** [*nbr-of-leases*]  
**lease-populate** [*nbr-of-leases*] **route-populate** [pd] na [ta]  
**lease-populate** [*nbr-of-leases*] **route-populate** pd [na] [ta] [exclude]  
**lease-populate** [*nbr-of-leases*] **route-populate** [pd] [na] ta  
**no lease-populate**

**Context** config>service>ies>if>ipv6>dhcp-relay

**Description** This command specifies the maximum number of DHCPv6 lease states allocated by the DHCPv6 relay function, allowed on this interface.

Optionally, by specifying “route-populate” parameter, system could:

- Create routes based on the IA\_PD/IA\_NA/IA\_TA prefix option in relay-reply message.
- Create black hole routes based on OPTION\_PD\_EXCLUDE in IA\_PD in relay-reply message.

These routes could be redistributed into IGP/BGP by using route-policy, following protocol types that could be used in “from protocol”:

- dhcpv6-pd
- dhcpv6-na
- dhcpv6-ta
- dhcpv6-pd-excl

**Parameters** *nbr-of-entries* — Defines the number lease state table entries allowed for this interface. If this parameter is omitted, only a single entry is allowed. Once the maximum number of entries has been reached, subsequent lease state entries are not allowed and subsequent DHCPv6 ACK messages are discarded.

**Values** 1 to 8000

**route-populate** — Specifies the route populate parameter.

**Values** pd/na/ta — Create route based on specified option.  
 exclude — Create blackhole route based on OPTION\_PD\_EXCLUDE.

## neighbor-resolution

**Syntax** [**no**] neighbor-resolution

| <b>Description</b> | This command specifies a list of servers where DHCPv6 requests will be forwarded. The list of servers can entered as either IP addresses or fully qualified domain names. There must be at least one server specified for DHCPv6 relay to work. If there are multiple servers then the request is forwarded to all of the servers in the list. There can be a maximum of 8 DHCPv6 servers configured. |               |                                     |  |                   |  |                |  |               |
| <b>Default</b>     | no server                                                                                                                                                                                                                                                                                                                                                                                             |               |                                     |  |                   |  |                |  |               |
| <b>Parameters</b>  | <i>ipv6-address</i> — Specifies the IPv6 addresses of the DHCP servers where the DHCPv6 requests will be forwarded. Up to 8 addresses can be specified.                                                                                                                                                                                                                                               |               |                                     |  |                   |  |                |  |               |

| <b>Syntax</b>      | <b>duid</b> <i>duid</i> [ <b>iaid</b> <i>iaid</i> ]<br><b>no duid</b>                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if>ipv6>dhcp6>pfx-delegate>prefix                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | This command configures the DHCP Unique Identifier (DUID) of the DHCP client.                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>duid</i> — Specifies the ID of the requesting router. If set to a non zero value the prefix defined will only be delegated to this router. If set to zero, the prefix will be delegated to any requesting router.</p> <p><b>iaid</b> <i>iaid</i> — Specifies the identity association identification (IAID) from the requesting router that needs to match in order to delegate the prefix defined in this row. If set to 0 no match on the received IAID is done.</p> |

## preferred-lifetime

|                    |                                                                                                                                                                                                                              |

| <b>Description</b> | This command specifies whether “packet-too-big” ICMPv6 messages should be sent. When enabled, ICMPv6 “packet-too-big” messages are generated by this interface.<br><br>The <b>no</b> form of the command disables the sending of ICMPv6 “packet-too-big” messages. |
| <b>Default</b>     | 100 10                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>number</i> — specifies the number of “packet-too-big” ICMPv6 messages to send in the time frame specified by the <i>seconds</i> parameter<br><br><b>Values</b> 10 to 1000<br><br><b>Default</b> 100                                                             |

*seconds* — specifies the time frame in seconds that is used to limit the number of “packet-too-big” ICMPv6 messages issued

**Values** 1 to 60

**Default** 10

## param-problem

**Syntax** **param-problem** [*number seconds*]  
**no packet-too-big**

**Context** config>service>ies>if>ipv6>icmp6

**Description** This command specifies whether “parameter-problem” ICMPv6 messages should be sent. When enabled, “parameter-problem” ICMPv6 messages are generated by this interface.

The **no** form of the command disables the sending of “parameter-problem” ICMPv6 messages.

**Default** 100 10

**Parameters** *number* — specifies the number of “parameter-problem” ICMPv6 messages to send in the time frame specified by the *seconds* parameter

**Values** 10 to 1000

**Default** 100

*seconds* — Specifies the time frame in seconds that is used to limit the number of “parameter-problem” ICMPv6 messages issued.

**Values** 1 to 60

**Default** 10

## redirects

**Syntax** **redirects** [*number seconds*]  
**no redirects**

**Context** config>service>ies>if>ipv6>icmp6

**Description** This command configures ICMPv6 redirect messages. When enabled, ICMPv6 redirects are generated when routes are not optimal on this router and another router on the same subnetwork has a better route in order to alert that node that a better route is available.

When disabled, ICMPv6 redirects are not generated.

**Default** 100 10

## proxy-nd-policy

|                    |                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>proxy-nd-policy</b> <i>policy-name</i> [ <i>policy-name...</i> (up to 5 max)]<br><b>no proxy-nd-policy</b>                                                                                                                                                                                                                                                    |
| <b>Context</b>     | config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | This command applies a proxy neighbor discovery policy for the interface.                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <i>policy-name</i> — Specifies an existing neighbor discovery policy name. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes. The specified policy name(s) must already be defined. |

## neighbor

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>neighbor</b> <i>ipv6-address mac-address</i><br><b>no neighbor</b> <i>ipv6-address</i> |
| <b>Context</b>     | config>service>ies>if>ipv6                                                                |
| <b>Description</b> | This command configures IPv6-to-MAC address mapping on the IES interface.                 |
| <b>Default</b>     | n/a                                                                                       |
| <b>Parameters</b>  | <i>ipv6-address</i> — The IPv6 address of the interface for which to display information. |

### Values

ipv6-address:    x:x:x:x:x:x:x (eight 16-bit pieces)  
                  x:x:x:x:x:d.d.d.d  
                  x - [0..FFFF]H  
                  d - [0..255]D

*mac-address* — Specifies the 48-bit MAC address for the IPv6-to-MAC address mapping in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

## neighbor-limit

|                |                                                                                                                 |
|----------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>neighbor-limit</b> <i>limit</i> [ <b>log-only</b> ] [ <b>threshold percent</b> ]<br><b>no neighbor-limit</b> |
| <b>Context</b> | config>service>ies>if>ipv6                                                                                      |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the maximum amount of dynamic IPv6 neighbor entries that can be learned on an IP interface.</p> <p>When the number of dynamic neighbor entries reaches the configured percentage of this limit, an SNMP trap is sent. When the limit is exceeded, no new entries are learned until an entry expires and traffic to these destinations will be dropped. Entries that have already been learned will be refreshed.</p> <p>The <b>no</b> form of the command removes the <b>neighbor-limit</b>.</p>                                                                            |
| <b>Default</b>     | 90 percent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <p><b>log-only</b> — Enables the warning message to be sent at the specified threshold percentage, and also when the limit is exceeded. However, entries above the limit will be learned.</p> <p><i>percent</i> — The threshold value (as a percentage) that triggers a warning message to be sent.</p> <p><b>Values</b> 0 to 100</p> <p><i>limit</i> — The number of entries that can be learned on an IP interface expressed as a decimal integer. If the limit is set to 0, dynamic neighbor learning is disabled and no dynamic neighbor entries are learned.</p> <p><b>Values</b> 0 to 102400</p> |

## backup

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] backup</b> <i>ip-address</i>                                   |
| <b>Context</b>     | config>service>ies>if>ipv6>vrrp                                        |
| <b>Description</b> | This command configures virtual router IP addresses for the interface. |

## init-delay

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>init-delay</b> <i>seconds</i><br><b>no init-delay</b>                                                              |
| <b>Context</b>     | config>service>ies>if>ipv6>vrrp                                                                                       |
| <b>Description</b> | This command configures a VRRP initialization delay timer.                                                            |
| <b>Default</b>     | no init-delay                                                                                                         |
| <b>Parameters</b>  | <p><i>seconds</i> — specifies the initialization delay timer for VRRP, in seconds</p> <p><b>Values</b> 1 to 65535</p> |

---

## mac

|                    |                                                                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mac</b> <i>mac-address</i><br><b>no mac</b>                                                                                                                                                                                                                                     |
| <b>Context</b>     | config>service>ies>if>ipv6>vrrp                                                                                                                                                                                                                                                    |
| <b>Description</b> | <p>This command assigns a specific MAC address to an IES IP interface.</p> <p>The <b>no</b> form of the command returns the MAC address of the IP interface to the default value.</p>                                                                                              |
| <b>Default</b>     | The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).                                                                                                         |
| <b>Parameters</b>  | <i>mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. |

## master-int-inherit

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] master-int-inherit</b>                                                                     |
| <b>Context</b>     | config>service>ies>if>ipv6>vrrp                                                                    |
| <b>Description</b> | This command allows the master instance to dictate the master down timer (non-owner context only). |
| <b>Default</b>     | no master-int-inherit                                                                              |

## message-interval

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers participating as a virtual router. Any VRRP advertisement message received with an Advertisement Interval field different than the virtual router instance configured message-interval value will be silently discarded.</p> <p>The message-interval command is available in both non-owner and owner <b>vrrp</b> <i>virtual-router-id</i> nodal contexts. If the message-interval command is not executed, the default message interval of 1 second will be used.</p> <p>The <b>no</b> form of this command restores the default message interval value of 1 second to the virtual router instance.</p> |

| <b>Description</b> | This command creates VRRP control policies. The VRRP policy ID must be created by the policy command prior to association with the virtual router instance. |

The policy command provides the ability to associate a VRRP priority control policy to a virtual router instance. The policy may be associated with more than one virtual router instance. The priority events within the policy either override or diminish the base-priority dynamically affecting the in-use priority. As priority events clear in the policy, the in-use priority may eventually be restored to the base-priority value.

The policy command is only available in the non-owner **vrrp** *virtual-router-id* nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed by VRRP priority control policies. For non-owner virtual router instances, if the policy command is not executed, the base-priority will be used as the in-use priority.

The **no** form of this command removes any existing VRRP priority control policy association from the virtual router instance. All such associations must be removed prior to the policy being deleted from the system.

|                   |                                                                                                                                                                                                                                                  |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | n/a                                                                                                                                                                                                                                              |
| <b>Parameters</b> | <i>vrrp-policy-id</i> — The vrrp-policy-id parameter associated the corresponding VRRP priority control policy-id with the virtual router instance. The vrrp-policy-id must already exist in the system for the policy command to be successful. |
| <b>Values</b>     | 1 to 9999                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>The preempt mode value controls whether a specific backup virtual router preempts a lower priority master.</p> <p>When preempt is enabled, the virtual router instance overrides any non-owner master with an “in use” message priority value less than the virtual router instance in-use priority value. If preempt is disabled, the virtual router only becomes master if the master down timer expires before a VRRP advertisement message is received from another virtual router.</p> <p>The IP address owner will always become master when available. Preempt mode cannot be disabled on the owner virtual router.</p> <p>The default value for preempt mode is enabled.</p> |
| <b>Default</b>     | preempt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Syntax</b>      | <b>[no] standby-forwarding</b>                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if>ipv6>vrrp                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command allows the forwarding of packets by a standby router.</p> <p>The <b>no</b> form of the command specifies that a standby router should not forward traffic sent to virtual router's MAC address. However, the standby router should forward traffic sent to the standby router's real MAC address.</p> |
| <b>Default</b>     | no standby-forwarding                                                                                                                                                                                                                                                                                                 |

## telnet-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] telnet-reply</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>ies>if>ipv6>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command enables the non-owner master to reply to TCP port 23 Telnet requests directed at the virtual router instances IP addresses. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parental IP interface or based on the Telnet source host address). Proper login and CLI command authentication is still enforced.</p> <p>When telnet-reply is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.</p> |

Non-owner backup virtual routers never respond to Telnet requests regardless of the telnet-reply configuration.

The **telnet-reply** command is only available in non-owner VRRP nodal context. If the telnet-reply command is not executed, Telnet packets to the virtual router instance IP addresses will be silently discarded.

The **no** form of this command restores the default operation of discarding all Telnet packets destined to the non-owner virtual router instance IP addresses.

**Default** no telnet-reply

## traceroute-reply

**Syntax** [no] traceroute-reply

**Context** config>service>ies>if>ipv6>vrrp

**Description** This command is valid only if the VRRP virtual router instance associated with this entry is a non-owner.

When this command is enabled, a non-owner master can reply to traceroute requests directed to the virtual router instance IP addresses.

A non-owner backup virtual router never responds to such traceroute requests regardless of the **trace-route-reply** status.

**Default** no traceroute-reply

## 2.5.2.10 IES Spoke SDP Commands

### spoke-sdp

**Syntax** [no] spoke-sdp sdp-id[:vc-id] [vc-type {ether | ipipe}] [create]

**Context** config>service>ies>if  
config>service>ies>redundant-interface

**Description** This command binds a service to an existing Service Distribution Point (SDP).

A spoke SDP is treated like the equivalent of a traditional bridge “port” where flooded traffic received on the spoke SDP is replicated on all other “ports” (other spoke and mesh SDPs or SAPs) and not transmitted on the port it was received.

The SDP has an operational state which determines the operational state of the SDP within the service. For example, if the SDP is administratively or operationally down, the SDP for the service will be down.

The SDP must already be defined in the **config>service>sdp** context in order to associate an SDP with an IES service. If the **sdp sdp-id** is not already configured, an error message is generated. If the *sdp-id* does exist, a binding between that *sdp-id* and the service is created.

SDPs must be explicitly associated and bound to a service. If an SDP is not bound to a service, no far-end devices can participate in the service.

The **no** form of this command removes the SDP binding from the service. The SDP configuration is not affected; only the binding of the SDP to a service. Once removed, no packets are forwarded to the far-end router. The spoke SDP must be shut down first before it can be deleted from the configuration.

|                      |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>       | No <i>sdp-id</i> is bound to a service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Special Cases</b> | <b>IES</b> — At most, only one <i>sdp-id</i> can be bound to an IES service.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>    | <p><i>sdp-id</i> — The SDP identifier. Allowed values are integers in the range of 1 and 17407 for existing SDPs.</p> <p><i>vc-id</i> — The virtual circuit identifier.</p> <p><b>Values</b> 1 to 4294967295</p> <p><i>vc-type</i> — The encapsulation and pseudowire type for the spoke-sdp.</p> <p><b>Values</b> ether: specifies Ethernet pseudowire as the type of virtual circuit (VC) associated with the SDP binding<br/>         ipipe: specifies lpipe pseudowire as the type of virtual circuit (VC) associated with the SDP binding</p> <p><b>Default</b> ether</p> |

## egress

|                    |                                                                        |
|--------------------|------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>egress</b>                                                          |
| <b>Context</b>     | config>service>ies>if>spoke-sdp<br>config>service>ies>red-if>spoke-sdp |
| <b>Description</b> | This command configures the egress SDP context.                        |

| <b>Description</b> | <p>This command is used to redirect pseudowire packets to an egress port queue-group for the purpose of shaping.</p> <p>The egress pseudowire shaping provisioning model allows the mapping of one or more pseudowires to the same instance of queues, or policers and queues, which are defined in the queue-group template.</p> <p>Operationally, the provisioning model consists of the following steps:</p> <ol style="list-style-type: none"> <li>1. Create an egress queue-group template and configure queues only or policers and queues for each FC that needs to be redirected.</li> <li>2. Apply the queue-group template to the network egress context of all ports where there exists a network IP interface on which the pseudowire packets can be forwarded. This creates one instance of the template on the egress of the port. One or more instances of the same template can be created.</li> <li>3. Configure FC-to-policer or FC-to-queue mappings together with the redirect to a queue-group in the egress context of a network QoS policy. No queue-group name is specified in this step, which means the same network QoS policy can redirect different pseudowires to different queue-group templates.</li> <li>4. Apply this network QoS policy to the egress context of a spoke-SPD inside a service or to the egress context of a pseudowire template and specify the redirect queue-group name.</li> </ol> |

One or more spoke-SPDs can have their FCs redirected to use queues only or queues and policers in the same queue-group instance.

The following are the constraints and rules of this provisioning model:

1. When a pseudowire FC is redirected to use a queue or a policer and a queue in a queue-group and the queue-group name does not exist, the association is failed at the time the user associates the egress context of a spoke-SPD to the named queue-group. In such a case, the pseudowire packet will be fed directly to the corresponding egress queue for that FC used by the IP network interface on which the pseudowire packet is forwarded. This queue can be a queue-group queue, or the egress shared queue for that FC defined in the network-queue policy applied to the egress of this port. This is the existing implementation and default behavior for a pseudowire packet.

2. When a pseudowire FC is redirected to use a queue or a policer, and a queue in a queue-group and the queue-group name exists, but the policer-id and/or the queue-id is not defined in the queue-group template, the association is failed at the time the user associates the egress context of a spoke-SPD to the named queue-group. In such a case, the pseudowire packet will be fed directly to the corresponding egress queue for that FC used by the IP network interface the pseudowire packet is forwarded on.
3. When a pseudowire FC is redirected to use a queue, or a policer and a queue in a queue-group, and the queue-group name exists and the policer-id or policer-id plus queue-id exist, it is not required to check that an instance of that queue-group exists in all egress network ports which have network IP interfaces. The handling of this is dealt with in the data path as follows:

When a pseudowire packet for that FC is forwarded and an instance of the referenced queue-group name exists on that egress port, the packet is processed by the queue-group policer and will then be fed to the queue-group queue.

When a pseudowire packet for that FC is forwarded and an instance of the referenced queue-group name does not exist on that egress port, the pseudowire packet will be fed directly to the corresponding egress shared queue for that FC defined in the network-queue policy applied to the egress of this port.

- If a network QoS policy is applied to the egress context of a pseudowire, any pseudowire FC, which is not explicitly redirected in the network QoS policy, will have the corresponding packets feed directly the corresponding the egress shared queue for that FC defined in the network-queue policy applied to the egress of this port.

When the queue-group name the pseudowire is redirected to exists and the redirection succeeds, the marking of the packet DEI/dot1p/DSCP and the tunnel DEI/dot1p/DSCP/EXP is performed; according to the relevant mappings of the (FC, profile) in the egress context of the network QoS policy applied to the pseudowire. This is true regardless, whether an instance of the queue-group exists or not on the egress port to which the pseudowire packet is forwarded. If the packet profile value changed due to egress child policer CIR profiling, the new profile value is used to mark the packet DEI/dot1p and the tunnel DEI/dot1p/EXP, and the DSCP/prec will be remarked if **enable-dscp-prec-marking** is enabled under the policer.

When the queue-group name the pseudowire is redirected does not exist, the redirection command is failed. In this case, the marking of the packet DEI/dot1p/DSCP and the tunnel DEI/dot1p/DSCP/EXP fields is performed according to the relevant commands in the egress context of the network QoS policy applied to the network IP interface to which the pseudowire packet is forwarded.

The **no** version of this command removes the redirection of the pseudowire to the queue-group.

**Parameters** *network-policy-id* — Specifies the network policy identification. The value uniquely identifies the policy on the system.

**Values** 1 to 65535

*queue-group-name* — This optional parameter specifies that the *queue-group-name* will be used for all egress forwarding class redirections within the network QoS policy ID. The specified *queue-group-name* must exist as a port egress queue group on the port associated with the IP interface.

*instance-id* — specifies the identification of a specific instance of the queue-group

**Values** 1 to 16384

| <b>Description</b> | <p>This command enables the use of the hash label on a VLL, VPLS, or VPRN service bound to any MPLS-type encapsulated SDP, as well as to a VPRN service using <b>auto-bind-tunnel</b> with the <b>resolution-filter</b> configures as any MPLS tunnel type. This feature is not supported on a service bound to a GRE SDP or for a VPRN service using the autobind mode with the gre option.</p> <p>When this feature is enabled, the ingress data path is modified such that the result of the hash on the packet header is communicated to the egress data path for use as the value of the label field of the hash label. The egress data path appends the hash label at the bottom of the stack (BoS) and sets the S-bit to 1 to indicate that.</p> <p>In order to allow for applications whereby the egress LER infers the presence of the hash label implicitly from the value of the label, the Most Significant Bit (MSB) of the result of the hash is set before copying into the hash label. This means that the value of the hash label will always be in the range [524,288 to 1,048,575] and will not overlap with the signaled/static LSP and signaled/static service label ranges. This also guarantees that the hash label will not match a value in the reserved label range.</p> <p>The (unmodified) result of the hash continues to be used for the purpose of ECMP and LAG spraying of packets locally on the ingress LER. For VLL services, the result of the hash is overwritten and the ECMP and LAG spraying will be based on service-id when ingress SAP shared queuing is not enabled. However, the hash label will still reflect the result of the hash such that an LSR can use it to perform fine grained load balancing of VLL pseudowire packets.</p> <p>Packets that are generated in CPM and forwarded labeled within the context of a service (for example, OAM packets) must also include a hash label at the BoS and set the S-bit accordingly.</p> <p>The TTL of the hash label is set to a value of 0.</p> <p>The user enables the signaling of the hash-label capability under a VLL spoke-sdp, a VPLS spoke-sdp or mesh-sdp, or an IES/VPRN spoke interface by adding the <b>signal-capability</b> option. In this case, the decision whether to insert the hash label on the user and control plane packets by the local PE is solely determined by the outcome of the signaling process and can override the local PE configuration. The following are the procedures:</p> <ul style="list-style-type: none"> <li>• The local PE will insert the flow label interface parameters sub-TLV with F=1 in the PW ID FEC element in the label mapping message for that spoke-sdp or mesh-sdp.</li> <li>• If the remote PE includes this sub-TLV with F=1 or F=0, then local PE must insert the hash label in the user and control plane packets.</li> <li>• If remote PE does not include this sub-TLV (for example, it does not support it, or it is supported but the user did not enable the <b>hash-label</b> option or the <b>signal-capability</b> option), then the local PE establishes the PW but must not insert the hash label in the user and control packets over that spoke-sdp or mesh-sdp. If the remote PE does not support the <b>signal-capability</b> option, then there are a couple of possible outcomes:</li> </ul> |

- If the **hash-label** option was enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the PW packets received by the local PE will have the hash label included. These packets must be dropped. The only way to solve this is to disable the signaling capability option on the local node which will result in the insertion of the hash label by both PE nodes.
- If the **hash-label** option is not supported or was not enabled on the local configuration of the spoke-sdp or mesh-sdp at the remote PE, the PW received by the local PE will not have the hash label included.
- The user can enable or disable the signal-capability option in CLI as needed. When doing so, the router must withdraw the label it sent to its peer and send a new label mapping message with the new value of the F bit in the flow label interface parameters sub-TLV of the PW ID FEC element.

The **no** form of this command disables the use of the hash label.

|                   |                                                                                                                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no hash-label                                                                                                                                                                                                  |
| <b>Parameters</b> | <b>signal-capability</b> — Enables the signaling and negotiation of the use of the hash label between the local and remote PE nodes. The <b>signal-capability</b> option is not supported on a VPRN spoke-sdp. |

## ingress

|                    |                                                                               |

**Description** This command is used to redirect pseudowire packets to an ingress forwarding plane queue-group for the purpose of rate-limiting.

The ingress pseudowire rate-limiting feature uses a policer in queue-group provisioning model. This model allows the mapping of one or more pseudowires to the same instance of policers, which are defined in a queue-group template.

Operationally, the provisioning model in the case of the ingress pseudowire shaping feature consists of the following steps:

- Step 1.** Create an ingress queue-group template and configure policers for each FC that needs to be redirected and optionally, for each traffic type (unicast, broadcast, unknown, or multicast).
- Step 2.** Apply the queue-group template to the network ingress forwarding plane where there exists a network IP interface to which the pseudowire packets can be received. This creates one instance of the template on the ingress of the FP. One or more instances of the same template can be created.
- Step 3.** Configure FC-to-policer mappings together with the policer redirect to a queue-group in the ingress context of a network QoS policy. No queue-group name is specified in this step, which means the same network QoS policy can redirect different pseudowires to different queue-group templates.
- Step 4.** Apply this network QoS policy to the ingress context of a spoke-SDP inside a service, or to the ingress context of a pseudowire template, and specify the redirect queue-group name.
- Step 5.** One or more spoke-SDPs can have their FCs redirected to use policers in the same policer queue-group instance.

The following are the constraints and rules of this provisioning model when used in the ingress pseudowire rate-limiting feature:

- Step 1.** When a pseudowire FC is redirected to use a policer in a named policer queue-group and the queue-group name does not exist, the association is failed at the time the user associates the ingress context of a spoke-SDP to the named queue-group. In such a case, the pseudowire packet will feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
- Step 2.** When a pseudowire FC is redirected to use a policer in a named policer queue-group and the queue-group name exists but the policer-id is not defined in the queue-group template, the association is failed at the time the user associates the ingress context of a spoke-SDP to the named queue-group. In such a case, the pseudowire packet will feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
- Step 3.** When a pseudowire FC is redirected to use a policer in a named policer queue-group and the queue-group name exists and the policer-id is defined in the queue-group template, it is not required to check that an instance of that queue-group exists in all ingress FPs which have network IP interfaces. The handling of this is dealt with in the data path as follows:

When a pseudowire packet for that FC is received and an instance of the referenced queue-group name exists on that FP, the packet is processed by the policer and will then feed the per-FP ingress shared queues referred to as *policer-output-queues*.

When a pseudowire packet for that FC is received and an instance of the referenced queue-group name does not exist on that FP, the pseudowire packets will be fed directly into the corresponding ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.

- If a network QoS policy is applied to the ingress context of a pseudowire, any pseudowire FC which is not explicitly redirected in the network QoS policy will have the corresponding packets feed directly the ingress network shared queue for that FC defined in the network-queue policy applied to the ingress of the MDA/FP.
- If no network QoS policy is applied to the ingress context of the pseudowire, then all packets of the pseudowire will feed:

the ingress network shared queue for the packet FC defined in the network-queue policy applied to the ingress of the MDA/FP. This is the default behavior.

a queue-group policer followed by the per-FP ingress shared queues referred to as *policer-output-queues* if the ingress context of the network IP interface from which the packet is received is redirected to a queue-group (csc-policing). The only exceptions to this behavior are for packets received from a IES/VP RN spoke interface and from an R-VPLS spoke-SPD, which is forwarded to the R-VPLS IP interface. In these two cases, the ingress network shared queue for the packet FC defined in the network-queue policy applied to the ingress of the MDA/FP is used.

When a pseudowire is redirected to use a policer queue-group, the classification of the packet for the purpose of FC and profile determination is performed according to default classification rule or the QoS filters defined in the ingress context of the network QoS policy applied to the pseudowire. This is true regardless of whether an instance of the named policer queue-group exists on the ingress FP on which the pseudowire packet is received. The user can apply a QoS filter matching the dot1.p in the VLAN tag corresponding to the Ethernet port encapsulation, the EXP in the outer label when the tunnel is an LSP, the DSCP in the IP header if the tunnel encapsulation is GRE, and the DSCP in the payload IP header if the user enabled the **ler-use-dscp** option and the pseudowire terminates in IES or VP RN service (spoke-interface).

When the policer queue-group name the pseudowire is redirected does not exist, the redirection command is failed. In this case, the packet classification is performed according to default classification rule or the QoS filters defined in the ingress context of the network QoS policy applied to the network IP interface on which the pseudowire packet is received.

The **no** version of this command removes the redirection of the pseudowire to the queue-group.

**Parameters**    *network-policy-id* — Specifies the network policy identification. The value uniquely identifies the policy on the system.

**Values**        1 to 65535

**fp-redirect-group** *queue-group-name* — specifies the name of the queue group template up to 32 characters in length

**ingress-instance** *instance-id* — specifies the identification of a specific instance of the queue-group

**Values** 1 to 16384

## vc-label

**Syntax** [no] **vc-label** *ingress-vc-label*

**Context** config>service>ies>if>spoke-sdp>ingress  
config>service>ies>red-if>spoke-sdp>ingress

**Description** This command configures the static MPLS VC label used by the far-end device to send packets to this device in this service via this SDP.

**Parameters** *ingress-vc-label* — a VC ingress value that indicates a specific connection

**Values** 2048 to 18431

## accounting-policy

**Syntax** **accounting-policy** *acct-policy-id*  
**no accounting-policy**

**Context** config>service>ies>if>spoke-sdp

**Description** This command configures an accounting-policy.

**Parameters** *acct-policy-id* — specifies an accounting policy ID

**Values** 1 to 99

## app-profile

**Syntax** **app-profile** *app-profile-name*  
**no app-profile**

**Context** config>service>ies>if>spoke-sdp

**Description** This command configures the application profile name.

**Parameters** *app-profile-name* — specifies the application profile name

---

## bfd-enable

|                    |                                                                                                                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>bfd-enable</b><br><b>no bfd-enable</b>                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>ies>if>spoke-sdp                                                                                                                                                                                                                      |
| <b>Description</b> | This command enables VCCV BFD on the PW associated with the VLL, BGP VPWS, or VPLS service. The parameters for the BFD session are derived from the named BFD template, which must have been first configured using the <b>bfd-template</b> command. |

## bfd-template

|                    |                                                                                                                                                                                                                                                                                                                                                             |

| <b>Syntax</b>      | <b>bfd-template</b> <i>name</i><br><b>no bfd-template</b>                                                                                                                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>spoke-sdp                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command configures a named BFD template to be used by VCCV BFD on PWs belonging to the VLL, BGP VPWS, or VPLS service. The template specifies parameters, such as the minimum transmit and receive control packet timer intervals, to be used by the BFD session. Template parameters are configured under the <b>config&gt;router&gt;bfd</b> context. |
| <b>Default</b>     | no bfd-template                                                                                                                                                                                                                                                                                                                                             |
| <b>Parameters</b>  | <i>name</i> — A text string name for the template of up to 32 characters in printable 7-bit ASCII, enclosed in double quotes.                                                                                                                                                                                                                               |

## collect-stats

|                    |                                                         |
|--------------------|---------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] collect-stats</b>                               |
| <b>Context</b>     | config>service>ies>if>spoke-sdp                         |
| <b>Description</b> | This command enables or disables statistics collection. |

## control-channel-status

|                    |                                                                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] control-channel-status</b>                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>ies>if>spoke-sdp                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command enables the configuration of static pseudowire status signaling on a spoke-SDP for which signaling for its SDP is set to OFF.</p> <p>A control-channel-status no shutdown is allowed only if all of the following are true:</p> |

- The system is using network chassis mode D
- SDP signaling is off.
- The control-word is enabled (the control-word is disabled by default)
- The service type is Epipe, Apipe, VPLS, Cpipe, or IES/VP RN
- Mate SDP signaling is off (in vc-switched services)
- The pw-path-id is configured for this spoke-SDP.

The **no** form of this command removes control channel status signaling from a spoke-SDP. It can only be removed if control channel status is shut down.

**Default** no control-channel-status

## acknowledgment

**Syntax** [no] acknowledgment

**Context** config>service>ies>if>spoke-sdp>control-channel-status

**Description** This command enables the acknowledgment of control channel status messages. By default, no acknowledgment packets are sent.

## refresh-timer

**Syntax** refresh-timer *value*  
no refresh-timer

**Context** config>service>ies>if>spoke-sdp>control-channel-status

**Description** This command configures the refresh timer for control channel status signaling packets. By default, no refresh packets are sent.

**Default** no refresh-timer

**Parameters** *value* — specifies the refresh timer value

|                |                     |
|----------------|---------------------|
| <b>Values</b>  | 10 to 65535 seconds |
| <b>Default</b> | 0 (off)             |

## request-timer

**Syntax** request-timer *timer1* retry-timer *timer2* timeout-multiplier *multiplier*  
no request-timer

**Context** config>service>ies>if>spoke-sdp>control-channel-status

---

|                           |                                                                                                                                                                                                                                                                                                           |
|---------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b>        | This command configures the control channel status request mechanism. When it is configured, control channel status request procedures are used. These augment the procedures for control channel status messaging from RFC 6478. This command is mutually exclusive with a non-zero refresh-timer value. |
| <b>Parameters</b>         | <i>timer1</i> — specifies the interval at which pseudowire status messages, including a reliable delivery TLV, with the “request” bit set, are sent                                                                                                                                                       |
| <b>Values</b>             | 10 to 65535 seconds                                                                                                                                                                                                                                                                                       |
| <b>retry-timer</b>        | <i>timer2</i> — Specifies the timeout interval if no response to a pseudowire status request is received. This parameter must be configured. A value of zero (0) disables retries.                                                                                                                        |
| <b>Values</b>             | 0, 3 to 60 seconds                                                                                                                                                                                                                                                                                        |
| <b>timeout-multiplier</b> | <i>multiplier</i> — If a requesting node does not receive a valid response to a pseudowire status request within this multiplier times the retry timer, then it will assume the pseudowire is down. This parameter is optional.                                                                           |
| <b>Values</b>             | 3 to 20 seconds                                                                                                                                                                                                                                                                                           |

## control-word

|                    |                                                                                                                                                                                                                                                                            |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] control-word</b>                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command associates a transit AA subscriber IP policy to the service. The transit IP policy must be defined prior to associating the policy with a SAP in the <b>config&gt;application assurance&gt;group&gt;policy&gt;transit-ip-policy</b> context.</p> <p>Transit AA subscribers are managed by the system through this service policy, which determines how transit subs are created and removed for that service.</p> |

The **no** form of the command removes the association of the policy to the service.

|                   |                                                                                                 |
|-------------------|-------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no transit-ip-policy                                                                            |
| <b>Parameters</b> | <i>ip-aasub-policy-id</i> — specifies an integer identifying an IP transit IP profile entry     |
| <b>Values</b>     | 1 to 65535                                                                                      |
|                   | <i>prefix-aasub-policy-id</i> — specifies an integer identifying a prefix transit profile entry |
| <b>Values</b>     | 1 to 65535                                                                                      |

| <b>Description</b> | <p>This command creates a Service Access Point (SAP) within a service. A SAP is a combination of port and encapsulation parameters which identifies the service access point on the interface and within the router. Each SAP must be unique.</p> <p>All SAPs must be explicitly created. If no SAPs are created within a service or on an IP interface, a SAP will not exist on that object.</p> <p>Enter an existing SAP without the <b>create</b> keyword to edit SAP parameters. The SAP is owned by the service in which it was created.</p> <p>A SAP can only be associated with a single service. A SAP can only be defined on a port that has been configured as an access port using the <b>config interface port-type port-id mode access</b> command. For the 7750 SR, channelized TDM ports are always access ports.</p> <p>If a port is shutdown, all SAPs on that port become operationally down. When a service is shutdown, SAPs for the service are not displayed as operationally down although all traffic traversing the service will be discarded. The operational state of a SAP is relative to the operational state of the port on which the SAP is defined.</p> <p>You can configure an IES interface as a loopback interface by issuing the <b>loopback</b> command instead of the <b>sap sap-id</b> command. The loopback flag cannot be set on an interface where a SAP is already defined and a SAP cannot be defined on a loopback interface.</p> |

The **no** form of this command deletes the SAP with the specified port. When a SAP is deleted, all configuration parameters for the SAP will also be deleted. For Internet Enhanced Service (IES), the IP interface must be shutdown before the SAP on that interface may be removed. The no form of this command causes the ptp-hw-assist to be disabled.

**Default** No SAPs are defined.

**Special Cases** **IES** — For the 7750 SR, an IES SAP can be defined with Ethernet ports, SONET/SDH or TDM channels. For the 7450 ESS, IES SAP can be defined with Ethernet or SONET/SDH ports. A SAP is defined within the context of an IP routed interface. Each IP interface is limited to a single SAP definition. For the 7750 SR, group interfaces allow more than one SAP. Attempts to create a second SAP on an IP interface will fail and generate an error; the original SAP will not be affected.

Command syntax for the 7750 SR: **sap ipsec-id.private | public:tag** associates an IPSec group SAP with this interface. This is the public side for an IPSec tunnel. Tunnels referencing this IPSec group in the private side may be created if their local IP is in the subnet of the interface subnet and the routing context specified matches with the one of the interface.

This context will provide a SAP to the tunnel. The operator may associate an ingress and egress QoS policies as well as filters and virtual scheduling contexts. Internally this creates an Ethernet SAP that will be used to send and receive encrypted traffic to and from the MDA. Multiple tunnels can be associated with this SAP. The “tag” will be a dot1q value. The operator may see it as an identifier. The range is limited to 1 to 4095.

**Parameters** *sap-id* — specifies the physical port identifier portion of the SAP definition

*port-id* — specifies the physical port ID

If the card in the slot has Media Dependent Adapters (MDAs) installed, the *port-id* must be in the slot\_number/MDA\_number/port\_number format. For example, 1/1/1 specifies port 1 on MDA 1 in slot 1.

The *port-id* must reference a valid port type. When the *port-id* parameter represents SONET/SDH and TDM channels (7750 SR), the port ID must include the channel ID. A period “.” separates the physical port from the *channel-id*. The port must be configured as an access port.

If the SONET/SDH port is configured as clear-channel then only the port is specified.

| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>if>spoke-sdp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | <p>This command associates an AARP instance with a multi-homed SAP or spoke SDP. This instance uses the same AARP ID in the same node or in a peer node (pre-configured) to provide traffic flow and packet asymmetry removal for a multi-homed SAP or spoke SDP.</p> <p>The type specifies the role of this service point in the AARP: either, primary (dual-homed) or secondary (dual-homed-secondary). The AA service attributes (app-profile and transit-policy) of the primary are inherited by the secondary endpoints. All endpoints within an AARP must be of the same type (SAP or spoke), and all endpoints with an AARP must be within the same service.</p> <p>The no form of the command removes the association between an AARP instance and a multi-homed SAP or spoke SDP.</p> |
| <b>Default</b>     | no aarp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>aarpld</i> — specifies the AARP instance associated with this SAP. If not configured, no AARP instance is associated with this SAP.</p> <p><b>Values</b> 1 to 65535</p> <p><i>type</i> — specifies the role of the SAP referenced by the AARP instance</p> <p><b>Values</b> <b>dual-homed</b> — the primary dual-homed AA subscriber side service-point of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.</p> <p><b>dual-homed-secondary</b> — one of the secondary dual-homed AA subscriber side service-points of an AARP instance; only supported for Epipe, IES, and VPRN SAP and spoke SDP.</p>                                                                                                                                                       |

| <b>Description</b> | <p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (<b>ip</b>, <b>ip-mac</b>, <b>nh-mac</b>) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The <b>no</b> form of the command disables anti-spoof filtering on the SAP.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Default</b>     | no anti-spoof                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><b>ip</b> — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type <b>ip</b> command will fail.</p> <p><b>mac</b> — Configures SAP anti-spoof filtering to use only the source MAC address in its lookup. Setting the anti-spoof filter type to <b>mac</b> is not allowed on non-Ethernet encapsulated SAPs. If a static host exists on the SAP without a specified MAC address, the anti-spoof type <b>mac</b> command will fail. The anti-spoof type <b>mac</b> command will also fail if the SAP does not support Ethernet encapsulation.</p> <p><b>ip-mac</b> — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the anti-spoof type <b>ip-mac</b> command will fail. This is also true if the default anti-spoof filter type of the SAP is <b>ip-mac</b> and the default is not overridden. The anti-spoof type <b>ip-mac</b> command will also fail if the SAP does not support Ethernet encapsulation.</p> |

## anti-spoof

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command enables anti-spoof filtering and optionally changes the anti-spoof matching type for the SAP.</p> <p>The type of anti-spoof filtering defines what information in the incoming packet is used to generate the criteria to lookup an entry in the anti-spoof filter table. The type parameter (<b>ip</b>, <b>ip-mac</b>) defines the anti-spoof filter type enforced by the SAP when anti-spoof filtering is enabled.</p> <p>The <b>no</b> form of the command disables anti-spoof filtering on the SAP.</p> |
| <b>Default</b>     | ip-mac                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><b>ip</b> — Configures SAP anti-spoof filtering to use only the source IP address in its lookup. If a static host exists on the SAP without an IP address specified, the anti-spoof type <b>ip</b> command will fail.</p>                                                                                                                                                                                                                                                                                                |

**ip-mac** — Configures SAP anti-spoof filtering to use both the source IP address and the source MAC address in its lookup. If a static host exists on the SAP without both the IP address and MAC address specified, the anti-spoof type **ip-mac** command will fail. This is also true if the default anti-spoof filter type of the SAP is **ip-mac** and the default is not overridden. The anti-spoof type **ip-mac** command will also fail if the SAP does not support Ethernet encapsulation.

**nh-mac** — Indicates that the ingress anti-spoof is based on the source MAC address and the egress anti-spoof is based on the nh-ip-address.

## app-profile

|                    |                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                                                                               |

| <b>Description</b> | This command configures the application profile name.                                                                                             |
| <b>Parameters</b>  | <i>app-profile-name</i> — specifies an existing application profile name configured in the <b>config&gt;app-assure&gt;group&gt;policy</b> context |

## ip-tunnel

|                    |                                                                                                                                                                                                                                                                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ip-tunnel</b> <i>name</i> [ <b>create</b> ]<br><b>no ip-tunnel</b> <i>name</i>                                                                                                                                                                                                                                                         |
| <b>Context</b>     | config>service>ies>if>sap                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | This command is used to configure an IP-GRE or IP-IP tunnel and associate it with a private tunnel SAP within an IES or VPRN service.<br><br>The <b>no</b> form of the command deletes the specified IP/GRE or IP-IP tunnel from the configuration. The tunnel must be administratively shutdown before issuing the no ip-tunnel command. |
| <b>Default</b>     | no ip tunnel <i>name</i>                                                                                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <b>ip-tunnel</b> <i>name</i> — Specifies the name of the IP tunnel. Tunnel names can be from 1 to 32 alphanumeric characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.                                                                                   |

## lag-link-map-profile

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>sub-if>grp-if>sap                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | <p>This command assigns a pre-configured lag link map profile to a SAP/network interface configured on a LAG or a PW port that exists on a LAG. Once assigned/de-assigned, the SAP/network interface egress traffic will be re-hashed over LAG as required by the new configuration.</p> <p>The <b>no</b> form of this command reverts the SAP/network interface to use per-flow, service or link hash as configured for the service/LAG.</p> |
| <b>Default</b>     | no lag-link-map-profile                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>lag-link-map-profile-id</i> — An integer from 1 to 64 that defines a unique lag link map profile on which the LAG the SAP/network interface exist.                                                                                                                                                                                                                                                                                         |

## lag-per-link-hash

|                    |                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lag-per-link-hash class {1   2   3} weight <i>weight</i></b><br><b>no per-link-hash</b>                                                                                                               |
| <b>Context</b>     | config>service>ies>if>sap<br>config>service>ies>sub-if>grp-if>sap                                                                                                                                        |
| <b>Description</b> | <p>This command configures weight and class to this SAP to be used on LAG egress when the LAG uses weighted per-link-hash.</p> <p>The <b>no</b> form of this command restores default configuration.</p> |
| <b>Default</b>     | no lag-per-link-hash (equivalent to weight 1 class 1)                                                                                                                                                    |
| <b>Parameters</b>  | <i>weight</i> — specifies the weight                                                                                                                                                                     |
| <b>Values</b>      | 1 to 1024                                                                                                                                                                                                |

## multi-service-site

|                |                                                                                                               |

|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command creates a new customer site or edits an existing customer site with the <i>customer-site-name</i> parameter. A customer site is an anchor point to create an ingress and egress virtual scheduler hierarchy. On the 7750 SR, when a site is created, it must be assigned to a chassis slot or port. When a site is created, it must be assigned to a chassis slot or port with the exception of the 7450 ESS-1 in which the slot is set to 1. When scheduler policies are defined for ingress and egress, the scheduler names contained in each policy are created according to the parameters defined in the policy. Multi-service customer sites exist for the sole purpose of creating a virtual scheduler hierarchy and making it available to queues on multiple Service Access Points (SAPs).</p> <p>The scheduler policy association with the customer site normally prevents the scheduler policy from being deleted until after the scheduler policy is removed from the customer site. The multi-service-site object will generate a log message indicating that the association was deleted due to scheduler policy removal.</p> <p>When the multi-service customer site is created, an ingress and egress scheduler policy association does not exist. This does not prevent the site from being assigned to a chassis slot or prevent service SAP assignment. After the site has been created, the ingress and egress scheduler policy associations can be assigned or removed at any time.</p>                                                                                                                                                                                                                                                |
| <b>Default</b>     | n/a — Each customer site must be explicitly created.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Parameters</b>  | <p><i>customer-site-name</i> — Each customer site must have a unique name within the context of the customer. If <i>customer-site-name</i> already exists for the customer ID, the CLI context changes to that site name for the purpose of editing the site scheduler policies or assignment. Any modifications made to an existing site will affect all SAPs associated with the site. Changing a scheduler policy association may cause new schedulers to be created and existing policers and queues on the SAPs to no longer be orphaned. Existing schedulers on the site may cease to exist, causing policers and queues relying on that scheduler to be orphaned.</p> <p>If the <i>customer-site-name</i> does not exist, it is assumed that an attempt is being made to create a site of that name in the customer ID context. The success of the command execution depends on the following:</p> <ul style="list-style-type: none"> <li>The maximum number of customer sites defined for the chassis has not been met.</li> <li>The <i>customer-site-name</i> is valid.</li> <li>The <b>create</b> keyword is included in the command line syntax (if the system requires it).</li> </ul> <p>When the maximum number of customer sites has been exceeded a configuration error occurs; the command will not execute and the CLI context will not change.</p> <p>If the <i>customer-site-name</i> is invalid, a syntax error occurs; the command will not execute and the CLI context will not change.</p> <p><b>Values</b> Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.</p> |

## static-host

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | This command configures a static host on this SAP.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <b>ip</b> <i>ip-address</i> — specifies the IPv4 unicast address<br><i>mac ieee-address</i> — Specify this optional parameter when defining a static host. Every static host definition must have at least one address defined, IP or MAC.<br><b>force</b> — specifies the forced removal of the static host addresses<br><b>sla-profile</b> <i>sla-profile-name</i> — This optional parameter is used to specify an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |

## ancp-string

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancp-string</b> <i>ancp-string</i><br><b>no ancp-string</b>                            |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>sub-if>grp-if>sap>static-host |
| <b>Description</b> | This command specifies the ANCP string associated to this SAP host.                       |
| <b>Parameters</b>  | <i>ancp-string</i> — specifies the ANCP string up to 63 characters in length              |

## app-profile

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>app-profile</b> <i>app-profile-name</i><br><b>no app-profile</b>                            |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>sub-if>grp-if>sap>static-host      |
| <b>Description</b> | This command specifies an application profile name.                                            |
| <b>Parameters</b>  | <i>app-profile-name</i> — specifies the application profile name up to 32 characters in length |

---

## inter-dest-id

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>inter-dest-id</b> <i>intermediate-destination-id</i><br><b>no inter-dest-id</b>                                    |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>sub-if>grp-if>sap>static-host                             |
| <b>Description</b> | Specifies to which intermediate destination (for example, a DSLAM) this host belongs.                                 |
| <b>Parameters</b>  | <i>intermediate-destination-id</i> — specifies the intermediate destination identifier, up to 32 characters in length |

## managed-routes

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <b>Syntax</b>      | <b>managed-routes</b>                                           |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>static-host>managed-routes |
| <b>Description</b> | This command configures managed routes.                         |

## route

|                    |                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>route</b> { <i>ip-prefix/length</i>   <i>ip-prefix netmask</i> } [ <b>create</b> ]<br><b>no route</b> { <i>ip-prefix/length</i>   <i>ip-prefix netmask</i> }                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>static-host>managed-routes                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | This command assigns managed-route to a given subscriber-host. As a consequence, a static route pointing subscriber-host ip address as a next hop will be installed in FIB. Up to 16 managed routes per subscriber-host can be configured.<br><br>The <b>no</b> form of the command removes the respective route. Per default, there are no managed-routes configured. |

## sla-profile

|                    |                                                                                                                                                                                                 |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>sla-profile</b> <i>sla-profile-name</i><br><b>no sla-profile</b>                                                                                                                             |
| <b>Context</b>     | config>service>ies>if>sap>static-host<br>config>service>ies>sub-if>grp-if>sap>static-host                                                                                                       |
| <b>Description</b> | This command specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |

---

**Parameters**    *sla-profile-name* — specifies the SLA profile name

## sub-profile

**Syntax**    **sub-profile** *sub-profile-name*  
**no sub-profile**

**Context**    config>service>ies>if>sap>static-host  
config>service>ies>sub-if>grp-if>sap>static-host

**Description**    This command specifies an existing subscriber profile name to be associated with the static subscriber host.

**Parameters**    *sub-profile-name* — specifies the sub-profile name

## subscriber

**Syntax**    **subscriber** *sub-ident*  
**no subscriber**

**Context**    config>service>ies>if>sap>static-host  
config>service>ies>sub-if>grp-if>sap>static-host

**Description**    This command specifies an existing subscriber identification profile to be associated with the static subscriber host.

**Parameters**    *sub-ident* — specifies the subscriber identification

## subscriber-sap-id

**Syntax**    **[no] subscriber-sap-id**

**Context**    config>service>ies>if>sap>static-host  
config>service>ies>sub-if>grp-if>sap>static-host

**Description**    This command enables using the SAP ID as subscriber id.

**Parameters**    **subscriber-sap-id** — specifies to use the sap-id as the subscriber-id

## transit-policy

**Syntax**    **transit-policy** {*ip ip-aasub-policy-id* | *prefix prefix-aasub-policy-id*}  
**no transit-policy**

**Context**    config>service>ies>if>sap>

```
config>service>ies>if>spoke-sdp>
```

**Description** This command associates an AA transit policy to the service. The transit IP policy must be defined prior to associating the policy with a SAP in the **config>application assurance>group>policy>transit-ip-policy** context.

Transit AA subscribers are managed by the system through this service policy, which determines how transit subs are created and removed for that service.

The no form of the command removes the association of the policy to the service.

**Default** no transit-policy

**Parameters** *ip-aasub-policy-id* — specifies an integer identifying an IP transit IP profile entry

**Values** 1 to 65535

*prefix-aasub-policy-id* — specifies an integer identifying a prefix transit profile entry

**Values** 1 to 65535

## pw-path-id

**Syntax** [no] pw-path-id

**Context** config>service>epipe>spoke-sdp  
config>service>cpipe>spoke-sdp  
config>service>apipe>spoke-sdp  
config>service>vpls>spoke-sdp  
config>service>ies>if>spoke-sdp  
config>service>vprn>if>spoke-sdp

**Description** This command enables the context to configure an MPLS-TP Pseudowire Path Identifier for a spoke-sdp. All elements of the PW path ID must be configured in order to enable a spoke-sdp with a PW path ID.

For an IES or VPRN spoke-sdp, the pw-path-id is only valid for Ethernet spoke-sdps.

The **pw-path-id** is only configurable if all of the following is true:

- The system is using network chassis mode D
- SDP signaling is off
- control-word is enabled (control-word is disabled by default)
- the service type is epipe, vpls, cpipe, apipe, or IES/VPRN interface
- mate SDP signaling is off for vc-switched services

The **no** form of the command deletes the PW path ID.

**Default** no pw-path-id

---

## agi

|                    |                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command enables IPv4 flowspec filtering on an access IP interface associated with a VPRN or IES service. Filtering is based on all of the IPv4 flowspec routes that have been received and accepted by the corresponding BGP instance. Ingress IPv4 traffic on an interface can be filtered by both a user-defined IPv4 filter and flowspec. Evaluation proceeds in this order:</p> |

- user-defined IPv4 filter entries
- flowspec-derived filter entries
- user-defined IPv4 filter default-action

The **no** form of the command removes IPv4 flowspec filtering from an IP interface.

**Default** no flowspec. No access interfaces have IPv4 flowspec enabled.

| <b>Description</b> | This command enables subscriber host connectivity verification for all hosts on this interface. This tool will periodically scan all known hosts (from dhcp-state) and perform a UC ARP request. The subscriber host connectivity verification will maintain state (connected vs. not-connected) for all hosts.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Default</b>     | no host-connectivity-verify                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><b>source {interface}</b> — Specifies the source to be used for generation of subscriber host connectivity verification packets. The <b>interface</b> keyword forces the use of the interface mac and ip addresses. There are up to 16 possible subnets on a given interface, therefore subscriber host connectivity verification tool will use always an address of the subnet to which the given host is pertaining. In case of group-interfaces, one of the parent subscriber-interface subnets (depending on host's address) will be used.</p> <p><b>interval interval</b> — The interval, in minutes, which specifies the time interval which all known sources should be verified. The actual rate is then dependent on number of known hosts and interval.</p> <p><b>Values</b> 1 to 6000<br/> A zero value can be used by the SNMP agent to disable host-connectivity-verify.</p> <p><b>action {remove   alarm}</b> — Defines the action taken on a subscriber host connectivity verification failure for a given host. The <b>remove</b> keyword raises an alarm and removes DHCP state and releases all allocated resources (queues, table entries and etc.). DHCP release will be signaled to corresponding DHCP server. Static host will never be removed. The <b>alarm</b> keyword raises an alarm indicating that the host is disconnected.</p> |

**timeout** *retry-timeout* — specifies the timeout in seconds between consecutive retries of subscriber host connectivity verification checks, in case the host does not respond

**Values** 10 to 60 seconds

**retry-count** *count* — specifies the number of retries that will be carried out before a subscriber host is considered to have failed the SHCV check

**Values** 2 to 29

**family** *family* — Indicates the IP address family for which subscriber host connectivity verification checks will be enabled. It can be set to ipv4 or ipv6 only, or both.

**Values** 2 to 29

| <b>Context</b>     | config>service>ies>if>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the source IPv4 or IPv6 address to use for an IP tunnel. This configuration applies to the outer IP header of the encapsulated packets. The IPv4 or IPv6 address must belong to the one of the IP subnets associated with the public SAP interface of the tunnel-group. The <b>source</b> address, <b>remote-ip</b> address and <b>backup-remote-ip</b> address of a tunnel must all belong to the same address family (IPv4 or IPv6). When the source address contains an IPv6 address it must be a global unicast address. |
| <b>Default</b>     | no source                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>ip-address</i> — An IPv4 address or an IPv6 address.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Context</b>     | config>service>ies>if>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the primary destination IPv4 or IPv6 address to use for an IP tunnel. This configuration applies to the outer IP header of the encapsulated packets. The <b>source</b> address, <b>remote-ip</b> address and <b>backup-remote-ip</b> address of a tunnel must all belong to the same address family (IPv4 or IPv6). When the remote-ip address contains an IPv6 address it must be a global unicast address. |
| <b>Default</b>     | no remote-ip                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>ip-address</i> — an IPv4 address or an IPv6 address                                                                                                                                                                                                                                                                                                                                                                               |

## backup-remote-ip

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>backup-remote-ip</b> <i>ip-address</i><br><b>no backup-remote-ip</b>                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Context</b>     | config>service>ies>if>sap>ip-tunnel<br>config>service>ies>if>sap<br>config>service>vprn>if>sap>ip-tunnel                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Description</b> | This command configures the alternate destination IPv4 or IPv6 address to use for an IP tunnel. This destination address is used only if the primary destination configured with the <b>remote-ip</b> command is unreachable in the delivery service. The <b>source</b> address, <b>remote-ip</b> address and <b>backup-remote-ip</b> address of a tunnel must all belong to the same address family (IPv4 or IPv6). When the backup-remote-ip address contains an IPv6 address it must be a global unicast address. |
| <b>Default</b>     | no remote-ip                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>ip-address</i> — an IPv4 address or an IPv6 address                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

### 2.5.2.12 SAP Subscriber Management Commands

## sub-sla-mgmt

|                    |                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] sub-sla-mgmt</b>                                                                     |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap                                                         |
| <b>Description</b> | This command enables the context to configure subscriber management parameters for this SAP. |
| <b>Default</b>     | no sub-sla-mgmt                                                                              |

## def-sla-profile

|                    |                                                                                                                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>def-sla-profile</b> <i>default-sla-profile-name</i><br><b>no def-sla-profile</b>                                                                                                                |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt                                                                                                                                                  |
| <b>Description</b> | This command specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |

An SLA profile is a named group of QoS parameters used to define per service QoS for all subscriber hosts common to the same subscriber within a provider service offering. A single SLA profile may define the QoS parameters for multiple subscriber hosts. SLA profiles are maintained in two locations, the subscriber identification policy and the subscriber profile templates. After a subscriber host is associated with an SLA profile name, either the subscriber identification policy used to identify the subscriber or the subscriber profile associated with the subscriber host must contain an SLA profile with that name. If both the subscriber identification policy and the subscriber profile contain the SLA profile name, the SLA profile in the subscriber profile is used.

The **no** form of the command removes the default SLA profile from the SAP configuration.

|                   |                                                                                                                                                                                                                         |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no def-sla-profile                                                                                                                                                                                                      |
| <b>Parameters</b> | <i>default-sla-profile-name</i> — Specifies a default SLA profile for this SAP. The SLA profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sla-profile</b> context. |

## def-sub-profile

|                    |                                                                                                                                                                                                                  |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>def-sub-profile</b> <i>default-subscriber-profile-name</i>                                                                                                                                                    |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt                                                                                                                                                                |
| <b>Description</b> | This command specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-profile</b> context. |

A subscriber profile defines the aggregate QoS for all hosts within a subscriber context. This is done through the definition of the egress and ingress scheduler policies that govern the aggregate SLA for subscriber using the subscriber profile. Subscriber profiles also allow for specific SLA profile definitions when the default definitions from the subscriber identification policy must be overridden.

The **no** form of the command removes the default SLA profile from the SAP configuration.

|                   |                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>default-sub-profile</i> — Specifies a default subscriber profile for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-profile</b> context. |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## sub-ident-policy

|                |                                                      |
|----------------|------------------------------------------------------|
| <b>Syntax</b>  | <b>sub-ident-policy</b> <i>sub-ident-policy-name</i> |
| <b>Context</b> | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt    |

---

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command associates a subscriber identification policy to this SAP. The subscriber identification policy must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context.</p> <p>Subscribers are managed by the system through the use of subscriber identification strings. A subscriber identification string uniquely identifies a subscriber. For static hosts, the subscriber identification string is explicitly defined with each static subscriber host.</p> <p>For dynamic hosts, the subscriber identification string must be derived from the DHCP ACK message sent to the subscriber host. The default value for the string is the content of Option 82 CIRCUIT-ID and REMOTE-ID fields interpreted as an octet string. As an option, the DHCP ACK message may be processed by a subscriber identification policy which has the capability to parse the message into an alternative ASCII or octet string value.</p> <p>When multiple hosts on the same port are associated with the same subscriber identification string they are considered to be host members of the same subscriber.</p> <p>The <b>no</b> form of the command removes the default subscriber identification policy from the SAP configuration.</p> |
| <b>Default</b>     | no sub-ident-policy                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Parameters</b>  | <i>sub-ident-policy-name</i> — Specifies a subscriber identification policy for this SAP. The subscriber profile must be defined prior to associating the profile with a SAP in the <b>config&gt;subscr-mgmt&gt;sub-ident-policy</b> context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## multi-sub-sap

|                    |                                                                                                                                                     |

| <b>Description</b> | <p>This command configures the maximum number of subscribers for this SAP.</p> <p>The <b>no</b> form of this command returns the default value.</p> |
| <b>Default</b>     | 1                                                                                                                                                   |
| <b>Parameters</b>  | <i>subscriber-limit</i> — specifies the maximum number of subscribers for this SAP                                                                  |
| <b>Values</b>      | 2 to 8000                                                                                                                                           |

## single-sub-parameters

|                |                                                   |
|----------------|---------------------------------------------------|
| <b>Syntax</b>  | <b>single-sub-parameters</b>                      |
| <b>Context</b> | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt |

---

**Description** This command enables the context to configure single subscriber parameters for this SAP.

## non-sub-traffic

**Syntax** **non-sub-traffic sub-profile** *sub-profile-name* **sla-profile** *sla-profile-name* [**subscriber** *sub-ident-string*]  
**no non-sub-traffic**

**Context** config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt>single-sub

**Description** This command configures non-subscriber traffic profiles. It is used in conjunction with the **profiled-traffic-only** command on single subscriber SAPs and creates a subscriber host which is used to forward non-IP traffic through the single subscriber SAP without the need for SAP queues.

The **no** form of the command removes the profiles and disables the feature.

**Parameters** **sub-profile** *sub-profile-name* — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the **config>subscr-mgmt>sub-profile** context.

**sla-profile** *sla-profile-name* — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscr-mgmt>sla-profile** context.

**subscriber** *sub-ident-string* — Specifies an existing subscriber identification profile to be associated with the static subscriber host. The subscriber identification profile is configured in the **config>subscr-mgmt>sub-ident-policy** context. The subscriber information is used by the VPRN SAP arp-reply-agent to determine the proper handling of received ARP requests from subscribers.

For VPRN SAPs with **arp-reply-agent** enabled with the optional *sub-ident* parameter, the static subscriber host's sub-ident-string is used to determine whether an ARP request received on the SAP is sourced from a host belonging to the same subscriber as the destination host. When both the destination and source hosts from the ARP request are known on the SAP and the subscriber identifications do not match, the ARP request may be forwarded to the rest of the VPRN destinations.

If the static subscriber host's *sub-ident* string is not defined, the host is not considered to belong to the same subscriber as another host on the SAP.

If source or destination host is unknown, the hosts are not considered to belong to the same subscriber. ARP messages from unknown hosts are subject to anti-spoof filtering rules applied at the SAP.

If *sub-ident* is not enabled on the SAP arp-reply-agent, subscriber identification matching is not performed on ARP requests received on the SAP.

ARP requests are never forwarded back to the same SAP or within the receiving SAP's split horizon group.

| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap>sub-sla-mgmt>single-sub                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables profiled traffic only for this SAP. The profiled traffic refers to single subscriber traffic on a dedicated SAP (in the VLAN-per-subscriber model). When enabled, subscriber queues are instantiated through the QOS policy defined in the sla-profile and the associated SAP queues are deleted. This can increase subscriber scaling by reducing the number of queues instantiated per subscriber (in the VLAN-per-subscriber model). In order for this to be achieved, any configured multi-sub-sap limit must be removed (leaving the default of 1).</p> <p>The <b>no</b> form of the command disables the command.</p> |

| <b>Description</b> | <p>This command creates the accounting policy context that can be applied to a SAP.</p> <p>An accounting policy must be defined before it can be associated with a SAP. If the <i>policy-id</i> does not exist, an error message is generated.</p> <p>A maximum of one accounting policy can be associated with a SAP at one time. Accounting policies are configured in the <b>config&gt;log</b> context.</p> <p>The <b>no</b> form of this command removes the accounting policy association from the SAP, and the accounting policy reverts to the default.</p> |
| <b>Default</b>     | Default accounting policy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Parameters</b>  | <i>acct-policy-id</i> — the accounting <i>policy-id</i> as configured in the <b>config&gt;log&gt;accounting-policy</b> context                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | 1 to 99                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## collect-stats

|                |                                                                   |
|----------------|-------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] collect-stats</b>                                         |
| <b>Context</b> | config>service>ies>if>sap<br>config>service>ies>sub-if>grp-if>sap |

**Description** This command enables accounting and statistical data collection for either the SAP, network port, or IP interface. When applying accounting policies the data, by default, is collected in the appropriate records and written to the designated billing file.

When the **no collect-stats** command is issued the statistics are still accumulated by the IOMCFM cards. However, the CPU will not obtain the results and write them to the billing file. If a subsequent **collect-stats** command is issued then the counters written to the billing file include all the traffic while the **no collect-stats** command was in effect.

**Default** no collect-stats

## calling-station-id

**Syntax** **calling-station-id** *calling-station-id*  
**no calling-station-id**

**Context** config>service>ies>if>sap  
config>service>ies>sub-if>grp-if>sap

**Description** This command enables the inclusion of the **calling-station-id** attribute in RADIUS authentication requests and RADIUS accounting messages. The value inserted is set at the SAP level. If no value is set at the SAP level, an empty string is included.

**Default** This attribute is not sent by default.

## cpu-protection

**Syntax** **cpu-protection** *policy-id* [mac-monitoring] | [eth-cfm-monitoring [aggregate] [car]] | [ip-src-monitoring]  
**no cpu-protection**

**Context** config>service>ies>if>sap

**Description** This command assigns an existing CPU protection policy to the associated service group interface SAP, interface or MSAP policy. The CPU protection policies are configured in the **config>sys>security>cpu-protection>policy** *cpu-protection-policy-id* context.

If no CPU protection policy is assigned to a service group interface SAP, then a the default policy is used to limit the overall-rate.

**Default** cpu-protection 254 (for access interfaces)

cpu-protection 255 (for network interfaces)

n/a (for video-interfaces (where applicable), shown as **no cpu-protection** in CLI)

The configuration of **no cpu-protection** returns the interface/SAP to the default policies as shown above.

---

|                   |                                                                                                                                                             |
|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>policy-id</i> — specifies an existing CPU protection policy                                                                                              |
| <b>Values</b>     | 1 to 255                                                                                                                                                    |
|                   | <b>mac-monitoring</b> — When specified, the per MAC rate limiting should be performed, using the per-source-rate from the associated cpu-protection policy. |

## default-host

|                    |                                                                                                                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-host</b> <i>ip-address/mask</i> <b>next-hop</b> <i>next-hop-ip</i><br><b>no default-host</b> <i>ip-address/mask</i>                                                                 |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap                                                                                                                                                           |
| <b>Description</b> | This command configures the default-host to be used. More than one default-host can be configured per SAP.<br><br>The <b>no</b> form of the command removes the values from the configuration. |
| <b>Parameters</b>  | <i>ip-address/mask</i> — Assigns an IP address/IP subnet format to the interface.<br><b>next-hop</b> <i>next-hop-ip</i> — Assigns the next hop IP address.                                     |

## dist-cpu-protection

|                    |                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>dist-cpu-protection</b> <i>policy-name</i><br><b>no dist-cpu-protection</b>                                                                                                                                    |
| <b>Context</b>     | config>service>ies>sub-if>grp-if>sap<br>config>service>ies>if>sap                                                                                                                                                 |
| <b>Description</b> | This command assigns a Distributed CPU Protection (DCP) policy to the SAP. Only a valid DCP policy can be assigned to a SAP or a network interface. This rule does not apply to templates such as an msap-policy. |
| <b>Default</b>     | no dist-cpu-protection                                                                                                                                                                                            |

### 2.5.2.13 ETH-CFM Service Commands

## eth-cfm

|                |                                                                                          |
|----------------|------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>eth-cfm</b>                                                                           |
| <b>Context</b> | config>service>ies><br>config>service>ies>sub-if>grp-if>sap<br>config>service>ies>if>sap |

```
config>service>ies>if>spoke-sdp
```

**Description** This command enables the context to configure ETH-CFM parameters.

## collect-lmm-stats

**Syntax** **collect-lmm-stats**  
**no collect-lmm-stats**

**Context** config>service>ies>if>sap>eth-cfm  
config>service>ies>if>spoke-sdp>eth-cfm  
config>service>ies>sub-if>grp-if>sap>eth-cfm

**Description** This command enables the collection of statistics on the SAP or MPLS SDP binding on which the ETH- LMM test is configured. The collection of LMM statistics must be enabled if a MEP is launching or responding to ETH-LMM packets. If LMM statistics collection is not enabled, the counters in the LMM and LMR PDU do not represent accurate measurements and all measurements should be ignored. The **show sap-using eth-cfm collect-lmm-stats** command and the **show sdp-using eth-cfm collect-lmm-stats** command can be used to display which entities are collecting stats.

The **no** form of the command disables and deletes the counters for this SAP or MPLS SDP binding.

**Default** no collect-lmm-stats

## mep

**Syntax** **mep** *mep-id* **domain** *md-index* **association** *ma-index* [**direction** {**up** | **down**}]  
**no mep** *mep-id* **domain** *md-index* **association** *ma-index*

**Context** config>service>ies>if>sap>eth-cfm  
config>service>ies>if>spoke-sdp>eth-cfm  
config>service>ies>sub-if>grp-if>sap>eth-cfm

**Description** This command configures the ETH-CFM maintenance endpoint (MEP).

**Parameters** *mep-id* — specifies the maintenance association end point identifier

**Values** 1 to 8191

*md-index* — specifies the maintenance domain (MD) index value

**Values** 1 to 4294967295

*ma-index* — specifies the MA index value

**Values** 1 to 4294967295

**direction up | down** — the direction in which the maintenance association (MEP) faces on the bridge port. Direction UP is not applicable to IES MEPs

down — sends ETH-CFM messages away from the MAC relay entity

up — sends ETH-CFM messages towards the MAC relay entity

## ais-enable

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ais-enable</b>                                                                                                      |
| <b>Context</b>     | config>service>ies>if>spoke-sdp>eth-cfm<br>config>service>vpls>sap>eth-cfm>mep<br>config>service>vpls>spoke-sdp>eth-cfm>mep |
| <b>Description</b> | This command configures the reception of Alarm Indication Signal (AIS) message.                                             |

## interface-support-enable

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] interface-support-enable</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>ies>sap>eth-cfm>mep>ais-enable<br>config>service>ies>spoke-sdp>eth-cfm>mep>ais-enable                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command enables the AIS function to consider the operational state of the entity on which it is configured. With this command, ETH-AIS on DOWN MEPs will be triggered and cleared based on the operational status of the entity on which it is configured. If CCM is also enabled then transmission of the AIS PDU will be based on either the non operational state of the entity or on ANY CCM defect condition. AIS generation will cease if BOTH operational state is UP and CCM has no defect conditions. If the MEP is not CCM enabled then the operational state of the entity is the only consideration assuming this command is present for the MEP. |
| <b>Default</b>     | no interface-support-enable (AIS will not be generated or stopped based on the state of the entity on which the DOWN MEP is configured).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## ccm-enable

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccm-enable</b>                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm>mep<br>config>service>ies>if>spoke-sdp>eth-cfm>mep<br>config>service>ies>sub-if>grp-if>sap>eth-cfm>mep |
| <b>Description</b> | This command enables the generation of CCM messages.<br><br>The <b>no</b> form of the command disables the generation of CCM messages.   |

## ccm-ltm-priority

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>ccm-ltm-priority</b> <i>priority</i><br><b>no ccm-ltm-priority</b>                                                                                                           |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm>mep<br>config>service>ies>if>spoke-sdp>eth-cfm>mep<br>config>service>ies>sub-if>grp-if>sap>eth-cfm>mep                                        |
| <b>Description</b> | This command specifies the priority value for CCMs and LTMs transmitted by the MEP.<br><br>The <b>no</b> form of the command removes the priority value from the configuration. |
| <b>Default</b>     | The highest priority on the bridge-port.                                                                                                                                        |
| <b>Parameters</b>  | <i>priority</i> — specifies the priority of CCM and LTM messages<br><br><b>Values</b> 0 to 7                                                                                    |

## ccm-padding-size

|                    |                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] ccm-padding-size</b> <i>ccm-padding</i>                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>ies>if>spoke-sdp>eth-cfm>mep                                                                                                                                                                                                                                                                                                                                     |
| <b>Description</b> | Set the byte size of the optional Data TLV to be included in the ETH-CC PDU. This will increase the size of the ETH-CC PDU by the configured value. The base size of the ETH-CC PDU, including the Interface Status TLV and Port Status TLV, is 83 bytes not including the Layer Two encapsulation. CCM padding is not supported when the CCM-Interval is less than one second. |
| <b>Default</b>     | ccm-padding-size                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <i>ccm-padding</i> — specifies the byte size of the Optional Data TLV<br><br><b>Values</b> 3 to 1500                                                                                                                                                                                                                                                                            |

## eth-test-enable

|                    |                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] eth-test-enable</b>                                                                                                                                                                                                                                                                                                                                |
| <b>Context</b>     | config>service>ies>if>sap>eth-cfm>mep<br>config>service>ies>if>spoke-sdp>eth-cfm>mep<br>config>service>ies>sub-if>grp-if>sap>eth-cfm>mep                                                                                                                                                                                                                   |
| <b>Description</b> | For ETH-test to work, operators need to configure ETH-test parameters on both sender and receiver nodes. The ETH-test then can be done using the following OAM commands:<br><br>oam eth-cfm eth-test <i>mac-address</i> mep <i>mep-id</i> domain <i>md-index</i> association <i>ma-index</i> [priority <i>priority</i> ] [data-length <i>data-length</i> ] |

A check is done for both the provisioning and test to ensure the MEP is an Y.1731 MEP (MEP provisioned with domain format none, association format icc-based). If not, the operation fails. An error message in the CLI and SNMP will indicate the problem.

## test-pattern

|                    |                                                                                                                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>test-pattern {all-zeros   all-ones} [crc-enable]</b><br><b>no test-pattern</b>                                                                                                                                    |

| Description | <p>This command defines the levels of the ETH-CFM PDUs that will silently be discarded on ingress into the SAP or SDP Binding from the wire. All ETH-CFM PDUs inbound to the SAP or SDP binding will be dropped that match the configured levels without regard for any other ETH-CFM criteria. No statistical information or drop count will be available for any ETH-PDU that is silently discarded by this option. The operator must configure a complete contiguous list of md-levels up to the highest level that will be dropped. The command must be retyped in complete form to modify a previous configuration, if the operator does not want to delete it first.</p> <p>The <b>no</b> form of the command removes the silent discarding of previously matching ETH-CFM PDUs.</p> |
| Default     | no squelch-ingress-levels                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | <p>Allows the individual service SAPs to react to changes in the tunnel MEP state. When tunnel-fault accept is configured at the service level, the SAP will react according to the service type, Epipe will set the operational flag and VPLS, IES and VPRN SAP operational state will become down on failure or up on clear. This command triggers the OAM mapping functions to mate SAPs and bindings in an Epipe service as well as setting the operational flag. If AIS generation is the requirement for the Epipe services this command is not required. See the command <code>ais-enable</code> under <code>epipe&gt;sap&gt;eth-cfm&gt;ais-enable</code> for more details. This works in conjunction with the tunnel-fault accept on the individual SAPs. Both must be set to accept to react to the tunnel MEP state. By default the service level command is “ignore” and the sap level command is “accept”. This means simply changing the service level command to “accept” will enable the feature for all SAPs. This is not required for Epipe services that only wish to generate AIS on failure.</p> |
| <b>Default</b>     | <p>tunnel-fault ignore (Service Level)</p> <p><b>accept</b> (SAP Level for Epipe and VPLS)</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <p><i>accept</i> — Share fate with the facility tunnel MEP</p> <p><i>ignore</i> — Do not share fate with the facility tunnel MEP</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## one-way-delay-threshold

|                    |                                                                                                                       |
|--------------------|-----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>one-way-delay-threshold</b> <i>time</i>                                                                            |

| <b>Description</b>   | <p>This command associates a filter policy with an ingress or egress Service Access Point (SAP). Filter policies control the forwarding and dropping of packets based on the matching criteria.</p> <p>The <b>filter</b> command is used to associate a filter policy with a specified <i>ip-filter-id</i> or <i>ipv6-filter-id</i> (7750 SR) with an ingress or egress SAP. The filter policy must already be defined before the <b>filter</b> command is executed. If the filter policy does not exist, the operation will fail and an error message returned.</p> <p>In general, filters applied to SAPs (ingress or egress) apply to all packets on the SAP. One exception is non-IP packets are not applied to the match criteria, so the default action in the filter policy applies to these packets.</p> <p>The <b>no</b> form of this command removes any configured filter ID association with the SAP. The filter ID itself is not removed from the system unless the scope of the created filter is set to <b>local</b>. To avoid deletion of the filter ID and only break the association with the service object, use <b>scope</b> command within the filter definition to change the scope to <b>local</b> or <b>global</b>. The default scope of a filter is <b>local</b>.</p> |
| <b>Special Cases</b> | <b>IES</b> — only IP filters are supported on an IES IP interface, and the filters only apply to routed traffic                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>    | <p><b>ip</b> — indicates the filter policy is an IP filter</p> <p><i>ip-filter-id</i> — Specifies the ID for the IP filter policy. Allowed values are an integer in the range of 1 and 65535 that corresponds to a previously created IP filter policy in the <b>configure&gt;filter&gt;ip-filter</b> context.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## filter

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>filter ip</b> <i>ip-filter-id</i><br><b>filter ipv6</b> <i>ipv6-filter-id</i><br><b>no filter</b> |
| <b>Context</b>     | config>service>ies>if>spoke-sdp>egress<br>config>service>ies>if>spoke-sdp>ingress                    |
| <b>Description</b> | This command associates an IP filter policy filter policy with an ingress or egress spoke SDP.       |

Filter policies control the forwarding and dropping of packets based on matching criteria.

MAC filters are only allowed on Epipe and Virtual Private LAN Service (VPLS) SAPs.

The **filter** command is used to associate a filter policy with a specified *ip-filter-id* with an ingress or egress spoke SDP. The *ip-filter-id* must already be defined in the **configure>filter** context before the **filter** command is executed. If the filter policy does not exist, the operation will fail and an error message returned.

In general, filters applied to SAPs or spoke SDPs (ingress or egress) apply to all packets on the SAP or spoke SDPs. One exception is non-IP packets are not applied to IP match criteria, so the default action in the filter policy applies to these packets.

The **no** form of this command removes any configured filter ID association with the SAP or IP interface. The filter ID itself is not removed from the system unless the scope of the created filter is set to local. To avoid deletion of the filter ID and only break the association with the service object, use **scope** command within the filter definition to change the scope to **local** or **global**. The default scope of a filter is **local**.

**Special Cases**    **IES** — only IP filters are supported on IES IP interfaces, and the filters only apply to routed traffic.

**Parameters**    **ip** — Keyword indicating the filter policy is an IP filter.  
*ip-filter-id* — The filter name acts as the ID for the IP filter policy. Allowed values are an integer in the range of 1 and 65535 that corresponds to a previously created IP filter policy. The filter ID must already exist within the created IP filters.

## egress

**Syntax**    **egress**

**Context**    config>service>ies>if>sap  
config>service>ies>sub-if>grp-if>sap

**Description**    This command enables the context to apply egress policies.

If no sap-egress QoS policy is defined, the system default sap-egress QoS policy is used for egress processing. If no egress filter is defined, no filtering is performed.

## ingress

**Syntax**    **ingress**

**Context**    config>service>ies>if>sap  
config>service>ies>sub-if>grp-if>sap

**Description**    This command enables the context to apply ingress policies.

If no sap-ingress QoS policy is defined, the system default sap-ingress QoS policy is used for ingress processing. If no ingress filter is defined, no filtering is performed.

## hsmdda-queue-override

|                    |                                                                       |
|--------------------|-----------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] hsmdda-queue-override</b>                                     |
| <b>Context</b>     | config>service>ies>if>sap>egress<br>config>service>vprn>if>sap>egress |
| <b>Description</b> | This command configures HSMDDA egress and ingress queue overrides.    |

## packet-byte-offset

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>packet-byte-offset {add <i>add-bytes</i>   subtract <i>sub-bytes</i>}</b><br><b>no packet-byte-offset</b>                                                                                                                                                                                                                                                                                                                                 |
| <b>Context</b>     | config>service>ies>if>sap>egress>hsmdda-queue-over                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Description</b> | This command adds or subtracts the specified number of bytes to the accounting function for each packet handled by the HSMDDA queue. Normally, the accounting and leaky bucket functions are based on the Ethernet DLC header, payload and the 4-byte CRC (everything except the preamble and inter-frame gap). For example, this command can be used to add the frame encapsulation overhead (20 bytes) to the queues accounting functions. |

The accounting functions affected include:

- Offered High Priority / In-Profile Octet Counter
- Offered Low Priority / Out-of-Profile Octet Counter
- Discarded High Priority / In-Profile Octet Counter
- Discarded Low Priority / Out-of-Profile Octet Counter
- Forwarded In-Profile Octet Counter
- Forwarded Out-of-Profile Octet Counter
- Peak Information Rate (PIR) Leaky Bucket Updates
- Committed Information Rate (CIR) Leaky Bucket Updates
- Queue Group Aggregate Rate Limit Leaky Bucket Updates

The secondary shaper leaky bucket, scheduler priority level leaky bucket and the port maximum rate updates are not affected by the configured packet-byte-offset. Each of these accounting functions are frame based and always include the preamble, DLC header, payload and the CRC regardless of the configured byte offset.

The packet-byte-offset command accepts either add or subtract as valid keywords which define whether bytes are being added or removed from each packet traversing the queue. Up to 20 bytes may be added to the packet and up to 43 bytes may be removed from the packet. An example use case for subtracting bytes from each packet is an IP based accounting function. Given a Dot1Q encapsulation, the command packet-byte-offset subtract 14 would remove the DLC header and the Dot1Q header from the size of each packet for accounting functions only. The 14 bytes are not actually removed from the packet, only the accounting size of the packet is affected.

As mentioned above, the variable accounting size offered by the packet-byte-offset command is targeted at the queue and queue group level. When the queue group represents the last-mile bandwidth constraints for a subscriber, the offset allows the HSMDA queue group to provide an accurate accounting to prevent overrun and underrun conditions for the subscriber. The accounting size of the packet is ignored by the secondary shapers, the scheduling priority level shapers and the scheduler maximum rate. The actual on-the-wire frame size is used for these functions to allow an accurate representation of the behavior of the subscriber's packets on an Ethernet aggregation network.

The packet-byte-offset value can be overridden for the HSMDA queue at the SAP or subscriber profile level.

The **no** form of the command removes any accounting size changes to packets handled by the queue. The command does not effect overrides that may exist on SAPs or subscriber profiles associated with the queue.

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>add</b> <i>add-bytes</i> — The <b>add</b> keyword is mutually exclusive with the subtract keyword. Either the add or subtract keyword must be specified. The add keyword is used to indicate that the following byte value should be added to the packet for queue and queue group level accounting functions. The corresponding byte value must be specified when executing the packet-byte-offset command.                  |
|                   | <b>Values</b> 0 to 31                                                                                                                                                                                                                                                                                                                                                                                                            |
|                   | <b>subtract</b> <i>sub-bytes</i> — The <b>subtract</b> keyword is mutually exclusive with the add keyword. Either the add or subtract keyword must be specified. The subtract keyword is used to indicate that the following byte value should be subtracted from the packet for queue and queue group level accounting functions. The corresponding byte value must be specified when executing the packet-byte-offset command. |
|                   | <b>Values</b> 1 to 64                                                                                                                                                                                                                                                                                                                                                                                                            |

## queue

|                |                                                                                   |
|----------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>queue</b> <i>queue-id</i> [ <b>create</b> ]<br><b>no queue</b> <i>queue-id</i> |
| <b>Context</b> | config>service>ies>if>sap>egress>hsmda-queue-over                                 |

**Description** This command, within the QoS policy hsmdda-queue context, is a container for the configuration parameters controlling the behavior of an HSMDA queue. Unlike the standard QoS policy queue command, this command is not used to actually create or dynamically assign the queue to the object which the policy is applied. The queue identified by queue-id always exists on the SAP or subscriber context whether the command is executed or not. In the case of HSMDA SAPs and subscribers, all eight queues exist at the moment the system allocates an HSMDA queue group to the object (both ingress and egress).

#### Best-Effort, Expedited and Auto-Expedite Queue Behavior Based on Queue-ID

With standard service queues, the scheduling behavior relative to other queues is based on two items, the queues Best-Effort or Expedited nature and the dynamic rate of the queue relative to the defined CIR. HSMDA queues are handled differently. The create time auto-expedite and explicit expedite and best-effort qualifiers have been eliminated and instead the scheduling behavior is based solely on the queues identifier. Queues with a queue-id equal to 1 are placed in scheduling class 1. Queues with queue-id 2 are placed in scheduling class 2. And so on up to scheduling class 8. Each scheduling class is either mapped directly to a strict scheduling priority level based on the class ID, or the class may be placed into a weighted scheduling class group providing byte fair weighted round robin scheduling between the members of the group. Two weighted groups are supported and each may contain up to three consecutive scheduling classes. The weighed group assumes its highest member class's inherent strict scheduling level for scheduling purposes. Strict priority level 8 has the highest priority; strict level 1 has the lowest priority. When grouping of scheduling classes is defined, some of the strict levels will not be in use.

#### Single Type of HSMDA Queues

Another difference between HSMDA queues and standard service queues is the lack of Multipoint queues. At ingress, an HSMDA SAP or subscriber does not require Multipoint queues since all forwarding types (broadcast, multicast, unicast and unknown) forward to a single destination in the ingress forwarding plane on the IOM. Instead of a possible eight queues per forwarding type (for a total of up to 32) within the SAP ingress QoS policy, the hsmdda-queues node supports a maximum of eight queues.

#### Every HSMDA Queue Supports Profile Mode Implicitly

Unlike standard service queues, the HSMDA queues do not need to be placed into the special mode profile at create time in order to support ingress color aware policing. Each queue may handle in-profile, out-of-profile and profile undefined packets simultaneously. As with standard queues, the explicit profile of a packet is dependent on the ingress sub-forwarding class to which the packet is mapped.

The **no** form of the command restores the defined queue-id to its default parameters. All HSMDA queues having the queue-id and associated with the QoS policy are re-initialized to default parameters.

**Parameters** *queue-id* — Specifies the HSMDA queue to use for packets in this forwarding class. This mapping is used when the SAP is on a HSMDA MDA.

**Values** 1 to 8

| <b>Context</b>     | config>service>ies>if>sap>egress>hsmdda-queue-over                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command assigns an HSMDDA slope policy to the SAP. The policy may be assigned to an ingress or egress HSMDDA queue. The policy contains the Maximum Buffer Size (MBS) that will be applied to the queue and the high and low priority RED slope definitions. The function of the MBS and RED slopes is to provide congestion control for an HSMDDA queue. The MBS parameter defines the maximum depth a queue may reach when accepting packets. The low and high priority RED slopes provides for random early detection of congestion and slope based discards based on queue depth.</p> <p>An HSMDDA slope policy can be applied to queues defined in the SAP ingress and SAP egress QoS policy HSMDDA queues context. Once an HSMDDA slope policy is applied to a SAP QoS policy queue, it cannot be deleted. Any edits to the policy are updated to all HSMDDA queues indirectly associated with the policy.</p> <p>Default HSMDDA Slope Policy</p> <p>An HSMDDA slope policy named <b>default</b> always exists on the system and does not need to be created. The default policy is automatically applied to all HSMDDA queues unless another HSMDDA slope policy is specified for the queue. The default policy cannot be modified or deleted. Attempting to execute the <b>no hsmdda-slope-policy default</b> command results in an error.</p> <p>The <b>no</b> form of the command removes the specified HSMDDA slope policy from the configuration. If the HSMDDA slope policy is currently associated with an HSMDDA queue, the command will fail.</p> |
| <b>Parameters</b>  | <i>hsmdda-slope-policy-name</i> — Specifies a HSMDDA slope policy up to 32 characters in length. The HSMDDA slope policy must be exist prior to applying the policy name to an HSMDDA queue.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## wrr-weight

|                    |                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>wrr-weight value</b><br><b>no wrr-weight</b>                                                                                                                 |
| <b>Context</b>     | config>service>ies>if>sap>egress>hsmda-queue-overider>queue                                                                                                     |
| <b>Description</b> | This command assigns the weight value to the HSMDA queue.<br><br>The <b>no</b> form of the command returns the weight value for the queue to the default value. |
| <b>Parameters</b>  | <i>percentage</i> — specifies the weight for the HSMDA queue<br><br><b>Values</b> 1 to 32                                                                       |

## wrr-policy

|                    |                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>wrr-policy hsmda-wrr-policy-name</b><br><b>no wrr-policy</b>                                                 |
| <b>Context</b>     | config>service>ies>if>sap>egress>hsmda-queue-overider                                                           |
| <b>Description</b> | This command associates an existing HSMDA weighted-round-robin (WRR) scheduling loop policy to the HSMDA queue. |
| <b>Parameters</b>  | <i>hsmda-wrr-policy-name</i> — specifies the existing HSMDA WRR policy name to associate to the queue           |

## secondary-shaper

|                    |                                                                                                |
|--------------------|------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary-shaper secondary-shaper-name</b><br><b>no secondary-shaper</b>                    |
| <b>Context</b>     | config>service>ies>if>sap>egress>hsmda-queue-over                                              |
| <b>Description</b> | This command configures an HSMDA egress secondary shaper.                                      |
| <b>Parameters</b>  | <i>secondary-shaper-name</i> — specifies a secondary shaper name up to 32 characters in length |

## policer-override

|                |                                                                       |
|----------------|-----------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] policer-override</b>                                          |
| <b>Context</b> | config>service>ies>if>sap>egress<br>config>service>ies>if>sap>ingress |

---

|                    |                                                                                                                                                                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command, within the SAP ingress or egress contexts, is used to create a CLI node for specific overrides to one or more policers created on the SAP through the sap-ingress or sap-egress QoS policies.</p> <p>The <b>no</b> form of the command is used to remove any existing policer overrides.</p> |
| <b>Default</b>     | no policer-override                                                                                                                                                                                                                                                                                           |

## policer

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Description</b> | <p>This command, within the SAP ingress or egress contexts, is used to create a CLI node for specific overrides to a specific policer created on the SAP through a sap-ingress or sap-egress QoS policy.</p> <p>The <b>no</b> form of the command is used to remove any existing overrides for the specified policer-id.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <p><i>policer-id</i> — This parameter is required when executing the policer command within the policer-override context. The specified <i>policer-id</i> must exist within the sap-ingress or sap-egress QoS policy applied to the SAP. If the policer is not currently used by any forwarding class or forwarding type mappings, the policer will not actually exist on the SAP. This does not preclude creating an override context for the <i>policer-id</i>.</p> <p><b>create</b> — The create keyword is required when a policer override node is being created and the system is configured to expect explicit confirmation that a new object is being created. When the system is not configured to expect explicit configuration, the <b>create</b> keyword is not required.</p> |

## match-qinq-dot1p

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| <b>Description</b> | <p>This command specifies which Dot1Q tag position Dot1P bits in a QinQ encapsulated packet should be used to evaluate Dot1P QoS classification.</p> <p>The <b>match-qinq-dot1p</b> command allows the top or bottom PBits to be used when evaluating the applied sap-ingress QoS policy's Dot1P entries. The <b>top</b> and <b>bottom</b> keywords specify which position should be evaluated for QinQ encapsulated packets.</p> |

The **no** form of the command restores the default dot1p evaluation behavior for the SAP.

By default, the bottom most service delineating Dot1Q tags Dot1P bits are used. [Table 7](#) defines the default behavior for Dot1P evaluation when the **match-qinq-dot1p** command is not executed.

**Table 7** Default QinQ and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| null            | none                          | none                 |
| null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| null            | Dot1Q                         | Dot1Q PBits          |
| null            | TopQ BottomQ                  | TopQ PBits           |
| null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | none (Default SAP)            | none                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Default** no match-qinq-dot1p — no filtering based on p-bits

top or bottom must be specified to override the default QinQ dot1p behavior.

**Parameters** **top** — The top parameter is mutually exclusive to the bottom parameter. When the top parameter is specified, the top most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 8](#) defines the dot1p evaluation behavior when the top parameter is specified.

**Table 8** Top Position QinQ and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags | PBits Used for Match |
|-----------------|----------------------|----------------------|
| null            | none                 | none                 |
| null            | Dot1P (VLAN-ID 0)    | Dot1P PBits          |
| null            | Dot1Q                | Dot1Q PBits          |
| null            | TopQ BottomQ         | TopQ PBits           |

**Table 8** Top Position QinQ and TopQ SAP Dot1P Evaluation (Continued)

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| null            | TopQ (No BottomQ)             | TopQ PBits           |
| Dot1Q           | none (Default SAP)            | none                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | TopQ PBits           |
| QinQ / QinQ     | TopQ BottomQ                  | TopQ PBits           |

**bottom** — The bottom parameter is mutually exclusive to the top parameter. When the bottom parameter is specified, the bottom most PBits are used (if existing) to match any dot1p dot1p-value entries. [Table 9](#) defines the dot1p evaluation behavior when the bottom parameter is specified.

**Table 9** Bottom Position QinQ and TopQ SAP Dot1P Evaluation

| Port / SAP Type | Existing Packet Tags          | PBits Used for Match |
|-----------------|-------------------------------|----------------------|
| null            | none                          | none                 |
| null            | Dot1P (VLAN-ID 0)             | Dot1P PBits          |
| null            | Dot1Q                         | Dot1Q PBits          |
| null            | TopQ BottomQ                  | BottomQ PBits        |
| null            | TopQ (no BottomQ)             | TopQ PBits           |
| Dot1Q           | none (default SAP)            | none                 |
| Dot1Q           | Dot1P (Default SAP VLAN-ID 0) | Dot1P PBits          |
| Dot1Q           | Dot1Q                         | Dot1Q PBits          |
| QinQ / TopQ     | TopQ                          | TopQ PBits           |
| QinQ / TopQ     | TopQ BottomQ                  | BottomQ PBits        |
| QinQ / QinQ     | TopQ BottomQ                  | BottomQ PBits        |

**Table 10** Default Dot1P Explicit Marking Actions

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                   |
|-----------------|-------------------------------------------------------|--------------------------------------------------------------|
| null            | no preserved Dot1P bits                               | none                                                         |
| null            | preserved Dot1P bits                                  | preserved tag PBits remarked using dot1p-value               |
| Dot1Q           | no preserved Dot1P bits                               | new PBits marked using dot1p-value                           |
| Dot1Q           | preserved Dot1P bits                                  | preserved tag PBits remarked using dot1p-value               |
| TopQ            | no preserved Dot1P bits                               | TopQ PBits marked using dot1p-value                          |
| TopQ            | preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved |
| QinQ            | no preserved Dot1P bits                               | TopQ PBits and BottomQ PBits marked using dot1p-value        |
| QinQ            | preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits and BottomQ PBits marked using dot1p-value        |

**Table 11** QinQ Mark Top Only Explicit Marking Actions

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                   |
|-----------------|-------------------------------------------------------|--------------------------------------------------------------|
| null            | no preserved Dot1P bits                               | none                                                         |
| null            | preserved Dot1P bits                                  | preserved tag PBits remarked using dot1p-value               |
| Dot1Q           | no preserved Dot1P bits                               | new PBits marked using dot1p-value                           |
| Dot1Q           | preserved Dot1P bits                                  | preserved tag PBits remarked using dot1p-value               |
| TopQ            | no preserved Dot1P bits                               | TopQ PBits marked using dot1p-value                          |
| TopQ            | preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits preserved |

**Table 11** QinQ Mark Top Only Explicit Marking Actions (Continued)

| Egress SAP Type | Ingress Packet Preserved Dot1P State                  | Marked (or Remarked) PBits                                                      |
|-----------------|-------------------------------------------------------|---------------------------------------------------------------------------------|
| QinQ            | no preserved Dot1P bits                               | TopQ PBits marked using dot1p-value, BottomQ PBits marked with zero             |
| QinQ            | preserved Dot1P bits (used as TopQ and BottomQ PBits) | TopQ PBits marked using dot1p-value, BottomQ PBits marked using preserved value |

The QinQ and TopQ SAP PBit/DEI bit marking follows the default behavior defined in the above tables when **qinq-mark-top-only** is not specified.

The dot1p dot1p-value command must be configured without the qinq-mark-top-only parameter to remove the TopQ PBits only marking restriction.

## agg-rate

|                    |                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] agg-rate</b>                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>sap>egress<br>config>service>ies>sub-if>grp-if>sap>egress                                                                                                                                        |
| <b>Description</b> | This command is used to control an HQoS aggregate rate limit. It is used in conjunction with the following parameter commands: <b>rate</b> , <b>limit-unused-bandwidth</b> , and <b>queue-frame-based-accounting</b> . |

## rate

|                    |                                                                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rate {max   rate}</b><br><b>no rate</b>                                                                                                                                                                                                   |
| <b>Context</b>     | config>service>ies>if>sap>egress>agg-rate<br>config>service>ies>sub-if>grp-if>sap>egress>agg-rate                                                                                                                                            |
| <b>Description</b> | This command defines the enforced aggregate rate for all queues associated with the agg-rate context. A rate must be specified for the agg-rate context to be considered to be active on the context's object (SAP, subscriber, VPORT etc.). |

## limit-unused-bandwidth

|                |                                           |
|----------------|-------------------------------------------|
| <b>Syntax</b>  | <b>[no] limit-unused-bandwidth</b>        |
| <b>Context</b> | config>service>ies>if>sap>egress>agg-rate |

```
config>service>ies>sub-if>grp-if>sap>egress>agg-rate
```

**Description** This command is used to enable (or disable) aggregate rate overrun protection on the agg-rate context.

## queue-frame-based-accounting

**Syntax** **[no] queue-frame-based-accounting**

**Context** config>service>ies>if>sap>egress>agg-rate  
config>service>ies>sub-if>grp-if>sap>egress>agg-rate

**Description** This command is used to enabled (or disable) frame based accounting on all policers and queues associated with the agg-rate context. Only supported on Ethernet ports. Not supported on HSMDA Ethernet ports. Packet byte offset settings are not included in the applied rate when queue frame-based accounting is configured, but the offsets are applied to the statistics.

## policer-control-policy

**Syntax** **policer-control-policy** *policy-name*  
**no policer-control-policy**

**Context** config>service>ies>sub-if>grp-if>sap>egress

**Description** This command is used to specify a policer control policy to apply to SAP egress.

**Default** N/A

**Parameters** *policy-name* — Specifies the name of a policer control policy. 32 characters maximum.

## qinq-mark-top-only

**Syntax** **[no] qinq-mark-top-only**

**Context** config>service>ies>if>sap>egress

**Description** When enabled (the encapsulation type of the access port where this SAP is defined as qinq), the **qinq-mark-top-only** command specifies which P-bits/DEI bit to mark during packet egress. When disabled, both set of P-bits/DEI bit are marked. When the enabled, only the P-bits/DEI bit in the top Q-tag are marked.

**Default** no qinq-mark-top-only

---

qos

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>This command associates a Quality of Service (QoS) policy with an egress Service Access Point (SAP).</p> <p>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the policy-id does not exist, an error will be returned.</p> <p>The qos command is used to associate both ingress and egress QoS policies. The qos command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>When an ingress QoS policy is defined on IES ingress IP interface that is bound to a VPLS, the policy becomes associated with every SAP on the VPLS and augments the QoS policy that is defined on each SAP. Packets that are bridged will be processed using the policy defined on the VPLS SAP; packets that are routed will be processed using the policy defined in the IES IP interface-binding context.</p> <p>By default, no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.</p> <p>The <b>no</b> form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <p><i>policy-id</i> — The ingress/egress policy ID to associate with SAP or IP interface on ingress/egress. The policy ID must already exist.<br/>1 to 65535</p> <p><i>port-redirect-group</i> — This keyword associates a SAP egress with an instance of a named queue group template on the egress port of a given IOM/IMM/XMA. The queue-group-name and instance instance-id are mandatory parameters when executing the command.</p> <p><i>queue-group-name</i> — Specifies the name of the egress port queue group of the IOM/IMM/XMA, up to 32 characters in length. The queue-group-name must correspond to a valid egress queue group, created under config&gt;port&gt;ethernet&gt;access&gt;egress.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

**instance** *instance-id* — specifies the instance of the named egress port queue group on the IOM/IMM/XMA

**Values** 1 to 40960

**Default** 1

| <b>Context</b>     | config>service>vprn>if>sap>ingress<br>config>service>vprn>sub-if>grp-if>sap>ingress                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command associates a Quality of Service (QoS) policy with an ingress Service Access Point (SAP).</p> <p>QoS ingress and egress policies are important for the enforcement of SLA agreements. The policy ID must be defined prior to associating the policy with a SAP. If the policy- id does not exist, an error will be returned.</p> <p>The qos command is used to associate both ingress and egress QoS policies. The qos command only allows ingress policies to be associated on SAP ingress and egress policies on SAP egress. Attempts to associate a QoS policy of the wrong type returns an error.</p> <p>Only one ingress and one egress QoS policy can be associated with a SAP or IP interface at one time. Attempts to associate a second QoS policy of a given type will return an error.</p> <p>By default, no specific QoS policy is associated with the SAP for ingress or egress, so the default QoS policy is used.</p> <p>The no form of this command removes the QoS policy association from the SAP, and the QoS policy reverts to the default.</p> <p>The <b>no</b> form of this command removes the QoS policy association from the SAP or IP interface, and the QoS policy reverts to the default.</p> |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Parameters</b>  | <p><i>policy-id</i> — The ingress/egress policy ID to associate with SAP or IP interface on ingress/ egress. The policy ID must already exist.<br/>1 to 65535</p> <p><b>shared-queuing</b> — Specifies the ingress shared queue policy used by this SAP. When the value of this object is null it means that the SAP will use individual ingress QoS queues instead of the shared ones.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**multipoint-shared** — This keyword specifies that this queue-id is for multipoint forwarded traffic only. This queue-id can only be explicitly mapped to the forwarding class multicast, broadcast, or unknown unicast ingress traffic. Attempting to map forwarding class unicast traffic to a multipoint queue generates an error; no changes are made to the current unicast traffic queue mapping.

A queue must be created as multipoint. The multipoint designator cannot be defined after the queue is created. If an attempt is made to modify the command to include the multipoint keyword, an error is generated and the command will not execute.

The multipoint keyword can be entered in the command line on a preexisting multipoint queue to edit queue-id parameters.

**Default** Present (the queue is created as non-multipoint).

**Values** **Multipoint** or not present.

**fp-redirect-group** — Creates an instance of a named queue group template on the ingress forwarding plane of a given IOM/IMM/XMA. The queue-group-name and instance instance-id are mandatory parameters when executing the command. The named queue group template can contain only policers. If it contains queues, then the command will fail.

*queue-group-name* — Specifies the name of the queue group template to be instantiated on the forwarding plane of the IOM/IMM/XMA, up to 32 characters in length. The queue-group-name must correspond to a valid ingress queue group template name, configured under *config>qos>queue-group-templates*.

*instance-id* — specifies the instance of the named queue group to be created on the IOM/IMM/XMA ingress forwarding plane

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's adaptation rule parameters. The adaptation rule controls the method used by the system to derive the operational CIR and PIR settings when the queue is provisioned in hardware. For the CIR and PIR parameters individually, the system attempts to find the best operational rate depending on the defined constraint.</p> <p>The <b>no</b> form of the command removes any explicitly defined constraints used to derive the operational CIR and PIR created by the application of the policy. When a specific <b>adaptation-rule</b> is removed, the default constraints for <b>rate</b> and <b>cir</b> apply.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Default</b>     | no adaptation-rule                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <p><b>pir</b> — The <b>pir</b> parameter defines the constraints enforced when adapting the PIR rate defined within the <b>queue queue-id rate</b> command. The <b>pir</b> parameter requires a qualifier that defines the constraint used when deriving the operational PIR for the queue. When the <b>rate</b> command is not specified, the default applies.</p> <p><b>max</b> — The <b>max</b> (maximum) option is mutually exclusive with the <b>min</b> and <b>closest</b> options. When <b>max</b> is defined, the operational PIR for the queue will be equal to or less than the administrative rate specified using the <b>rate</b> command.</p> <p><b>min</b> — The <b>min</b> (minimum) option is mutually exclusive with the <b>max</b> and <b>closest</b> options. When <b>min</b> is defined, the operational PIR for the queue will be equal to or greater than the administrative rate specified using the <b>rate</b> command.</p> <p><b>closest</b> — The <b>closest</b> parameter is mutually exclusive with the <b>min</b> and <b>max</b> parameter. When <b>closest</b> is defined, the operational PIR for the queue will be the rate closest to the rate specified using the <b>rate</b> command.</p> <p><b>cir</b> — The <b>cir</b> parameter defines the constraints enforced when adapting the CIR rate defined within the <b>queue queue-id rate</b> command. The <b>cir</b> parameter requires a qualifier that defines the constraint used when deriving the operational CIR for the queue. When the <b>cir</b> parameter is not specified, the default constraint applies.</p> |

| <b>Syntax</b>      | <b>avg-frame-overhead</b> <i>percent</i><br><b>no avg-frame-overhead</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if>sap>egress>queue-override<br>config>service>ies>if>sap>ingress>queue-override>queue<br>config>service>ies>sub-if>grp-if>sap>egress>queue-override>queue                                                                                                                                                                                                                                                                                                                                                                                   |
| <b>Description</b> | This command configures the average frame overhead to define the average percentage that the offered load to a queue will expand during the frame encapsulation process before sending traffic on-the-wire. While the avg-frame-overhead value may be defined on any queue, it is only used by the system for queues that egress a Sonet or SDH port or channel. Queues operating on egress Ethernet ports automatically calculate the frame encapsulation overhead based on a 20 byte per packet rule (8 bytes for preamble and 12 bytes for inter-frame gap). |

When calculating the frame encapsulation overhead for port scheduling purposes, the system determines the following values:

- **Offered-load** — The offered-load of a queue is calculated by starting with the queue depth in octets, adding the received octets at the queue and subtracting queue discard octets. The result is the number of octets the queue has available to transmit. This is the packet based offered-load.
- **Frame encapsulation overhead** — Using the avg-frame-overhead parameter, the frame encapsulation overhead is simply the queue's current offered-load (how much has been received by the queue) multiplied by the avg-frame-overhead. If a queue had an offered load of 10000 octets and the avg-frame-overhead equals 10%, the frame encapsulation overhead would be  $10000 \times 0.1$  or 1000 octets.

For egress Ethernet queues, the frame encapsulation overhead is calculated by multiplying the number of offered-packets for the queue by 20 bytes. If a queue was offered 50 packets then the frame encapsulation overhead would be  $50 \times 20$  or 1000 octets.

- **Frame based offered-load** — The frame based offered-load is calculated by adding the offered-load to the frame encapsulation overhead. If the offered-load is 10000 octets and the encapsulation overhead was 1000 octets, the frame based offered-load would equal 11000 octets.
- **Packet to frame factor** — The packet to frame factor is calculated by dividing the frame encapsulation overhead by the queue's offered-load (packet based). If the frame encapsulation overhead is 1000 octets and the offered-load is 10000 octets then the packet to frame factor would be  $1000 / 10000$  or 0.1. When in use, the avg-frame-overhead will be the same as the packet to frame factor making this calculation unnecessary.
- **Frame based CIR** — The frame based CIR is calculated by multiplying the packet to frame factor with the queue's configured CIR and then adding that result to that CIR. If the queue CIR is set at 500 octets and the packet to frame factor equals 0.1, the frame based CIR would be  $500 \times 1.1$  or 550 octets.

- **Frame based within-cir offered-load** — The frame based within-cir offered-load is the portion of the frame based offered-load considered to be within the frame-based CIR. The frame based within-cir offered-load is the lesser of the frame based offered-load and the frame based CIR. If the frame based offered-load equaled 11000 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would be limited to 550 octets. If the frame based offered-load equaled 450 octets and the frame based CIR equaled 550 octets, the frame based within-cir offered-load would equal 450 octets (or the entire frame based offered-load).

As a special case, when a queue or associated intermediate scheduler is configured with a CIR-weight equal to 0, the system automatically sets the queue's frame based within-cir offered-load to 0, preventing it from receiving bandwidth during the port scheduler's within-cir pass.

- **Frame based PIR** — The frame based PIR is calculated by multiplying the packet to frame factor with the queue's configured PIR and then adding the result to that PIR. If the queue PIR is set to 7500 octets and the packet to frame factor equals 0.1, the frame based PIR would be  $7500 \times 1.1$  or 8250 octets.
- **Frame based within-pir offered-load** — The frame based within-pir offered-load is the portion of the frame based offered-load considered to be within the frame based PIR. The frame based within-pir offered-load is the lesser of the frame based offered-load and the frame based PIR. If the frame based offered-load equaled 11000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered-load would be limited to 8250 octets. If the frame based offered-load equaled 7000 octets and the frame based PIR equaled 8250 octets, the frame based within-pir offered load would equal 7000 octets.

**Port scheduler operation using frame transformed rates** — The port scheduler uses the frame based rates to determine the maximum rates that each queue may receive during the within-cir and above-cir bandwidth allocation passes. During the within-cir pass, a queue may receive up to its frame based within-cir offered-load. The maximum it may receive during the above-cir pass is the difference between the frame based within-pir offered load and the amount of actual bandwidth allocated during the within-cir pass.

**SAP and subscriber SLA-profile average frame overhead override** — The average frame overhead parameter on a sap-egress may be overridden at an individual egress queue basis. On each SAP and within the sla-profile policy used by subscribers an avg-frame-overhead command may be defined under the queue-override context for each queue. When overridden, the queue instance will use its local value for the average frame overhead instead of the sap-egress defined overhead.

The **no** form of this command restores the average frame overhead parameter for the queue to the default value of 0 percent. When set to 0, the system uses the packet based queue statistics for calculating port scheduler priority bandwidth allocation. If the no avg-frame-overhead command is executed in a queue-override queue id context, the avg-frame-overhead setting for the queue within the sap-egress QoS policy takes effect.

**Default** 0

**Parameters**     *percent* — This parameter sets the average amount of packet-to-frame encapsulation overhead expected for the queue. This value is not used by the system for egress Ethernet queues.

**Values**        0 to 100

## cbs

**Syntax**        **cbs** *size-in-kbytes*  
**no cbs**

**Context**        config>service>ies>if>sap>egress>queue-override>queue  
config>service>ies>if>sap>ingress>queue-override>queue

**Description**    This command can be used to override specific attributes of the specified queue's CBS parameters. It is permissible, and possibly desirable, to oversubscribe the total CBS reserved buffers for a given access port egress buffer pool. Oversubscription may be desirable due to the potential large number of service queues and the economy of statistical multiplexing the individual queue's CBS setting into the defined reserved total.

When oversubscribing the reserved total, it is possible for a queue depth to be lower than its CBS setting and still not receive a buffer from the buffer pool for an ingress frame. As more queues are using their CBS buffers and the total in use exceeds the defined reserved total, essentially the buffers are being removed from the shared portion of the pool without the shared in use average and total counts being decremented. This can affect the operation of the high and low priority RED slopes on the pool, causing them to miscalculate when to start randomly drop packets.

If the CBS value is larger than the MBS value, an error will occur, preventing the CBS change.

The **no** form of this command returns the CBS size to the default value.

**Default**        no cbs

**Parameters**    *size-in-kbytes* — The size parameter is an integer expression of the number of kilobytes reserved for the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that no reserved buffers are required by the queue (a minimal reserved size can still be applied for scheduling purposes).

**Values**        0 to 131072, default

## high-prio-only

**Syntax**        **high-prio-only** *percent*  
**no high-prio-only**

**Context**        config>service>ies>if>sap>egress>queue-override>queue  
config>service>ies>if>sap>ingress>queue-override>queue

|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's high-prio-only parameters. The <b>high-prio-only</b> command configures the percentage of buffer space for the queue, used exclusively by high priority packets.</p> <p>The priority of a packet can only be set in the SAP ingress QoS policy and is only applicable on the ingress queues for a SAP. The <b>high-prio-only</b> parameter is used to override the default value derived from the <b>network-queue</b> command.</p> <p>The defined <b>high-prio-only</b> value cannot be greater than the MBS size of the queue. Attempting to change the MBS to a value smaller than the high priority reserve will generate an error and fail execution. Attempting to set the <b>high-prio-only</b> value larger than the current MBS size will also result in an error and fail execution.</p> <p>The <b>no</b> form of this command restores the default high priority reserved size.</p> |
| <b>Parameters</b>  | <p><i>percent</i> — The <i>percent</i> parameter is the percentage reserved for high priority traffic on the queue. If a value of 10KBytes is desired, enter the value 10. A value of 0 specifies that none of the MBS of the queue will be reserved for high priority traffic. This does not affect RED slope operation for packets attempting to be queued.</p> <p><b>Values</b>      0 to 100, default</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## mbs

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's MBS parameters. The MBS is a mechanism to override the default maximum size for the queue.</p> <p>The sum of the MBS for all queues on an egress access port can oversubscribe the total amount of buffering available. When congestion occurs and buffers become scarce, access to buffers is controlled by the RED slope a packet is associated with. A queue that has not exceeded its MBS size is not guaranteed that a buffer will be available when needed or that the packet's RED slope will not force the discard of the packet. Setting proper CBS parameters and controlling CBS oversubscription is one major safeguard to queue starvation (when a queue does not receive its fair share of buffers). Another is properly setting the RED slope parameters for the needs of services on this port or channel.</p> <p>If the CBS value is larger than the MBS value, an error will occur, preventing the MBS change.</p> <p>The <b>no</b> form of this command returns the MBS size assigned to the queue.</p> |
| <b>Default</b>     | mbs default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | This command can be used to override the scheduler's parent weight and cir-weight information. The weights apply to the associated level/cir-level configured in the applied scheduler policy. The scheduler name must exist in the scheduler policy applied to the ingress or egress of the SAP or multi-service site.<br><br>The override weights are ignored if the scheduler does not have a parent command configured in the scheduler policy – this allows the parent of the scheduler to be removed from the scheduler policy without having to remove all of the SAP/MSS overrides. If the parent scheduler does not exist causing the configured scheduler to be fostered on an egress port scheduler, the override weights will be ignored and the default values used; this avoids having non default weightings for fostered schedulers.<br><br>The <b>no</b> form of the command returns the scheduler's parent weight and cir-weight to the value configured in the applied scheduler policy. |
| <b>Default</b>     | no parent                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <p><b>weight</b> <i>weight</i> — <b>Weight</b> defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same strict <b>level</b> defined by the <b>level</b> parameter in the applied scheduler policy. Within the level, all weight values from active children at that level are summed and the ratio of each active child's weight to the total is used to distribute the available bandwidth at that level. A weight is considered to be active when the queue or scheduler the weight pertains to has not reached its maximum rate and still has packets to transmit.</p> <p>A 0 (zero) weight value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict level.</p> <p><b>Values</b>      0 to 100</p> <p><b>Default</b>      1</p> <p><b>cir-weight</b> <i>cir-weight</i> — The <b>cir-weight</b> keyword defines the relative weight of this scheduler in comparison to other child schedulers and queues at the same <i>cir-level</i> defined by the <b>cir-level</b> parameter in the applied scheduler policy. Within the strict <b>cir-level</b>, all <b>cir-weight</b> values from active children at that level are summed and the ratio of each active child's <b>cir-weight</b> to the total is used to distribute the available bandwidth at that level. A <b>cir-weight</b> is considered to be active when the policer, queue, or scheduler that the <b>cir-weight</b> pertains to has not reached the CIR and still has packets to transmit.</p> <p>A 0 (zero) <b>cir-weight</b> value signifies that the child scheduler will receive bandwidth only after bandwidth is distributed to all other non-zero weighted children in the strict <i>cir-level</i>.</p> <p><b>Values</b>      0 to 100</p> <p><b>Default</b>      1</p> |

| <b>Description</b> | <p>The <b>percent-rate</b> command supports a queue's shaping rate and CIR rate as a percentage of the egress port's line rate. When the rates are expressed as a percentage within the template, the actual rate used per instance of the queue group queue-id will vary based on the port speed. For example, when the same template is used to create a queue group on a 1-Gigabit and a 10-Gigabit Ethernet port, the queue's rates will be 10 times greater on the 10 Gigabit port due to the difference in port speeds. This enables the same template to be used on multiple ports without needing to use port based queue overrides to modify a queue's rate to get the same relative performance from the queue.</p> <p>If the port's speed changes after the queue is created, the queue's shaping and CIR rates will be recalculated based on the defined percentage value.</p> |

The rate and percent-rate commands override one another. If the current rate for a queue is defined using the percent-rate command and the rate command is executed, the percent-rate values are deleted. In a similar fashion, the percent-rate command causes any rate command values to be deleted. A queue's rate may dynamically be changed back and forth from a percentage to an explicit rate at anytime.

An egress port queue group queue rate override may be expressed as either a percentage or an explicit rate independent on how the queue's template rate is expressed.

The **no** form of this command returns the queue to its default shaping rate and cir rate. When **no percent-rate** is defined within a port egress queue group queue override, the queue reverts to the defined shaping and CIR rates within the egress queue group template associated with the queue.

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified queue's Peak Information Rate (PIR) and the Committed Information Rate (CIR) parameters.</p> <p>The PIR defines the maximum rate that the queue can transmit packets out an egress interface (for SAP egress queues). Defining a PIR does not necessarily guarantee that the queue can transmit at the intended rate. The actual rate sustained by the queue can be limited by oversubscription factors or available egress bandwidth.</p> |

The CIR defines the rate at which the system prioritizes the queue over other queues competing for the same bandwidth. In-profile and then out-of-profile packets are preferentially queued by the system at egress and at subsequent next hop nodes where the packet can traverse. To be properly handled throughout the network, the packets must be marked accordingly for profiling at each hop.

The CIR can be used by the queue's parent commands *cir-level* and *cir-weight* parameters to define the amount of bandwidth considered to be committed for the child queue during bandwidth allocation by the parent scheduler.

The **rate** command can be executed at any time, altering the PIR and CIR rates for all queues created through the association of the SAP egress QoS policy with the *queue-id*.

The **no** form of the command returns all queues created with the *queue-id* by association with the QoS policy to the default PIR and CIR parameters (**max**, 0).

| <b>Default</b>    | <b>rate max cir 0</b> – The <b>max</b> default specifies the amount of bandwidth in kilobits per second (thousand bits per second). The <b>max</b> value is mutually exclusive to the <b>pir-rate</b> value.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b> | <p><i>pir-rate</i> — Defines the administrative PIR rate, in kilobits, for the queue. When the <b>rate</b> command is executed, a valid PIR setting must be explicitly defined. When the <b>rate</b> command has not been executed, the default PIR of <b>max</b> is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer.</p> <p>The actual PIR rate is dependent on the queue's <b>adaptation-rule</b> parameters and the actual hardware where the queue is provisioned.</p> <p>For <b>egress&gt;queue-override&gt;queue</b> and <b>ingress&gt;queue-override&gt;queue</b>:</p> <p><b>Values</b> 1 to 2000000000, <b>max</b> in kb/s</p> <p><b>Default</b> max</p> <p>For <b>egress&gt;sched-override&gt;scheduler</b> and <b>ingress&gt;sched-override&gt;scheduler</b>:</p> <p><b>Values</b> 1 to 3200000000, <b>max</b> in kb/s</p> <p><b>Default</b> max</p> <p><b>cir</b> <i>cir-rate</i> — The <b>cir</b> parameter overrides the default administrative CIR used by the queue. When the <b>rate</b> command is executed, a CIR setting is optional. When the <b>rate</b> command has not been executed or the <b>cir</b> parameter is not explicitly specified, the default CIR (0) is assumed.</p> <p>Fractional values are not allowed and must be given as a positive integer. The <b>sum</b> keyword specifies that the CIR be used as the summed CIR values of the children schedulers or queues.</p> <p>For <b>egress&gt;queue-override&gt;queue</b> and <b>ingress&gt;queue-override&gt;queue</b>:</p> <p><b>Values</b> 0 to 2000000000, <b>sum</b>, <b>max</b> in kb/s</p> <p><b>Default</b> 0</p> |

For **egress>sched-override>scheduler** and **ingress>sched-override>scheduler**:

**Values**      0 to 3200000000, **sum**, **max** in kb/s  
**Default**      0

| <b>Description</b> | <p>This command can be used to override specific attributes of the specified scheduler name.</p> <p>A scheduler defines a bandwidth controls that limit each child (other schedulers, policers, and queues) associated with the scheduler. Scheduler objects are created within the hierarchical tiers of the policy. It is assumed that each scheduler created will have policers, queues, or other schedulers defined as child associations. The scheduler can be a child (take bandwidth from a scheduler in a higher tier, except for schedulers created in tier 1). A total of 32 schedulers can be created within a single scheduler policy with no restriction on the distribution between the tiers.</p> <p>Each scheduler must have a unique name within the context of the scheduler policy; however the same name can be reused in multiple scheduler policies. If <i>scheduler-name</i> already exists within the policy tier level (regardless of the inclusion of the keyword create), the context changes to that scheduler name for the purpose of editing the scheduler parameters. Modifications made to an existing scheduler are executed on all instantiated schedulers created through association with the policy of the edited scheduler. This can cause queues or schedulers to become orphaned (invalid parent association) and adversely affect the ability of the system to enforce service level agreements (SLAs).</p> <p>If the <i>scheduler-name</i> exists within the policy on a different tier (regardless of the inclusion of the keyword create), an error occurs and the current CLI context will not change.</p> |

If the *scheduler-name* does not exist in this or another tier within the scheduler policy, it is assumed that an attempt is being made to create a scheduler of that name. The success of the command execution is dependent on the following:

- Step 1.** The maximum number of schedulers has not been configured.
- Step 2.** The provided *scheduler-name* is valid.
- Step 3.** The **create** keyword is entered with the command if the system is configured to require it (enabled in the **environment create** command).

When the maximum number of schedulers has been exceeded on the policy, a configuration error occurs and the command will not execute, nor will the CLI context change.

If the provided scheduler-name is invalid according to the criteria below, a name syntax error will occur, the command will not execute, and the CLI context will not change.

**Parameters** *scheduler-name* — The name of the scheduler.

- Values** Valid names consist of any string up to 32 characters long composed of printable, 7-bit ASCII characters. If the string contains special characters (#, \$, spaces, etc.), the entire string must be enclosed within double quotes.
- Default** None. Each scheduler must be explicitly created.

**create** — This optional keyword explicitly specifies that it is acceptable to create a scheduler with the given *scheduler-name*. If the **create** keyword is omitted, **scheduler-name** is not created when the system environment variable create is set to true. This safeguard is meant to avoid accidental creation of system objects (such as schedulers) while attempting to edit an object with a mistyped name or ID. The keyword has no effect when the object already exists.

rate

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| <b>Description</b> | This command can be used to override specific attributes of the specified scheduler rate. The <b>rate</b> command defines the maximum bandwidth that the scheduler can offer its child queues or schedulers. The maximum rate is limited to the amount of bandwidth the scheduler can receive from its parent scheduler. If the scheduler has no parent, the maximum rate is assumed to be the amount available to the scheduler. When a parent is associated with the scheduler, the CIR parameter provides the amount of bandwidth to be considered during the parent scheduler's 'within CIR' distribution phase. |

The actual operating rate of the scheduler is limited by bandwidth constraints other than its maximum rate. The scheduler's parent scheduler may not have the available bandwidth to meet the scheduler's needs or the bandwidth available to the parent scheduler could be allocated to other child schedulers or child queues on the parent based on higher priority. The children of the scheduler may not need the maximum rate available to the scheduler due to insufficient offered load or limits to their own maximum rates.

When a scheduler is defined without specifying a rate, the default rate is **max**. If the scheduler is a root scheduler (no parent defined), the default maximum rate must be changed to an explicit value. Without this explicit value, the scheduler will assume that an infinite amount of bandwidth is available and allow all child queues and schedulers to operate at their maximum rates.

The **no** form of this command returns all queues created with this *queue-id* by association with the QoS policy to the default PIR and CIR parameters.

**Parameters** *pir-rate* — The **pir** parameter accepts a value of 1 to 3200000000, or the keyword **max**. Any other value will result in an error without modifying the current PIR rate.

**Values** 1 to 3200000000, **max**

**Default** max

**cir** *cir-rate* — This parameter accepts a step-multiplier value that specifies the multiplier used to determine the CIR rate at which the queue will operate. A value of 1 to 3200000000 or the keywords **max** or **sum** is accepted. Any other value will result in an error without modifying the current CIR rate.

If the **cir** is set to max, then the CIR rate is set to infinity but is restricted by the PIR rate.

The **sum** keyword specifies that the CIR be used as the summed CIR values of the children schedulers, policers, or queues.

For **egress>sched-override>scheduler** and **ingress>sched-override>scheduler**:

**Values** 0 to 3200000000, **max**, **sum**

**Default** sum

## scheduler-policy

**Syntax** **scheduler-policy** *scheduler-policy-name*  
**no scheduler-policy**

**Context** config>service>ies>sap>ingress  
config>service>ies>sap>egress

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command applies an existing scheduler policy to an ingress or egress scheduler used by SAP queues associated with this multi-service customer site. The schedulers defined in the scheduler policy can only be created once the customer site has been appropriately assigned to a chassis port, channel or slot. Scheduler policies are defined in the <b>config&gt;qos&gt;scheduler-policy scheduler-policy-name</b> context.</p> <p>The <b>no</b> form of this command removes the configured ingress or egress scheduler policy from the multi-service customer site. When the policy is removed, the schedulers created due to the policy are removed also making them unavailable for the ingress SAP queues associated with the customer site. Queues that lose their parent scheduler association are deemed to be orphaned and are no longer subject to a virtual scheduler. The SAPs that have ingress queues reliant on the removed schedulers enter into an operational state depicting the orphaned status of one or more queues. When the <b>no scheduler-policy</b> command is executed, the customer site ingress or egress node will not contain an applied scheduler policy.</p> |
| <b>Parameters</b>  | <p><i>scheduler-policy-name</i>: — The <i>scheduler-policy-name</i> parameter applies an existing scheduler policy that was created in the <b>config&gt;qos&gt;scheduler-policy scheduler-policy-name</b> context to create the hierarchy of ingress or egress virtual schedulers. The scheduler names defined within the policy are created and made available to any ingress or egress queues created on associated SAPs.</p> <p><b>Values</b> Any existing valid scheduler policy name.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

### 2.5.2.15 ATM Commands

#### atm

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| <b>Description</b> | <p>This command configures AIS/RDI fault management on a PVCC. Fault management allows PVCC termination to monitor and report the status of their connection by propagating fault information through the network and by driving PVCC's operational status.</p> <p>When alarm-cells functionality is enabled, a PVCC's operational status is affected when a PVCC goes into an AIS or RDI state because of an AIS/RDI processing (assuming nothing else affects PVCC's operational status, for example, if the PVCC goes DOWN, or enters a fault state and comes back UP, or exits that fault state). RDI cells are generated when PVCC is operationally DOWN. No OAM-specific SNMP trap is raised whenever an endpoint enters/exits an AIS or RDI state, however, if as result of an OAM state change, the PVCC changes operational status, then a trap is expected from an entity the PVCC is associated with (for example a SAP).</p> <p>The <b>no</b> command disables alarm-cells functionality for a PVCC. When alarm-cells functionality is disabled, a PVCC's operational status is no longer affected by a PVCC's OAM state changes due to AIS/RDI processing (when alarm-cells is disabled, a PVCC will change operational status to UP due to alarm-cell processing) and RDI cells are not generated as result of the PVCC going into AIS or RDI state. The PVCC's OAM status, however, will record OAM faults as described above.</p> |
| <b>Default</b>     | Enabled for PVCCs delimiting IES SAPs                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Description</b> | <p>This command enables periodic OAM loopbacks on this SAP. This command is only configurable on IES and VPRN SAPs. When enabled, an ATM OAM loopback cell is transmitted every period as configured in the config&gt;system&gt;atm&gt;oam&gt;loopback-period <i>period</i> context.</p> <p>If a response is not received and consecutive retry-down retries also result in failure, the endpoint will transition to an alarm indication signal/loss of clock state. Then, an ATM OAM loopback cell will be transmitted every period as configured in the loopback-period <i>period</i>. If a response is received for the periodic loopback and consecutive retry-up retries also each receive a response, the endpoint will transition back to the up state.</p> <p>The <b>no</b> form of the command sets the value back to the default.</p> |
| <b>Default</b>     | no periodic-loopback                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## 2.5.2.16 IES Interface VRRP Commands

| <b>Context</b>       | config>service>ies>if<br>config>service>ies>if>ipv6                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Description</b>   | <p>This command creates or edits a Virtual Router ID (VRID) on the service IP interface. A VRID is internally represented in conjunction with the IP interface name. This allows the VRID to be used on multiple IP interfaces while representing different virtual router instances.</p> <p>Two VRRP nodes can be defined on an IP interface. One, both, or none may be defined as the owner. The nodal context of <b>vrrp</b> <i>virtual-router-id</i> is used to define the configuration parameters for the VRID.</p> <p>The <b>no</b> form of this command removes the specified VRID from the IP interface. This terminates VRRP participation for the virtual router and deletes all references to the VRID. The VRID does not need to be shutdown in order to remove the virtual router instance.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| <b>Default</b>       | n/a                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Special Cases</b> | <p><b>Virtual Router Instance Owner IP Address Conditions</b> — The virtual router instance <b>owner</b> can be created prior to assigning the parent IP interface primary or secondary IP addresses. In this case, the virtual router instance is not associated with an IP address. The operational state of the virtual router instance is down.</p> <p><b>VRRP Owner Command Exclusions</b> — By specifying the VRRP <i>vrid</i> as <b>owner</b>, the following commands are no longer available:</p> <ul style="list-style-type: none"><li>• <b>vrrp priority</b> — The virtual router instance <b>owner</b> is hard-coded with a <b>priority</b> value of 255 and cannot be changed.</li><li>• <b>vrrp master-int-inherit</b> — Owner virtual router instances do not accept VRRP advertisement messages; the advertisement interval field is not evaluated and cannot be inherited.</li><li>• <b>ping-reply</b>, <b>telnet-reply</b> and <b>ssh-reply</b> — The <b>owner</b> virtual router instance always allows Ping, Telnet and SSH if the management and security parameters are configured to accept them on the parent IP interface.</li><li>• <b>vrrp shutdown</b> — The <b>owner</b> virtual router instance cannot be shut down on the <b>vrrp</b> node. If this was allowed, VRRP messages would not be sent, but the parent IP interface address would continue to respond to ARPs and forward IP packets. Another virtual router instance may detect the missing master due to the termination of VRRP advertisement messages and become master. This would result in two routers responding to ARP requests for the same IP</li></ul> |

addresses. To shut down the **owner** virtual router instance, use the **shutdown** command in the parent IP interface context. This will prevent VRRP participation, IP ARP reply and IP forwarding. To continue parent IP interface ARP reply and forwarding without VRRP participation, remove the **vrrp vrid** instance.

- **traceroute-reply**

**VRRP Passive Command Exclusions** — By specifying the VRRP *vrid* as **passive**, the following commands related to the master election and processing of VRRP advertisement messages are no longer available:

- **vrrp priority**
- **policy**
- **preempt**
- **master-int-inherit**
- **standby-forwarding**
- **int-delay**
- **message-interval**
- **authentication-key**
- **bfd-enable**

**Parameters**     *virtual-router-id* — The virtual-router-id parameter specifies a new virtual router ID or one that can be modified on the IP interface.

**Values**            1 to 255

**owner** — Identifies this virtual router instance as owning the virtual router IP addresses. If the **owner** keyword is not specified at the time of *vrid* creation, the **vrrp backup** commands must be specified to define the virtual router IP addresses. The **owner** keyword is not required when entering the *vrid* for editing purposes. Once created as **owner**, a *vrid* on an IP interface cannot have the **owner** parameter removed. The *vrid* must be deleted, and then recreated without the **owner** keyword, to remove ownership.

**passive** — Identifies this virtual router instance as **passive**, and therefore, owning the virtual router IP addresses. A **passive vrid** does not send or receive VRRP advertisement messages, and is always in either the **master** state (if the interface is operational-up), or the **init** state (if the interface is operational-down). The **passive** keyword is not required when entering the *vrid* for editing purposes. Once a *vrid* on an IP interface is created as **passive**, the parameter cannot be removed from the *vrid*. The *vrid* must be deleted, and then recreated without the **passive** keyword, to remove parameter.

authentication-key

**Syntax**            **authentication-key** [*authentication-key* | *hash-key*] [**hash** | **hash2**]  
                      **no authentication-key**

**Context**            config>service>ies>if>vrrp

**Description**     The **authentication-key** command, within the **vrrp virtual-router-id** context, is used to assign a simple text password authentication key to generate master VRRP advertisement messages and validating received VRRP advertisement messages.

The authentication-key command is one of the few commands not affected by the presence of the owner keyword. If simple text password authentication is not required, the authentication-key command is not required. If the command is re-executed with a different password key defined, the new key will be used immediately. If a no authentication-key command is executed, the password authentication key is restored to the default value. The authentication-key command may be executed at any time.

To change the current in-use password key on multiple virtual router instances:

- Identify the current master
- Shutdown the virtual router instance on all backups
- Execute the authentication-key command on the master to change the password key
- Execute the authentication-key command and no shutdown command on each backup key

The **no** form of this command restores the default null string to the value of key.

**Default**     No default. The authentication data field contains the value 0 in all 16 octets.

**Parameters**     *authentication-key* — The *key* parameter identifies the simple text password used when VRRP Authentication Type 1 is enabled on the virtual router instance. Type 1 uses a string eight octets long that is inserted into all transmitted VRRP advertisement messages and compared against all received VRRP advertisement messages. The authentication data fields are used to transmit the key.

The *key* parameter is expressed as a string consisting up to eight alpha-numeric characters. Spaces must be contained in quotation marks (" "). The quotation marks are not considered part of the string.

The string is case sensitive and is left-justified in the VRRP advertisement message authentication data fields. The first field contains the first four characters with the first octet (starting with IETF RFC bit position 0) containing the first character. The second field holds the fifth through eighth characters. Any unspecified portion of the authentication data field is padded with the value 0 in the corresponding octet.

**Values**     Any 7-bit printable ASCII character.

|             |                  |          |
|-------------|------------------|----------|
| Exceptions: | Double quote (") | ASCII 34 |
|             | Carriage Return  | ASCII 13 |
|             | Line Feed        | ASCII 10 |
|             | Tab              | ASCII 9  |
|             | Backspace        | ASCII 8  |

*hash-key* — The hash key. The key can be any combination of ASCII characters up to 22 characters in length (encrypted). If spaces are used in the string, enclose the entire string in quotation marks (" ").

This is useful when a user must configure the parameter, but, for security purposes, the actual unencrypted key value is not provided.

**hash** — Specifies the key is entered in an encrypted form. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

**hash2** — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the **hash2** encrypted variable cannot be copied and pasted. If the **hash** or **hash2** parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the **hash** or **hash2** parameter specified.

## backup

| <b>Description</b> | <p>This commands assigns a bi-directional forwarding (BFD) session providing heart-beat mechanism for the given VRRP/SRRP instance. There can be only one BFD session assigned to any given VRRP/SRRP instance, but there can be multiple SRRP/VRRP sessions using the same BFD session.</p> <p>BFD control the state of the associated interface. By enabling BFD on a given protocol interface, the state of the protocol interface is tied to the state of the BFD session between the local node and the remote node. The parameters used for the BFD are set via the BFD command under the IP interface. The specified interface may not be configured with BFD; however, when it is, the virtual router will then initiate the BFD session.</p> <p>The <b>no</b> form of this command removes BFD from the configuration.</p> |
| <b>Default</b>     | none                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><i>service-id</i> — specifies the service ID of the interface running BFD</p> <p><b>Values</b>      <i>service-id</i>: 1 to 2147483648<br/>No service ID indicates a network interface.</p> <p><b>interface</b> <i>interface-name</i> — specifies the name of the interface running BFD</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

---

**dst-ip** *ip-address* — specifies the destination address to be used for the BFD session

## init-delay

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>init-delay</b> <i>seconds</i><br><b>no init-delay</b>                                                   |
| <b>Context</b>     | config>service>ies>if>vrrp                                                                                 |
| <b>Description</b> | This command configures a VRRP initialization delay timer.                                                 |
| <b>Default</b>     | no init-delay                                                                                              |
| <b>Parameters</b>  | <i>seconds</i> — specifies the initialization delay timer for VRRP, in seconds<br><b>Values</b> 1 to 65535 |

## mac

|                    |                                                                                                                                                                                                                                                                                     |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mac</b> <i>mac-address</i><br><b>no mac</b>                                                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                          |
| <b>Description</b> | This command assigns a specific MAC address to an IES IP interface.<br><br>The <b>no</b> form of the command returns the MAC address of the IP interface to the default value.                                                                                                      |
| <b>Default</b>     | The physical MAC address associated with the Ethernet interface that the SAP is configured on (the default MAC address assigned to the interface, assigned by the system).                                                                                                          |
| <b>Parameters</b>  | <i>mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff, where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. |

## master-int-inherit

|                    |                                                                                                    |
|--------------------|----------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] master-int-inherit</b>                                                                     |
| <b>Context</b>     | config>service>ies>if>vrrp                                                                         |
| <b>Description</b> | This command allows the master instance to dictate the master down timer (non-owner context only). |
| <b>Default</b>     | no master-int-inherit                                                                              |

| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Description</b> | <p>This command sets the advertisement timer and indirectly sets the master down timer on the virtual router instance. The message-interval setting must be the same for all virtual routers participating as a virtual router. Any VRRP advertisement message received with an Advertisement Interval field different than the virtual router instance configured message-interval value will be silently discarded.</p> <p>The message-interval command is available in both non-owner and owner <b>vrrp</b> <i>virtual-router-id</i> nodal contexts. If the message-interval command is not executed, the default message interval of 1 second will be used.</p> <p>The <b>no</b> form of this command restores the default message interval value of 1 second to the virtual router instance.</p> |
| <b>Parameters</b>  | <p><i>seconds</i> — The number of seconds that will transpire before the advertisement timer expires.</p> <p><b>Values</b> 1 to 255</p> <p><b>Default</b> 1</p> <p><b>milliseconds milliseconds</b> — Specifies the time interval, in milliseconds, between sending advertisement messages. This parameter is not supported on non-redundant chassis.</p> <p><b>Values</b> 100 to 900</p>                                                                                                                                                                                                                                                                                                                                                                                                             |

## ping-reply

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Context</b>     | config>service>ies>if>vrrp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <b>Description</b> | <p>This command enables the non-owner master to reply to ICMP Echo Requests directed at the virtual router instances IP addresses. The ping request can be received on any routed interface.</p> <p>Ping must not have been disabled at the management security level (either on the parental IP interface or based on the Ping source host address). When ping-reply is not enabled, ICMP Echo Requests to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to ICMP Echo Requests regardless of the setting of ping-reply configuration.</p> |

The ping-reply command is only available in non-owner **vrrp** *virtual-router-id* nodal context. If the ping-reply command is not executed, ICMP Echo Requests to the virtual router instance IP addresses will be silently discarded.

The **no** form of this command restores the default operation of discarding all ICMP Echo Request messages destined to the non-owner virtual router instance IP addresses.

**Default** no ping-reply

## policy

**Syntax** **policy** *vrrp-policy-id*  
**no policy**

**Context** config>service>ies>if>vrrp

**Description** This command creates VRRP control policies. The VRRP policy ID must be created by the policy command prior to association with the virtual router instance.

The policy command provides the ability to associate a VRRP priority control policy to a virtual router instance. The policy may be associated with more than one virtual router instance. The priority events within the policy either override or diminish the base-priority dynamically affecting the in-use priority. As priority events clear in the policy, the in-use priority may eventually be restored to the base-priority value.

The policy command is only available in the non-owner **vrrp** *virtual-router-id* nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed by VRRP priority control policies. For non-owner virtual router instances, if the policy command is not executed, the base-priority will be used as the in-use priority.

The **no** form of this command removes any existing VRRP priority control policy association from the virtual router instance. All such associations must be removed prior to the policy being deleted from the system.

**Default** n/a

**Parameters** *vrrp-policy-id* — The vrrp-policy-id parameter associated the corresponding VRRP priority control policy-id with the virtual router instance. The vrrp-policy-id must already exist in the system for the policy command to be successful.

**Values** 1 to 9999

## preempt

**Syntax** **preempt**  
**no preempt**

**Context** config>service>ies>if>vrrp

|             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Description | <p>The preempt command provides the ability of overriding an existing non-owner master to the virtual router instance. Enabling preempt mode is almost required for proper operation of the base-priority and vrrp-policy-id definitions on the virtual router instance. If the virtual router cannot preempt an existing non-owner master, the affect of the dynamic changing of the in-use priority is greatly diminished.</p> <p>The preempt command is only available in the non-owner vrrp virtual-router-id nodal context. The owner may not be preempted due to the fact that the priority of non-owners can never be higher than the owner. The owner will always preempt all other virtual routers when it is available.</p> <p>Non-owner virtual router instances will only preempt when preempt is set and the current master has an in-use message priority value less than the virtual router instances in-use priority.</p> <p>A master non-owner virtual router will only allow itself to be preempted when the incoming VRRP Advertisement message Priority field value is one of the following:</p> <ul style="list-style-type: none"><li>• Greater than the virtual router in-use priority value</li><li>• Equal to the in-use priority value and the source IP address (primary IP address) is greater than the virtual router instance primary IP address</li></ul> <p>The <b>no</b> form of this command prevents a non-owner virtual router instance from preempting another, less desirable virtual router. Use the preempt command to restore the default mode.</p> |

| Description | <p>The priority command provides the ability to configure a specific priority value to the virtual router instance. In conjunction with an optional policy command, the base-priority is used to derive the in-use priority of the virtual router instance.</p> <p>The priority command is only available in the non-owner vrrp virtual-router-id nodal context. The priority of owner virtual router instances is permanently set to 255 and cannot be changed. For non-owner virtual router instances, if the priority command is not executed, the base-priority will be set to 100.</p> <p>The <b>no</b> form of this command restores the default value of 100 to base-priority.</p> |

|                   |                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>base-priority</i> — The base-priority parameter configures the base priority used by the virtual router instance. If a VRRP Priority Control policy is not also defined, the base-priority will be the in-use priority for the virtual router instance. |
| <b>Values</b>     | 1 to 254                                                                                                                                                                                                                                                   |
| <b>Default</b>    | 100                                                                                                                                                                                                                                                        |

| <b>Description</b> | <p>This command enables the non-owner master to reply to SSH Requests directed at the virtual router instances IP addresses. The SSH request can be received on any routed interface. SSH must not have been disabled at the management security level (either on the parental IP interface or based on the SSH source host address). Proper login and CLI command authentication is still enforced.</p> <p>When ssh-reply is not enabled, SSH packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to SSH regardless of the ssh-reply configuration.</p> <p>The ssh-reply command is only available in non-owner vrrp virtual-router-id nodal context. If the ssh-reply command is not executed, SSH packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all SSH packets destined to the non-owner virtual router instance IP addresses.</p> |

| <b>Description</b> | <p>The telnet-reply command enables the non-owner master to reply to TCP port 23 Telnet Requests directed at the virtual router instances IP addresses. The Telnet request can be received on any routed interface. Telnet must not have been disabled at the management security level (either on the parental IP interface or based on the Telnet source host address). Proper login and CLI command authentication is still enforced.</p> <p>When telnet-reply is not enabled, TCP port 23 Telnet packets to non-owner master virtual IP addresses are silently discarded.</p> <p>Non-owner backup virtual routers never respond to Telnet Requests regardless of the telnet-reply configuration.</p> <p>The telnet-reply command is only available in non-owner VRRP nodal context. If the telnet-reply command is not executed, Telnet packets to the virtual router instance IP addresses will be silently discarded.</p> <p>The <b>no</b> form of this command restores the default operation of discarding all Telnet packets destined to the non-owner virtual router instance IP addresses.</p> |
| <b>Default</b>     | no telnet-reply                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| <b>Context</b>     | config>service>ies>if>sap                 |
| <b>Description</b> | This command configures an IPsec gateway. |

### default-secure-service

|                    |                                                                                                                                                                                              |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-secure-service</b> <i>service-id</i> <b>interface</b> <i>ip-int-name</i><br><b>no default-secure-service</b>                                                                      |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                                                                                                                                      |
| <b>Description</b> | This command specifies a service ID or service name of the default security service used by this SAP IPsec gateway.                                                                          |
| <b>Parameters</b>  | <i>service-id</i> — specifies a default secure service<br><br><b>Values</b> <i>service-id</i> : 1 to 2147483648<br><i>svc-name</i> : An existing service name up to 64 characters in length. |

### default-tunnel-template

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-tunnel-template</b> <i>ipsec template identifier</i><br><b>no default-tunnel-template</b> |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                                              |
| <b>Description</b> | This command configures a default tunnel policy template for the gateway.                            |

### local-gateway-address

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-gateway-address</b> <i>ip-address</i><br><b>no local-gateway-address</b> |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                           |
| <b>Description</b> | This command configures an ipsec-gateway local address.                           |

## pre-shared-key

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>pre-shared-key</b> <i>key</i><br><b>no pre-shared-key</b>                       |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                                            |
| <b>Description</b> | This command specifies the shared secret between the two peers forming the tunnel. |
| <b>Parameters</b>  | <i>key</i> — specifies a pre-shared-key for dynamic-keying                         |

## cert

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cert</b>                                                         |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway                             |
| <b>Description</b> | This command configures cert parameters used by this IPSec gateway. |

## cert

|                    |                                                                                                            |
|--------------------|------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cert</b> <i>file-name</i><br><b>no cert</b>                                                             |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert                                                               |
| <b>Description</b> | This command configures cert with a local file URL used by this IPSec gateway.                             |
| <b>Parameters</b>  | <i>file-name</i> — Specifies the local file to use in the cert. Specify a file name, 95 characters maximum |

## cert-profile

|                    |                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cert-profile</b> <i>profile-name</i><br><b>no cert-profile</b>                                                                                                       |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gw>cert                                                                                                                                 |
| <b>Description</b> | This command specifies the cert-profile for the ipsec-tunnel or ipsec-gw. This command will override “cert” and “key” configuration under the ipsec-tunnel or ipsec-gw. |
| <b>Default</b>     | n/a                                                                                                                                                                     |
| <b>Parameters</b>  | <i>profile-name</i> — specifies the name of cert-profile                                                                                                                |

---

## key

|                    |                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>key</b> <i>file-name</i><br><b>no cert</b>                                                        |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert                                                         |
| <b>Description</b> | This command configures a key with the CA profile used by this IPSec gateway.                        |
| <b>Parameters</b>  | <i>file-name</i> — Specifies the file to use in the key. Specify a file name, 95 characters maximum. |

## status-verify

|                    |                                                                                           |
|--------------------|-------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>status-verify</b>                                                                      |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert                                              |
| <b>Description</b> | This command enables the context to configure certificate status verification parameters. |

## default-result

|                    |                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-result</b> {revoked   good}<br><b>no default-result</b>                                                                                                                                                      |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert>status-verify                                                                                                                                                              |
| <b>Description</b> | This command specifies the default result of Certificate Status Verification (CSV) when both primary and secondary method failed to provide an answer.<br><br>The <b>no</b> form of the command reverts to the default. |
| <b>Default</b>     | revoked                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <b>revoked</b> — specifies that the certificate is considered as revoked<br><b>good</b> — specifies that the certificate is considered as acceptable                                                                    |

## primary

|                    |                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>primary</b> {ocsp   crl}<br><b>no primary</b>                                                                                       |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert>status-verify                                                                             |
| <b>Description</b> | This command specifies the primary method that used to verify revocation status of the peer's certificate; could be either CRL or OCSP |

OCSP or CRL will use the corresponding configuration in the ca-profile of the issuer of the certificate in question.

|                   |                                                                                                                                                                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | primary crl                                                                                                                                                                                                                                  |
| <b>Parameters</b> | <p><b>ocsp</b> — Specifies to use the OCSP protocol. The OCSP server is configured in the corresponding ca-profile.</p> <p><b>crl</b> — Specifies to use the local CRL file. The CRL file is configured in the corresponding ca-profile.</p> |

## secondary

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>secondary {ocsp   crl}</b><br><b>no secondary</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert>status-verify                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | <p>This command specifies the secondary method used to verify the revocation status of the peer's certificate, either <b>crl</b> or <b>ocsp</b>.</p> <p>OCSP or CRL will use the corresponding configuration in the ca-profile of the issuer of the certificate in question.</p> <p>The secondary method will only be used when the primary method failed to provide an answer:</p> <ul style="list-style-type: none"> <li>• OCSP — Unreachable or any answer other than “good” or “revoked”. <b>ocsp</b> is not configured in the ca-profile/ OCSP response is not signed/Invalid nextUpdate.</li> <li>• CRL — The CRL expired.</li> </ul> |
| <b>Default</b>     | no secondary                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| <b>Parameters</b>  | <p><b>ocsp</b> — Specifies to use the OCSP protocol. The OCSP server is configured in the corresponding ca-profile.</p> <p><b>crl</b> — Specifies to use the local CRL file. The CRL file is configured in the corresponding ca-profile.</p>                                                                                                                                                                                                                                                                                                                                                                                                |

## trust-anchor

|                    |                                                                                    |
|--------------------|------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>trust-anchor ca-profile-name</b><br><b>no trust-anchor</b>                      |
| <b>Context</b>     | config>service>ies>if>sap>ipsec-gateway>cert                                       |
| <b>Description</b> | This command configures trust anchor with a CA profile used by this IPSec gateway. |

**Parameters** *ca-profile-name* — Specifies the CA profile to use in the trust anchor. Specify a file name, 95 characters maximum.

## local-id

**Syntax** **local-id type** {**ipv4** | **fqdn**} [**value** [*value*]]  
**no local-id**

**Context** config>service>ies>if>sap>ipsec-gateway

**Description** This command specifies the local ID of the 7750 SR used for IDi or IDr for IKEv2 tunnels. The local-id can only be changed or removed when tunnel or gateway is shutdown.

**Default** Depends on local-auth-method such as:

- Psk:local tunnel ip address
- Cert-auth: subject of the local certificate

**Parameters** **type** — specifies the type of local ID payload, it could be ipv4 address/FQDN domain name

**Values**

- ipv4** — Use ipv4 as the local ID type, the default value is the local tunnel end-point address.
- fqdn** — Use FQDN as the local ID type, the value must be configured.
- dn** — Use the subject of the certificate configured for the tunnel or gateway.

## 2.5.2.18 Threat Management Service Interface Commands

### tms-interface

**Syntax** **tms-interface** *interface-name* [**create**] [**off-ramp-vprn** *off-ramp-svc*] [**mgmt-vprn** *mgmt-svc*]  
**no tms-interface** *interface-name*

**Context** config>service>ies

**Description** This command configures a Threat Management Service interface.  
The **no** form of the command removes the interface name from the configuration.

**Parameters** *interface-name* — specifies the interface name up to 22 characters in length  
**create** — Creates the interface name. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

*off-ramp-svc* — specifies the service ID or service name for the off-ramp VPRN

**Values**     *service-id*: 1 to 2148007978  
                 *svc-name*: An existing service name up to 64 characters in length.

*mgmt-svc* — specifies the service ID or service name for management VPRN

**Values**     *service-id*: 1 to 2148007978  
                 *svc-name*: An existing service name up to 64 characters in length.

2.6.2.1 IES Show Commands

Note: The command outputs in the following section are examples only; actual displays may differ depending on supported functionality and user configuration.

customer

Syntax	customer [<i>customer-id</i>] [site <i>customer-site-name</i>]
Context	show>service
Description	This command displays service customer information.
Parameters	<i>customer-id</i> — displays only information for the specified customer ID Values 1 to 2147483647 Default displays all customer IDs site <i>customer-site-name</i> — specifies the customer site which is an anchor point for an ingress and egress virtual scheduler hierarchy
Output	Show Customer Command Output Table 12 describes the show customer command output fields.

Table 12 Show Customer Field Descriptions

Label	Description
Customer-ID	the ID that uniquely identifies a customer
Contact	the name of the primary contact person
Description	generic information about the customer
Phone	the phone/pager number to reach the primary contact person

Table 12 Show Customer Field Descriptions (Continued)

Label	Description (Continued)
Total Customers	the total number of customers configured
Multi-service site	
Site	multi-service site name. A multi-service customer site is a group of SAPs with common origination and termination points.
Description	information about a specific customer's multi-service site
Assignment	the port ID, MDA, or card number, where the SAP's that are members of this multi- service site are defined
I. Sched Pol	the ingress QoS scheduler policy assigned to this multi-service site
E. Sched Pol	the egress QoS scheduler policy assigned to this multi-service site
Service Association	
Service-ID	the ID that uniquely identifies a service
SAP	the SAP assigned to the service

Sample Output

```

*A:ALA-12# show service customer

egress-label

- Syntax

egress-label *egress-label1* [*egress-label2*]
- Context

show>service
- Description

Display services using the range of egress labels.

If only the mandatory *egress-label1* parameter is specified, only services using the specified label are displayed.

If both *egress-label1* and *egress-label2* parameters are specified, the services using the range of labels X where *egress-label1* <= X <= *egress-label2* are displayed.

Use the **show router ldp bindings** command to display dynamic labels.
- Parameters

egress-label1 — The starting egress label value for which to display services using the label range. If only *egress-label1* is specified, services only using *egress-label1* are displayed.

Values

0, 2049 to 131071

egress-label2 — the ending egress label value for which to display services using the label range

Values

2049 to 131071

Default

the *egress-label1* value

Output

Show Service Egress Command Output

Table 13 describes show service egress label output fields.
- Table 13 Show Service Egress-Label Field Descriptions
- | Label | Description |
|--------|---|
| Svc Id | the value that identifies a service |
| Sdp Id | the value that identifies a SDP |
| Type | indicates whether the SDP binding is a spoke or a mesh |
| I. Lbl | the VC label used by the far-end device to send packets to this device in this service by the SDP |
| E. Lbl | the VC label used by this device to send packets to the far-end device in this service by the SDP |
- 290
- 3HE 10789 AAAB TQZZA 01
- Issue: 01

Table 13 Show Service Egress-Label Field Descriptions (Continued)

Label	Description (Continued)
Number of bindings found	the total number of SDP bindings that exist within the specified egress label range

Sample Output

```
*A:ALA-12# show service egress-label 0 10000

ingress-label

Syntax **ingress-label** *start-label* [*end-label*]

Context show>service

Description This command displays services using the range of ingress labels. If only the mandatory *start-label* parameter is specified, only services using the specified label are displayed.

If both *start-label* and *end-label* parameters are specified, the services using the range of labels X where *start-label* <= X <= *end-label* are displayed.

For 7750 only, use the **show router vprn-service-id ldp bindings** command to display dynamic labels.

Parameters *start-label* — The starting ingress label value for which to display services using the label range. If only *start-label* is specified, services only using *start-label* are displayed.

Values 0, 2048 to 131071

end-label — the ending ingress label value for which to display services using the label range

Values 2049 to 131071

Default the *start-label* value

Output **Show Service Ingress-Label**

Table 14 describes show service ingress-label output fields.

Table 14 Show Service Ingress-Label Field Descriptions

Label	Description
Svc ID	the service identifier
SDP Id	the SDP identifier
Type	indicates whether the SDP is spoke or mesh
I.Lbl	the ingress label used by the far-end device to send packets to this device in this service by the SDP
E.Lbl	the egress label used by this device to send packets to the far-end device in this service by the SDP
Number of Bindings Found	the number of SDP bindings within the label range specified

Sample Output

```
*A:ALA-12# show service ingress-label 0

sap-using

Syntax

```

sap-using [msap] [dyn-script] [description]
sap-using [sap sap-id] [vlan-translation | anti-spoof] [description]
sap-using [sap sap-id]
sap-using interface [ip-address | ip-int-name]
sap-using [ingress | egress] atm-td-profile td-profile-id
sap-using [ingress | egress] filter filter-id
sap-using [ingress | egress] qos-policy qos-policy-id
sap-using authentication-policy policy-name

```

Context show>service

Description Displays SAP information.

If no optional parameters are specified, the command displays a summary of all defined SAPs. The optional parameters restrict output to only SAPs matching the specified properties.

Parameters **sap** *sap-id* — specifies the physical port identifier portion of the SAP definition

ingress — specifies matching an ingress policy

egress — specifies matching an egress policy

qos-policy *qos-policy-id* — The ingress or egress QoS Policy ID for which to display matching SAPs. This parameter only applies the 7450 ESS and 7750 SR.

Values 1 to 65535

atm-td-profile *td-profile-id* — Displays SAPs using this traffic description. This parameter only applies to the 7750 SR.

filter *filter-id* — the ingress or egress filter policy ID for which to display matching SAPs.

Values 1 to 65535

dyn-script — displays dynamic service SAPs information

authentication *policy-name* — The session authentication policy for which to display matching SAPs. This parameter only applies to the 7450 ESS and 7750 SR.

interface — specifies matching SAPs with the specified IP interface

ip-addr — the IP address of the interface for which to display matching SAPs

Values 1.0.0.0 to 223.255.255.255

ip-int-name — the IP interface name for which to display matching SAPs

Output **Show Service SAP**

Table 15 describes show service SAP output fields.

Table 15 Show Service SAP Field Descriptions

Label	Description
Port ID	the ID of the access port where the SAP is defined
Svc ID	the value that identifies the service
SapMTU	the SAP MTU value
Ingr.QoS	the SAP ingress QoS policy number specified on the ingress SAP
Ingr.Fltr	the MAC or IP filter policy ID applied to the ingress SAP
E.QoS	the SAP egress QoS policy number specified on the egress SAP
Egr.Fltr	the MAC or IP filter policy ID applied to the egress SAP
A.Pol	the accounting policy ID assigned to the SAP
Adm	the administrative state of the SAP
Opr	the actual state of the SAP

Sample Output

The following is a sample output for the 7450 ESS:

```

sdp

Syntax	sdp [<i>sdp-id</i> far-end <i>ip-address</i>] [detail keep-alive-history]
Context	show>service
Description	This command displays SDP information. If no optional parameters are specified, a summary SDP output for all SDPs is displayed.
Parameters	sdp-id — specifies the SDP ID for which to display information Values1 to 17407 Defaultall SDPs far-end ip-address — displays only SDPs matching with the specified far-end IP address DefaultSDPs with any far-end IP address detail — displays detailed SDP information DefaultSDP summary output keep-alive-history — displays the last fifty SDP keepalive events for the SDP DefaultSDP summary output
Output	Show Service SDP

[Table 16](#) describes show service SDP output fields:

Table 16 Show Service SDP Field Descriptions

Label	Description
SDP Id	the SDP identifier
Adm MTU	specifies the desired largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Opr MTU	specifies the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
IP address	specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP
Adm	Admin State — specifies the administrative state of the SDP
Opr	Oper State — specifies the operational state of the SDP
Deliver	specifies the type of delivery used by the SDP: GRE or MPLS
Flags	specifies the conditions that affect the operating status of this SDP
Signal Signaling	specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on the SDP
Last Status Change	specifies the time of the most recent operating status change to this SDP

Sample Output

```

sdp-using

- Syntax** **sdp-using** [*sdp-id[:vc-id]* | **far-end** *ip-address*]
- Context** show>service
- Description** This command displays services using SDP or far-end address options.
- Parameters**

sdp-id — displays only services bound to the specified SDP ID

Values 1 to 17407

vc-id — displays information about the virtual circuit identifier

Values 1 to 4294967295

far-end *ip-address* — displays only services matching with the specified far-end IP address

Default services with any far-end IP address

Output **Show Service SDP Using X**

[Table 17](#) describes the show service sdp-using output fields.

Table 17 Show Service Sdp-Using Field Descriptions

Label	Description
Svc ID	the service identifier
Sdp ID	the SDP identifier
Type	type of SDP: spoke or mesh
Far End	the far-end address of the SDP

Table 17 Show Service Sdp-Using Field Descriptions (Continued)

Label	Description (Continued)
Oper State	the operational state of the service
I.Label	the label used by the far-end device to send packets to this device in this service by this SDP
E.Label	the label used by this device to send packets to the far-end device in this service by this SDP

Sample Output

```

service-using

- Syntax** **service-using** [**ies**] [**customer** *customer-id*]
- Context** show>service
- Description** This command displays the services matching certain usage properties. If no optional parameters are specified, all services defined on the system are displayed.
- Parameters** **ies** — Displays matching IES services.
- sdp** *sdp-id* — Displays only services bound to the specified SDP ID. This parameter only applies to the 7450 ESS and 7750 SR.
- Values** 1 to 17407
- Default** services bound to any SDP ID
- customer** *customer-id* — displays services only associated with the specified customer ID
- Values** 1 to 2147483647
- Default** services associated with an customer

Output Show Service Service-Using

Table 18 describes show service service-using output fields.

Context show>service>subscriber-using

Description This command displays subscribers using certain options.

Parameters	service-id <i>service-id</i> — display subscriber information about the specified service ID
Values	1 to 2147483648
	sap-id <i>sap-id</i> — specifies the physical port identifier portion of the SAP definition
	interface <i>ip-int-name</i> — display subscriber information about the specified interface
	ip <i>ip-address[/mask]</i> — display subscriber information about the specified IP address
	mac <i>ieee-address</i> — display subscriber information about the specified MAC address
	sub-profile <i>sub-profile-name</i> — display subscriber information about the specified subscriber profile name
	sla-profile <i>sla-profile-name</i> — display subscriber information about the specified SLA profile name

id

Syntax	id <i>service-id</i> { all arp base sap sdp }
Context	show>service
Description	This command displays information for a particular service-id.
Parameters	<i>service-id</i> — the unique service identification number to identify the service in the service domain all — display detailed information about the service arp — display ARP entries for the service arp-host — displays ARP host related information (applies only to the 7450 ESS and 7750 SR) base — display basic service information interface — display service interfaces sap — display SAPs associated to the service sdp — display SDPs associated with the service (applies only to the 7450 ESS and 7750 SR)

all

Syntax	all
Context	show>service>id
Description	This command displays detailed information for all aspects of the service.

Output Show All Service-ID Output

[Table 19](#) describes the show all service-id command output fields.

Table 19 Show All Service-ID Field Descriptions

Label	Description
Service Detailed Information	
Service Id	the service identifier
VPN Id	the number which identifies the VPN
Service Type	specifies the type of service
SDP Id	the SDP identifier
Description	generic information about the service
Customer Id	the customer identifier
Last Mgmt Change	the date and time of the most recent management-initiated change to this customer
SAP Count	the number of SAPs specified for this service
SDP Bind Count	the number of SDPs bound to this service
Service Destination Points (SDPs)	
SDP Id	the SDP identifier
Type	indicates whether this Service SDP binding is a spoke or a mesh
Admin Path MTU	the largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Oper Path MTU	the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Delivery	specifies the type of delivery used by the SDP: GRE or MPLS
Admin State	the administrative state of this SDP
Oper State	the operational state of this SDP
Ingress Label	the label used by the far-end device to send packets to this device in this service by this SDP
Egress Label	the label used by this device to send packets to the far-end device in this service by this SDP
Ingress Filter	The ID of the ingress filter policy.
Egress Filter	The ID of the egress filter policy.

Table 19 Show All Service-ID Field Descriptions (Continued)

Label	Description (Continued)
Far End	Specifies the IP address of the remote end of the GRE or MPLS tunnel defined by this SDP.
Last Changed	The date and time of the most recent change to this customer.
Signaling	Specifies the signaling protocol used to obtain the ingress and egress labels used in frames transmitted and received on this SDP.
Admin State	Specifies the operating status of the service.
Oper State	The current status of the service.
Hello Time	Specifies how often the SDP echo request messages are transmitted on this SDP.
Hello Msg Len	Specifies the length of the SDP echo request messages transmitted on this SDP.
Max Drop Count	Specifies the maximum number of consecutive SDP Echo Request messages that can be unacknowledged before the keepalive protocol reports a fault.
Hold Down Time	Specifies the amount of time to wait before the keepalive operating status is eligible to enter the alive state.
SDP Delivery Mechanism	When the SDP type is MPLS, a list of LSPs used to reach the far-end router displays. All the LSPs in the list must terminate at the IP address specified in the far-end field. If the SDP type is GRE, then the following message displays: "SDP Delivery Mechanism is not MPLS"
Number of SDPs	The total number SDPs applied to this service ID.
Service Access Points	
Service Id	The service identifier.
Port Id	The ID of the access port where this SAP is defined.
Description	Generic information about the SAP.
Encap	The value of the label used to identify this SAP on the access port.
Admin State	The desired state of the SAP.
Oper State	The operating state of the SAP.
Last Changed	the date and time of the last change
Admin MTU	the largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Oper MTU	the actual largest service frame size (in octets) that can be transmitted through this SDP to the far-end router, without requiring the packet to be fragmented
Ingress qos-policy	the SAP ingress QoS policy ID

Table 19 Show All Service-ID Field Descriptions (Continued)

Label	Description (Continued)
Egress qos-policy	the SAP egress QoS policy ID
Ingress Filter-Id	the SAP ingress filter policy ID
Egress Filter-Id	the SAP egress filter policy ID
Multi Svc Site	indicates the multi-service site that the SAP is a member
Ingress sched-policy	indicates the ingress QoS scheduler for the SAP
Egress sched-policy	indicates the egress QoS scheduler for the SAP
Acct. Pol	indicates the accounting policy applied to the SAP
Collect Stats	specifies whether accounting statistics are collected on the SAP
SAP Statistics	
Dropped	the number of packets or octets dropped
Offered Hi Priority	the number of high priority packets, as determined by the SAP ingress QoS policy
Offered Low Priority	the number of low priority packets, as determined by the SAP ingress QoS policy
Forwarded In Profile	the number of in-profile packets or octets (rate below CIR) forwarded
Forwarded Out Profile	the number of out-of-profile packets or octets (rate above CIR) forwarded
Queueing Stats	
Dropped In Profile	the number of in-profile packets or octets discarded
Dropped Out Profile	the number of out-of-profile packets or octets discarded
Forwarded In Profile	the number of in-profile packets or octets (rate below CIR) forwarded
Forwarded Out Profile	the number of out-of-profile packets or octets (rate above CIR) forwarded
SAP per Queue stats	
Ingress Queue 1	the index of the ingress QoS queue of this SAP
High priority offered	the packets or octets count of the high priority traffic for the SAP
High priority dropped	the number of high priority traffic packets/octets dropped
Low priority offered	the packets or octets count of the low priority traffic
Low priority dropped	the number of low priority traffic packets/octets dropped
In profile forwarded	the number of in-profile packets or octets (rate below CIR) forwarded
Out profile forwarded	the number of out-of-profile octets (rate above CIR) forwarded

Table 19 Show All Service-ID Field Descriptions (Continued)

Label	Description (Continued)
Egress Queue 1	the index of the egress QoS queue of the SAP
In profile forwarded	the number of in-profile packets or octets (rate below CIR) forwarded
IPCP Address Extension Details	
In profile dropped	the number of in-profile packets or octets dropped for the SAP
Peer IP Addr	specifies the remote IP address to be assigned to the far-end of the associated PPP/MLPPP link via IPCP extensions
Peer Pri DNS Addr	specifies a unicast IPv4 address for the primary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions
Peer Sec DNS Addr	specifies a unicast IPv4 address for the secondary DNS server to be signaled to the far-end of the associate PPP/MLPPP link via IPCP extensions (optional)

Sample Output

arp

Syntax **arp** [*ip-address*] | [*mac ieee-address*] | [*sap sap-id*] | [*interface ip-int-name*] [*sdp sdp-id:vc-*

*id]***Context** show>service>id**Description** Displays the ARP table for the IES instance. The ARP entries are displayed uniquely. Each MAC associated with the child group-interfaces are displayed with each ARP entry. They do not reflect actual ARP entries but are displayed along the interfaces ARP entry for easy lookup.**Parameters** *ip-address* — displays only ARP entries in the ARP table with the specified IP address**Default** All IP addresses.**mac** *ieee-address* — Displays only ARP entries in the ARP table with the specified 48-bit MAC address. The MAC address can be expressed in the form *aa:bb:cc:dd:ee:ff* or *aa-bb-cc-dd-ee-ff* where *aa*, *bb*, *cc*, *dd*, *ee* and *ff* are hexadecimal numbers.**Default** All MAC addresses.**sap** *sap-id* — displays SAP information for the specified SAP ID**interface** — specifies matching service ARP entries associated with the IP interface*ip-address* — the IP address of the interface for which to display matching ARP entries**Values** 1.0.0.0 to 223.255.255.255*ip-int-name* — the IP interface name for which to display matching ARPs*sdp-id* — the SDP identifier*vc-id* — the virtual circuit identifier**Values** 1 to 4294967295**Output** Show Service-ID ARP[Table 20](#) describes the show service-ID ARP output fields.**Table 20** Show Service-ID ARP Field Descriptions

Label	Description
IP Address	the IP address
MAC Address	the specified MAC address
Type	Static — FDB entries created by management Learned — dynamic entries created by the learning process OAM — entries created by the OAM process Other — local entries for the IP interfaces created
Expiry	the age of the ARP entry
Interface	the interface applied to the service
SAP	the SAP ID

Sample Output

```

A:ALA-49# show service id 88 arp

dhcp

Syntax	dhcp
Context	show>service>id
Description	This command enables the context to display DHCP information for the specified service.

lease-state

Syntax	lease-state [[sap <i>sap-id</i>] [sdp <i>sdp-id:vc-id</i>] [interface <i>interface-name</i>] [ip-address <i>ip-address</i>]] [detail]
Context	show>service>id>dhcp
Description	This command displays DHCP lease state related information.

Parameters **sap** *sap-id* — specifies the physical port identifier portion of the SAP definition

sdp-id — The SDP identifier.

Values 1 to 17407

vc-id — the virtual circuit ID on the SDP ID for which to display information

Values 1 to 4294967295

interface *interface-name* — displays information for the specified IP interface

ip-address *ip-address* — displays information associated with the specified IP address

detail — displays detailed information

Output The following is a sample output of the **dhcp** command.

Sample Output

statistics

- Syntax** **statistics** [*sap sap-id*
 statistics [**sdp** *sdp-id:vc-id*]
 statistics [**interface** *interface-name*]
- Context** show>service>id>dhcp
- Description** Displays DHCP statistics information.
- Parameters** **sap** *sap-id* — specifies the physical port identifier portion of the SAP definition
 sdp-id — the SDP identifier
 Values 1 to 17407
 vc-id — the virtual circuit ID on the SDP ID for which to display information
 Values 1 to 4294967295
 interface *interface-name* — displays information for the specified IP interface

summary

- Syntax** **summary**
- Context** show>service>id>dhcp
- Description** Displays DHCP configuration summary information.
- Output** **Show DHCP Summary Output**
[Table 21](#) describes the output fields for DHCP summary.

Table 21 **Show DHCP Summary Field Descriptions**

Label	Description
Interface Name	name of the router interface
Arp Populate	specifies whether or not ARP populate is enabled

Table 21 Show DHCP Summary Field Descriptions (Continued)

Label	Description (Continued)
Used/Provided	Used — The number of lease-states that are currently in use on a specific interface, that is, the number of clients on that interface got an IP address by DHCP. This value is always less than or equal to the 'Provided' field.
	Provided — the lease-populate value that is configured for a specific interface
Info Option	indicates whether Option 82 processing is enabled on the interface
Admin State	indicates the administrative state

Sample Output (7750 SR)

```

gsmp

Syntax	gsmp
Context	show>service>id
Description	This command enables the context to display GSMP information.

neighbors

Syntax	neighbors group [<i>name</i>] [<i>ip-address</i>]
Context	show>service>id>gsmp
Description	This command displays GSMP neighbor information.
Parameters	group — a GSMP group defines a set of GSMP neighbors which have the same properties <i>name</i> — specifies a GSMP group name is unique only within the scope of the service in which it is defined <i>ip-address</i> — specifies the ip-address of the neighbor

Output

Sample Output

These commands show the configured neighbors per service, regardless of the fact there exists an open TCP connection with this neighbor. The admin state is shown because for a neighbor to be admin enabled, the service, gsmp node, group node and the neighbor node in this service must all be in 'no shutdown' state. Session gives the number of session (open TCP connections) for each configured neighbor.

sessions

- Syntax** **sessions** [**group name**] **neighbor** *ip-address*] [**port** *port-number*] [**association**] [**statistics**]
- Context** show>service>id>gsmp
- Description** This command displays GSMP sessions information.
- Parameters**
 - group** — a GSMP group defines a set of GSMP neighbors which have the same properties
 - name* — specifies a GSMP group name is unique only within the scope of the service in which it is defined
 - ip-address* — specifies the ip-address of the neighbor
 - port* — specifies the neighbor TCP port number use for this ANCP session
 - Values** 0 to 65535
 - association** — displays to what object the ANCP-string is associated
 - statistics** — displays statistics information about an ANCP session known to the system

Output

Sample Output

This show command gives information about the open TCP connections with DSLAMs.

interface

- Syntax

interface *[[ip-address | ip-int-name] [interface-type] [detail] [family] | summary]*
- Context

show>service>id
- Description

This command displays information for the IP interfaces associated with the IES service. If no optional parameters are specified, a summary of all IP interfaces associated to the service are displayed.
- Parameters

ip-address — the IP address of the interface for which to display information

Values

<ip-address>

ipv4-address

a.b.c.d (host bits must be 0)

ipv6-address

x:x:x:x:x:x:x (eight 16-bit pieces)

x:x:x:x:x:d.d.d.d

x - [0 to FFFF]H

d - [0 to 255]D

ip-int-name — specifies the IP interface name for which to display information.

Values

32 characters maximum

family — Displays the router IP interface table to display.

Values

ipv4 — displays only those peers that have the IPv4 family enabled

ipv6 — displays the peers that are IPv6-capable

interface-type — specifies whether to display groups, interfaces, or redundant interfaces

Values

group, subscriber, redundant

detail — displays detailed IP interface information

summary — displays IP interface information summary
- Output Show Service-ID
- Table 24 describes show service-id output fields.
- Table 24 Show Service-ID Field Descriptions
- | Label | Description |
|------------|---|
| If Name | the name used to refer to the IES interface |
| Type | specifies the interface type |
| IP-Address | specifies the IP address/IP subnet/broadcast address of the interface |
- 330
- 3HE 10789 AAAB TQZZA 01
- Issue: 01

Table 24 Show Service-ID Field Descriptions (Continued)

Label	Description (Continued)
Adm	the administrative state of the interface
Opr	the operational state of the interface
Admin State	the administrative state of the interface
Oper State	the operational state of the interface
IP Addr/mask	specifies the IP address/IP subnet/broadcast address of the interface
If Index	the index corresponding to this IES interface. The primary index is 1; all IES interfaces are defined in the base virtual router context
If Type	specifies the interface type
SAP Id	specifies the SAP's port ID
SNTP B.Cast	specifies whether SNTP broadcast client mode is enabled or disabled
Arp Timeout	specifies the timeout for an ARP entry learned on the interface
MAC Address	specifies the 48-bit IEEE 802.3 MAC address
ICMP Mask Reply	specifies whether ICMP mask reply is enabled or disabled
Cflowd	specifies whether Cflowd collection and analysis on the interface is enabled or disabled
Redirects	specifies the rate for ICMP redirect messages
Unreachables	specifies the rate for ICMP unreachable messages
TTL Expired	specifies the rate for ICMP TTL messages

Sample Output

```

sdp

- Syntax** `sdp sdp-id pw-port [pw-port-id]`
`sdp sdp-id pw-port`
`sdp sdp-id pw-port [pw-port-id] [statistics]`
`sdp [consistent | inconsistent | na] egressifs`
`sdp sdp-id keep-alive-history`
`sdp far-end ip-address | ipv6-address keep-alive-history`
`sdp [sdp-id] detail`
`sdp far-end ip-address | ipv6-address detail`
- Context** `show>service>sdp`
- Description** Displays information for the SDPs associated with the service.
- If no optional parameters are specified, a summary of all associated SDPs is displayed.
- Parameters** *sdp-id* — specifies the SDP ID for which to display information
- Values** 1 to 17407
- Default** all SDPs
- pw-port-id* — specifies the pseudo-wire port identifier
- Values** 1 to 10239
- far-end ip-address* — displays only SDPs matching with the specified far-end IP address
- Default** SDPs with any far-end IP address
- detail** — displays detailed SDP information
- Default** SDP summary output
- keep-alive-history** — displays the last fifty SDP keepalive events for the SDP
- Default** SDP summary output

Output

pw-port

- Syntax** **pw-port** [*pw-port-id*] [**detail**]
pw-port sdp *sdp-id*
pw-port sdp none
- Context** show>pw-port
- Description** Displays pseudo-wire port information.
- If no optional parameters are specified, the command displays a summary of all defined PW ports. The optional parameters restrict output to only ports matching the specified properties.
- Parameters** *pw-port-id* — specifies the pseudo-wire port identifier
- Values** 1 to 10239
- detail** — displays detailed port information that includes all the **pw-port** output fields
- sdp** *sdp-id* — the SDP ID for which to display matching PW port information
- Values** 1 to 17407
- Output** **Show PW-Port**
- [Table 26](#) describes **show pw-port** output fields:

Table 26 Show PW-Port Field Descriptions

Label	Description
PW Port	the PW Port identifier

Table 26 Show PW-Port Field Descriptions (Continued)

Label	Description (Continued)
Encap	the encapsulation type of the PW Port
SDP	the SDP identifier
IfIndex	the interface index used for the PW Port
VC-Id	the Virtual Circuit identifier
Description	the description string for the PW Port

Sample Output

sap

- Syntax** `sap sap-id [detail]`
- Context** show>service>id
- Description** Displays information for the SAPs associated with the service.
- If no optional parameters are specified, a summary of all associated SAPs is displayed.
- Parameters** *sap-id* — the ID that displays SAPs for the service in the *slot/mdalport[.channel]* format
detail — displays detailed information for the SAP
- Output** **Show Service-ID SAP**
- [Table 27](#) describes the show service id SAP fields.

Table 27 Show Service-ID SAP Field Descriptions

Label	Description
Service Id	the service identifier
SAP	the type of SAP
Encap	the encapsulation type of the SAP
Ethertype	specifies an Ethernet type II Ethertype value
Admin State	the administrative state of the SAP
Oper State	the operational state of the SAP

Table 27 **Show Service-ID SAP Field Descriptions (Continued)**

Label	Description (Continued)
Flags	specifies the conditions that affect the operating status of this SAP display output includes: ServiceAdminDown, SapAdminDown, InterfaceAdminDown, PortOperDown, PortMTUTooSmall, L2OperDown, SapIngressQoSMismatch, SapEgressQoSMismatch, RelearnLimitExceeded, RxProtSrcMac, ParentIfAdminDown, NoSapPipeCelpAddr, SapParamMismatch, CemSapNoEcidOrMacAddr, StandByForMcRing, ServiceMTUTooSmall, SapIngressNamedPoolMismatch, SapEgressNamedPoolMismatch, NoSapEpipeRingNode.
Last Status Change	specifies the time of the most recent operating status change to this SAP
Last Mgmt Change	specifies the time of the most recent management-initiated change to this SAP
Admin MTU	the desired largest service frame size (in octets) that can be transmitted through the SAP to the far-end router, without requiring the packet to be fragmented.
Ingress qos-policy	the ingress QoS policy ID assigned to the SAP
Egress qos-policy	the egress QoS policy ID assigned to the SAP
Ingress Filter-Id	the ingress filter policy ID assigned to the SAP
Egress Filter-Id	the egress filter policy ID assigned to the SAP
Acct. Pol	the accounting policy ID assigned to the SAP
Collect Stats	specifies whether statistics collection is enabled
Dropped	the number of packets and octets dropped due to SAP state, ingress MAC or IP filter, same segment discard, bad checksum, etc.
Received Valid	the number of valid packets and octets received on the SAP
Off. HiPrio	the number of high priority packets and octets, as determined by the SAP ingress QoS policy
Off. LowPrio	the number of low priority packets and octets, as determined by the SAP ingress QoS policy
Off. Uncolor	the number of uncolored packets and octets, as determined by the SAP ingress QoS policy, offered by the Pchip to the Qchip
Dro. HiPrio	the number of high priority packets and octets, as determined by the SAP ingress QoS policy, dropped by the Qchip due to: MBS exceeded, buffer pool limit exceeded, etc
Dro. LowPrio	the number of low priority packets and octets, as determined by the SAP ingress QoS policy, dropped by the Qchip due to: MBS exceeded, buffer pool limit exceeded, etc
For. InProf	the number of in-profile packets and octets (rate below CIR) forwarded by the ingress Qchip

Table 27 Show Service-ID SAP Field Descriptions (Continued)

Label	Description (Continued)
For. OutProf	the number of out-of-profile packets and octets (rate below CIR) forwarded by the ingress Qchip
Dro. InProf	the number of in-profile packets and octets discarded by the egress Qchip due to MBS exceeded, buffer pool limit exceeded, etc.
Ingress TD Profile	the profile ID applied to the ingress SAP
Egress TD Profile	the profile ID applied to the egress SAP
Alarm Cell Handling	the OAM operational status of the VCL
AAL-5 Encap	the AAL-5 encapsulation type
Mult Svc Site	specifies the customer's multi-service-site name
I. Sched Pol	the ingress scheduler policy applied to the customer's multi-service-site
E. Sched Pol	the egress scheduler policy applied to the customer's multi-service-site

Sample Output

```

A:ALA-49# show service id 88 sap 771/1/1.2.2

sdp

Syntax	sdp [{sdp-id far-end ip-address }] [detail]
Context	show>service>id
Description	Displays information for the SDPs associated with the service. If no optional parameters are specified, a summary of all associated SDPs is displayed.
Parameters	sdp-id — the SDP ID for which to display information Values 1 to 17407

far-end ip-address — when specified, displays SDP having the specified far-end IP address

detail — displays detailed information for the SDP

Output

Sample Output

```

subscriber-hosts

Syntax	subscriber-hosts [sap <i>sap-id</i>] [ip <i>ip-address</i> [/ <i>mask</i>]] [mac <i>ieee-address</i>] [sub-profile <i>sub-profile-name</i>] [sla-profile <i>sla-profile-name</i>] [detail]
Context	show>service>id
Description	Displays subscriber host information.
Parameters	<i>sap sap-id</i> — displays the specified subscriber host SAP information <i>ip-address/mask</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Values allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). mask: 1 to 32 <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses. sub-profile <i>sub-profile-name</i> — Specifies an existing subscriber profile name to be associated with the static subscriber host. The subscriber profile is configured in the config>subscr-mgmt>sub-profile context.

sla-profile *sla-profile-name* — Specifies an existing SLA profile name to be associated with the static subscriber host. The SLA profile is configured in the **config>subscriber>sla-profile** context.

detail — displays detailed information

statistics

Syntax **statistics** [*ip-int-name* | *ip-address*]

Context show>router>dhcp

Description Display statistics for DHCP relay and DHCP snooping. If no IP address or interface name is specified, then all configured interfaces are displayed. If an IP address or interface name is specified, then only data regarding the specified interface is displayed.

Parameters *ip-int-name* | *ip-address* — displays statistics for the specified IP interface

Output **Show DHCP Statistics Output**

[Table 28](#) describes the output fields for DHCP statistics.

Table 28 Show DHCP Statistics Field Descriptions

Label	Description
Received Packets	the number of packets received from the DHCP clients
Transmitted Packets	the number of packets transmitted to the DHCP clients
Received Malformed Packets	the number of malformed packets received from the DHCP clients
Received Untrusted Packets	the number of untrusted packets received from the DHCP clients
Client Packets Discarded	the number of packets received from the DHCP clients that were discarded
Client Packets Relayed	the number of packets received from the DHCP clients that were forwarded
Client Packets Snooped	the number of packets received from the DHCP clients that were snooped
Server Packets Discarded	the number of packets received from the DHCP server that were discarded
Server Packets Relayed	the number of packets received from the DHCP server that were forwarded
Server Packets Snooped	the number of packets received from the DHCP server that were snooped

Sample Output

```
*A:ALA-1# show router dhcp statistics
=====
DHCP Global Statistics
=====
Rx Packets                               : 0
```

```

Tx Packets                : 0

summary

- Syntax** **summary**
- Context** show>router>dhcp
- Description** This command displays the status of the DHCP relay and DHCP snooping functions on each interface.
- Output** **Show DHCP Summary Output**
- [Table 29](#) describes the output fields for the DHCP summary.

Table 29 Show DHCP Summary Field Descriptions

Label	Description
Interface Name	name of the router interface
SapId/Sdp	specifies the associated SAP ID or SDP ID
Arp Populate	specifies whether or not ARP populate is enabled
Used/Provided	Used — The number of lease-states currently in use on a specific interface (the number of clients on that interface got an IP address by DHCP). This value is always less than or equal to the 'Provided' field.
	Provided — the configured for a specific interface
Info Option	indicates whether Option 82 processing is enabled on the interface
Admin State	indicates the administrative state

Sample Output

The following sample output applies to the 7750 SR:

```

A:ALA-49# show router dhcp summary
=====
DHCP Summary (Router: Base)
=====

```

Interface Name SapId/Sdp	Arp Populate	Used/ Provided	Info Option	Admin State

Interfaces: 9				

vrrp

Syntax	vrrp
Context	show>router
Description	This command displays information VRRP instances.

instance

Syntax	instance instance interface <i>interface-name</i> [vrid <i>virtual-router-id</i>] instance interface <i>interface-name</i> vrid <i>virtual-router-id</i> <i>ipv6</i>
Context	show>router>vrrp
Description	This command displays statistics for the VRRP instance.
Parameters	<i>interface-name</i> — displays statistics for the specified interface <i>virtual-router-id</i> — displays statistics for the specified virtual router ID
Values	1 to 255

statistics

Syntax	statistics
Context	show>router>vrrp
Description	This command displays statistics for the VRRP instance.

retailers

Syntax	retailers
Context	show>service>id
Description	This command displays the service ID of the retailer subscriber service to which this DHCP lease belongs.

wholesalers

Syntax	wholesalers
Context	show>service>id

Description This command displays service wholesaler information.

2.6.2.2 IES Clear Commands

dhcp

Syntax **dhcp**

Context clear>router>dhcp
clear>service>id

Description This command enables the context to clear DHCP parameters.

dhcp6

Syntax **dhcp6**

Context clear>router>dhcp6
clear>service>id

Description This command enables the context to clear DHCPv6 parameters and only applies to the 7750 SR.

statistics

Syntax *statistics [ip-int-name | ip-address]*

Context clear>router>dhcp

Description Clears DHCP statistics.

id

Syntax **id service-id**

Context clear>service
clear>service>statistics

Description This command clears parameters for a specific service.

Parameters *service-id* — the ID that uniquely identifies the service to clear

arp-host

Syntax	arp-host arp-host { mac <i>ieee-address</i> sap <i>sap-id</i> ip-address <i>ip-address</i> [<i>lmask</i>] } arp-host [port <i>port-id</i>] [inter-dest-id <i>intermediate-destination-id</i> no-inter-dest-id] arp-host statistics [sap <i>sap-id</i> interface <i>interface-name</i>]
Context	clear>service>id
Description	This command clears ARP host data.

interface

Syntax	interface [<i>ip-int-name</i> <i>ip-addr</i>] [icmp]
Context	clear>router
Description	This command clears IP interface statistics. If no IP interface is specified either by IP interface name or IP address, the command will perform the clear operation on all IP interfaces.
Parameters	<i>ip-int-name</i> <i>ip-addr</i> — the IP interface name or IP interface address Default all IP interfaces icmp — specifies to reset the ICMP statistics for the IP interface(s) used for ICMP rate limit

interface

Syntax	interface <i>interface-name</i> [vrid <i>virtual-router-id</i>] interface <i>interface-name</i> vrid <i>virtual-router-id</i> ipv6
Context	clear>router>vrrp
Description	This command clears and resets VRRP instances.
Parameters	<i>interface-name</i> — specifies an existing interface name up to 32 characters in length <i>virtual-router-id</i> — specifies the virtual router identifier Values 1 to 255

statistics

Syntax	statistics interface <i>interface-name</i> [vrid <i>virtual-router-id</i>] statistics

statistics interface *interface-name* **vrid** *virtual-router-id* **ipv6**

Context	clear>router>vrrp
Description	This command clears statistics for VRRP instances.
Parameters	<i>interface-name</i> — specifies an existing interface name up to 32 characters in length <i>virtual-router-id</i> — specifies the virtual router identifier
Values	1 to 255

fdb

Syntax	fdb { all mac <i>ieee-address</i> sap <i>sap-id</i>] mesh-sdp <i>sdp-id</i> [: <i>vc-id</i>] spoke-sdp <i>sdp-id</i> [: <i>vc-id</i>]
Context	clear>service>id
Description	This command clears FDB entries for the service.
Parameters	all — clears all FDB entries mac <i>ieee-address</i> — Clears only FDB entries in the FDB table with the specified 48-bit MAC address. The MAC address can be expressed in the form <i>aa:bb:cc:dd:ee:ff</i> or <i>aa-bb-cc-dd-ee-ff</i> where <i>aa</i> , <i>bb</i> , <i>cc</i> , <i>dd</i> , <i>ee</i> and <i>ff</i> are hexadecimal numbers sap <i>sap-id</i> — clears the specified SAP information mesh-sdp — clears only service FDB entries associated with the specified mesh SDP ID. For a mesh SDP, the VC ID is optional spoke-sdp — Clears only service FDB entries associated with the specified spoke SDP ID. For a spoke SDP, the VC ID must be specified <i>sdp-id</i> — the SDP ID for which to clear associated FDB entries Values 1 to 17407 <i>vc-id</i> — the virtual circuit ID on the SDP ID for which to clear associated FDB entries Values 1 to 4294967295 Default For mesh SDPs only, all VC IDs.

site

Syntax	site <i>service-id</i>
Context	clear>service>id
Description	This command clears site-specific information for the service.

Parameters	<i>service-id</i> — specifies the service ID or service name up to 64 characters in length
Values	1 to 2147483648

spoke-sdp

Syntax	spoke-sdp <i>sdp-id:vc-id ingress-vc-label</i>
Context	clear>service>id
Description	Clears and resets the spoke SDP bindings for the service.
Parameters	<i>sdp-id</i> — the spoke SDP ID to be reset
Values	1 to 17407
	<i>vc-id</i> — the virtual circuit ID on the SDP ID to be reset
Values	1 to 4294967295

stp

Syntax	stp
Context	clear>service>statistics>id
Description	Clears all spanning tree statistics for the service ID.

lease-state

Syntax	lease-state lease-state ip-address <i>ip-address</i> lease-state mac <i>ieee-address</i> lease-state sap <i>sap-id</i> lease-state sdp <i>sdp-id:vc-id</i>
Context	clear>service>id>dhcp
Description	Clears DHCP lease state information for this service.
Parameters	<i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

ieee-address — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

sap *sap-id* — clears the specified lease state SAP information

sdp-id — the specified SDP to be cleared

Values 1 to 17407

vc-id — the virtual circuit ID on the SDP ID to be cleared

Values 1 to 4294967295

lease-state

Syntax	lease-state [ip-address <i>ipv6-address/prefix-length</i>] [mac <i>ieee-address</i>]								
Context	clear>service>id>dhcp6								
Description	This command clears DHCPv6 lease state information for this service.								
Parameters	<i>ip-address</i> <i>ipv6-address/prefix-length</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets). Values <table><tr><td>ipv6-address:</td><td>x:x:x:x:x:x:x (eight 16-bit pieces)</td></tr><tr><td></td><td>x:x:x:x:x:d.d.d.d</td></tr><tr><td></td><td>x - [0 to FFFF]H</td></tr><tr><td></td><td>d - [0 to 255]D</td></tr></table>	ipv6-address:	x:x:x:x:x:x:x (eight 16-bit pieces)		x:x:x:x:x:d.d.d.d		x - [0 to FFFF]H		d - [0 to 255]D
ipv6-address:	x:x:x:x:x:x:x (eight 16-bit pieces)								
	x:x:x:x:x:d.d.d.d								
	x - [0 to FFFF]H								
	d - [0 to 255]D								
	<i>mac</i> <i>ieee-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.								

statistics

Syntax	statistics [<i>ip-int-name</i> <i>ipv6-address</i>]
Context	clear>router>dhcp6
Description	This command clears DHCP6 statistics.
Parameters	<i>ip-int-name</i> — specifies the IP interface name up to 32 characters in length

ip-address ipv6-address/prefix-length — The IP address of the IP interface. The *ip-address* portion of the **address** command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

Values

ipv6-address: x:x:x:x:x:x:x:x (eight 16-bit pieces)
 x:x:x:x:x:d.d.d.d
 x - [0 to FFFF]H
 d - [0 to 255]D

statistics

Syntax **statistics [sap sap-id | sdp sdp-id:vc-id | interface ip-address | ip-int-name]**

Context clear>service>id>dhcp

Description This command clears DHCP statistics.

Parameters **sap sap-id** — clears the specified SAP information
 sdp sdp-id — the specified SDP to be cleared

Values 1 to 17407

vc-id — the virtual circuit ID on the SDP ID to be cleared

Values 1 to 4294967295

interface ip-address — the interface IP address

ip-int-name — the interface name

2.6.2.3 IES Debug Commands

host-connectivity-verify

Syntax **[no] host-connectivity-verify**

Context debug>service>id

Description This command enables Subscriber Host Connectivity Verification (SHCV) debugging.

 The **no** form of the command disables the SHCV debugging.

ip

Syntax	[no] ip <i>ip-address</i>
Context	debug>service>id>host-connectivity-verify
Description	This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular IP address.
Parameters	<i>ip-address</i> — The IP address of the IP interface. The <i>ip-address</i> portion of the address command specifies the IP host address that will be used by the IP interface within the subnet. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 – 223.255.255.255 (with support of /31 subnets).

mac

Syntax	[no] mac <i>ieee-address</i>
Context	debug>service>id>host-connectivity-verify
Description	This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular MAC address.
Parameters	<i>mac-address</i> — Specifies the 48-bit MAC address for the static ARP in the form aa:bb:cc:dd:ee:ff or aa-bb-cc-dd-ee-ff where aa, bb, cc, dd, ee, and ff are hexadecimal numbers. Allowed values are any non-broadcast, non-multicast MAC and non-IEEE reserved MAC addresses.

sap

Syntax	[no] sap <i>sap-id</i>
Context	debug>service>id>host-connectivity-verify
Description	This command displays Subscriber Host Connectivity Verification (SHCV) events for a particular SAP.
Parameters	<i>sap-id</i> — specifies the physical port identifier portion of the SAP definition

packets

Syntax	[no] packets [no] packets interface <i>ip-int-name</i> [vrid <i>virtual-router-id</i>] [no] packets interface <i>ip-int-name</i> vrid <i>virtual-router-id</i> ipv6
Context	debug>router>vrrp

Description	This command enables or disables debugging for VRRP packets.
Parameters	<i>ip-int-name</i> — specifies the interface name <i>virtual-router-id</i> — specifies the router ID
Values	1 to 255

events

Syntax	[no] events [no] events interface <i>ip-int-name</i> [vrid <i>virtual-router-id</i>] [no] events interface <i>ip-int-name</i> vrid <i>virtual-router-id</i> ipv6
Context	debug>router>vrrp
Description	This command enables or disables debugging for VRRP events.
Parameters	<i>ip-int-name</i> — specifies the interface name <i>virtual-router-id</i> — specifies the router ID
Values	1 to 255

2.6.2.4 IES Monitor Commands

instance

Syntax	instance interface <i>interface-name</i> vr-id <i>virtual-router-id</i> [ipv6] [interval <i>seconds</i>] [repeat <i>repeat</i>] [absolute rate]
Context	monitor>router>vrrp
Description	This command enables monitoring for statistics for VRRP instances.

3 Virtual Private Routed Network Service

3.1 In This Chapter

This chapter provides information about the Virtual Private Routed Network (VPRN) service and implementation notes.

Topics in this chapter include:

- [VPRN Service Overview](#)
 - [Routing Prerequisites](#)
 - [Core MP-BGP Support](#)
 - [Route Distinguishers](#)
 - [Route Reflector](#)
 - [Constrained Route Distribution \(RT Constraint\)](#)
 - [BGP Fast Reroute in a VPRN](#)
 - [BGP Best-External in a VPRN Context](#)
- [VPRN Features](#)

- Configuring a VPRN Service with CLI
- Common Configuration Tasks
- Service Management Tasks

3.2 VPRN Service Overview

RFC 2547b is an extension to the original RFC 2547, *BGP/MPLS VPNs*, which details a method of distributing routing information using BGP and MPLS forwarding data to provide a Layer 3 Virtual Private Network (VPN) service to end customers.

Each Virtual Private Routed Network (VPRN) consists of a set of customer sites connected to one or more PE routers. Each associated PE router maintains a separate IP forwarding table for each VPRN. Additionally, the PE routers exchange the routing information configured or learned from all customer sites via MP-BGP peering. Each route exchanged via the MP-BGP protocol includes a Route Distinguisher (RD), which identifies the VPRN association and handles the possibility of IP address overlap.

The service provider uses BGP to exchange the routes of a particular VPN among the PE routers that are attached to that VPN. This is done in a way which ensures that routes from different VPNs remain distinct and separate, even if two VPNs have an overlapping address space. The PE routers peer with locally connected CE routers and exchange routes with other PE routers in order to provide end-to-end connectivity between CEs belonging to a given VPN. Since the CE routers do not peer with each other there is no overlay visible to the CEs.

When BGP distributes a VPN route it also distributes an MPLS label for that route. On an SR series router, the method of allocating a label to a VPN route depends on the VPRN label mode and the configuration of the VRF export policy. SR series routers support three label allocation methods: label per VRF, label per next hop, and label per prefix.

Before a customer data packet travels across the service provider's backbone, it is encapsulated with the MPLS label that corresponds, in the customer's VPN, to the route which best matches the packet's destination address. The MPLS packet is further encapsulated with one or additional MPLS labels or GRE tunnel header so that it gets tunneled across the backbone to the proper PE router. Each route exchanged by the MP-BGP protocol includes a route distinguisher (RD), which identifies the VPRN association. Thus the backbone core routers do not need to know the VPN routes. [Figure 9](#) displays a VPRN network diagram example.

Figure 9 Virtual Private Routed Network

3.2.1 Routing Prerequisites

RFC4364 requires the following features:

- multi-protocol extensions to BGP
- extended BGP community support
- BGP capability negotiation

Tunneling protocol options are as follows:

- Label Distribution Protocol (LDP)
- MPLS RSVP-TE tunnels
- Generic Router Encapsulation (GRE) tunnels
- BGP route tunnel (RFC3107)

3.2.2 Core MP-BGP Support

BGP is used with BGP extensions mentioned in [Routing Prerequisites](#) to distribute VPRN routing information across the service provider's network.

BGP was initially designed to distribute IPv4 routing information. Therefore, multi-protocol extensions and the use of a VPN-IP address were created to extend BGP’s ability to carry overlapping routing information. A VPN-IPv4 address is a 12-byte value consisting of the 8-byte route distinguisher (RD) and the 4-byte IPv4 IP address prefix. A VPN-IPv6 address is a 24-byte value consisting of the 8-byte RD and 16-byte IPv6 address prefix. Service providers typically assign one or a small number of RDs per VPN service network-wide.

3.2.3 Route Distinguishers

The route distinguisher (RD) is an 8-byte value consisting of two major fields, the **Type** field and **Value** field. The **Type** field determines how the **Value** field should be interpreted. The 7750 SR and 7950 XRS implementation supports the three (3) **Type** values as defined in the standard.

Figure 10 **Route Distinguisher**

The three Type values are:

- Type 0: Value Field — Administrator subfield (2 bytes)
Assigned number subfield (4 bytes)

The administrator field must contain an AS number (using private AS numbers is discouraged). The Assigned field contains a number assigned by the service provider.

- Type 1: Value Field — Administrator subfield (4 bytes)
Assigned number subfield (2 bytes)

The administrator field must contain an IP address (using private IP address space is discouraged). The Assigned field contains a number assigned by the service provider.

- Type 2: Value Field — Administrator subfield (4 bytes)
Assigned number subfield (2 bytes)

The administrator field must contain a 4-byte AS number (using private AS numbers is discouraged). The Assigned field contains a number assigned by the service provider.

3.2.3.1 eiBGP Load Balancing

eiBGP load balancing allows a route to have multiple nexthops of different types, using both IPv4 nexthops and MPLS LSPs simultaneously.

Figure 11 displays a basic topology that could use eiBGP load balancing. In this topology CE1 is dual homed and thus reachable by two separate PE routers. CE 2 (a site in the same VPRN) is also attached to PE1. With eiBGP load balancing, PE1 will utilize its own local IPv4 nexthop as well as the route advertised by MP-BGP, by PE2.

Figure 11 Basic eiBGP Topology

Another example displayed in Figure 12 shows an extra net VPRN (VRF). The traffic ingressing the PE that should be load balanced is part of a second VPRN and the route over which the load balancing is to occur is part of a separate VPRN instance and are leaked into the second VPRN by route policies.

Here, both routes can have a source protocol of VPN-IPv4 but one will still have an IPv4 nexthop and the other can have a VPN-IPv4 nexthop pointing out a network interface. Traffic will still be load balanced (if eiBGP is enabled) as if only a single VRF was involved.

Figure 12 Extranet Load Balancing

al_0162

Traffic will be load balanced across both the IPv4 and VPN-IPv4 next hops. This helps to use all available bandwidth to reach a dual-homed VPRN.

3.2.4 Route Reflector

The use of Route Reflectors is supported in the service provider core. Multiple sets of route reflectors can be used for different types of BGP routes, including IPv4 and VPN-IPv4 as well as multicast and IPv6 (multicast and IPv6 apply to the 7750 SR only).

3.2.5 CE to PE Route Exchange

Routing information between the Customer Edge (CE) and Provider Edge (PE) can be exchanged by the following methods:

- Static Routes
- E-BGP
- RIP
- OSPF
- OSPF3

Each protocol provides controls to limit the number of routes learned from each CE router.

3.2.5.1 Route Redistribution

Routing information learned from the CE-to-PE routing protocols and configured static routes should be injected in the associated local VPN routing/forwarding (VRF). In the case of dynamic routing protocols, there may be protocol specific route policies that modify or reject certain routes before they are injected into the local VRF.

Route redistribution from the local VRF to CE-to-PE routing protocols is to be controlled via the route policies in each routing protocol instance, in the same manner that is used by the base router instance.

The advertisement or redistribution of routing information from the local VRF to or from the MP-BGP instance is specified per VRF and is controlled by VRF route target associations or by VRF route policies.

VPN-IP routes imported into a VPRN, have the protocol **type bgp-vpn** to denote that it is an VPRN route. This can be used within the route policy match criteria.

3.2.5.2 CPE Connectivity Check

Static routes are used within many IES services and VPRN services. Unlike dynamic routing protocols, there is no way to change the state of routes based on availability information for the associated CPE. CPE connectivity check adds flexibility so that unavailable destinations will be removed from the VPRN routing tables dynamically and minimize wasted bandwidth.

Figure 13 Directly Connected IP Target

Fig_18

Figure 14 Multiple Hops to IP Target

Fig_19

The availability of the far-end static route is monitored through periodic polling. The polling period is configured. If the poll fails a specified number of sequential polls, the static route is marked as inactive.

Either ICMP ping or unicast ARP mechanism can be used to test the connectivity. ICMP ping is preferred.

If the connectivity check fails and the static route is deactivated, the router will continue to send polls and re-activate any routes that are restored.

3.2.6 Constrained Route Distribution (RT Constraint)

3.2.6.1 Constrained VPN Route Distribution Based on Route Targets

Constrained Route Distribution (or RT Constraint) is a mechanism that allows a router to advertise Route Target membership information to its BGP peers to indicate interest in receiving only VPN routes tagged with specific Route Target extended communities. Upon receiving this information, peers restrict the advertised VPN routes to only those requested, minimizing control plane load in terms of protocol traffic and possibly also RIB memory.

The Route Target membership information is carried using MP-BGP, using an AFI value of 1 and SAFI value of 132. In order for two routers to exchange RT membership NLRI they must advertise the corresponding AFI/SAFI to each other during capability negotiation. The use of MP-BGP means RT membership NLRI are propagated, loop-free, within an AS and between ASes using well-known BGP route selection and advertisement rules.

ORF can also be used for RT-based route filtering, but ORF messages have a limited scope of distribution (to direct peers) and therefore do not automatically create pruned inter-cluster and inter-AS route distribution trees.

3.2.6.2 Configuring the Route Target Address Family

RT Constraint is supported only by the base router BGP instance. When the **family** command at the BGP router group or neighbor CLI context includes the **route-target** keyword, the RT Constraint capability is negotiated with the associated set of EBGP and IBGP peers.

ORF is mutually exclusive with RT Constraint on a particular BGP session. The CLI will not attempt to block this configuration, but if both capabilities are enabled on a session, the ORF capability will not be included in the OPEN message sent to the peer.

3.2.6.3 Originating RT Constraint Routes

When the base router has one or more RTC peers (BGP peers with which the RT Constraint capability has been successfully negotiated), one RTC route is created for each RT extended community imported into a locally-configured L2 VPN or L3 VPN service. These imported route targets are configured in the following contexts:

- `config>service>vpn`
- `config>service>vpn>mvpn`
- `config>service>vpls>bgp`
- `config>service>epipe>bgp`

By default, these RTC routes are automatically advertised to all RTC peers, without the need for an export policy to explicitly “accept” them. Each RTC route has a prefix, a prefix length and path attributes. The prefix value is the concatenation of the origin AS (a 4 byte value representing the 2- or 4-octet AS of the originating router, as configured using the **config>router>autonomous-system** command) and 0 or 16-64 bits of a route target extended community encoded in one of the following formats: 2-octet AS specific extended community, IPv4 address specific extended community, or 4-octet AS specific extended community.

A router may be configured to send the default RTC route to any RTC peer. This is done using the new **default-route-target** group/neighbor CLI command. The default RTC route is a special type of RTC route that has zero prefix length. Sending the default RTC route to a peer conveys a request to receive all VPN routes (regardless of route target extended community) from that peer. The default RTC route is typically advertised by a route reflector to its clients. The advertisement of the default RTC route to a peer does not suppress other more specific RTC routes from being sent to that peer.

3.2.6.4 Receiving and Re-Advertising RT Constraint Routes

All received RTC routes that are deemed valid are stored in the RIB-IN. An RTC route is considered invalid and treated as withdrawn, if any of the following applies:

- The prefix length is 1-31.
- The prefix length is 33-47.
- The prefix length is 48-96 and the 16 most-significant bits are not 0x0002, 0x0102 or 0x0202.

If multiple RTC routes are received for the same prefix value then standard BGP best path selection procedures are used to determine the best of these routes.

The best RTC route per prefix is re-advertised to RTC peers based on the following rules:

- The best path for a default RTC route (prefix-length 0, origin AS only with prefix-length 32, or origin AS plus 16 bits of an RT type with prefix-length 48) is never propagated to another peer.
- A PE with only IBGP RTC peers that is neither a route reflector or an ASBR does not re-advertise the best RTC route to any RTC peer due to standard IBGP split horizon rules.
- A route reflector that receives its best RTC route for a prefix from a client peer re-advertises that route (subject to export policies) to all of its client and non-client IBGP peers (including the originator), per standard RR operation. When the route is re-advertised to client peers, the RR (i) sets the ORIGINATOR_ID to its own router ID and (ii) modifies the NEXT_HOP to be its local address for the sessions (for example, system IP).
- A route reflector that receives its best RTC route for a prefix from a non-client peer re-advertises that route (subject to export policies) to all of its client peers, per standard RR operation. If the RR has a non-best path for the prefix from any of its clients, it advertises the best of the client-advertised paths to all non-client peers.
- An ASBR that is neither a PE nor a route reflector that receives its best RTC route for a prefix from an IBGP peer re-advertises that route (subject to export policies) to its EBGp peers. It modifies the NEXT_HOP and AS_PATH of the re-advertised route per standard BGP rules. No aggregation of RTC routes is supported.
- An ASBR that is neither a PE nor a route reflector that receives its best RTC route for a prefix from an EBGp peer re-advertises that route (subject to export policies) to its EBGp and IBGP peers. When re-advertised routes are sent to EBGp peers, the ASBR modifies the NEXT_HOP and AS_PATH per standard BGP rules. No aggregation of RTC routes is supported.

Note: These advertisement rules do not handle hierarchical RR topologies properly. This is a limitation of the current RT constraint standard.

3.2.6.5 Using RT Constraint Routes

In general (ignoring IBGP-to-IBGP rules, Add-Path, Best-external, etc.), the best VPN route for every prefix/NLRI in the RIB is sent to every peer supporting the VPN address family, but export policies may be used to prevent some prefix/NLRI from being advertised to specific peers. These export policies may be configured statically or created dynamically based on use of ORF or RT constraint with a peer. ORF and RT Constraint are mutually exclusive on a session.

When RT Constraint is configured on a session that also supports VPN address families using route targets (that is: vpn-ipv4, vpn-ipv6, l2-vpn, mvpn-ipv4, mvpn-ipv6, mcast-vpn-ipv4 or evpn), the advertisement of the VPN routes is affected as follows:

- When the session comes up, the advertisement of the VPN routes is delayed for a short while to allow RTC routes to be received from the peer.
- After the initial delay, the received RTC routes are analyzed and acted upon. If S1 is the set of routes previously advertised to the peer and S2 is the set of routes that should be advertised based on the most recent received RTC routes then:
 - Set of routes in S1 but not in S2 should be withdrawn immediately (subject to MRAI).
 - Set of routes in S2 but not in S1 should be advertised immediately (subject to MRAI).
- If a default RTC route is received from a peer P1, the VPN routes that are advertised to P1 is the set that:
 - a. are eligible for advertisement to P1 per BGP route advertisement rules AND
 - b. have not been rejected by manually configured export policies AND
 - c. have not been advertised to the peer

Note: This applies whether or not P1 advertised the best route for the default RTC prefix.

In this context, a default RTC route is any of the following:

1. a route with NLRI length = zero
2. a route with NLRI value = origin AS and NLRI length = 32
3. a route with NLRI value = {origin AS+0x0002 | origin AS+0x0102 | origin AS+0x0202} and NLRI length = 48

- If an RTC route for prefix A (origin-AS = A1, RT = A2/n, $n > 48$) is received from an IBGP peer I1 in autonomous system A1, the VPN routes that are advertised to I1 is the set that:
 - a. are eligible for advertisement to I1 per BGP route advertisement rules AND
 - b. have not been rejected by manually configured export policies AND
 - c. carry at least one route target extended community with value A2 in the n most significant bits AND
 - d. have not been advertised to the peer

Note: This applies whether or not I1 advertised the best route for A.

- If the best RTC route for a prefix A (origin-AS = A1, RT = A2/n, $n > 48$) is received from an IBGP peer I1 in autonomous system B, the VPN routes that are advertised to I1 is the set that:
 - a. are eligible for advertisement to I1 per BGP route advertisement rules AND
 - b. have not been rejected by manually configured export policies AND
 - c. carry at least one route target extended community with value A2 in the n most significant bits AND
 - d. have not been advertised to the peer

Note: This applies only if I1 advertised the best route for A.

- If the best RTC route for a prefix A (origin-AS = A1, RT = A2/n, $n > 48$) is received from an EBGP peer E1, the VPN routes that are advertised to E1 is the set that:
 - a. are eligible for advertisement to E1 per BGP route advertisement rules AND
 - b. have not been rejected by manually configured export policies AN
 - c. carry at least one route target extended community with value A2 in the n most significant bits AND
 - d. have not been advertised to the peer

Note: This applies only if E1 advertised the best route for A.

3.2.7 BGP Fast Reroute in a VPRN

BGP fast reroute is a feature that brings together indirection techniques in the forwarding plane and pre-computation of BGP backup paths in the control plane to support fast reroute of BGP traffic around unreachable/failed next-hops. In a VPRN context BGP fast reroute is supported using unlabeled IPv4, unlabeled IPv6, VPN-IPv4, and VPN-IPv6 VPN routes. The supported VPRN scenarios are outlined in [Table 30](#).

BGP fast reroute information specific to the base router BGP context is described in the BGP Fast Reroute section of the Unicast Routing Protocols Guide.

Table 30 BGP Fast Reroute Scenarios (VPRN Context)

Ingress Packet	Primary Route	Backup Route	Prefix Independent Convergence
IPv4 (ingress PE)	IPv4 route with next-hop A resolved by an IPv4 route	IPv4 route with next-hop B resolved by an IPv4 route	Yes
IPv4 (ingress PE)	VPN-IPv4 route with next-hop A resolved by a GRE, LDP, RSVP or BGP tunnel	VPN-IPv4 route with next-hop A resolved by a GRE, LDP, RSVP or BGP tunnel	Yes, but if the VPN-IP routes are label-per-prefix the ingress card must be FP2 or better
MPLS (egress PE)	IPv4 route with next-hop A resolved by an IPv4 route	IPv4 route with next-hop B resolved by an IPv4 route	Yes
MPLS (egress PE)	IPv4 route with next-hop A resolved by an IPv4 route	VPN-IPv4 route* with next-hop B resolved by a GRE, LDP, RSVP or BGP tunnel	Yes, but if the VPN-IP routes are label-per-prefix the ingress card must be FP2 or better for PIC
IPv6 (ingress PE)	IPv6 route with next-hop A resolved by an IPv6 route	IPv6 route with next-hop B resolved by an IPv6 route	Yes
IPv6 (ingress PE)	VPN-IPv6 route with next-hop A resolved by a GRE, LDP, RSVP or BGP tunnel	VPN-IPv6 route with next-hop B resolved by a GRE, LDP, RSVP or BGP tunnel	Yes, but if the VPN-IP routes are label-per-prefix the ingress card must be FP2 or better

Table 30 BGP Fast Reroute Scenarios (VPRN Context) (Continued)

Ingress Packet	Primary Route	Backup Route	Prefix Independent Convergence
MPLS (egress)	IPv6 route with next-hop A resolved by an IPv6 route	IPv6 route with next-hop B resolved by an IPv6 route	Yes
MPLS (egress)	IPv6 route with next-hop A resolved by an IPv6 route	Yes, but if the VPN-IP routes are label-per-prefix the ingress card must be FP2 or better for PIC	VPRN label mode must be VRF. VPRN must export its VPN-IP routes with RD $\neq$ y. For the best performance the backup next-hop must advertise the same VPRN label value with all routes (e.g. per VRF label).

3.2.7.1 BGP Fast Reroute in a VPRN Configuration

In a VPRN context, BGP fast reroute is optional and must be enabled. Fast reroute can be applied to all IPv4 prefixes, all IPv6 prefixes, all IPv4 and IPv6 prefixes, or to a specific set of IPv4 and IPv6 prefixes.

If all IP prefixes require backup path protection, use a combination of the BGP instance-level **backup-path** and VPRN-level **enable-bgp-vpn-backup** commands. The VPRN BGP **backup-path** command enables BGP fast reroute for all IPv4 prefixes and/or all IPv6 prefixes that have a best path through a VPRN BGP peer. The VPRN-level **enable-bgp-vpn-backup** command enables BGP fast reroute for all IPv4 prefixes and/or all IPv6 prefixes that have a best path through a remote PE peer.

If only some IP prefixes require backup path protection, use route policies to apply the **install-backup-path** action to the best paths of the IP prefixes requiring protection. See BGP Fast Reroute section of the Unicast Routing Protocols Guide for more information.

3.2.8 BGP Best-External in a VPRN Context

If two or more PE routers connect to a multi-homed site and learn routes for a common set of IP prefixes from that site, then the failure of one of the PE routers or a PE-CE link can be handled by rerouting the traffic over the alternate paths. The traffic failover time in this situation can be reduced if all the PE routers have advance knowledge of the potential backup paths and do not have to wait for BGP route advertisements and/or withdrawals to reprogram their forwarding tables. This can be challenging with normal BGP procedures because a PE router is not allowed to advertise, to other PE routers, a BGP route that it has learned from a connected CE device if that route is not its active route for the destination in the route table. If the multi-homing scenario calls for all traffic destined for an IP prefix to be carried over a preferred primary path (passing through PE1-CE1 for example), then all other PE routers (PE2, PE3, and so on) will have that VPN route as their active route for the destination, and they will not be able to advertise their own routes for the same IP prefix.

The SR OS supports a VPRN feature, configured using the **export-inactive-bgp** command, that resolves the issue described above. When a VPRN is configured with this command, it is allowed to advertise (as a VPN-IP route towards other PEs) its best CE-BGP route for an IP prefix, even when that CE-BGP route is inactive in the route table due to the presence of a more-preferred VPN-IP route from another PE. In order for the CE-BGP route to be advertised, the CE-BGP route must be accepted by the VRF export policy. When a VPN-IP route is advertised due to the **export-inactive-bgp** command, the label carried in the route is a per-next-hop label corresponding to the next-hop IP address of the CE-BGP route, or a per-prefix label; this helps avoid packet looping issues due to unsynchronized IP FIBs.

When a PE router that advertised a backup path for an IP prefix receives a withdrawal for the VPN-IP route that it was using as the primary/active route, its backup path may be promoted to the primary path; that is, the CE-BGP route may become the active route for the destination. In this case, the PE router is required to readvertise the VPN-IP route with a per-VRF label if that is the default allocation policy and there is no label-per-prefix policy override. It will take some time for the new VPN-IP route to reach all the ingress routers and for them to update their forwarding tables. In the meantime, traffic will continue to be received with the old per-next-hop label. The egress PE will drop this in-flight traffic unless **label-retention** is configured using the **bgp-labels-hold-timer** command in the **config>router>mpls-labels** context. This command configures a delay (in seconds) between the withdrawal of a VPN-IP route with a per-next-hop label and the deletion of the corresponding label forwarding entry in the IOM. The value of **bgp-labels-hold-timer** should be large enough to account for the propagation delay of the route withdrawal to all the ingress routers.

3.3 VPRN Features

This section describes various VPRN features and any special capabilities or considerations as they relate to VPRN services.

- [IP Interfaces](#)
- [Subscriber Interfaces](#)
- [SAPs](#)
 - [Encapsulations](#)
 - [QoS Policies](#)
 - [Filter Policies](#)
- [CE to PE Routing Protocols](#)
 - [PE to PE Tunneling Mechanisms](#)
 - [Per VRF Route Limiting](#)
 - [Using OSPF in IP-VPNs](#)
- [Spoke SDPs](#)
 - [Carrier Supporting Carrier \(CsC\)](#)
- [Multicast in IP-VPN Applications](#)

3.3.1 IP Interfaces

VPRN customer IP interfaces can be configured with most of the same options found on the core IP interfaces. The advanced configuration options supported are:

- VRRP
- Cflowd
- Secondary IP addresses
- ICMP Options

Configuration options found on core IP interfaces not supported on VPRN IP interfaces are:

- NTP broadcast receipt

3.3.1.1 QoS Policy Propagation Using BGP (QPPB)

This section discusses QPPB as it applies to VPRN, IES, and router interfaces. Refer to the [QoS Policy Propagation Using BGP \(QPPB\)](#) section and the IP Router Configuration section in the Router Configuration Guide.

The QoS Policy Propagation Using BGP (QPPB) feature applies only to the 7450 ESS and 7750 SR.

QoS policy propagation using BGP (QPPB) is a feature that allows a route to be installed in the routing table with a forwarding-class and priority so that packets matching the route can receive the associated QoS. The forwarding-class and priority associated with a BGP route are set using BGP import route policies. In the industry this feature is called QPPB, and even though the feature name refers to BGP specifically. On SR OS, QPPB is supported for BGP (IPv4, IPv6, VPN-IPv4, VPN-IPv6), RIP and static routes.

While SAP ingress and network QoS policies can achieve the same end result as QPPB, assigning a packet arriving on a particular IP interface to a specific forwarding-class and priority/profile based on the source IP address or destination IP address of the packet ?the effort involved in creating the QoS policies, keeping them up-to-date, and applying them across many nodes is much greater than with QPPB. In a typical application of QPPB, a BGP route is advertised with a BGP community attribute that conveys a particular QoS. Routers that receive the advertisement accept the route into their routing table and set the forwarding-class and priority of the route from the community attribute.

3.3.1.2 QPPB Applications

There are two typical applications of QPPB:

1. coordination of QoS policies between different administrative domains, and
2. traffic differentiation within a single domain, based on route characteristics.

3.3.1.3 Inter-AS Coordination of QoS Policies

The operator of an administrative domain A can use QPPB to signal to a peer administrative domain B that traffic sent to certain prefixes advertised by domain A should receive a particular QoS treatment in domain B. More specifically, an ASBR of domain A can advertise a prefix XYZ to domain B and include a BGP community attribute with the route. The community value implies a particular QoS treatment, as

agreed by the two domains (in their peering agreement or service level agreement, for example). When the ASBR and other routers in domain B accept and install the route for XYZ into their routing table, they apply a QoS policy on selected interfaces that classifies traffic towards network XYZ into the QoS class implied by the BGP community value.

QPPB may also be used to request that traffic sourced from certain networks receive appropriate QoS handling in downstream nodes that may span different administrative domains. This can be achieved by advertising the source prefix with a BGP community, as discussed above. However, in this case other approaches are equally valid, such as marking the DSCP or other CoS fields based on source IP address so that downstream domains can take action based on a common understanding of the QoS treatment implied by different DSCP values.

In the above examples, coordination of QoS policies using QPPB could be between a business customer and its IP VPN service provider, or between one service provider and another.

3.3.1.4 Traffic Differentiation Based on Route Characteristics

There may be times when a network operator wants to provide differentiated service to certain traffic flows within its network, and these traffic flows can be identified with known routes. For example, the operator of an ISP network may want to give priority to traffic originating in a particular ASN (the ASN of a content provider offering over-the-top services to the ISP's customers), following a certain AS_PATH, or destined for a particular next-hop (remaining on-net vs. off-net).

[Figure 15](#) shows an example of an ISP that has an agreement with the content provider managing AS300 to provide traffic sourced and terminating within AS300 with differentiated service appropriate to the content being transported. In this example we presume that ASBR1 and ASBR2 mark the DSCP of packets terminating and sourced, respectively, in AS300 so that other nodes within the ISP's network do not need to rely on QPPB to determine the correct forwarding-class to use for the traffic. The DSCP or other COS markings could be left unchanged in the ISP's network and QPPB used on every node.

Figure 15 Use of QPPB to Differentiate Traffic in an ISP Network

3.3.1.5 QPPB

There are two main aspects of the QPPB feature on the 7450 ESS and 7750 SR:

- the ability to associate a forwarding-class and priority with certain routes in the routing table, and
- the ability to classify an IP packet arriving on a particular IP interface to the forwarding-class and priority associated with the route that best matches the packet.

3.3.1.6 Associating an FC and Priority with a Route

This feature uses a command in the route-policy hierarchy to set the forwarding class and optionally the priority associated with routes accepted by a route-policy entry. The command has the following structure:

fc *fc-name* [**priority** {**low** | **high**}]

The use of this command is illustrated by the following example:

```
config>router>policy-options
begin
community gold members 300:100
```

```
policy-statement qppb_policy
entry 10
from
protocol bgp
community gold
exit
action accept
fc hl priority high
exit
exit
exit
commit
```

The **fc** command is supported with all existing from and to match conditions in a route policy entry and with any action other than reject, it is supported with next-entry, next-policy and accept actions. If a next-entry or next-policy action results in multiple matching entries then the last entry with a QPPB action determines the forwarding class and priority.

A route policy that includes the **fc** command in one or more entries can be used in any import or export policy but the **fc** command has no effect except in the following types of policies:

- VRF import policies:
 - config>service>vprn>vrf-import
- BGP import policies:
 - config>router>bgp>import
 - config>router>bgp>group>import
 - config>router>bgp>group>neighbor>import
 - config>service>vprn>bgp>import
 - config>service>vprn>bgp>group>import
 - config>service>vprn>bgp>group>neighbor>import
- RIP import policies:
 - config>router>rip>import
 - config>router>rip>group>import
 - config>router>rip>group>neighbor>import
 - config>service>vprn>rip>import
 - config>service>vprn>rip>group>import
 - config>service>vprn>rip>group>neighbor>import

As evident from above, QPPB route policies support routes learned from RIP and BGP neighbors of a VPRN as well as for routes learned from RIP and BGP neighbors of the base/global routing instance.

QPPB is supported for BGP routes belonging to any of the address families listed below:

- IPv4 (AFI=1, SAFI=1)
- IPv6 (AFI=2, SAFI=1)
- VPN-IPv4 (AFI=1, SAFI=128)
- VPN-IPv6 (AFI=2, SAFI=128)

A VPN-IP route may match both a VRF import policy entry and a BGP import policy entry (if `vpn-apply-import` is configured in the base router BGP instance). In this case the VRF import policy is applied first and then the BGP import policy, so the QPPB QoS is based on the BGP import policy entry.

This feature also introduces the ability to associate a forwarding-class and optionally priority with IPv4 and IPv6 static routes. This is achieved by specifying the forwarding-class within the static-route-entry next-hop or indirect context.

Priority is optional when specifying the forwarding class of a static route, but once configured it can only be deleted and returned to unspecified by deleting the entire static route.

3.3.1.7 Displaying QoS Information Associated with Routes

The following commands are enhanced to show the forwarding-class and priority associated with the displayed routes:

- `show router route-table`
- `show router fib`
- `show router bgp routes`
- `show router rip database`
- `show router static-route`

This feature uses a **qos** keyword to the **show>router>route-table** command. When this option is specified the output includes an additional line per route entry that displays the forwarding class and priority of the route. If a route has no fc and priority information then the third line is blank. The following CLI shows an example:

```
show router route-table [family] [ip-prefix[/prefix-length]] [longer | exact]  
[protocol protocol-name] qos
```

An example output of this command is shown below:

```
A:Dut-A# show router route-table 10.1.5.0/24 qos
```

```

3.3.1.8 Enabling QPPB on an IP interface

To enable QoS classification of ingress IP packets on an interface based on the QoS information associated with the routes that best match the packets the **qos-route-lookup** command is necessary in the configuration of the IP interface. The **qos-route-lookup** command has parameters to indicate whether the QoS result is based on lookup of the source or destination IP address in every packet. There are separate qos-route-lookup commands for the IPv4 and IPv6 packets on an interface, which allows QPPB to be enabled for IPv4 only, IPv6 only, or both IPv4 and IPv6. Current QPPB based on a source IP address is not supported for IPv6 packets nor is it supported for ingress subscriber management traffic on a group interface.

The qos-route-lookup command is supported on the following types of IP interfaces:

- base router network interfaces (config>router>interface)
- VPRN SAP and spoke SDP interfaces (config>service>vprn>interface)
- VPRN group-interfaces (config>service>vprn>sub-if>grp-if)
- IES SAP and spoke SDP interfaces (config>service>ies>interface)
- IES group-interfaces (config>service>ies>sub-if>grp-if)

When the qos-route-lookup command with the destination parameter is applied to an IP interface and the destination address of an incoming IP packet matches a route with QoS information the packet is classified to the fc and priority associated with that route, overriding the fc and priority/profile determined from the SAP-Ingress or network qos policy associated with the IP interface. If the destination address of the incoming packet matches a route with no QoS information the fc and priority of the packet remain as determined by the SAP-Ingress or network qos policy.

Similarly, when the `qos-route-lookup` command with the `source` parameter is applied to an IP interface and the source address of an incoming IP packet matches a route with QoS information the packet is classified to the `fc` and priority associated with that route, overriding the `fc` and priority/profile determined from the SAP-Ingress or network qos policy associated with the IP interface. If the source address of the incoming packet matches a route with no QoS information the `fc` and priority of the packet remain as determined by the SAP-Ingress or network qos policy.

Currently, QPPB is not supported for ingress MPLS traffic on network interfaces or on CsC PE'-CE' interfaces (`config>service>vpn>nw-if`).

3.3.1.9 QPPB When Next-Hops are Resolved by QPPB Routes

In some circumstances (IP VPN inter-AS model C, Carrier Supporting Carrier, indirect static routes, etc.) an IPv4 or IPv6 packet may arrive on a QPPB-enabled interface and match a route A1 whose next-hop N1 is resolved by a route A2 with next-hop N2 and perhaps N2 is resolved by a route A3 with next-hop N3, etc. In release 9.0 the QPPB result is based only on the forwarding-class and priority of route A1. If A1 does not have a forwarding-class and priority association then the QoS classification is not based on QPPB, even if routes A2, A3, etc. have forwarding-class and priority associations.

3.3.1.10 QPPB and Multiple Paths to a Destination

When ECMP is enabled some routes may have multiple equal-cost next-hops in the forwarding table. When an IP packet matches such a route the next-hop selection is typically based on a hash algorithm that tries to load balance traffic across all the next-hops while keeping all packets of a given flow on the same path. The QPPB configuration model described in [Associating an FC and Priority with a Route](#) allows different QoS information to be associated with the different ECMP next-hops of a route. The forwarding-class and priority of a packet matching an ECMP route is based on the particular next-hop used to forward the packet.

When BGP FRR is enabled some BGP routes may have a backup next-hop in the forwarding table in addition to the one or more primary next-hops representing the equal-cost best paths allowed by the ECMP/multipath configuration. When an IP packet matches such a route a reachable primary next-hop is selected (based on the hash result) but if all the primary next-hops are unreachable then the backup next-hop is used. The QPPB configuration model described in [Associating an FC and Priority with a Route](#) allows the forwarding-class and priority associated with the backup path to be different from the QoS characteristics of the equal-cost best paths. The forwarding class and priority of a packet forwarded on the backup path is based

on the **fc** and priority of the backup route.

3.3.1.11 QPPB and Policy-Based Routing

When an IPv4 or IPv6 packet with destination address X arrives on an interface with both QPPB and policy-based-routing enabled:

- There is no QPPB classification if the IP filter action redirects the packet to a directly connected interface, even if X is matched by a route with a forwarding-class and priority
- QPPB classification is based on the forwarding-class and priority of the route matching IP address Y if the IP filter action redirects the packet to the indirect next-hop IP address Y, even if X is matched by a route with a forwarding-class and priority.

3.3.1.12 QPPB and GRT Lookup

Source-address based QPPB is not supported on any SAP or spoke SDP interface of a VPRN configured with the **grt-lookup** command.

3.3.1.13 QPPB Interaction with SAP Ingress QoS Policy

When QPPB is enabled on a SAP IP interface the forwarding class of a packet may change from **fc1**, the original **fc** determined by the SAP ingress QoS policy to **fc2**, the new **fc** determined by QPPB. In the ingress datapath SAP ingress QoS policies are applied in the first P chip and route lookup/QPPB occurs in the second P chip. This has the implications listed below:

- Ingress remarking (based on profile state) is always based on the original **fc** (**fc1**) and sub-class (if defined).
- The profile state of a SAP ingress packet that matches a QPPB route depends on the configuration of **fc2** only. If the de-1-out-profile flag is enabled in **fc2** and **fc2** is not mapped to a priority mode queue then the packet will be marked out of profile if its DE bit = 1. If the profile state of **fc2** is explicitly configured (in or out) and **fc2** is not mapped to a priority mode queue then the packet is assigned this profile state. In both cases there is no consideration of whether or not **fc1** was mapped to a priority mode queue.

- The priority of a SAP ingress packet that matches a QPPB route depends on several factors. If the de-1-out-profile flag is enabled in **fc2** and the DE bit is set in the packet then priority will be low regardless of the QPPB priority or **fc2** mapping to profile mode queue, priority mode queue or policer. If **fc2** is associated with a profile mode queue then the packet priority will be based on the explicitly configured profile state of **fc2** (in profile = high, out profile = low, undefined = high), regardless of the QPPB priority or **fc1** configuration. If **fc2** is associated with a priority mode queue or policer then the packet priority will be based on QPPB (unless DE=1), but if no priority information is associated with the route then the packet priority will be based on the configuration of **fc1** (if **fc1** mapped to a priority mode queue then it is based on DSCP/IP prec/802.1p and if **fc1** mapped to a profile mode queue then it is based on the profile state of **fc1**).

Table 31 summarizes these interactions.

Table 31 QPPB Interactions with SAP Ingress QoS

Original FC object mapping	New FC object mapping	Profile	Priority (drop preference)	DE=1 override	In/out of profile marking
Profile mode queue	Profile mode queue	From new base FC unless overridden by DE=1	From QPPB, unless packet is marked in or out of profile in which case follows profile. Default is high priority	From new base FC	From original FC and sub-class
Priority mode queue	Priority mode queue	Ignored	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Policer	Policer	From new base FC unless overridden by DE=1	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class

Table 31 QPPB Interactions with SAP Ingress QoS (Continued)

Original FC object mapping	New FC object mapping	Profile	Priority (drop preference)	DE=1 override	In/out of profile marking
Priority mode queue	Policer	From new base FC unless overridden by DE=1	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Policer	Priority mode queue	Ignored	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then from original dot1p/exp/DSCP mapping or policy default.	From new base FC	From original FC and sub-class
Profile mode queue	Priority mode queue	Ignored	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then follows original FC's profile mode rules.	From new base FC	From original FC and sub-class
Priority mode queue	Profile mode queue	From new base FC unless overridden by DE=1	From QPPB, unless packet is marked in or out of profile in which case follows profile. Default is high priority	From new base FC	From original FC and sub-class
Profile mode queue	Policer	From new base FC unless overridden by DE=1	If DE=1 override then low otherwise from QPPB. If no DEI or QPPB overrides then follows original FC's profile mode rules.	From new base FC	From original FC and sub-class
Policer	Profile mode queue	From new base FC unless overridden by DE=1	From QPPB, unless packet is marked in or out of profile in which case follows profile. Default is high priority	From new base FC	From original FC and sub-class

3.3.1.14 Object Grouping and State Monitoring

This feature introduces a generic operational group object which associates different service endpoints (pseudowires and SAPs) located in the same or in different service instances. The operational group status is derived from the status of the individual components using certain rules specific to the application using the concept. A number of other service entities, the monitoring objects, can be configured to monitor the operational group status and to perform certain actions as a result of status transitions. For example, if the operational group goes down, the monitoring objects will be brought down.

3.3.1.15 VPRN IP Interface Applicability

This concept is used by an IPv4 VPRN interface to affect the operational state of the IP interface monitoring the operational group. Individual SAP and spoke SDPs are supported as monitoring objects.

The following rules apply:

- An object can only belong to one group at a time.
- An object that is part of a group cannot monitor the status of a group.
- An object that monitors the status of a group cannot be part of a group.
- An operational group may contain any combination of member types: SAP or Spoke-SDPs.
- An operational group may contain members from different VPLS service instances.
- Objects from different services may monitor the oper-group.

There are two steps involved in enabling the functionality:

- Step 1.** Identify a set of objects whose forwarding state should be considered as a whole group then group them under an operational group using the **oper-group** command.
- Step 2.** Associate the IP interface to the oper-group using the **monitor-group** command

The status of the operational group (oper-group) is dictated by the status of one or more members according to the following rule:

- The oper-group goes down if all the objects in the oper-group go down. The oper-group comes up if at least one of the components is up.

- An object in the group is considered down if it is not forwarding traffic in at least one direction. That could be because the operational state is down or the direction is blocked through some validation mechanism.
- If a group is configured but no members are specified yet then its status is considered up.
- As soon as the first object is configured the status of the operational group is dictated by the status of the provisioned member(s).

The simple configuration below shows the oper-group g1, the VPLS SAP that is mapped to it and the IP interfaces in VPRN service 2001 monitoring the oper-group g1. This example uses an R-VPLS context. The VPLS instance includes the **allow-ip-int-bind** and the **service-name v1**. The VPRN interface links to the VPLS using the **vpls v1** option. All commands are under the configuration service hierarchy.

To further explain the configuration. Oper-group g1 has a single SAP (1/1/1:2001) mapped to it and the IP interfaces in the VPRN service 2001 will derive its state from the state of oper-group g1.

```
oper-group g1 create

vpls 1 customer 1 create
    allow-ip-int-bind
    stp
        shutdown
    exit
    service-name "v1"
    sap 1/1/1:2001 create
        oper-group g1
        eth-cfm
            mep domain 1 association 1 direction down
    ccm-enable
        no shutdown
        exit
    exit
    sap 1/1/2:2001 create
    exit
    sap 1/1/3:2001 create
    exit
no shutdown

vprn 2001 customer 1 create
    interface "i2001" create
        address 21.1.1.1/24
        monitor-oper-group "g1"
        vpls "v1"
    exit
    no shutdown
    exit
```

3.3.2 Subscriber Interfaces

Subscriber interfaces are composed of a combination of two key technologies, subscriber interfaces and group interfaces. While the subscriber interface defines the subscriber subnets, the group interfaces are responsible for aggregating the SAPs.

Subscriber Interfaces apply only to the 7450 ESS and 7750 SR.

- Subscriber interface — an interface that allows the sharing of a subnet among one or many group interfaces in the routed CO model
- Group interface — aggregates multiple SAPs on the same port
- Redundant interfaces — a special spoke-terminated Layer 3 interface. It is used in a Layer 3 routed CO dual-homing configuration to shunt downstream (network to subscriber) to the active node for a given subscriber

3.3.3 SAPs

3.3.3.1 Encapsulations

The following SAP encapsulations are supported on the 7750 SR and 7950 XRS VPRN service:

- Ethernet null
- Ethernet dot1q
- SONET/SDH IPCP
- SONET/SDH ATM
- ATM - LLC SNAP or VC-MUX
- Cisco HDLC
- QinQ
- LAG
- Tunnel (IPSec or GRE)
- Frame Relay

3.3.3.2 ATM SAP Encapsulations for VPRN Services

The router supports ATM PVC service encapsulation for VPRN SAPs on the 7750 SR only. Both UNI and NNI cell formats are supported. The format is configurable on a SONET/SDH path basis. A path maps to an ATM VC. All VCs on a path must use the same cell format.

The following ATM encapsulation and transport modes are supported:

- RFC 2684, *Multiprotocol Encapsulation over ATM Adaptation Layer 5*:
 - AAL5 LLC/SNAP IPv4 routed
 - AAL5 VC mux IPv4 routed
 - AAL5 LLC/SNAP IPv4 bridged
 - AAL5 VC mux IPv4 bridged

3.3.3.3 Pseudowire SAPs

Pseudowire SAPs are supported on VPRN interfaces for the 7750 SR in the same way as on IES interfaces. For details of pseudowire SAPs, see [Pseudowire SAPs](#).

3.3.4 QoS Policies

When applied to a VPRN SAP, service ingress QoS policies only create the unicast queues defined in the policy if PIM is not configured on the associated IP interface; if PIM is configured, the multipoint queues are applied as well.

With VPRN services, service egress QoS policies function as with other services where the class-based queues are created as defined in the policy.

Both Layer 2 or Layer 3 criteria can be used in the QoS policies for traffic classification in an VPRN.

3.3.5 Filter Policies

Ingress and egress IPv4 and IPv6 filter policies can be applied to VPRN SAPs.

3.3.6 DSCP Marking

Specific DSCP, forwarding class, and Dot1P parameters can be specified to be used by every protocol packet generated by the VPRN. This enables prioritization or de-prioritization of every protocol (as required). The markings effect a change in behavior on ingress when queuing. For example, if OSPF is not enabled, then traffic can be de-prioritized to best effort (be) DSCP. This change de-prioritizes OSPF traffic to the CPU complex.

DSCP marking for internally generated control and management traffic by marking the DSCP value should be used for the given application. This can be configured per routing instance. For example, OSPF packets can carry a different DSCP marking for the base instance and then for a VPRN service. ISIS and ARP traffic is not an IP-generated traffic type and is not configurable.

When an application is configured to use a specified DSCP value then the MPLS EXP, Dot1P bits will be marked in accordance with the network or access egress policy as it applies to the logical interface the packet will be egressing.

The DSCP value can be set per application. This setting will be forwarded to the egress line card. The egress line card does not alter the coded DSCP value and marks the LSP-EXP and IEEE 802.1p (Dot1P) bits according to the appropriate network or access QoS policy.

Table 32 DSCP/FC Marking

*The default forwarding class mapping is used for all DSCP names/values for which there is no explicit forwarding class mapping.

3.3.7 Configuration of TTL Propagation for VPRN Routes

This feature allows the separate configuration of TTL propagation for in transit and CPM generated IP packets, at the ingress LER within a VPRN service context. The following commands are supported:

- config router ttl-propagate vprn-local [none | vc-only | all]
- config router ttl-propagate vprn-transit [none | vc-only | all]

You can enable TTL propagation behavior separately as follows:

- for locally generated packets by CPM (vprn-local)
- for user and control packets in transit at the node (vprn-transit)

The following parameters can be specified:

- The **all** parameter enables TTL propagation from the IP header into all labels in the stack, for VPN-IPv4 and VPN-IPv6 packets forwarded in the context of all VPRN services in the system.
- The **vc-only** parameter reverts to the default behavior by which the IP TTL is propagated into the VC label but not to the transport labels in the stack. You can explicitly set the default behavior by configuring the vc-only value.
- The **none** parameter disables the propagation of the IP TTL to all labels in the stack, including the VC label. This is needed for a transparent operation of UDP traceroute in VPRN inter-AS Option B such that the ingress and egress ASBR nodes are not traced.

This command does not use a no version.

The user can override the global configuration within each VPRN instance using the following commands:

- config service vprn ttl-propagate local [inherit | none | vc-only | all]
- config service vprn ttl-propagate transit [inherit | none | vc-only | all]

The default behavior for a VPRN instance is to inherit the global configuration for the same command. You can explicitly set the default behavior by configuring the inherit value.

This command does not have a no version.

The commands do not apply when the VPRN packet is forwarded over GRE transport tunnel.

If a packet is received in a VPRN context and a lookup is done in the Global Routing Table (GRT), (when leaking to GRT is enabled for example), the behavior of the TTL propagation is governed by the LSP shortcut configuration as follows:

- when the matching route is an RSVP LSP shortcut:
 - configure router mpls shortcut-transit-ttl-propagate
- when the matching route is an LDP LSP shortcut:
 - configure router ldp shortcut-transit-ttl-propagate

When the matching route is a RFC 3107 label route or a 6PE route, It is governed by the BGP label route configuration

When a packet is received on one VPRN instance and is redirected using Policy Based Routing (PBR) to be forwarded in another VPRN instance, the TTL propagation is governed by the configuration of the outgoing VPRN instance.

Packets that are forwarded in different contexts can use different TTL propagation over the same BGP tunnel, depending on the TTL configuration of each context. An example of this might be VPRN using a BGP tunnel and an IPv4 packet forwarded over a BGP label route of the same prefix as the tunnel.

3.3.8 CE to PE Routing Protocols

The 7750 SR and 7950 XRS VPRN supports the following PE to CE routing protocols:

- BGP
- Static
- RIP
- OSPF

3.3.8.1 PE to PE Tunneling Mechanisms

The 7750 SR and 7950 XRS support multiple mechanisms to provide transport tunnels for the forwarding of traffic between PE routers within the 2547bis network.

The 7750 SR and 7950 XRS VPRN implementation supports the use of:

- RSVP-TE protocol to create tunnel LSP's between PE routers
- LDP protocol to create tunnel LSP's between PE routers
- GRE tunnels between PE routers

These transport tunnel mechanisms provide the flexibility of using dynamically created LSPs where the service tunnels are automatically bound (the autobind feature) and the ability to provide certain VPN services with their own transport tunnels by explicitly binding SDPs if desired. When the autobind is used, all services traverse the same LSPs and do not allow alternate tunneling mechanisms (like GRE) or the ability to craft sets of LSP's with bandwidth reservations for specific customers as is available with explicit SDPs for the service.

3.3.8.2 Per VRF Route Limiting

The 7750 SR and 7950 XRS allow setting the maximum number of routes that can be accepted in the VRF for a VPRN service. There are options to specify a percentage threshold at which to generate an event that the VRF table is near full and an option to disable additional route learning when full or only generate an event.

3.3.9 Spoke SDPs

Distributed services use service distribution points (SDPs) to direct traffic to another router via service tunnels. SDPs are created on each participating router and then bound to a specific service. SDP can be created as either GRE or MPLS. Refer to the *7450 ESS, 7750 SR, and 7950 XRS Services Overview Guide* for information about configuring SDPs.

This feature provides the ability to cross-connect traffic entering on a spoke SDP, used for Layer 2 services (VLLs or VPLS), on to an IES or VPRN service. From a logical point of view, the spoke SDP entering on a network port is cross-connected to the Layer 3 service as if it entered by a service SAP. The main exception to this is traffic entering the Layer 3 service by a spoke SDP is handled with network QoS policies not access QoS policies.

Figure 16 depicts traffic terminating on a specific IES or VPRN service that is identified by the *sdp-id* and VC label present in the service packet.

Figure 16 SDP-ID and VC Label Service Identifiers

al_0163

3.3.9.1 T-LDP Status Signaling for Spoke-SDPs Terminating on IES/VPRN

T-LDP status signaling and PW active/standby signaling capabilities are supported on ipipe and epipe spoke SDPs.

Spoke SDP termination on an IES or VPRN provides the ability to cross-connect traffic entering on a spoke SDP, used for Layer 2 services (VLLs or VPLS), on to an IES or VPRN service. From a logical point of view the spoke SDP entering on a network port is cross-connected to the Layer 3 service as if it had entered using a service SAP. The main exception to this is traffic entering the Layer 3 service using a spoke SDP is handled with network QoS policies instead of access QoS policies.

When a SAP down or SDP binding down status message is received by the PE in which the Ipipe or Ethernet Spoke-SDP is terminated on an IES or VPRN interface, the interface is brought down and all associated routes are withdrawn in a similar way when the Spoke-SDP goes down locally. The same actions are taken when the standby T-LDP status message is received by the IES/VPRN PE.

This feature can be used to provide redundant connectivity to a VPRN or IES from a PE providing a VLL service, as shown in [Figure 17](#).

Figure 17 Active/Standby VRF Using Resilient Layer 2 Circuits

OSSG407

3.3.9.2 Spoke SDP Redundancy into IES/VPRN

This feature can be used to provide redundant connectivity to a VPRN or IES from a PE providing a VLL service, as shown in [Figure 17](#), using either Epipe or Ipipe spoke-SDPs. This feature is supported on the 7450 ESS and 7750 SR only.

In [Figure 17](#), PE1 terminates two spoke-SDPs that are bound to one SAP connected to CE1. PE1 chooses to forward traffic on one of the spoke SDPs (the active spoke-SDP), while blocking traffic on the other spoke-SDP (the standby spoke-SDP) in the transmit direction. PE2 and PE3 take any spoke-SDPs for which PW forwarding standby has been signaled by PE1 to an operationally down state.

The 7450 ESS, 7750 SR, and 7950 XRS routers are expected to fulfill both functions (VLL and VPRN/IES PE), while the 7705 SAR must be able to fulfill the VLL PE function. [Figure 18](#) illustrates the model for spoke-SDP redundancy into a VPRN or IES.

Figure 18 Spoke-SDP Redundancy Model

3.3.10 IP-VPNs

3.3.10.1 Using OSPF in IP-VPNs

Using OSPF as a CE to PE routing protocol allows OSPF that is currently running as the IGP routing protocol to migrate to an IP-VPN backbone without changing the IGP routing protocol, introducing BGP as the CE-PE or relying on static routes for the distribution of routes into the service providers IP-VPN. The following features are supported:

- Advertisement/redistribution of BGP-VPN routes as summary (type 3) LSAs flooded to CE neighbors of the VPRN OSPF instance. This occurs if the OSPF route type (in the OSPF route type BGP extended community attribute carried with the VPN route) is not external (or NSSA) and the locally configured domain-id matches the domain-id carried in the OSPF domain ID BGP extended community attribute carried with the VPN route.
- OSPF sham links. A sham link is a logical PE-to-PE unnumbered point-to-point interface that essentially rides over the PE-to-PE transport tunnel. A sham link can be associated with any area and can therefore appear as an intra-area link to CE routers attached to different PEs in the VPN.

3.3.11 IPCP Subnet Negotiation

This feature enables negotiation between Broadband Network Gateway (BNG) and customer premises equipment (CPE) so that CPE is allocated both ip-address and associated subnet.

Some CPEs use the network up-link in PPPoE mode and perform dhcp-server function for all ports on the LAN side. Instead of wasting 1 subnet for p2p uplink, CPEs use allocated subnet for LAN portion as shown in [Figure 19](#).

Figure 19 CPEs Network Up-link Mode

From a BNG perspective, the given PPPoE host is allocated a subnet (instead of /32) by RADIUS, external dhcp-server, or local-user-db. And locally, the host is associated with managed-route. This managed-route will be subset of the subscriber-interface subnet (on a 7450 ESS or 7750 SR), and also, subscriber-host ip-address will be from managed-route range. The negotiation between BNG and CPE allows CPE to be allocated both ip-address and associated subnet.

3.3.12 Cflowd for IP-VPNs

The cflowd feature allows service providers to collect IP flow data within the context of a VPRN. This data can be used to monitor types and general proportion of traffic traversing an VPRN context. This data can also be shared with the VPN customer to see the types of traffic traversing the VPN and use it for traffic engineering.

This feature should not be used for billing purposes. Existing queue counters are designed for this purpose and provide very accurate per bit accounting records.

3.3.13 Inter-AS VPRNs

Inter-AS IP-VPN services have been driven by the popularity of IP services and service provider expansion beyond the borders of a single Autonomous System (AS) or the requirement for IP VPN services to cross the AS boundaries of multiple providers. Three options for supporting inter-AS IP-VPNs are described in RFC 4364, *BGP/MPLS IP Virtual Private Networks (VPNs)*.

This feature applies to the 7450 ESS and 7750 SR only.

The first option, referred to as Option-A ([Figure 20](#)), is considered inherent in any implementation. This method uses a back-to-back connection between separate VPRN instances in each AS. As a result, each VPRN instance views the inter-AS connection as an external interface to a remote VPRN customer site. The back-to-back VRF connections between the ASBR nodes require individual sub-interfaces, one per VRF.

Figure 20 Inter-AS Option-A: VRF-to-VRF Model

OSSG255

The second option, referred to as Option-B ([Figure 21](#)), relies heavily on the AS Boundary Routers (ASBRs) as the interface between the autonomous systems. This approach enhances the scalability of the eBGP VRF-to-VRF solution by eliminating the need for per-VPRN configuration on the ASBR(s). However it requires that the ASBR(s) provide a control plane and forwarding plane connection between the autonomous systems. The ASBR(s) are connected to the PE nodes in its local autonomous system using iBGP either directly or through route reflectors. This

means the ASBR(s) receive all the VPRN information and will forward these VPRN updates, VPN-IPV4, to all its EBGP peers, ASBR(s), using itself as the next-hop. It also changes the label associated with the route. This means the ASBR(s) must maintain an associate mapping of labels received and labels issued for those routes. The peer ASBR(s) will in turn forward those updates to all local IBGP peers.

Figure 21 Inter-AS Option-B

OSSG256

This form of inter-AS VPRNs performs all necessary mapping functions and the PE routers do not need to perform any additional functions than in a non-Inter-AS VPRN.

On the 7750 SR, this form of inter-AS VPRNs does not require instances of the VPRN to be created on the ASBR, as in option-A, as a result there is less management overhead. This is also the most common form of Inter-AS VPRNs used between different service providers as all routes advertised between autonomous systems can be controlled by route policies on the ASBRs by the **config>router>bgp>transport-tunnel** CLI command. The third option, referred to as Option-C (Figure 22), allows for a higher scale of VPRNs across AS boundaries but also expands the trust model between ASNs. As a result this model is typically used within a single company that may have multiple ASNs for various reasons. This model differs from Option-B, in that in Option-B all direct knowledge of the remote AS is contained and limited to the ASBR. As a result, in option-B the ASBR performs all necessary mapping functions and the PE routers do not need to perform any additional functions than in a non-Inter-AS VPRN.

Figure 22 Option C Example

OSSG257

With Option-C, knowledge from the remote AS is distributed throughout the local AS. This distribution allows for higher scalability but also requires all PEs and ASBRs involved in the Inter-AS VPRNs to participate in the exchange of inter-AS routing information.

In Option-C, the ASBRs distribute reachability information for remote PE's system IP addresses only. This is done between the ASBRs by exchanging MP-eBGP labeled routes, using RFC 3107, *Carrying Label Information in BGP-4*. Either RSVP-TE or LDP LSP can be selected to resolve next-hop for multi-hop eBGP peering by the **config>router>bgp>transport-tunnel** CLI command.

Distribution of VPRN routing information is handled by either direct MP-BGP peering between PEs in the different ASNs or more likely by one or more route reflectors in ASN.

3.3.14 Carrier Supporting Carrier (CsC)

Carrier Supporting Carrier (CSC) is a solution for the 7750 SR and 7950 XRS that allows one service provider (the "Customer Carrier") to use the IP VPN service of another service provider (the "Super Carrier") for some or all of its backbone transport. RFC 4364 defines a Carrier Supporting Carrier solution for BGP/MPLS IP VPNs that uses MPLS on the interconnections between the two service providers in order to provide a scalable and secure solution.

CsC support in SR OS allows a 7750 SR or 7950 XRS to be deployed as any of the following devices shown in [Figure 23](#):

- PE1 (service provider PE)
- CSC-CE1, CSC-CE2 and CSC-CE3 (CE device from the point of view of the backbone service provider)
- CSC-PE1, CSC-PE2 and CSC-PE3 (PE device of the backbone service provider)
- ASBR1 and ASBR2 (ASBR of the backbone service provider)

Figure 23 Carrier Supporting Carrier Reference Diagram

3.3.14.1 Terminology

CE — customer premises equipment dedicated to one particular business/enterprise

PE — service provider router that connects to a CE to provide a business VPN service to the associated business/enterprise

CSC-CE — an ASBR/peering router that is connected to the CSC-PE of another service provider for purposes of using the associated CsC IP VPN service for backbone transport

CSC-PE — a PE router belonging to the backbone service provider that supports one or more CSC IP VPN services

3.3.14.2 CSC Connectivity Models

A PE router deployed by a customer service provider to provide Internet access, IP VPNs, and/or L2 VPNs may connect directly to a CSC-PE device, or it may back haul traffic within its local “site” to the CSC-CE that provides this direct connection. Here, “site” means a set of routers owned and managed by the customer service provider that can exchange traffic through means other than the CSC service. The function of the CSC service is to provide IP/MPLS reachability between isolated sites.

The CSC-CE is a “CE” from the perspective of the backbone service provider. There may be multiple CSC-CEs at a given customer service provider site and each one may connect to multiple CSC-PE devices for resiliency/multi-homing purposes.

The CSC-PE is owned and managed by the backbone service provider and provides CSC IP VPN service to connected CSC-CE devices. In many cases, the CSC-PE also supports other services, including regular business IP VPN services. A single CSC-PE may support multiple CSC IP VPN services. Each customer service provider is allocated its own VRF within the CSC-PE; VRFs maintain routing and forwarding separation and permit the use of overlapping IP addresses by different customer service providers.

A backbone service provider may not have the geographic span to connect, with reasonable cost, to every site of a customer service provider. In this case, multiple backbone service providers may coordinate to provide an inter-AS CSC service. Different inter-AS connectivity options are possible, depending on the trust relationships between the different backbone service providers.

The CSC Connectivity Models apply to the 7750 SR and 7950 XRS only.

3.3.14.3 CSC-PE Configuration and Operation

This section applies to CSC-PE1, CSC-PE2 and CSC-PE3 in [Carrier Supporting Carrier Reference Diagram](#).

This section applies only to the 7750 SR.

3.3.14.4 CSC Interface

From the point of view of the CSC-PE, the IP/MPLS interface between the CSC-PE and a CSC-CE has these characteristics:

1. The CSC interface is associated with one (and only one) VPRN service. Routes with the CSC interface as next-hop are installed only in the routing table of the associated VPRN.
2. The CSC interface supports EBGp or IBGP for exchanging labeled IPv4 routes (RFC 3107). The BGP session may be established between the interface addresses of the two routers or else between a loopback address of the CSC-PE VRF and a loopback address of the CSC-CE. In the latter case, the BGP next-hop is resolved by either a static or OSPFv2 route.
3. An MPLS packet received on a CSC interface is dropped if the top-most label was not advertised over a BGP (RFC 3107) session associated with one of the VPRN's CSC interfaces.
4. The CSC interface supports ingress QoS classification based on 802.1p or MPLS EXP. It is possible to configure a default FC and default profile for the CSC interface.
5. The CSC interface supports QoS (re)marking for egress traffic. Policies to remark 802.1p or MPLS EXP based on forwarding-class and profile are configurable per CSC interface.
6. By associating a port-based egress queue group instance with a CSC interface, the egress traffic can be scheduled/shaped with per-interface, per-forwarding-class granularity.
7. By associating a forwarding-plane based ingress queue group instance with a CSC interface, the ingress traffic can be policed to per-interface, per-forwarding-class granularity.
8. Ingress and egress statistics and accounting are available per CSC interface. The exact set of collected statistics depends on whether a queue-group is associated with the CSC interface, the traffic direction (ingress vs. egress), and the stats mode of the queue-group policers.

CSC interfaces are only supported on Ethernet ports and LAGs residing on FP2 or better cards and systems. An Ethernet port or LAG with a CSC interface can be configured in hybrid mode or network mode. The port or LAG supports null, dot1q or qinq encapsulation. To create a CSC interface on a port or LAG in null mode, the following commands are used:

```
config>service>vprn>nw-if>port port-id  
config>service>vprn>nw-if>lag lag-id
```

To create a CSC interface on a port or LAG in dot1q mode, the following commands are used:

```
config>service>vprn>nw-if>port port-id:qtag1  
config>service>vprn>nw-if>lag port-id:qtag1
```

To create a CSC interface on a port or LAG in qinq mode, the following commands are used:

```
config>service>vprn>nw-if>port port-id:qtag1.qtag2
config>service>vprn>nw-if>port port-id:qtag1.*
config>service>vprn>nw-if>lag port-id:qtag1.qtag2
config>service>vprn>nw-if>lag port-id:qtag1.*
```

A CSC interface supports the same capabilities (and supports the same commands) as a base router network interface except it does not support:

- IPv6
- LDP
- RSVP
- Proxy ARP (local/remote)
- Network domain configuration
- DHCP
- Ethernet CFM
- Unnumbered interfaces

3.3.14.5 QoS

Egress

Egress traffic on a CSC interface can be shaped and scheduled by associating a port-based egress queue-group instance with the CSC interface. The steps for doing this are summarized below:

- Step 1.** Create an egress queue-group-template.
- Step 2.** Define one or more queues in the egress queue-group. For each one specify scheduling parameters such as CIR, PIR, CBS and MBS and, if using H-QoS, the parent scheduler.
- Step 3.** Apply an instance of the egress queue-group template to the network egress context of the Ethernet port with the CSC interface. When doing so, and if applicable, associate an accounting policy and/or a scheduler policy with this instance.
- Step 4.** Create a network QoS policy.
- Step 5.** In the egress part of the network QoS policy define EXP remarking rules, if necessary.

Step 6. In the egress part of the network QoS policy map a forwarding-class to a queue-id using the port-redirect-group command. For example:

```
config>qos>network>egress>fc$ port-redirect-group queue 5
```

Step 7. Apply the network QoS policy created in step 4 to the CSC interface and specify the name of the egress queue-group created in step 1 and the specific instance defined in Step 3.

Ingress

Ingress traffic on a CSC interface can be policed by associating a forwarding-plane based ingress queue-group instance with the CSC interface. The steps for doing this are summarized below:

Step 1. Create an ingress queue-group-template.

Step 2. Define one or more policers in the ingress queue-group. For each one specify parameters such as CIR, PIR, CBS and MBS and, if using H-Pol, the parent arbiter.

Step 3. Apply an instance of the ingress queue-group template to the network ingress context of the forwarding plane (FP2 or better) with the CSC interface. When doing so, and if applicable, associate an accounting policy and/or a policer-control-policy with this instance.

Step 4. Create a network QoS policy.

Step 5. In the ingress part of the network QoS policy define EXP classification rules, if necessary.

Step 6. In the ingress part of the network QoS policy map a forwarding-class to a policer-id using the fp-redirect-group policer command. For example:

```
config>qos>network>ingress>fc$ fp-redirect-group policer 5
```

Step 7. Apply the network QoS policy created in step 4 to the CSC interface and specify the name of the ingress queue-group created in step 1 and the specific instance defined in step 3.

3.3.14.6 MPLS

BGP-3107 is used as the label distribution protocol on the CSC interface. When BGP in a CSC VPRN needs to distribute a label corresponding to a received VPN-IPv4 route, it takes the label from the global label space. The allocated label will not be re-used for any other FEC regardless of the routing instance (base router or VPRN). If a label L is advertised to the BGP peers of CSC VPRN A then a received packet with label L as the top most label is only valid if received on an interface of VPRN A, otherwise the packet is discarded.

To use BGP-3107 as the label distribution protocol on the CSC interface, add the **family label-ipv4** command to the family configuration at the instance, group, or neighbor level. This causes the capability to send and receive labeled-IPv4 routes {AFI=1, SAFI=4} to be negotiated with the CSC-CE peers.

3.3.14.7 CSC VPRN Service Configuration

To configure a VPRN to support CSC service, the **carrier-carrier-vpn** command must be enabled in its configuration. The command will fail if the VPRN has any existing SAP or spoke-SDP interfaces. A CSC interface can be added to a VPRN (using the **network-interface** command) only if the **carrier-carrier-vpn** command is present.

A VPRN service with the **carrier-carrier-vpn** command may be provisioned to use auto-bind, configured spoke SDPs or some combination. All SDP types are supported except for:

- GRE SDPs
- LDP over RSVP-TE tunnel SDPs

Other aspects of VPRN configuration are the same in a CSC model as in a non-CSC model.

3.3.15 Traffic Leaking to GRT

Traffic leaking to Global Route Table (GRT) for the 7750 SR and 7950 XRS allows service providers to offer VPRN and Internet services to their customers over a single VRF interface. This currently supports IPv4 and, for the 7750 SR, requires the customer VPRN interfaces to terminate on a minimum of IOM3-XP and IMM hardware. It is also supported on the 7750 SR-c12.

Packets entering a local VRF interface can have route processing results derived from the VPRN forwarding table or the GRT. The leaking and preferred lookup results are configured on a per VPRN basis. Configuration options can be general (for example, any lookup miss in the VPRN forwarding table can be resolved in the GRT), or specific (for example, specific route(s) should only be looked up in the GRT and ignored in the VPRN). In order to provide operational simplicity and improve streamlining, the CLI configuration is all contained within the context of the VPRN service.

This feature is enabled within the VPRN service context under **config>service>vprn>grt-lookup**. This is an administrative context and provides the container under which all specific commands can be entered, except for policy definition. Policy definitions remain unchanged but are referenced from this context.

The **enable-grt** command establishes the basic functionality. When it is configured, any lookup miss in the VRF table will be resolved in the GRT, if available. By itself, this only provides part of the solution. Packet forwarding within GRT must understand how to route packets back to the proper node and to the specific VPRN from which the destination exists. Destination prefixes must be leaked from the VPRN to the GRT through the use of policy. Policies are created under the **config>router>policy-options** hierarchy. By default, the number of prefixes leaked from the VPRN to the GRT is limited to five. The **export-limit** command under the **grt-lookup** hierarchy allows the service provider to override the default, or remove the limit.

When a VPRN forwarding table consists of a default route or an aggregate route, the customer may require the service provider to poke holes in those, or provide more specific route resolution in the GRT. In this case, the service provider may configure a static-route-entry and specify the GRT as the nexthop type.

The lookup result will prefer any successful lookup in the GRT that is equal to or more specific than the static route, bypassing any successful lookup in the local VPRN.

This feature and Unicast Reverse Path Forwarding (uRPF) are mutually exclusive. When a VPRN service is configured with either of these functions, the other cannot be enabled. Also, prefixes leaked from any VPRN should never conflict with prefixes leaked from any other VPRN or existing prefixes in the GRT. Prefixes should be globally unique with the service provider network and if these are propagated outside of a single providers network, they must be from the public IP space and globally unique. Network Address Translation (NAT) is not supported as part of this feature. The following type of routes will not be leaked from VPRN into the Global Routing Table (GRT):

- Aggregate routes
- Blackhole routes
- BGP VPN extranet routes

3.3.16 Traffic Leaking from VPRN to GRT for IPv6

This feature allows IPv6 destination lookups in two distinct routing tables and applies only to the 7750 SR and 7950 XRS. IPv6 packets within a Virtual Private Routed Network (VPRN) service is able to perform a lookup for IPv6 destination against the Global Route Table (GRT) as well as within the local VPRN.

Currently, VPRN to VPRN routing exchange is accomplished through the use of import and export policies based on Route Targets (RTs), the creation of extranets. This new feature allows the use of a single VPRN interface for both corporate VPRN routing and other services (for example, Internet) that are reachable outside the local routing context. This feature takes advantage of the dual lookup capabilities in two separate routing tables in parallel.

This feature enables IPv6 capability in addition to the existing IPv4 VPRN-to-GRT Route Leaking feature.

3.3.17 RIP Metric Propagation in VPRNs

When RIP is used as the PE-CE protocol for VPRNs (IP-VPNs), the RIP metric is only used by the local node running RIP with the Customer Equipment (CE). The metric is not used to or encoded into and MP-BGP path attributes exchanged between PE routers.

The RIP metric can also be used to exchanged between PE routers so if a customer network is dual homed to separate PEs the RIP metric learned from the CE router can be used to choose the best route to the destination subnet. By using the learned RIP metric to set the BGP MED attribute, remote PEs can choose the lowest MED and in turn the PE with the lowest advertised RIP metric as the preferred egress point for the VPRN.

Figure 24 RIP Metric Propagation in VPRNs

OSSG181

3.3.18 NTP Within a VPRN Service

The NTP within a VPRN service enables the service router to act as the NTP server to CPE devices on a VPRN interface. Individual VPRN interfaces may be configured to listen to and respond to client requests, or additionally may be configured to send NTP broadcast messages. Authentication keys are configurable on a per-VPRN basis.

Only a single instance of NTP remains in the node that is time sourced to as many as five NTP servers attached to the “base” or “management” network.

The NTP show command displays NTP servers and all known clients. Because NTP is UDP based only, no state is maintained. As a result, the show command output only displays when the last message from the client was received.

3.3.19 PTP Within a VPRN Service

The PTP within a VPRN service provides access to the PTP clock within the 7750 SR through one or more VPRN services. Only one VPRN or the base routing instance may have configured peers, but all may have discovered peers. If desired, a limit on the maximum number of dynamic peers allowed may be configured on a per routing instance basis.

For more detail on PTP see the Basic System Configuration Guide.

3.3.20 VPN Route Label Allocation

The method used for allocating a label value to an originated VPN-IP route (exported from a VPRN) depends on the configuration of the VPRN service and its VRF export policies. SR OS supports three 3 label modes:

- label per VRF
- label per next hop (LPN)
- label per prefix (LPP)

Label per VRF is the label allocation default. It is used when the label mode is configured as VRF (or not configured) and the VRF export policies do not apply an advertise-label per-prefix action. All routes exported from the VPRN with the per-VRF label have the same label value. When the PE receives a terminating MPLS packet with a per-VRF label, the label value selects the VRF context in which to perform a forwarding table lookup and this lookup determines the outgoing interface (or set of interfaces if ECMP applies).

Label per next hop is used when the exported route is not a local or aggregate route, the label mode is configured as next-hop, and the VRF export policies do not apply an advertise-label per-prefix override. It is also used when an inactive (backup path) BGP route is exported by effect of the export-inactive-bgp command if there is no advertise-label per-prefix override. All LPN-exported routes with the same primary next hop have the same per-next-hop label value. When the PE receives a terminating MPLS packet with a per-next-hop label, the label lookup selects the outgoing interface for forwarding, without any FIB lookup that might cause problems with overlapping prefixes. LPN does not support ECMP, BGP fast reroute, QPPB, or policy accounting features that might otherwise apply.

Label per-prefix is used when a qualifying IP route is exported by matching a VRF export policy action with advertise-label per-prefix. Any IPv4 or IPv6 route that is not a local route, aggregate route, BGP-VPN route, or GRT lookup static route qualifies. With LPP, every prefix is associated with its own unique label value that does not change while the route is present in the route table. When the PE receives a terminating MPLS packet with a per-prefix label value, the packet is forwarded as if the FIB lookup found only the matching prefix route and not any of the more specific prefix routes that would normally be selected. LPP supports ECMP, QPPB, and policy accounting as part of the egress forwarding decision. It does not support BGP fast reroute or BGP sticky ECMP.

The following points summarize the logic that determines the label allocation method for an exported route:

- If the IP route is LOCAL, AGGREGATE, or BGP-VPN always use the VRF label.
- If the IP route is accepted by a VRF export policy with the advertise-label per-prefix action, use LPP.
- If the IP (BGP) route is exported by the export-inactive-bgp command (VPRN best external), use LPN.
- If the IP route is exported by a VPRN configured for label-mode next-hop, use LPN.
- Else, use the per-VRF label.

3.3.20.1 Configuring the Service Label Mode

To change the service label mode of the VPRN for the 7750 SR, the **config>service>vprn>label-mode {vrf | next-hop}** command is used:

The default mode (if the command is not present in the VPRN configuration) is **vrf** meaning distribution of one service label for all routes of the VPRN. When a VPRN X is configured with the **label-mode next-hop** command the service label that it distributes with an IPv4 or IPv6 route that it exports depends on the type of route as summarized in [Table 33](#).

Table 33 Service Labels Distributed in Service Label per Next-Hop Mode

Route Type	Distributed Service Label
remote route with IP A (associated with a SAP) as resolved next-hop	platform-wide unique label allocated to next-hop A
remote route with IP B (associated with a spoke SDP) as resolved next-hop	platform-wide unique label allocated to next-hop B
local route	platform-wide unique label allocated to VPRN X
aggregate route	platform-wide unique label allocated to VPRN X
ECMP route	platform-wide unique label allocated to next-hop A (the lowest next-hop address in the ECMP set)
BGP route with a backup next-hop (BGP FRR)	platform-wide unique label allocated to next-hop A (the lowest next-hop address of the primary next-hops)

A change to the label-mode of a VPRN requires the VPRN to first be shutdown.

3.3.20.2 Restrictions and Usage Notes

The service label per next-hop mode has the following restrictions (applies only to the 7750 SR):

- **ECMP** — The VPRN label mode should be set to **VRF** if distribution of traffic across the multiple PE-CE next-hop interfaces of an ECMP route is desired.

- Hub and spoke VPN — The VPRN label mode should not be set to next-hop if the operator does not want the hub-connected CE to be involved in the forwarding of spoke-to-spoke traffic.
- BGP next-hop indirection — BGP next-hop indirection has no benefit in service label per next-hop mode. When the resolved next-hop interface of a BGP next-hop changes all of the affected BGP routes must be re-advertised to VPRN peers with the new service label corresponding to the new resolved next-hop.
- BGP anycast — When a PE failure results in redirection of MPLS packets to the other PE in a dual-homed pair, the service label mode is forced to VRF, for example, FIB lookup will determine the next-hop even if the label mode of the VPRN is configured as next-hop.
- U-turn routing — U-turn routing is effectively disabled by service-label per next-hop.
- Carrier Supporting Carrier — The label-mode configuration of a VPRN with CSC interfaces is ignored for BGP-3107 routes learned from connected CSC-CE devices.

3.3.21 VPRN Support for BGP Flowspec

When a VPRN BGP instance receives an IPv4 or IPv6 flow route, and that route is valid/best, the system attempts to construct an IPv4 or IPv6 filter entry from the NLRI contents and the actions encoded in the UPDATE message. If the attempt is successful, the filter entry is added to the system-created “fSpec-*n*” IPv4 embedded filter or to the “fSpec-*n*” IPv6 embedded filter, where *n* is the service-id of the VPRN. These embedded filters may be inserted into configured IPv4 and IPv6 filter policies that are applied to ingress traffic on a selected set of the VPRN’s IP interfaces. These interfaces can include SAP and spoke SDP interfaces, but not CsC network interfaces.

When flowspec rules are embedded into a user-defined filter policy, the insertion point of the rules is configurable through the **offset** parameter of the **embed-filter** command. The offset is 0 by default, meaning that the flowspec rules are evaluated after all other rules. The sum of the *ip-filter-max-size* value parameter and the highest offset in any IPv4 or IPv6 filter that embeds IPv4 or IPv6 flowspec rules from this routing instance (excluding filters that embed at offset 65535) must not exceed 65535.

3.3.22 MPLS Entropy Label and Hash Label

The router supports both the MPLS entropy label (RFC 6790) and the Flow Aware Transport label, known as the hash label (RFC 6391). These labels allow LSR nodes in a network to load-balance labeled packets in a much more granular fashion than allowed by simply hashing on the standard label stack. See the *MPLS Guide* for further information.

3.4 QoS on Ingress Bindings

Traffic is tunneled between VPRN service instances on different PEs over service tunnels bound to MPLS LSPs or GRE tunnels. The binding of the service tunnels to the underlying transport is achieved either automatically (using the **auto-bind-tunnel** command) or statically (using the **spoke-sdp** command; not that under the VPRN IP interface). QoS control can be applied to the service tunnels for traffic ingressing into a VPRN service, see [Figure 25](#).

Figure 25 Ingress QoS Control on VPRN Bindings

An ingress queue group must be configured and applied to the ingress network FP where the traffic is received for the VPRN. All traffic received on that FP for any binding in the VPRN (either automatically or statically configured) which is redirected to a policer in the FP queue group (using **fp-redirect-group** in the network QoS policy) will be controlled by that policer. As a result, the traffic from all such bindings is treated as a single entity (per forwarding class) with regard to ingress QoS control. Any **fp-redirect-group multicast-policer**, **broadcast-policer** or **unknown-policer** commands in the network QoS policy are ignored for this traffic (IP multicast traffic would use the ingress network queues or queue group related to the network interface).

Ingress classification is based on the configuration of the ingress section of the specified network QoS policy, noting that the dot1p and exp classification is based on the outer Ethernet header and MPLS label whereas the DSCP applies to the outer IP header if the tunnel encapsulation is GRE, or the DSCP in the first IP header in the payload if **ler-use-dscp** is enabled in the ingress section of the referenced network QoS policy.

Ingress bandwidth control does not take into account the outer Ethernet header, the MPLS labels/control word or GRE headers, or the FCS of the incoming frame.

The following command configures the association of the network QoS policy and the FP queue group and instance within the network ingress of a VPRN:

```
configure
  vprn
    network
      ingress
        qos <network-policy-id> fp-redirect-group <queue-group-name>
          instance <instance-id>
```

When this command is configured, it overrides the QoS applied to the related network interfaces for unicast traffic arriving on bindings in that VPRN. The IP and IPv6 criteria statements are not supported in the applied network QoS policy.

This is supported for all available transport tunnel types and is independent of the label mode (**vrf** or **next-hop**) used within the VPRN. It is also supported for Carrier-Supporting-Carrier VPRNs.

The ingress network interfaces on which the traffic is received must be on FP2- and higher-based hardware. The above command is ignored on FP1-based hardware.

3.5 Multicast in IP-VPN Applications

This section and its subsections focuses on Multicast in IP VPN functionality. Refer to the Multicast Routing Protocols Guide for information about multicast protocols.

Applications for this feature include enterprise customer implementing a VPRN solution for their WAN networking needs, customer applications including stock-ticker information, financial institutions for stock and other types of trading data and video delivery systems.

Implementation of multicast in IP VPNs entails the support and separation of the providers core multicast domain from the various customer multicast domains and the various customer multicast domains from each other.

Figure 26 Multicast in IP-VPN Applications

Figure 26 depicts an example of multicast in an IP-VPN application. The provider's domain encompasses the core routers (1 through 4) and the edge routers (5 through 10). The various IP-VPN customers each have their own multicast domain, VPN-1 (CE routers 12, 13 and 16) and VPN-2 (CE Routers 11, 14, 15, 17 and 18). Multicast in this VPRN example, the VPN-1 data generated by the customer behind router 16 will be multicast only by PE 9 to PE routers 6 and 7 for delivery to CE routers 12 and 13 respectively. Data generated for VPN-2 generated by the customer behind router 15 will be forwarded by PE 8 to PE routers 5, 7 and 10 for delivery to CE routers 11, 14 and 17 respectively.

The demarcation of these domains is in the PE's (routers 5 through 10). The PE router participates in both the customer multicast domain and the provider's multicast domain. The customer's CEs are limited to a multicast adjacency with the multicast instance on the PE specifically created to support that specific customer's IP-VPN. This way, customers are isolated from the provider's core multicast domain and other customer multicast domains while the provider's core routers only participate in the provider's multicast domain and are isolated from all customers' multicast domains.

The PE for a given customer's multicast domain becomes adjacent to the CE routers attached to that PE and to all other PE's that participate in the IP-VPN (or customer) multicast domain. This is achieved by the PE who encapsulates the customer multicast control data and multicast streams inside the provider's multicast packets. These encapsulated packets are forwarded only to the PE nodes that are attached to the same customer's edge routers as the originating stream and are part of the same customer VPRN. This prunes the distribution of the multicast control and data traffic to the PEs that participate in the customer's multicast domain. The Rosen draft refers to this as the default multicast domain for this multicast domain; the multicast domain is associated with a unique multicast group address within the provider's network.

3.5.1 Use of Data MDTs

Using the above method, all multicast data offered by a given CE is always delivered to all other CEs that are part of the same multicast. It is possible that a number of CEs do not require the delivery of a particular multicast stream because they have no downstream receivers for a specific multicast group. At low traffic volumes, the impact of this is limited. However, at high data rates this could be optimized by devising a mechanism to prune PEs from the distribution tree that although forming part of the customer multicast have no need to deliver a given multicast stream to the CE attached to them. To facilitate this optimization, the Rosen draft specifies the use of data MDTs. These data MDTs are signaled once the bandwidth for a given SG exceeds the configurable threshold.

Once a PE detects it is transmitting data for the SG in excess of this threshold, it sends an MDT join TLV (at 60 second intervals) over the default MDT to all PEs. All PEs that require the SG specified in the MDT join TLV will join the data MDT that will be used by the transmitting PE to send the given SG. PEs that do not require the SG will not join the data MDT, thus pruning the multicast distribution tree to just the PEs requiring the SG. After providing sufficient time for all PEs to join the data MDT, the transmitting PE switches the given multicast stream to the data MDT.

PEs that do not require the SG to be delivered, keep state to allow them to join the data MDT as required.

When the bandwidth requirement no longer exceeds the threshold, the PE stops announcing the MDT join TLV. At this point the PEs using the data MDT will leave this group and transmission resumes over the default MDT.

Sampling to check if an s,g has exceeded the threshold occurs every ten seconds. If the rate has exceeded the configured rate in that sample period then the data MDT is created. If during that period the transmission rate has not exceeded the configured threshold then the data MDT is not created. If the data MDT is active and the transmission rate in the last sample period has not exceeded the configured rate then the data MDT is torn down and the multicast stream resumes transmission over the default MDT.

3.5.2 Multicast Protocols Supported in the Provider Network

When MVPN auto-discovery is disabled, PIM-SM can be used for I-PMSI, and PIM-SSM or PIM-SM (Draft-Rosen Data MDT) can be used for S-PMSI; When MVPN S-PMSI auto-discovery is enabled, both PIM-SM and PIM SSM can be used for I-PMSI, and PIM-SSM can be used for S-PMSI. In the customer network, both PIM-SM and PIM-SSM are supported.

An MVPN is defined by two sets of sites: sender sites set and receiver sites set, with the following properties:

- Hosts within the sender sites set could originate multicast traffic for receivers in the receiver sites set.
- Receivers not in the receiver sites set should not be able to receive this traffic.
- Hosts within the receiver sites set could receive multicast traffic originated by any host in the sender sites set.
- Hosts within the receiver sites set should not be able to receive multicast traffic originated by any host that is not in the sender sites set.

A site could be both in the sender sites set and receiver sites set, which implies that hosts within such a site could both originate and receive multicast traffic. An extreme case is when the sender sites set is the same as the receiver sites set, in which case all sites could originate and receive multicast traffic from each other.

Sites within a given MVPN may be either within the same, or in different organizations, which implies that an MVPN can be either an intranet or an extranet. A given site may be in more than one MVPN, which implies that MVPNs may overlap. Not all sites of a given MVPN have to be connected to the same service provider, which implies that an MVPN can span multiple service providers.

Another way to look at MVPN is to say that an MVPN is defined by a set of administrative policies. Such policies determine both sender sites set and receiver site set. Such policies are established by MVPN customers, but implemented by MVPN service providers using the existing BGP/MPLS VPN mechanisms, such as route targets, with extensions, as necessary.

3.5.3 MVPN Membership Auto-discovery using BGP

BGP-based auto-discovery is performed by a multicast VPN address family. Any PE that attaches to an MVPN must issue a BGP update message containing an NLRI in this address family, along with a specific set of attributes.

The PE router uses route targets to specify MVPN route import and export. The route target may be the same as the one used for the corresponding unicast VPN, or it may be different. The PE router can specify separate import route targets for sender sites and receiver sites for a given MVPN.

The route distinguisher (RD) that is used for the corresponding unicast VPN can also be used for the MVPN.

When BGP auto-discovery is enabled, PIM peering on the I-PMSI is disabled, so no PIM hellos are sent on the I-PMSI. C-trees to P-tunnels bindings are also discovered using BGP S-PMSI AD routes, instead of PIM join TLVs. Configure PIM join TLVs when **c-mcast-signaling** is set to **pim** in the **config>service>vpn>mvpn>provider-tunnel>selective>auto-discovery-disable** context.

[Table 34](#) and [Table 35](#) describe the supported configuration combinations. If the CLI combination is not allowed, the system returns an error message. If the CLI command is marked as “ignored” in the table, the configuration is not blocked, but its value is ignored by the software.

Table 34 Supported Configuration Combinations

Auto-Discovery	Inclusive PIM SSM	Action
Yes	Yes	Allowed
MDT-SAFI	Yes	Allowed
No	Yes	Not Allowed
Yes or No	No	Allowed
MDT-SAFI	No	Ignored

Table 34 Supported Configuration Combinations (Continued)

Auto-Discovery	Inclusive PIM SSM	Action
MDT-SAFI	No (RSVP and MLDP)	Not Allowed

Table 35 Supported Configuration Combinations

Auto-Discovery	C-Mcast-Signaling	s-PMSI Auto-Discovery	Action
Yes	BGP	Ignored	Allowed
Yes	PIM	Yes	Allowed
Yes	PIM	No	Allowed
No	BGP	Ignored	Not Allowed
No	PIM	Ignored	Allowed
MDT-SAFI	Ignored (PIM behavior)	Ignored ("No" behavior)	Allowed

For example, if **auto-discovery** is disabled, the **c-mcast-signaling bgp** command will fail with an error message stating:

C-multicast signaling in BGP requires auto-discovery to be enabled

If **c-mcast-signaling** is set to **bgp** then **no auto-discovery** will fail with an error message stating

C-multicast signaling in BGP requires auto-discovery to be enabled

When **c-mcast-signaling** is set to **bgp**, S-PMSI A-D is always enabled (its configuration is ignored);

When **auto-discovery** is disabled, S-PMSI A-D is always disabled (its configuration is ignored).

When **auto-discovery** is enabled and **c-multicast-signaling** is set to **pim**, the S-PMSI A-D configuration value is used.

mdt-safi uses **pim c-mcast-signaling** and **s-pmsi-signaling** regardless of what is configured. A **c-mcast-signaling** or **s-pmsi-signaling** configuration is ignored, but both **pim** and **bgp** values are allowed.

mdt-safi is only applicable to PIM-SSM I-PMSI. PIM-SM (ASM) I-PMSI is configurable but is ignored. RSVP and MLDP I-PMSI are not allowed.

MVPN implementation based on RFC 6037, *Cisco Systems' Solution for Multicast in MPLS/BGP IP VPNs* can support membership auto-discovery using BGP MDT-SAFI. A CLI option is provided per MVPN instance to enable auto-discovery either using BGP MDT-SAFI or NG-MVPN. Only PIM-MDT is supported with BGP MDT-SAFI method.

3.5.4 PE-PE Transmission of C-Multicast Routing using BGP

MVPN c-multicast routing information is exchanged between PEs by using c-multicast routes that are carried using MCAST-VPN NLRI.

3.5.5 VRF Route Import Extended Community

VRF route import is an IP address-specific extended community, of an extended type, and is transitive across AS boundaries (RFC 4360, *BGP Extended Communities Attribute*).

To support MVPN, in addition to the import/export route target extended communities used by the unicast routing, each VRF on a PE must have an import route target extended community that controls imports of C-multicast routes into a particular VRF.

The c-multicast import RT uniquely identifies a VRF, and is constructed as follows:

- The Global Administrator field of the c-multicast import RT must be set to an IP address of the PE. This address should be common for all the VRFs on the PE (this address may be the PE's loopback address).
- The Local Administrator field of the c-multicast import RT associated with a given VRF contains a 2 octets long number that uniquely identifies that VRF within the PE that contains the VRF.

A PE that has sites of a given MVPN connected to it communicates the value of the c-multicast import RT associated with the VRF of that MVPN on the PE to all other PEs that have sites of that MVPN. To accomplish this, a PE that originates a (unicast) route to VPN-IP addresses includes in the BGP updates message that carries this route the VRF route import extended community that has the value of the c-multicast import RT of the VRF associated with the route, except if it is known a priori that none of these addresses will act as multicast sources and/or RP, in which case the (unicast) route need not carry the VRF Route Import extended community.

All c-multicast routes with the c-multicast import RT specific to the VRF must be accepted. In this release, vrf-import and vrfrtarget policies don't apply to C-multicast routes.

The decision flow path is shown below.

```
if (route-type == c-mcast-route)
    if (route_target_list includes C-multicast_Import_RT){
    else
        drop;
    else
        Run vrf_import and/or vrf-target;
```

3.5.6 Provider Tunnel Support

3.5.6.1 Point-to-Multipoint Inclusive (I-PMSI) and Selective (S-PMSI) Provider Multicast Service Interface

BGP C-multicast signaling must be enabled for an MVPN instance to use P2MP RSVP-TE or LDP as I-PMSI (equivalent to 'Default MDT', as defined in draft Rosen MVPN) and S-PMSI (equivalent to 'Data MDT', as defined in draft Rosen MVPN).

By default, all PE nodes participating in an MVPN receive data traffic over I-PMSI. Optionally, (C-*, C-*) wildcard S-PMSI can be used instead of I-PMSI. For more details, see [Wildcard \(C-*, C-*\) P2MP LSP S-PMSI](#). For efficient data traffic distribution, one or more S-PMSIs can be used, in addition to the default PMSI, to send traffic to PE nodes that have at least one active receiver connected to them. For more details, see [P2MP LSP S-PMSI](#).

Only one unique multicast flow is supported over each P2MP RSVP-TE or P2MP LDP LSP S-PMSI. Number of S-PMSI that can be initiated per MVPN instance is restricted by CLI command **maximum-p2mp-spmsi**. P2MP LSP S-PMSI cannot be used for more than one (S,G) stream (that is, multiple multicast flow) as number of S-PMSI per MVPN limit is reached. Multicast flows that cannot switch to S-PMSI remain on I-PMSI.

3.5.6.2 P2MP RSVP-TE I-PMSI and S-PMSI

Point-to-Multipoint RSVP-TE LSP as inclusive or selective provider tunnel is available with BGP NG-MVPN only. P2MP RSVP-TE LSP is dynamically setup from root node on auto discovery of leaf PE nodes that are participating in multicast VPN. Each RSVP-TE I-PMSI or S-PMSI LSP can be used with a single MVPN instance only.

RSVP-TE LSP template must be defined (see MPLS user guide) and bound to MVPN as inclusive or selective (S-PMSI is for efficient data distribution and is optional) provider tunnel to dynamically initiate P2MP LSP to the leaf PE nodes learned via NG-MVPN auto-discovery signaling. Each P2MP LSP S2L is signaled based on parameters defined in LSP template.

3.5.6.3 P2MP LDP I-PMSI and S-PMSI

Point-to-Multipoint LDP LSP as inclusive or selective provider tunnel is available with BGP NG-MVPN only. P2MP LDP LSP is dynamically setup from leaf nodes on auto discovery of leaf node PE nodes that are participating in multicast VPN. Each LDP I-PMSI or S-PMSI LSP can be used with a single MVPN instance only.

The **multicast-traffic** CLI command must be configured per LDP interface to enable P2MP LDP setup. P2MP LDP must also be configured as inclusive or selective (S-PMSI is for efficient data distribution and is optional) provider tunnel per MVPN to dynamically initiate P2MP LSP to leaf PE nodes learned via NG-MVPN auto-discovery signaling.

3.5.6.4 Wildcard (C-*, C-*) P2MP LSP S-PMSI

Wildcard S-PMSI allows usage of selective tunnel as a default tunnel for a given MVPN. By using wildcard S-PMSI, operators can avoid full mesh of LSPs between MVPN PEs, reducing related signaling, state, and BW consumption for multicast distribution (no traffic is sent to PEs without any receivers active on the default PMSI).

The SR OS allows an operator to configure wildcard S-PMSI for ng-MVPN (**config>service>vprn>mvpn>pt>inclusive>wildcard-spmsi**), using LDP and RSVP-TE in P-instance. Support includes:

- IPv4 and IPv6
- PIM ASM and SSM

- directly attached receivers

The SR OS (C-*, C-*) wildcard implementation uses wildcard S-PMSI instead of I-PMSI for a given MVPN. To switch MVPN from I-PMSI to (C-*, C-*) S-PMSI a VPRN shutdown is required. ISSU and UMH redundancy can be used to minimize the impact.

To minimize outage, the following upgrade order is recommended:

1. Route Reflector
2. Receiver PEs
3. backup UMH
4. active UMH

RSVP-TE/mLDP configuration under inclusive provider tunnel
(**config>service>vprn>mvpn>pt>inclusive**) apply to wildcard S-PMSI when enabled.

Wildcard C-S and C-G values are encoded as defined in RFC6625: using zero for Multicast Source Length and Multicast Group Length and omitting Multicast Source and Multicast Group values respectively in MCAST_VPN_NLRI. For example, a (C-*, C-*) will be advertised as: RD, 0x00, 0x00, and originating router's IP address.

Note: All SR OSs with BGP peering session to the PE with RFC6625 support enabled must be upgraded to SR OS release 13.0 before the feature is enabled. Failure to do so will result in the following processing on a router with BGP peering session to an RFC6625-enabled PE:

- BGP peer running Release 12.0 version R4 or newer will accept 0-length address and it will keep encoding length 4 with all zeros for the address
- BGP peer running Release 12 version R3 or older will not accept 0-length address and will keep restarting BGP session

The procedures implemented by SR OS are compliant to section 3 and 4 of RFC, 6625. Wildcards encoded as described above are carried in NLRI field of MP_REACH_NLRF_ATTRIBUTE. Both IPv4 and IPv6 are supported: (AFI) of 1 or 2 and a Subsequent AFI (SAFI) of MCAST-VPN.

The (C-*, C-*) S-PMSI is established as follows:

- UMH PEs advertise I-PMSI A-D routes without tunnel information present (empty PTA) - encoded as per RFC6513/6514 prior to advertising wildcard S-PMSI. I-PMSI needs to be signaled and installed on receiver PEs, because (C-*, C-*) S-PMSI is only installed when a first receiver is added. However, no LSP is established for I-PMSI).

- UMH PEs advertise S-PMSI A-D route whose NLRI contains (C-*, C-*) with tunnel information encoded as per RFC 6625.
- Receiver PEs join wildcard S-PMSI if there are any receivers present.

Note: If UMH PE does not encode I-PMSI/S-PMSI A-D routes as per the above, or advertises both I-PMSI and wildcard S-PMSI with the tunnel information present, no interoperability can be achieved.

To ensure proper operation of BSR between PEs with (C-*, C-*) S-PMSI signaling, SR OS implements two modes of operations for BSR.

By default (bsr unicast):

- BSR PDUs are sent/forwarded as unicast PDUs to neighbor PEs when I-PMSI with Pseudo-tunnel interface is installed.
- At every BSR interval timer BSR Unicast PDU are sent to all IPMSI interfaces when this is an elected BSR.
- BSMs received as multicast from C-instance interfaces are flooded as unicast in the P-instance.
- All PEs process BSR PDU's received on I-PMSI Pseudo-tunnel interface as unicast packets.
- BSR PDU's are not forwarded to PE's management control interface.
- BSR unicast PDU's use PE's System IP address as destination IP and sender PE's System address as Source IP.
- The BSR unicast functionality ensures that no special state needs to be created for BSR when (C-*, C-*) S-PMSI is enabled, which is beneficiary considering low volume of BSR traffic.

Note:

- For bsr unicast, the base IPv4 system address (IPv4) or the mapped version of the base IPv4 system address (IPv6) must be configured under the VPRN to ensure bsr unicast messages can reach the VPRN.
- For bsr spmsi, the base IPv4/IPv6 system address must be configured under the VPRN to ensure B-SR S-PMSI's are established.

BSR S-PMSI mode can be enabled to allow interoperability with other vendors. In that mode full mesh S-PMSI is required and created between all PEs in MVPN to exchange BSR PDUs between all PEs in MVPN. To operate as expected, the BSR S-PMSI mode requires a selective P-tunnel configuration. For IPv6 support (including dual-stack) of BSR S-PMSI mode, the IPv6 default system interface address must be configured as a loopback interface address under the VPRN and VPRN PIM contexts. Changing BSR signaling requires a VPRN shutdown.

Other key feature interactions and caveats for (C-*, C-*) include the following:

- Extranet is fully supported with wildcard S-PMSI trees.
- (C-S, C-G) S-PMSIs are supported when (C-*, C-*) S-PMSI is configured (including both BW and receiver PE driven thresholds).
- Geo-redundancy is supported (deploying with geo-redundancy eliminates traffic duplication when geo-redundant source has no active receivers at a cost of slightly increased outage upon a switch since wildcard S-PMSI may need to be re-establish).
- PIM in P-instance is not supported.
- SR OS implementation requires wildcard encoding as per RFC6625 and I-PMSI/ S-PMSI signaling as defined above (I-PMSI signaled with empty PTA then S-PMSI signaled with P-tunnel PTA) for interoperability. Implementations that do not adhere to RFC6625 encoding, or signal both I-PMSI and S-PMSI with P-tunnel PTA will not inter-operate with SR OS implementation).

3.5.6.5 P2MP LSP S-PMSI

NG-MVPN support P2MP RSVP-TE and P2MP LDP LSPs as selective provider multicast service interface (S-PMSI). S-PMSI is used to avoid sending traffic to PEs that participate in multicast VPN, but do not have any receivers for a given C-multicast flow. This allows more-BW efficient distribution of multicast traffic over the provider network, especially for high bandwidth multicast flows. S-PMSI is spawned dynamically based on configured triggers as described in S-PMSI trigger thresholds section.

In MVPN, the head-end PE firstly discovers all the leaf PEs via I-PMSI A-D routes. It then signals the P2MP LSP to all the leaf PEs using RSVP-TE. In the scenario of S-PMSI:

1. The head-end PE sends an S-PMSI A-D route for a specific C-flow with the Leaf Information Required bit set.
2. The PEs who are interested in the C-flow respond with Leaf A-D routes.

3. The head-end PE then signals the P2MP LSP to all the leaf PEs using RSVP-TE.

Also, because the receivers may come and go, the implementation supports dynamically adding and pruning leaf nodes to and from the P2MP LSP.

When the tunnel type in the PMSI attribute is set to RSVP-TE P2MP LSP, the tunnel identifier is <Extended Tunnel ID, Reserved, Tunnel ID, P2MP ID>, as carried in the RSVP-TE P2MP LSP SESSION Object.

The PE can also learn via an A-D route that it needs to receive traffic on a particular RSVP-TE P2MP LSP before the LSP is actually setup. In this case, the PE needs to wait until the LSP is operational before it can modify its forwarding tables as directed by the A-D route.

Because of the way that LDP normally works, mLDP P2MP LSPs are setup without solicitation from the leaf PEs towards the head-end PE. The leaf PE discovers the head-end PE via I-PMSI or S-PMSI A-D routes. The tunnel identifier carried in the PMSI attribute is used as the P2MP FEC element. The tunnel identifier consists of the head-end PE's address, along with a Generic LSP identifier value. The Generic LSP identifier value is automatically generated by the head-end PE.

3.5.6.6 Dynamic Multicast Signaling over P2MP LDP in VRF

This feature provides a multicast signaling solution for IP-VPNs, allowing the connection of IP multicast sources and receivers in C-instances, which are running PIM multicast protocol using Rosen MVPN with BGP SAFI and P2MP mLDP in P-instance. The solution dynamically maps each PIM multicast flow to a P2MP LDP LSP on the source and receiver PEs.

The feature uses procedures defined in RFC 7246: *Multipoint Label Distribution Protocol In-Band Signaling in Virtual Routing and Forwarding (VRF) Table Context*. On the receiver PE, PIM signaling is dynamically mapped to the P2MP LDP tree setup. On the source PE, signaling is handed back from the P2MP mLDP to the PIM. Due to dynamic mapping of multicast IP flow to P2MP LSP, provisioning and maintenance overhead is eliminated as multicast distribution services are added and removed from the VRF. Per (C-S, C-G) IP multicast state is also removed from the network, since P2MP LSPs are used to transport multicast flows.

Figure 27 illustrates dynamic mLDP signaling for IP multicast in VPRN.

Figure 27 Dynamic mLDP Signaling for IP Multicast in VPRN

As illustrated in [Figure 27](#), P2MP LDP LSP signaling is initiated from the receiver PE that receives PIM JOIN from a downstream router (Router A). To enable dynamic multicast signaling, the **p2mp-ldp-tree-join** must be configured on PIM customer-facing interfaces for the given VPRN of Router A. This enables handover of multicast tree signaling from the PIM to the P2MP LDP LSP. Being a leaf node of the P2MP LDP LSP, Router A selects the upstream-hop as the root node of P2MP LDP FEC, based on a routing table lookup. If an ECMP path is available for a given route, then the number of trees are equally balanced towards multiple root nodes. The PIM joins are carried in the Transit Source PE (Router B), and multicast tree signaling is handed back to the PIM and propagated upstream as native-IP PIM JOIN toward C-instance multicast source.

The feature is supported with IPv4 and IPv6 PIM SSM and IPv4 mLDP. Directly connected IGMP/MLD receivers are also supported, with PIM enabled on outgoing interfaces and SSM mapping configured, if required.

The following are feature caveats:

- Dynamic mLDP signaling in a VPRN instance is mutually exclusive with Rosen or NG-MVPN.
- A single instance of P2MP LDP LSP is supported between the receiver PE and Source PE per multicast flow; there is no stitching of dynamic trees.
- Extranet functionality is not supported.
- The router LSA link ID or the advertising router ID must be a routable IPv4 address (including IPv6 into IPv4 mLDP use cases).
- IPv6 PIM with dynamic IPv4 mLDP signaling is not supported with e-BGP or i-BGP with IPv6 next-hop.

- Inter-AS and IGP inter-area scenarios where the originating router is altered at the ASBR and ABR respectively, (hence PIM has no way to create the LDP LSP towards the source), are not supported.
- When dynamic mLDP signaling is deployed, a change in Route Distinguisher (RD) on the Source PE is not acted upon for any (C-S, C-G)s until the receiver PEs learn about the new RD (via BGP) and send explicit delete and create with the new RD.
- Procedures of Section 2 of RFC 7246 for a case where UMH and the upstream PE do not have the same IP address are not supported.
- The feature requires chassis mode C.

3.5.6.7 MVPN Sender-only/Receiver-only

In multicast MVPN, by default, if multiple PE nodes form a peering with a common MVPN instance then each PE node originates a multicast tree locally towards the remaining PE nodes that are member of this MVPN instance. This behavior creates a mesh of I-PMSI across all PE nodes in the MVPN. It is often a case, that a given VPN has many sites that will host multicast receivers, but only few sites that either host both receivers and sources or sources only.

MVPN Sender-only/Receiver-only allows optimization of control and data plane resources by preventing unnecessary I-PMSI mesh when a given PE hosts multicast sources only or multicast receivers only for a given MVPN.

For PE nodes that host only multicast sources for a given VPN, operators can now block those PEs, through configuration, from joining I-PMSIs from other PEs in this MVPN. For PE nodes that host only multicast receivers for a given VPN, operators can now block those PEs, through configuration, to set-up a local I-PMSI to other PEs in this MVPN.

MVPN Sender-only/Receiver-only is supported with ng-MVPN using IPv4 RSVP-TE or IPv4 LDP provider tunnels for both IPv4 and IPv6 customer multicast. [Figure 28](#) depicts 4-site MVPN with sender-only, receiver-only and sender-receiver (default) sites.

Figure 28 MVPN Sender-only/Receiver-only Example

Extra attention needs to be paid to BSR/RP placement when Sender-only/Receiver-only is enabled. Source DR sends unicast encapsulated traffic towards RP, therefore, RP shall be at sender-receiver or sender-only site, so that *G traffic can be sent over the tunnel. BSR shall be deployed at the sender-receiver site. BSR can be at sender-only site if the RPs are at the same site. BSR needs to receive packets from other candidate-BSR and candidate-RPs and also needs to send BSM packets to everyone.

3.5.6.8 S-PMSI Trigger Thresholds

The mLDP and RSVP-TE S-PMSIs support two types of data thresholds: bandwidth-driven and receiver-PE-driven. The threshold evaluation and bandwidth driven threshold functionality are described in [Use of Data MDTs](#).

In addition to the bandwidth threshold functionality, an operator can enable receiver-PE-driven threshold behavior. Receiver PE thresholds ensure that S-PMSI is only created when BW savings in P-instance justify extra signaling required to establish a new S-PMSI. For example, the number of receiver PEs interested in a given C-multicast flow is meaningfully smaller than the number of receiver PEs for default PMSI (I-PMSI or wildcard S-PSMI). To ensure that S-PMSI is not constantly created/deleted, two thresholds need to be specified: receiver PE add threshold and receiver PE delete threshold (expected to be significantly higher).

When a (C-S, C-G) crosses a data threshold to create S-PMSI, instead of regular S-PMSI signaling, sender PE originates S-PMSI explicit tracking procedures to detect how many receiver PEs are interested in a given (C-S, C-G). When receiver PEs receive an explicit tracking request, each receiver PE responds, indicating whether there are multicast receivers present for that (C-S, C-G) on the given PE (PE is interested in a given (C-S, C-G)). If the geo-redundancy feature is enabled, receiver PEs do not respond to explicit tracking requests for suppressed sources and therefore only Receiver PEs with an active join are counted against the configured thresholds on Source PEs.

Upon regular sampling and check interval, if the previous check interval had a non-zero receiver PE count (one interval delay to not trigger S-PMSI prematurely) and current count of receiver PEs interested in the given (C-S, C-G) is non-zero and is less than the configured receiver PE add threshold, Source PE will set-up S-PMSI for this (C-S, C-G) following standard ng-MVPN procedures augmented with explicit tracking for S-PMSI being established.

Data threshold timer should be set to ensure enough time is given for explicit tracking to complete (for example, setting the timer to value that is too low may create S-PMSI prematurely).

Upon regular data-delay-interval expiry processing, when BW threshold validity is being checked, a current receiver PE count is also checked (for example, explicit tracking continues on the established S-PMSI). If BW threshold no longer applies or the receiver PEs exceed receiver PE delete threshold, the S-PMSI is torn down and (C-S, C-G) joins back the default PMSI.

Changing of thresholds (including enabling disabling the thresholds) is allowed in service. The configuration change is evaluated at the next periodic threshold evaluation.

The explicit tracking procedures follow RFC6513/6514 with clarification and wildcard S-PMSI explicit tracking extensions as described in IETF Draft: *draft-dolganow-l3vpn-expl-track-00*.

3.5.6.9 Migration from Existing Rosen Implementation

The existing Rosen implementation is compatible to provide an easy migration path.

The following migration procedure are supported:

- Upgrade all the PE nodes that need to support MVPN to the newer release.
- The old configuration will be converted automatically to the new style.
- Node by node, MCAST-VPN address-family for BGP is enabled. Enable auto-discovery using BGP.
- Change PE-to-PE signaling to BGP.

3.5.6.10 Policy-based S-PMSI

SR OS creates a single Selective P-Multicast Service Interface (S-PMSI) per multicast stream: (S,G) or (*,G). To manage bandwidth allocation in the network better, multiple multicast streams are often bundled starting from the same root node into a single, multi-stream S-PMSI. Network bandwidth is usually managed per package or group of packages, rather than per channel.

Multi-stream S-PMSI supports a single S-PMSI for one or more IPv4 (C-S, C-G) or IPv6 (C-S, C-G) streams. Multiple multicast streams starting from the same VPRN going to the same set of leafs can use a single S-PMSI. Multi-stream S-PMSIs can:

- carry exclusively IPv4 or exclusively IPv6, or a mix of channels
- co-exist with a single group S-PMSI

To create a multi-stream S-PMSI, an S-PMSI policy needs to be configured in the VPN context on the source node. This policy maps multiple (C-S, C-G) streams to a single S-PMSI. Because this configuration is done per MVPN, multiple VPNs can have identical policies, each configured for its own VPN context.

When mapping a multicast stream to a multi-stream S-PMSI policy, the data will traverse the S-PMSI without first using the I-PMSI. (Before this feature, when a multicast stream was sourced, the data used the I-PMSI first until a configured threshold was met. After this, if the multicast data exceeded the threshold, it would signal the S-PMSI tunnel and switch from I-PMSI to S-PMSI.)

For multi-stream S-PMSI, if the policy is configured and the multicast data matches the policy rules, the multi-stream S-PMSI is used from the start without using the default I-PMSI.

Multiple multi-stream S-PMSI policies could be assigned to a specific S-PMSI configuration. In this case, the policy acts as a link list. The first (lowest index) that matches the multi-stream S-PMSI policy is used for that specific stream.

The rules for matching a multi-stream S-PMSI on the source node are listed here.

Rules for S-PMSI to (C-S, C-G) mapping on Source-PE, in sequence:

1. The multi-stream S-PMSI policy is evaluated, starting from the lowest numerical policy index. This allows the feature to be enabled in the service when per-(C-S, C-G) stream configuration is present. Only entries that are not shut down are evaluated. First, the multi-stream S-PMSI (the lowest policy index) that the (C-S, C-G) stream maps to is selected.
2. If (C-S, C-G) does not map to any of multi-stream S-PMSIs, per-(C-S, C-G) S-PMSIs are used for transmission if a (C-S, C-G) maps to an existing S-PMSI (based on data-thresholds).
3. If S-PMSI cannot be used, the default PMSI is used.

Rule for multi-stream S-PMSI P-tunnel failure handling:

- If an S-PMSI P-tunnel is not available, then a default PMSI tunnel is used. When an S-PMSI tunnel fails, all (C-S, C-G) streams using this multi-stream S-PMSI move to the default PMSI. The groups move back to S-PMSI when the S-PMSI tunnel is restored.

3.5.6.10.1 Supported MPLS Tunnels

Multi-stream S-PMSI is configured in the context of an **auto-discovery** default (that is, NG-MVPN). It supports all existing per-mLDP/RSVP-TE P2MP S-PMSI tunnel functionality for multi-stream S-PMSI LSP templates (RSVP-TE P-instance).

Notes:

- Per-multicast group statistics are not available for multi-stream S-PMSIs on S-PMSI level.
- GRE tunnels are not supported for multi-stream S-PMSI.

3.5.6.10.2 Supported Multicast Features

S-PMSI is supported with PIM ASM and PIM SSM in C-instances.

Notes:

- The multi-stream S-PMSI model uses BSR RP co-located with the source PE or an RP between the source PE and multicast source (upstream of receivers). Both **bsr unicast** and **bsr spmsi** can be deployed (as applicable).
- The model also supports other RP types.

3.5.6.10.3 In-service Changes to Multi-stream S-PMSI

The operator can change the mapping in service; that is, the operator can move active streams (C-S, C-G) from one S-PMSI to another using the configuration, or from the default PMSI to the S-PMSI, without having to stop data transmission or disable a PMSI.

The change is performed by moving a (C-S, C-G) stream from a per-group S-PMSI to a multi-stream S-PMSI and vice versa, and to moving a (C-S, C-G) stream from one multi-stream S-PMSI to another multi-stream S-PMSI.

Notes:

- During re-mapping, a changed (C-S, C-G) stream will first be moved to the default PMSI before it is moved to a new S-PMSI, regardless of the type of move. Unchanged (C-S, C-G) streams must remain on an existing PMSIs.
- Any change to a multi-stream S-PMSI policy or to a preferred multi-stream S-PMSI policy (for example, an index change equivalent to less than or equal to the current policy) might cause a traffic outage. Therefore, it is recommended that any change to a multi-stream S-PMSI policy be done in a maintenance window.

3.5.6.10.4 Configuration example

In this example, two policies are created on the source node: multi-stream S-PMSI 1 and multi-stream-S-PMSI 10.

A multicast stream with group 224.0.0.x and source 138.120.1.0/24 will map to the first multi-stream policy. The group in the range of 224.0.1.0/24 and source 138.120.2.0/24 will map to policy 10.

```

```

3.5.7 MVPN (NG-MVPN) Upstream Multicast Hop Fast Failover

MVPN upstream PE or P node fast failover detection method is supported with RSVP P2MP I-PMSI only. A receiver PE achieves fast upstream failover based on the capability to subscribe multicast flow from multiple UMH nodes and the capability to monitor the health of the upstream PE and intermediate P nodes using an unidirectional multi-point BFD session running over the provider tunnel.

A receiver PE subscribes multicast flow from multiple upstream PE nodes to have active redundant multicast flow available during failure of primary flow. Active redundant multicast flow from standby upstream PE allows instant switchover of multicast flow during failure of primary multicast flow.

Faster detection of multicast flow failure is achieved by keeping track of unidirectional multi-point BFD sessions enabled on the provider tunnel. Multi-point BFD sessions must be configured with 10 ms transmit interval on sender (root) PE to achieve sub-50ms fast failover on receiver (leaf) PE.

UMH **tunnel-status** selection option must be enabled on the receiver PE for upstream fast failover. Primary and standby upstream PE pairs must be configured on the receiver PE to enable active redundant multicast flow to be received from the standby upstream PE.

3.5.8 Multicast VPN Extranet

Multicast VPN extranet distribution allows multicast traffic to flow across different routing instances. A routing instance that received a PIM/IGMP JOIN but cannot reach source of multicast source directly within its own instance is selected as receiver routing instance (receiver C-instance). A routing instance that has source of multicast stream and accepts PIM/IGMP JOIN from other routing instances is selected as source routing instance (source C-instance). A routing instance that does not have either source or receivers but is used in the core is selected as a transit instance (transit P-instance). The following subsections detail supported functionality.

3.5.8.1 Multicast Extranet for Rosen MVPN for PIM SSM

Multicast extranet is supported for Rosen MVPN with MDT SAFI. Extranet is supported for IPv4 multicast stream for default and data MDTs (PIM and IGMP).

The following extranet cases are supported:

- local replication into a receiver VRF from a source VRF on a source PE
- Transit replication from a source VRF onto a tunnel of a transit core VRF on a source PE. A source VRF can replicate its streams into multiple core VRFs as long as any given stream from source VRF uses a single core VRF (the first tunnel in any core VRF on which a join for the stream arrives). Streams with overlapping group addresses (same group address, different source address) are supported in the same core VRF.
- remote replication from source/transit VRF into one or more receiver VRFs on receiver PEs
- multiple replications from multiple source/transit VRFs into a receiver VRF on receiver PEs

Rosen MVPN extranet requires routing information exchange between the source VRF and the receiver VRF based on route export/import policies:

- Routing information for multicast sources must be exported using an RT export policy from the source VRF instance.

- Routing information must be imported into the receiver/transit VRF instance using an RT import policy.

Caveats:

- Multicast extranet functionality requires all network ports to be on FP2 or newer line cards.
- The source VRF instance and receiver VRF instance of extranet must exist on a common PE node (to allow local extranet mapping).
- SSM translation is required for IGMP (C-*, C-G).
- An I-PMSI route cannot be imported into multiple VPRNs, and NG-MVPN routes do not need to be imported into multiple VPRNs.

In [Figure 29](#), VPRN-1 is the source VPRN instance and VPRN-2 and VPRN-3 are receiver VPRN instances. The PIM/IGMP JOIN received on VPRN-2 or VPRN-3 is for (S1, G1) multicast flow. Source S1 belongs to VPRN-1. Due to the route export policy in VPRN-1 and the import policy in VPRN-2 and VPRN-3, the receiver host in VPRN-2 or VPRN-3 can subscribe to the stream (S1, G1).

Figure 29 Multicast VPN Traffic Flow

al_0164

3.5.8.2 Multicast Extranet for NG-MVPN for PIM SSM

Multicast extranet is supported for ng-MVPN with IPv4 RSVP-TE and mLDP I-PMSIs and S-PMSIs including (C-*, C-*) S-PMSI support where applicable. Extranet is supported for IPv4 C-multicast traffic (PIM/IGMP joins).

The following extranet cases are supported:

- local replication into a receiver C-instance MVPN(s) on a source PE from a source P-instance MVPN
- remote replication from P-instance MVPN into one or more receiver C-instance MVPNs on receiver PEs
- multiple replications from multiple source/transit P-instance MVPNs into a receiver C-instance MVPN on receiver PEs
- Transit replication on Source PE is not supported.

Multicast extranet for ng-MVPN, similarly to extranet for Rosen MVPN, requires routing information exchange between source ng-MVPN and receiver ng-MVPN based on route export and import policies. Routing information for multicast sources is exported using an RT export policy from a source ng-MVPN instance and imported into a receiver ng-MVPN instance using an RT import policy. S-PMSI/I-PMSI establishment and C-multicast route exchange occurs in a source ng-MVPN P-instance only (import and export policies are not used for MVPN route exchange). Sender-only functionality must not be enabled for the source/transit ng-MVPN on the receiver PE. It is recommended to enable receiver-only functionality on a receiver ng-MVPN instance.

Caveats:

- Multicast extranet functionality requires all network ports to be on FP2 or newer line cards.
- Source P-instance MVPN and receiver C-instance MVPN must reside on the receiver PE (to allow local extranet mapping).
- SSM translation is required for IGMP (C-*, C-G).

3.5.8.3 Multicast Extranet with Per-group Mapping for PIM SSM

In some deployments, such as IPTV or wholesale multicast services, it may be desirable to create one or more transit MVPNs to optimize delivery of multicast streams in the provider core. [Figure 30](#) represents a sample deployment model.

Figure 30 Source PE Transit Replication and Receiver PE Per-group SSM Extranet Mapping

The architecture displayed in [Figure 30](#) requires a source routing instance MVPN to place its multicast streams into one or more transit core routing instance MVPNs (each stream mapping to a single transit core instance only). It also requires receivers within each receiver routing instance MVPN to know which transit core routing instance MVPN they need to join for each of the multicast streams. To achieve this functionality, transit replication from a source routing instance MVPN onto a tunnel of a transit core routing instance MVPN on a source PE (see earlier sub-sections for MVPN topologies supporting transit replication on source PEs) and per-group mapping of multicast groups from receiver routing instance MVPNs to transit core routing instance MVPNs (as defined below) are required.

For per-group mapping on a receiver PE, the operator must configure a receiver routing instance MVPN per-group mapping to one or more source/transit core routing instance MVPNs. The mapping allows propagation of PIM joins received in the receiver routing instance MVPN into the core routing MVPN instance defined by the map. All multicast streams sourced from a single multicast source address are always mapped to a single core routing instance MVPN for a given receiver routing instance MVPN (multiple receiver MVPNs can use different core MVPNs for groups from the same multicast source address). If per-group map in receiver MVPN maps multicast streams sourced from the same multicast source address to multiple core routing instance MVPNs, then the first PIM join processed for those streams selects the core routing instance MVPN to be used for all multicast streams from a given source address for this receiver MVPN. PIM joins for streams sourced from the

source address not carried by the selected core VRF MVPN instance will remain unresolved. When a PIM join/prune is received in a receiver routing instance MVPN with per-group mapping configured, if no mapping is defined for the PIM join's group address, non-extranet processing applies when resolving how to forward the PIM join/prune.

The main attributes for per-group SSM extranet mapping on receiver PE include support for:

- Rosen MVPN with MDT SAFI. * RFC6513/6514 NG-MVPN with IPv4 RSVP-TE/mLDP in P-instance (a P-instance tunnel must be in the same VPRN service as multicast source)
- IPv4 PIM SSM
- IGMP (C-S, C-G), and for IGMP (C-*, C-G) using SSM translation
- a receiver routing instance MVPN to map groups to multiple core routing instance MVPNs
- in-service changes of the map to a different transit/source core routing instance (this is service affecting)

Caveats:

- When a receiver routing instance MVPN is on the same PE as a source routing instance MVPN, basic extranet functionality and not per-group (C-S, C-G) mapping must be configured (extranet from receiver routing instance to core routing instance to source routing instance on a single PE is not supported).
- Local receivers in the core routing instance MVPN are not supported when per-group mapping is deployed.
- Receiver routing instance MVPN that has per-group mapping enabled cannot have tunnels in its OIF lists.
- Per-group mapping is blocked if GRT/VRF extranet is configured.
- Per-group mapping requires network interfaces to be on FP2-based or newer line cards.

3.5.8.4 Multicast GRT-source/VRF-receiver Extranet with Per Group Mapping for PIM SSM

Multicast GRT-source/VRF-receiver (GRT/VRF) extranet with per-group mapping allows multicast traffic to flow from GRT into VRF MVPN instances. A VRF routing instance that received a PIM/IGMP join but cannot reach the source multicast stream directly within its own instance is selected as receiver routing instance. A GRT instance that has sources of multicast streams and accepts PIM joins from other VRF MVPN instances is selected as source routing instance.

Figure 31 depicts a sample deployment.

Figure 31 GRT/VRF Extranet

Routing information is exchanged between GRT and VRF receiver MVPN instances of extranet by enabling grt-extranet under a receiver MVPN PIM configuration for all or a subset of multicast groups. When enabled, multicast receivers in a receiver routing instance(s) can subscribe to streams from any multicast source node reachable in GRT source instance.

The main feature attributes are:

- GRT/VRF extranet can be performed on all streams or on a configured group of prefixes within a receiver routing instance.
- GRT instance requires Classic Rosen multicast.
- IPv4 PIM joins are supported in receiver VRF instances.
- Local receivers using IGMP: (C-S, C-G) and (C-*, C-G) using SSM translation are supported.
- The feature is blocked if a per-group mapping extranet is configured in receiver VRF.
- The feature requires FP2-based line cards or newer for all network ports.

3.5.8.5 Multicast Extranet with Per-group Mapping for PIM ASM

Multicast extranet with per-group mapping for PIM ASM allows multicast traffic to flow from a source routing instance to a receiver routing instance when a PIM ASM join is received in the receiver routing instance.

Figure 32 depicts PIM ASM extranet map support.

Figure 32 Multicast Extranet with per group PIM ASM mapping

al_0692

PIM ASM extranet is achieved by local mapping from the receiver to source routing instances on a receiver PE. The mapping allows propagation of anycast RP PIM register messages between the source and receiver routing instances over an auto-created internal extranet interface. This PIM register propagation allows the receiver routing instance to resolve PIM ASM joins to multicast source(s) and to propagate PIM SSM joins over an auto-created extranet interface to the source routing instance. PIM SSM joins are then propagated towards the multicast source within the source routing instance.

The following MVPN topologies are supported:

- Rosen MVPN with MDT SAFI: a local replication on a source PE and multiple-source/multiple-receiver replication on a receiver PE
- RFC 6513/6514 NG-MVPN (including RFC 6625 (C-*, C-*) wildcard S-PMSI): a local replication on a source PE and a multiple source/multiple receiver replication on a receiver PE

- Extranet for GRT-source/VRF receiver with a local replication on a source PE and a multiple-receiver replication on a receiver PE
- Locally attached receivers are supported without SSM mapping.

To achieve the extranet replication, the operator must configure:

- local PIM ASM mapping on a receiver PE from a receiver routing instance to a source routing instance (**config>service>vprn>mvpn>rpf-select>core-mvpn** or **config>service>vprn>pim>grt-extranet** as applicable)
- an anycast RP mesh between source and receiver PEs in the source routing instance

Caveats:

- This feature is supported for IPv4 multicast.
- The multicast source must reside in the source routing instance the ASM map points to on a receiver PE (the deployment of transit replication extranet from source instance to core instance on Source PE with ASM map extranet from receiver instance to core instance on a receiver PE is not supported).
- A given multicast group can be mapped in a receiver routing instance using either PIM SSM mapping or PIM ASM mapping but not both.
- A given multicast group cannot map to multiple source routing instances.
- This feature requires network chassis mode D.

3.5.9 Non-Congruent Unicast and Multicast Topologies for Multicast VPN

Operators that prefer to keep unicast and multicast traffic on separate links in a network have the option to maintain two separate instances of the route table (unicast and multicast) per VPRN.

Multicast BGP can be used to advertise separate multicast routes using Multicast NLRI (SAFI 2) on PE-CE link within VPRN instance. Multicast routes maintained per VPRN instance can be propagated between PE-PE using BGP Multicast-VPN NLRI (SAFI 129).

Figure 33 **Incongruent Multicast and Unicast Topology for Non-Overlapping Traffic Links**

SR OS supports option to perform RPF check per VPRN instance using multicast route table, unicast route table or both.

Non-congruent unicast and multicast topology is supported with NG-MVPN. Draft Rosen is not supported.

3.5.10 Automatic Discovery of Group-to-RP Mappings (Auto-RP)

Auto-RP is a proprietary group discovery and mapping mechanism for IPv4 PIM that is described in *cisco-ipmulticast/pim-autorp-spec*, *Auto-RP: Automatic discovery of Group-to-RP mappings for IP multicast*. The functionality is similar to the IETF standard bootstrap router (BSR) mechanism that is described in RFC 5059, *Bootstrap Router (BSR) Mechanism for Protocol Independent Multicast (PIM)*, to dynamically learn about the availability of Rendezvous Points (RPs) in a network. When a router is configured as an RP-mapping agent with the **pim>rp>auto-rp-discovery** command, it listens to the CISCO-RP-ANNOUNCE (224.0.1.39) group and caches the announced mappings. The RP-mapping agent then periodically sends out RP-mapping packets to the CISCO-RP-DISCOVERY (224.0.1.40) group. PIM dense-mode (PIM-DM) as described in RFC 3973, *Protocol Independent Multicast - Dense Mode (PIM-DM): Protocol Specification (Revised)*, is used for the auto-RP groups to support multihoming and redundancy. The RP-mapping agent supports announcing, mapping, and discovery functions; candidate RP functionality is not supported.

Auto-RP is supported for IPv4 in multicast VPNs and in the global routing instance. Either BSR or auto-RP for IPv4 can be configured; the two mechanisms cannot be enabled together. BSR for IPv6 and auto-RP for IPv4 can be enabled together. In a multicast VPN, auto-RP cannot be enabled together with sender-only or receiver-only multicast distribution trees (MDTs), or wildcard S-PMSI configurations that could block flooding.

3.5.11 IPv6 MVPN Support

IPv6 multicast support in SR OS allows operators to offer customers IPv6 multicast MVPN service. An operator utilizes IPv4 mLDP or RSVP-TE core to carry IPv6 c-multicast traffic inside IPv4 mLDP or RSVP-TE provider tunnels (p-tunnels). The IPv6 customer multicast on a given MVPN can be blocked, enabled on its own or in addition to IPv4 multicast per PE or per interface. When both IPv4 and IPv6 multicast is enabled for a given MVPN, a single tree is used to carry both IPv6 and IPv4 traffic. [Figure 34](#) shows an example of an operator with IPv4 MPLS backbone providing IPv6 MVPN service to Customer 1 and Customer 2.

Figure 34 IPv6 MVPN Example

al_0168

SR OS IPv6 MVPN multicast implementation provides the following functionality:

- IPv6 C-PIM-SM (ASM and SSM)
- MLDv1 and MLDv2
- SSM mapping for MLDv1
- I-PMSI and S-PMSI using IPv4 P2MP mLDP p-tunnels
- I-PMSI and S-PMSI using IPv4 P2MP RSVP p-tunnels
- BGP auto-discovery
- PE-PE transmission of C-multicast routing using BGP mvpn-ipv6 address family
- IPv6 BSR/RP functions on functional par with IPv4 (auto-RP using IPv4 only)
- Embedded RP

- Inter-AS Option A

The following known caveats exist for IPv6 MVPN support:

1. IPv6 MVPN requires chassis mode D
2. Non-congruent topologies are not supported
3. IPv6 is not supported in MCAC
4. If IPv4 and IPv6 multicast is enabled, per-MVPN multicast limits apply to entire IPv4 and IPv6 multicast traffic as it is carried in a single PMSI. For example IPv4 AND IPv6 S-PMSIs are counted against a single S-PMSI maximum per MVPN.
5. IPv6 Auto-RP is not supported

3.5.12 Multicast Core Diversity for Rosen MDT_SAFI MVPNs

Figure 35 depicts Rosen MVPN core diversity deployment:

Figure 35 Multicast Core Diversity

al_0485

Core diversity allows operator to optionally deploy multicast MVPN in either default IGP instance or one of two non-default IGP instances to provide, for example, topology isolation or different level of services. The following describes main feature attributes:

1. Rosen MVPN IPv4 multicast with MDT SAFI is supported with default and data MDTs.
2. Rosen MVPN can use a non-default OSPF or ISIS instance (using their loopback addresses instead of a system address).
3. Up to 3 distinct core instances are supported: system + 2 non-default OSPF instances – referred as “red” and “blue” below.
4. The BGP Connector also uses non-default OSPF loopback as NH, allowing Inter-AS Option B/C functionality to work with Core diversity as well.
5. The feature is supported with CSC-VRPN.

On source PEs (PE1: UMH, PE2: UMH in [Figure 35](#)), an MVPN is assigned to a non-default IGP core instance as follows:

1. MVPN is statically pointed to use one of the non-default “red”/“blue” IGP instances loopback addresses as source address instead of system loopback IP.
2. MVPN export policy is used to change unicast route next-hop VPN address (no longer required as of SR OS Release 12.0.R4 - BGP Connector support for non-default instances).

The above configuration ensures that MDT SAFI and IPVPN routes for the non-default core instance use non-default IGP loopback instead of system IP. This ensures PIM advertisement/joins run in the proper core instance and GRE tunnels for multicast can be set-up using and terminated on non-system IP.

If BGP export policy is used to change unicast route next-hop VPN address, unicast traffic must be forwarded in non-default “red” or “blue” core instance LDP or RSVP (terminating on non-system IP) must be used. GRE unicast traffic termination on non-system IP is not supported, and any GRE traffic arriving at the PE in “blue”, “red” instances destined to non-default IGP loopback IP will be forwarded to CPM (ACL or CPM filters can be used to prevent the traffic from reaching the CPM). This limitation does not apply if BGP connector attribute is used to resolve the multicast route.

No configuration is required on non-source PEs.

Feature caveats:

- VRPN instance must be shutdown to change the mdt-safi source-address. The CLI rollback that includes change of the auto-discovery is thus service impacting.
- To reset mdt-safi source-address to system IP, operator must first execute no auto-discovery (or auto-discovery default) then auto-discovery mdt-safi
- Configuring system IP as a source-address will consume one of the 2 IP addresses allowed, thus it should not be done.

- Operators must configure proper IGP instance loopback IP addresses within Rosen MVPN context and must configure proper BGP policies (prior to release 12.0.R4) for the feature to operate as expected. There is no verification that the address entered for MVPN provider tunnel source-address is such an address or is not a system IP address.
- The feature requires all ports to be present on IOM3-XP or newer (Chassis Mode D). The restriction is not enforced. Failing to observe this restriction will prevent the feature to operate properly in the network.

3.5.13 NG-MVPN Multicast Source Geo-Redundancy

Multicast source geo-redundancy is targeted primarily for MVPN deployments for multicast delivery services like IPTV. The solution allows operators to configure a list of geographically dispersed redundant multicast sources (with different source IPs) and then, using configured BGP policies, ensure that each Receiver PE (a PE with receivers in its C-instance) selects only a single, most-preferred multicast source for a given group from the list. Although the data may still be replicated in P-instance (each multicast source sends (C-S, C-G) traffic onto its I-IPMSI tree or S-PMSI tree), each Receiver PE only forwards data to its receivers from the preferred multicast source. This allows operators to support multicast source geo-redundancy without the replication of traffic for each (C-S, C-G) in the C-instance while allowing fast recovery of service when an active multicast source fails.

[Figure 36](#) shows an operational example of multicast source geo-redundancy:

Figure 36 Preferred Source Selection for Multicast Source Geo-Redundancy

Operators can configure a list of prefixes for multicast source redundancy per MVPN on Receiver PEs:

- Up to 8 multicast source prefixes per VPRN are supported.
- Any multicast source that is not part of the source prefix list is treated as a unique source and automatically joined in addition to joining the most preferred source from the redundant multicast source list.

A Receiver PE selects a single, most-preferred multicast source from the list of pre-configured sources for a given MVPN during (C-*, C-G) processing as follows:

- A single join for the group is sent to the most preferred multicast source from the operator-configured multicast source list. Joins to other multicast sources for a given group are suppressed. Operator can see active and suppressed joins on a Receiver PE. Although a join is sent to a single multicast source only, (C-S, C-G) state is created for every source advertising Type-5 S-A route on the Receiver PE.
- The most preferred multicast source is a reachable source with the highest local preference for Type-5 SA route based on the BGP policy, as described later in this section.

- On a failure of the preferred multicast source or when a new multicast source with a better local preference is discovered, Receiver PE will join the new most-preferred multicast source. The outage experienced will depend on how quickly Receiver PE receives Type-5 S-A route withdrawal or loses unicast route to multicast source, and how quickly the network can process joins to the newly selected preferred multicast source(s).
- Local multicast sources on a Receiver PE are not subject to the most-preferred source selection, regardless of whether they are part of redundant source list or not.

BGP policy on Type-5 SA advertisements is used to determine the most preferred multicast source based on the best local preference as following:

- Each Source PE (a PE with multicast sources in its C-instance) tags Type-5 SA routes with a unique standard community attribute using global BGP policy or MVPN vrf-export policy. Depending on multicast topology, the policy may require source-aware tagging in the policy. Either all MVPN routes or Type 5 SA routes only can be tagged in the policy (new attribute **mvpn-type 5**).
- Each receiver PE has a BGP VRF import policy that sets local preference using match on Type-5 SA routes (new attribute **mvpn-type 5**) and standard community attribute value (as tagged by the Source PEs). Using policy statements that also include group address match, allows receiver PEs to select the best multicast source per group. The BGP VRF import policy must be applied as **vrf-import** under *config>service>vpn>mvpn* context. It must have default-action **accept** specified, or all MVPN routes other than those matched by specified entries will be rejected. In addition, it must have **vrf-target** as a community match condition, because **vrf-target mvpn** configuration is ignored when **vrf-import** policy is defined.

Operators can change redundant source list or BGP policy affecting source selection in service. If such a change of the list/policy results in a new preferred multicast source election, make-before-break is used to join the new source and prune the previously best source.

For the proper operations, MVPN multicast source geo-redundancy requires the router:

- To maintain the list of eligible multicast sources on Receiver PEs, Source PE routers must generate Type-5 S-A route even if the Source PE sees no active joins from any receiver for a given group.
- To trigger a switch from a currently active multicast source on a Receiver PE, Source PE routers must withdraw Type-5 S-A route when the multicast source fails or alternatively unicast route to multicast source must be withdrawn or go down on a Receiver PE.

MVPN multicast source redundancy solutions is supported for the following configurations only. Enabling the feature in unsupported configuration must be avoided:

1. NG-MVPN with RSVP-TE or mLDP or PIM with BGP c-multicast signaling in P-instance. Both I-PMSI and S-PMSI trees are supported.
2. IPv4 and IPv6 (C-*, C-G) PIM ASM joins in the C-instance.
3. Both **intersite-shared enabled** and **disabled** are supported. For **intersite-shared enabled**, operators must enable generation of Type-5 S-A routes even in the absence of receivers seen on Source PEs (intersite-shared persistent-type5-adv must be enabled).
4. The Source PEs must be configured as a sender-receiver, the Receiver PEs can be configured as a sender-receiver or a receiver-only.
5. The RP(s) must be on the Source PE(s) side. Static RP, anycast-RP, embedded-RP types are supported.
6. UMH redundancy can be deployed to protect Source PE to any multicast source. When deployed, UMH selection is executed independently of source selection after the most preferred multicast source had been chosen. Supported **umh-selection** options include: **highest-ip**, **hash-based**, **tunnel-status** (not supported for IPv6), and **unicast-rt-pref**.

3.5.14 Multicast Core Diversity for Rosen MDT SAFI MVPNs

[Figure 37](#) shows a Rosen MVPN core diversity deployment.

Figure 37 Multicast Core Diversity

Core diversity allows operators to optionally deploy multicast MVPN in either default IGP instance, or one of two non-default IGP instances to provide; for example, topology isolation or different level of services. The following describes the main feature attributes:

- Rosen MVPN IPv4 multicast with MDT SAFI is supported with default and data MDTs.
- Rosen MVPN can use a non-default OSPF or ISIS instance (using their loopback addresses instead of a system address).
- Up to 3 distinct core instances are supported: system + 2 non-default OSPF instances shown in [Figure 37](#).
- The BGP Connector also uses non-default OSPF loopback as NH, allowing Inter-AS Option B/C functionality to work with Core diversity as well.
- The feature is supported with CSC-VRPN.

On source PEs (PE1: UMH, PE2: UMH in the above picture), an MVPN is assigned to a non-default IGP core instance as follows:

- MVPN is statically pointed to use one of the non-default IGP instances loopback addresses as source address instead of system loopback IP.

- MVPN export policy is used to change unicast route next-hop VPN address.
- BGP Connector support for non-default instances.

The configuration shown above ensures that MDT SAFI and IPVPN routes for the non-default core instance use non-default IGP loopback instead of system IP. This ensures PIM advertisement/joins run in the proper core instance and GRE tunnels for multicast can be set-up using and terminated on non-system IP. If BGP export policy is used to change unicast route next-hop VPN address instead of BGP Connector attribute-based processing and unicast traffic must be forwarded in non-default core instances 1 or 2, LDP or RSVP (terminating on non-system IP) must be used. GRE unicast traffic termination on non-system IP is not supported and any GRE traffic arriving at the PE in instances 1 or 2, destined to non-default IGP loopback IP will be forwarded to CPM (ACL or CPM filters can be used to prevent the traffic from reaching the CPM).

No configuration is required on non-source PEs.

Known feature caveats include:

- VPRN instance must be shutdown to change the mdt-safi source-address. The CLI rollback that includes change of the auto-discovery is thus service impacting.
- To reset mdt-safi source-address to system IP, operator must first execute no auto-discovery (or auto-discovery default) then auto-discovery mdt-safi
- Configuring system IP as a source-address will consume one of the 2 IP addresses allowed, thus it should not be done.
- Operators must configure proper IGP instance loopback IP addresses within Rosen MVPN context and must configure proper BGP policies (prior to release R12.0R4) for the feature to operate as expected. There is no verification that the address entered for MVPN provider tunnel source-address is such an address or is not a system IP address.
- The feature requires all ports to be present on IOM3-XP or newer (Chassis Mode D). The restriction is not enforced. Failing to observe this restriction will prevent the feature to operate properly in the network.

3.5.15 Inter-AS MVPN

The Inter-AS MVPN feature allows set-up of Multicast Distribution Trees (MDTs) that span multiple Autonomous Systems (ASes). This section focuses on multicast aspects of the Inter-AS MVPN solution.

To support Inter-AS option for MVPNs, a mechanism is required that allows setup of Inter-AS multicast tree across multiple ASes. Due to limited routing information across AS domains, it is not possible to setup the tree directly to the source PE. Inter-AS VPN Option A does not require anything specific to inter-AS support as customer instances terminate on ASBR and each customer instance is handed over to the other AS domain via a unique instance. This approach allows operators to provide full isolation of ASes, but the solution is the least scalable case, as customer instances across the network have to exist on ASBR.

Inter-AS MVPN Option B allows operators to improve upon the Option A scalability while still maintaining AS isolation, while Inter-AS MVPN Option C further improves Inter-AS scale solution but requires exchange of Inter-AS routing information and thus is typically deployed when a common management exists across all ASes involved in the Inter-AS MVPN. The following sub-sections provide further details on Inter-AS Option B and Option C functionality.

3.5.15.1 BGP Connector Attribute

BGP connector attribute is a transitive attribute (unchanged by intermediate BGP speaker node) that is carried with VPNv4 advertisements. It specifies the address of source PE node that originated the VPNv4 advertisement.

With Inter-AS MVPN Option B, BGP next-hop is modified by local and remote ASBR during re-advertisement of VPNv4 routes. On BGP next-hop change, information regarding the originator of prefix is lost as the advertisement reaches the receiver PE node.

BGP connector attribute allows source PE address information to be available to receiver PE, so that a receiver PE is able to associate VPNv4 advertisement to the corresponding source PE.

3.5.15.2 PIM RPF Vector

In case of Inter-AS MVPN Option B, routing information towards the source PE is not available in a remote AS domain, since IGP routes are not exchanged between ASes. Routers in an AS other than that of a source PE, have no routes available to reach the source PE and thus PIM JOINS would never be sent upstream. To enable setup of MDT towards a source PE, BGP next-hop (ASBR) information from that PE's

MDT-SAFI advertisement is used to fake a route to the PE. If the BGP next-hop is a PIM neighbor, the PIM JOINS would be sent upstream. Otherwise, the PIM JOINS would be sent to the immediate IGP next-hop (P) to reach the BGP next-hop. Since the IGP next-hop does not have a route to source PE, the PIM JOIN would not be propagated forward unless it carried extra information contained in RPF Vector.

In case of Inter-AS MVPN Option C, unicast routing information towards the source PE is available in a remote AS PEs/ASBRs as BGP 3107 tunnels, but unavailable at remote P routers. If the tunneled next-hop (ASBR) is a PIM neighbor, the PIM JOINS would be sent upstream. Otherwise, the PIM JOINS would be sent to the immediate IGP next-hop (P) to reach the tunneled next-hop. Since the IGP next-hop does not have a route to source PE, the PIM JOIN would not be propagated forward unless it carried extra information contained in RPF Vector.

To enable setup of MDT towards a source PE, PIM JOIN thus carries BGP next hop information in addition to source PE IP address and RD for this MVPN. For option-B, both these pieces of information are derived from MDT-SAFI advertisement from the source PE. For option-C, both these pieces of information are obtained from the BGP tunneled route.

The RPF vector is added to a PIM join at a PE router when configure router **pim rpfv** option is enabled. P routers and ASBR routers must also have the option enabled to allow RPF Vector processing. If the option is not enabled, the RPF Vector is dropped and the PIM JOIN is processed as if the PIM Vector were not present.

For further details about RPF Vector processing please refer to [RFCs 5496, 5384 and 6513]

3.5.15.3 Inter-AS MVPN Option B

Inter-AS Option B is supported for Rosen MVPN PIM SSM using BGP MDT SAFI, PIM RPF Vector and BGP Connector attribute. The [Figure 38](#) depict set-up of a default MDT:

Figure 38 Inter-AS Option B Default MDT Setup

al_0165

SR OS inter-AS Option B is designed to be standard compliant based on the following RFCs:

- RFC 5384 - The Protocol Independent Multicast (PIM) Join Attribute Format
- RFC 5496 - The Reverse Path Forwarding (RPF) Vector TLV
- RFC 6513 - Multicast in MPLS/BGP IP VPNs

The SR OS implementation was designed also to interoperate with older routers Inter-AS implementations that do not comply with the RFC 5384 and RFC 5496.

3.5.15.4 Inter-AS MVPN Option C

Inter-AS Option C is supported for Rosen MVPN PIM SSM using BGP MDT SAFI and PIM RPF Vector. [Figure 39](#) depicts a default MDT setup:

Figure 39 Inter-AS Option C Default MDT Setup

Additional caveats for Inter-AS MVPN Option B and C support are the following:

1. Inter-AS MVPN Option B is not supported with duplicate PE addresses.
2. For Inter-AS Option C, BGP 3107 routes are installed into unicast rtm (rtable-u), unless routes are installed by some other means into multicast rtm (rtable-m), and Option C will not build core MDTs, therefore, rpf-table is configured to rtable-u or both.
3. Additional Cisco interoperability notes are the following:
 - RFC 5384 - the Protocol Independent Multicast (PIM) Join Attribute Format
 - RFC 5496 - the Reverse Path Forwarding (RPF) Vector TLV
 - RFC 6513 - multicast in MPLS/BGP IP VPNs

The SR OS implementation was designed to inter-operate with Cisco routers Inter-AS implementations that do not comply with the RFC5384 and RFC5496.

When **configure router pim rpfv mvpn** option is enabled, Cisco routers need to be configured to include RD in an RPF vector using the following command: **ip multicast vrf vrf-name rpf proxy rd vector** for interoperability. When Cisco routers are not configured to include RD in an RPF vector, operator should configure SR OS router (if supported) using **configure router pim rpfv core mvpn**: PIM joins received can be a mix of core and mvpn RPF vectors.

3.5.15.5 NG-MVPN Non-segmented Inter-AS Solution

This feature allows multicast services to use segmented protocols and span them over multiple autonomous systems (ASs), as done in unicast services. As IP VPN or GRT services span multiple IGP areas or multiple ASs, either due to a network designed to deal with scale or as result of commercial acquisitions, operators may require Inter-AS VPN (unicast) connectivity. For example, an Inter-AS VPN can break the IGP, MPLS and BGP protocols into access segments and core segments, allowing higher scaling of protocols by segmenting them into their own islands. SR OS also allows for similar provision of multicast services and for spanning these services over multiple IGP areas or multiple ASs.

For multicast VPN (MVPN), SR OS previously supported Inter-AS Model A/B/C for Rosen MVPN; however, when MPLS was used, only Model A was supported for Next Generation Multicast VPN (NG-MVPN) and d-mLDP signaling.

For unicast VPRNs, the Inter-AS or Intra-AS Option B and C breaks the IGP, BGP and MPLS protocols at ABR routers (in case of multiple IGP areas) and ASBR routers (in case of multiple ASs). At ABR and ASBR routers, a stitching mechanism of MPLS transport is required to allow transition from one segment to next, as shown in [Figure 40](#) and [Figure 41](#).

In [Figure 40](#), the Service Label (S) is stitched at the ASBR routers.

Figure 40 Unicast VPN Option B with Segmented MPLS

In [Figure 41](#), the 3107 BGP Label Route (LR) is stitched at ASBR1 and ASBR3. At ASBR1, the LR1 is stitched with LR2, and at ASBR3, the LR2 is stitched with TL2.

Figure 41 Unicast VPN Option C with Segmented MPLS

Previously, in case of NG-MVPN, segmenting an LDP MPLS tunnel at ASBRs or ABRs was not possible. As such, RFC 6512 and 6513 used a non-segmented mechanism to transport the multicast data over P-tunnels end-to-end through ABR and ASBR routers. The signaling of LDP needed to be present and possible between two ABR routers or two ASBR routers in different ASs.

Note: For unicast VPNs, it was usually preferred to only have eBGP between ASBR routers. The non-segmented behavior of d-mLDP would have broken this by requiring LDP signaling between ASBR routers.

SR OS now has d-mLDP non-segmented intra-AS and inter-AS signaling for NG-MVPN and GRT multicast. The non-segmented solution for d-mLDP is possible for inter-ASs as Option B and C.

3.5.15.5.1 Non-Segmented d-mLDP and Inter-AS VPN

There are three types of VPN Inter-AS solutions:

- [Inter-AS Option A](#)
- [Inter-AS Option B](#)
- [Inter-AS Option C](#)

Options B and C use recursive opaque types 8 and 7 respectively, from [Table 36](#).

Table 36 Recursive Opaque Types

Opaque Type	Opaque Name	RFC	SR OS Use
1	Basic Type	RFC 6388	VPRN Local AS
3	Transit IPv4	RFC 6826	IPv4 multicast over mLDP in GRT
4	Transit IPv6	RFC 6826	IPv6 multicast over mLDP in GRT
7	Recursive Opaque (Basic Type)	RFC 6512	Inter-AS Option C MVPN over mLDP
8	Recursive Opaque (VPN Type)	RFC 6512	Inter-AS Option B MVPN over mLDP

Inter-AS Option A

In Inter-AS Option A, ASBRs communicate using VPN access interfaces, which need to be configured under PIM for the two ASBRs to exchange multicast information.

Inter-AS Option B

The recursive opaque type used for Inter-AS Option B is the Recursive Opaque (VPN Type), shown as opaque type 8 in [Table 36](#).

Inter-AS Option B Support for NG-MVPN

Inter-AS Option B requires additional processing on ASBR routers and recursive FEC encoding than that of Inter-AS Option A. Because BGP adjacency is not e2e, ASBRs must cache and use a PMSI route to build the tree. For that, mLDP recursive FEC must carry RD information—thus, VPN recursive FEC is required (opaque type 8).

In Inter-AS Option B, the PEs in two different ASs do not have their system IP address in the RTM. As such, for NG-MVPN, a recursive opaque value in mLDP FEC is required to signal the LSP to the first ASBR in the local AS path.

Because the system IPs of the peer PEs (Root-1 and Root-2) are not installed on the local PE (leaf), it is possible to have two PEs in different ASs with same system IP address, as shown in [Figure 42](#). However, SR OS does not support this topology. The system IP address of all nodes (root or leaf) in different ASs must be unique.

Figure 42 Identical System IP on Multiple PEs (Option B)

For inter-AS Option B and NG-MVPN, SR OS as a leaf does not support multiple roots in multiple ASs with the same system IP and different RDs; however, the first root that is advertised to an SR OS leaf will be used by PIM to generate an MLDP tunnel to this actual root. Any dynamic behavior after this point, such as removal of the root and its replacement by a second root in a different AS, is not supported and the SR OS behavior is nondeterministic.

I-PMSI and S-PMSI Establishment

I-PMSI and S-PMSI functionality follows RFC 6513 section 8.1.1 and RFC 6512 sections 3.1 and 3.2.1. For routing, the same rules as for GRT d-MLDP use case apply, but the VRR Route Import External community now encodes the VRF instance in the local administrator field.

Option B uses an outer opaque of type 8 and inter opaque of type 1 (see [Table 36](#)).

[Figure 43](#) depicts the processing required for I-PMSI and S-PMSI Inter-AS establishment.

Figure 43 Non-segmented mLDP PMSI Establishment (Option B)

1031

For non-segmented mLDP trees, A-D procedures follow those of the Intra-AS model, with the exception that NO EXPORT community must be excluded; LSP FEC includes mLDP VPN-recursive FEC.

For I-PMSI on Inter-AS Option B:

- A-D routes must be installed by ASBRs and next-hop information is changed as the routes are propagated, as shown in [Figure 43](#).
- PMSI A-D routes are used to provide inter-domain connectivity on remote ASBRs.

On a receipt of an Intra-AS PMSI A-D route, PE2 resolves PE1's address (next-hop in PMSI route) to a labeled BGP route with a next-hop of ASBR3, because PE1 (Root-1) is not known via IGP. Because ASBR3 is not the originator of the PMSI route, PE2 sources an mLDP VPN recursive FEC with a root node of ASBR3, and an opaque value containing the information advertised by Root-1 (PE-1) in the PMSI A-D route, shown below, and forwards the FEC to ASBR 3 using IGP.

PE-2 LEAF FEC: (Root ASBR3, Opaque value {Root: ROOT-1, RD 60:60, Opaque Value: P2MPLSP-ID xx})

When the mLDP VPN-recursive FEC arrives at ASBR3, it notes that it is the identified root node, and that the opaque value is a VPN-recursive opaque value. Because Root-1 PE1 is not known via IGP, ASBR3 resolves the root node of the VPN-Recursive FEC using PMSI A-D (I or S) matching the information in the VPN-recursive FEC (the originator being PE1 (Root-1), RD being 60:60, and P2MP LSP ID xx). This yields ASBR1 as next hop. ASBR3 creates a new mLDP FEC element with a root node of ASBR1, and an opaque value being the received recursive opaque value, as shown below. ASBR then forwards the FEC using IGP.

ASBR-3 FEC: {Root ASBR 1, Opaque Value {Root: ROOT-1, RD 60:60, Opaque Value: P2MPLSP-ID xx}}

When the mLDP FEC arrives at ASBR1, it notes that it is the root node and that the opaque value is a VPN-recursive opaque value. As PE1's ROOT-1 address is known to ASBR1 through the IGP, no further recursion is required. Regular processing begins, using received Opaque mLDP FEC information.

ASBR-1 FEC: {Root: ROOT-1, Opaque Value: P2MP LSP-ID xx}

Note: VPN-Recursive FEC carries P2MPLSP ID. The P2MPLSP ID is used in addition to PE RD and Root to select a route to the mLDP root using the correct I-PMSI or S-PMSI route.

The functionality as described above for I-PMSI applies also to S-PMSI and (C-*, C-*) S-PMSI.

C-multicast Route Processing

C-multicast route processing functionality follows RFC 6513 section 8.1.2 (BGP used for route exchange). The processing is analogous to BGP Unicast VPN route exchange described in [Figure 40](#) and [Figure 41](#). [Figure 44](#) shows C-multicast route processing with non-segmented mLDP PMSI details.

Figure 44 Non-segmented mLDP C-multicast Exchange (Option B)

1032

Inter-AS Option C

In Inter-AS Option C, the PEs in two different ASs have their system IP address in the RTM, but the intermediate nodes in the remote AS do not have the system IP of the PEs in their RTM. As such, for NG-MVPN, a recursive opaque value in mLDP FEC is need to signal the LSP to the first ASBR in the local AS path.

The recursive opaque type used for Inter-AS Option B is the Recursive Opaque (Basic Type), shown as opaque type 7 in [Table 36](#).

Inter-AS Option C support for NG-MVPN

For Inter-AS Option C, on a leaf PE, a route exists to reach root PE's system IP and, as ASBRs can use BGP unicast routes, recursive FEC processing using BGP unicast routes and *not* VPN recursive FEC processing using PMSI routes is required.

I-PMSI and S-PMSI Establishment

I-PMSI and S-PMSI functionality follows RFC 6513 section 8.1.1 and RFC 6512 Section 2. The same rules as per the GRT d-mLDP use case apply, but the VRR Route Import External community now encodes the VRF instance in the local administrator field.

Option C uses an outer opaque of type 7 and inter opaque of type 1.

Figure 45 shows the processing required for I-PMSI and S-PMSI Inter-AS establishment.

Figure 45 Non-segmented mLDP PMSI Establishment (Option C)

1029

For non-segmented mLDP trees, A-D procedures follow those of the Intra-AS model, with the exception that NO EXPORT Community must be excluded; LSP FEC includes mLDP recursive FEC (and not VPN recursive FEC).

For I-PMSI on Inter-AS Option C:

- A-D routes are not installed by ASBRs and next-hop information is not changed in MVPN A-D routes.
- BGP-labeled routes are used to provide inter-domain connectivity on remote ASBRs.

On a receipt of an Intra-AS I-PMSI A-D route, PE2 resolves PE1's address (N-H in PMSI route) to a labeled BGP route with a next-hop of ASBR3, because PE1 is not known via IGP. PE2 sources an mLDP FEC with a root node of ASBR3, and an opaque value, shown below, containing the information advertised by PE1 in the I-PMSI A-D route.

PE-2 LEAF FEC: {Root = ASBR3, Opaque Value: {Root: ROOT-1, Opaque Value: P2MP-ID xx}}

When the mLDP FEC arrives at ASBR3, it notes that it is the identified root node, and that the opaque value is a recursive opaque value. ASBR3 resolves the root node of the Recursive FEC (ROOT-1) to a labeled BGP route with the next-hop of ASBR1, because PE-1 is not known via IGP. ASBR3 creates a new mLDP FEC element with a root node of ASBR1, and an opaque value being the received recursive opaque value.

ASBR3 FEC: {Root: ASBR1, Opaque Value: {Root: ROOT-1, Opaque Value: P2MP-ID xx}}

When the mLDP FEC arrives at ASBR1, it notes that it is the root node and that the opaque value is a recursive opaque value. As PE-1's address is known to ASBR1 through the IGP, no further recursion is required. Regular processing begins, using the received Opaque mLDP FEC information.

The functionality as described above for I-PMSI applies to S-PMSI and (C-*, C-*) S-PMSI.

C-multicast Route Processing

C-multicast route processing functionality follows RFC 6513 section 8.1.2 (BGP used for route exchange). The processing is analogous to BGP Unicast VPN route exchange. [Figure 46](#) shows C-multicast route processing with non-segmented mLDP PMSI details.

Figure 46 Non-segmented mLDP C-multicast Exchange (Option C)

1030

LEAF Node Cavities

Caution: The SR OS ASBR does not currently support receiving a non-recursive opaque FEC (opaque type 1).

The LEAF (PE-2) has to have the ROOT-1 system IP installed in RTM via BGP. If the ROOT-1 is installed in RTM via IGP, the LEAF will not generate the recursive opaque FEC. As such, the ASBR 3 will not process the LDP FEC correctly.

3.5.15.5.2 Configuration Example

No configuration is required for Option B or Option C on ASBRs, although for Option B, **configure>router>bgp>enable-inter-as-vpn** is required to enable inter-as-non-segmented MLDP through the ASBR router.

Policy is required for a root or leaf PE for removing the NO_EXPORT community from MVPN routes, which can be configured using an export policy on the PE.

The following is an example for configuring a policy on PEs to remove the **no-export**:

```
*A:Dut-A>config>router>policy-options# info
-----
community "no-export" members "no-export"
policy-statement "remNoExport"
  default-action accept
  community remove "no-export"
exit
exit
-----
*A:Dut-A>config>router>policy-options#
```

The following is an example for configuring in BGP the policy in a global, group, or peer context:

```
*A:Dut-A>config>router>bgp# info
-----
vpn-apply-export
export "remNoExport"
```

3.5.15.5.3 Inter-AS Non-segmented MLDP

Refer to the “Inter-AS Non-segmented MLDP” section of the *MPLS Guide* for more information.

3.5.15.5.4 ECMP

Refer to the “ECMP” section of the *MPLS Guide* for more information about ECMP.

3.6 VPRN Off-Ramp

This feature enhances the operation and deployment options service providers will have with the TMS-ISA DDoS and threat mitigation on the 7750 SR.

To enhance the operational flexibility of the DDoS scrubbing capabilities supported by MS-ISA TMS, this section discusses support for VPRN off-ramp to MS-ISA Threat Management Server (TMS) adding to the GRT (Global Routing Table) off-ramp already supported.

The current deployment model works as follows:

1. Off-ramping suspect traffic — Upon detection of a destination IP prefix under attack, the Collector Platform (CP) will communicate with a version of TMS running on MS-ISA (if licensed) instructing TMS-ISA to communicate with the router Control Processing Module (CPM) to issue a BGP route advertisement setting a 7750 SR interface as the next-hop for traffic destined for the IP under attack. At the same time, the 7750 SR sets up an internal route across one or more TMS-ISAs so when traffic arrives destined for the route under attack, those packets will be forwarded to the TMS-ISA for DDoS scrubbing.
2. On-ramping of clean traffic — Once traffic is forwarded to the TMS-ISA, the attack traffic is separated from the legitimate traffic destined to the address or address range under attack, the “clean” traffic is forced into a clean VRF that must contain the original PE serving the IP under attack. The traffic is then tunneled (by LDP or GRE) to the originally intended PE where it can be routed to its destination.

This features offer the ability to off-ramp traffic directly from VPN context where MS-ISA TMS may communicate with may communicate with CPM to insert internal re-direct routes within specific VPNs used as either DDoS scrubbing VRFs (where an operator designates one or more VPRNs for carrying traffic to be scrubbed) or where the VPRN contains the global routes using the MPLS network to transport Internet traffic.

In this case, rather than having the MS-ISA TMS trigger an internal re-direct route from GRT to one or more MS-ISA TMS instances, we allow the operator to configure a VPRN associated with carrying off-ramp traffic to be scrubbed so that prefixes under attack are added to that VPRN VRF ensuring traffic coming in on that VPN is off-ramped to MS-ISA TMS for scrubbing.

This model allows operational flexibility and simplicity where GRTs throughout the network do not need to be constantly changed for off-ramping of traffic, but instead off-ramp traffic can be isolated into a “dirty VRF” for cleaning after which it is returned to an unmodified global routing table or another operator defined VPN used for on-ramping clean traffic toward customers.

In addition, allowing VRF-based redirection to MS-ISA TMS provides a critical piece of a full flowspec directed DDoS scrubbing solution where flowspec policies are used to separate attack flows into “dirty VRF” where 7750 SRs running MS-ISA TMS scan then be configured to forward traffic from these DDoS VRFs to the TMS running on MS-ISA for scrubbing. Clean traffic would then be returned to the network by either a VPN or the GRT.

3.6.1 DDoS Off-Ramping Through Flowspec

Flowspec policy can be used on the 7750 SR to further simplify DDoS scrubbing architecture resulting in more scalable and operationally simplified topologies.

In this case, CP detectors will detect the destination under attack, including the flows (src/dest pairs) involved in the attack and either directly (or through interaction with an operator’s scripting engine) advertise flowspec extended BGP updates to peering and edge routers.

Peering/edge routes with flowspec enabled can redirect traffic to a VPN ensuring that traffic signaled for off-ramp by a CP is placed into a “dirty VPN” which will then be used to forward traffic to MS-ISA TMS for scrubbing.

Rather than altering the GRT table (as in the routed off-ramp model), flowspec policy allows granular policy redirection to take place to off-ramp VRF.

Since the GRT has not been altered, clean traffic is forwarded back to either a clean VRF or the GRT for routing to its originally intended destination.

Flowspec forwarding requires the IOM-3.

3.7 FIB Prioritization

The RIB processing of specific routes can be prioritized through the use of the **rib-priority** command. This command allows specific routes to be prioritized through the protocol processing so that updates are propagated to the FIB as quickly as possible.

The **rib-priority** command can be configured within the VPRN instance of the OSPF or IS-IS routing protocols. For OSPF, a prefix list can be specified that identifies which route prefixes should be considered high priority. If the **rib-priority high** command is configured under an **VPRN>OSPF>area>interface** context then all routes learned through that interface is considered high priority. For the IS-IS routing protocol, RIB prioritization can be either specified through a prefix-list or an IS-IS tag value. If a prefix list is specified then route prefixes matching any of the prefix list criteria will be considered high priority. If instead an IS-IS tag value is specified then any IS-IS route with that tag value will be considered high priority.

The routes that have been designated as high priority will be the first routes processed and then passed to the FIB update process so that the forwarding engine can be updated. All known high priority routes should be processed before the routing protocol moves on to other standard priority routes. This feature will have the most impact when there are a large number of routes being learned through the routing protocols.

3.8 Configuring a VPRN Service with CLI

This section provides information to configure Virtual Private Routed Network (VPRN) services using the command line interface.

Topics in this section include:

- [Basic Configuration](#)
- [Common Configuration Tasks](#)
 - [Configuring VPRN Components](#)
 - [Creating a VPRN Service](#)
 - [Configuring Global VPRN Parameters](#)
 - [Configuring VPRN Log Parameters](#)
 - [Configuring VPRN Protocols - PIM](#)
 - [Configuring VPRN Protocols - BGP](#)
 - [Configuring VPRN Protocols - RIP](#)
 - [Configuring VPRN Protocols - OSPF](#)
 - [Configuring a VPRN Interface](#)
 - [Configuring a VPRN Interface SAP](#)
- [Configuring Overload State on a Single SFM](#)
- [Service Management Tasks](#)
 - [Modifying VPRN Service Parameters](#)
 - [Deleting a VPRN Service](#)
 - [Disabling a VPRN Service](#)
 - [Re-enabling a VPRN Service](#)

3.8.1 Basic Configuration

The following fields require specific input (there are no defaults) to configure a basic VPRN service:

- customer ID (refer to the *7450 ESS, 7750 SR, and 7950 XRS Services Overview Guide*)
- specify interface parameters
- specify spoke SDP parameters

The following example displays a sample configuration of a VPRN service.

```
*A:ALA-1>config>service>vprn# info
-----
vrf-import "vrfImpPolCust1"
vrf-export "vrfExpPolCust1"
ecmp 8
autonomous-system 10000
route-distinguisher 10001:1
auto-bind-tunnel
    resolution filter
    resolution-filter ldp
vrf-target target:10001:1
interface "to-cel" create
    address 11.1.0.1/24
    proxy-arp
    exit
    sap 1/1/10:1 create
        ingress
            qos 100
        exit
        egress
            qos 1010
            filter ip 10
        exit
    exit
    dhcp
        description "DHCP test"
    exit
    vrrp 1
    exit
exit

```

3.8.2 Common Configuration Tasks

This section provides a brief overview of the tasks that must be performed to configure a VPRN service and provides the CLI commands.

- Step 1.** Associate a VPRN service with a customer ID.
- Step 2.** Define an autonomous system (optional).
- Step 3.** Define a route distinguisher (mandatory).
- Step 4.** Define VRF route-target associations or VRF import/export policies.
- Step 5.** Define PIM parameters (optional).
- Step 6.** Create a subscriber interface (applies to the 7750 SR only and is optional).
- Step 7.** Create an interface.
- Step 8.** Define SAP parameters on the interface.
 - Select node(s) and port(s).
 - Optional - select QoS policies other than the default (configured in config>qos context).
 - Optional - select filter policies (configured in config>filter context).
 - Optional - select accounting policy (configured in config>log context).
 - Optional - configure DHCP features. (applies to the 7450 ESS and 7750 SR)
- Step 9.** Define BGP parameters (optional).
 - BGP must be enabled in the **config>router>bgp** context.
- Step 10.** Define RIP parameters (optional).
- Step 11.** Define spoke SDP parameters (optional).
- Step 12.** Create confederation autonomous systems within an AS. (optional).
- Step 13.** Enable the service.

3.8.3 Configuring VPRN Components

This section provides VPRN configuration examples for the following entities:

- [Creating a VPRN Service](#)
- [Configuring Global VPRN Parameters](#)
- [Configuring VPRN Log Parameters](#)
- [Configuring VPRN Protocols - PIM](#)
- [Configuring Router Interfaces](#)
- [Configuring VPRN Protocols - OSPF](#)
- [Configuring a VPRN Interface SAP](#)
- [Configuring VPRN Protocols - BGP](#)
- [Configuring VPRN Protocols - RIP](#)

3.8.3.1 Creating a VPRN Service

Use the following CLI syntax to create a VPRN service. A route distinguisher must be defined and the VPRN service must be administratively up in order for VPRN to be operationally active.

CLI Syntax:

```
config>service# vprn service-id [customer customer-id]  
route-distinguisher [ip-address:number1 | asn:number2]  
description description-string  
no shutdown
```

The following example displays a VPRN service configuration.

```
*A:ALA-1>config>service# info  
-----  
...  
    vprn 1 customer 1 create  
        route-distinguisher 10001:0  
        no shutdown  
    exit  
...  
-----  
*A:ALA-1>config>service>vprn#
```

3.8.3.2 Configuring Global VPRN Parameters

Refer to [VPRN Service Configuration Commands](#) for CLI syntax to configure VPRN parameters.

The following example displays a VPRN service with configured parameters.

```
*A:ALA-1>config>service# info
-----
...
    vprn 1 customer 1 create
        vrf-import "vrfImpPolCust1"
        vrf-export "vrfExpPolCust1"
        autonomous-system 10000
        route-distinguisher 10001:1
        spoke-sdp 2 create
        exit
        no shutdown
    exit
...
-----
*A:ALA-1>config>service#
```

3.8.3.3 Configuring VPRN Log Parameters

The following output displays a VPRN log configuration example.

```
B:Dut-C>config>service>vprn# info
-----
    dhcp
        local-dhcp-server "vprn_1" create
            use-pool-from-client
            force-renews
            no shutdown
        exit
    exit
    snmp
        community "YsMv96H2KZVKQeakNAq.38gvyr.MH9vA" hash2 r version both
        community "gkYL94L90FFgu91PiRNvn3Rn10edkMU1" hash2 rw version v2c
        access
    log
        filter 1
            default-action forward
            entry 1
                action forward
            exit
        exit
        syslog 1
            address 3ffe::e01:403
            log-prefix "vprn1"
        exit
        snmp-trap-group 3
            trap-target "3" address 3ffe::e01:403 port 9000 snmpv2c notify-
community "vprn1"
        exit
        log-id 1
            filter 1
                from main change
                to syslog 1
            exit
        log-id 3
```

```

        filter 1
        from main change
        to snmp
    exit
exit
...
-----
B:Dut-C>config>service>vprn#

```

3.8.3.3.1 Configuring a Spoke-SDP

Use the following CLI syntax to configure spoke SDP parameters:

CLI Syntax:

```

config>service# vprn service-id [customer customer-id]
spoke-sdp sdp-id
    no shutdown
interface ip-int-name
    spoke-sdp sdp-id:vc-id [vc-type {ether | vlan}]
        egress
            filter {ip ip-filter-id}
            vc-label egress-vc-label
        ingress
            filter {ip ip-filter-id}
            vc-label ingress-vc-label
        tos-marking-state {trusted | untrusted}
    no shutdown

```

Use the following CLI syntax to configure spoke SDP parameters for the 7750 SR:

CLI Syntax:

```

config>service# vprn service-id [customer customer-id]
spoke-sdp sdp-id
    no shutdown
interface ip-int-name
    spoke-sdp sdp-id:vc-id [vc-type {ether | vlan |
        vpls}]
        egress
            filter {ip ip-filter-id}
            vc-label egress-vc-label
        ingress
            filter {ip ip-filter-id}
            vc-label ingress-vc-label
        tos-marking-state {trusted | untrusted}
    no shutdown

```

The following output displays a spoke SDP configuration.

```

A:ALA-48>config>service>vprn# info

```

```
-----
...
        interface "SpokeSDP" create
        spoke-sdp 3:4 create
        ingress
            vc-label 3000
            filter ip 10
        exit
        egress
            vc-label 2000
            filter ip 10
        exit
    exit
exit
...
    spoke-sdp 3 create
    exit
    no shutdown
-----
A:ALA-48>config>service>vprn#
```

3.8.3.4 Configuring VPRN Protocols - PIM

Refer to [VPRN Service Configuration Commands](#) for CLI syntax to configure VPRN parameters.

The following example displays a VPRN PIM configuration for the 7750 SR:

```
config>service# info
#-----
...
    vprn 1 customer 2 create
    route-distinguisher 1:11
    interface "if1" create
    address 12.13.14.15/32
    loopback
    exit
    interface "if2" create
    address 14.14.14.1/24
    sap 1/1/2:0 create
    exit
    exit
    pim
    interface "if1"
    exit
    interface "if2"
    exit
    rp
        static
        exit
        bsr-candidate
        shutdown
        exit
        rp-candidate
```

```

                                shutdown
                                exit
                                exit
                                exit
                                no shutdown
                                exit
                                exit
                                exit
#-----
config>service#

```

3.8.3.4.1 Configuring Router Interfaces

Refer to the Router Configuration Guide for command descriptions and syntax information to configure router interfaces.

The following example displays a router interface configurations:

```

ALA48>config>router# info
#-----
echo "IP Configuration"
#-----
...
    interface "if1"
        address 2.2.2.1/24
        port 1/1/33
    exit
    interface "if2"
        address 10.49.1.46/24
        port 1/1/34
    exit
    interface "if3"
        address 11.11.11.1/24
        port 1/1/35
    exit
...
#-----
ALA48>config>router#

```

3.8.3.4.2 Configuring VPRN Protocols - BGP

The autonomous system number and router ID configured in the VPRN context only applies to that particular service.

The minimal parameters that should be configured for a VPRN BGP instance are:

- Specify an autonomous system number for the router. See [Configuring Global VPRN Parameters](#).

- Specify a router ID - If a new or different router ID value is entered in the BGP context, then the new values takes precedence and overwrites the VPRN-level router ID. See [Configuring Global VPRN Parameters](#).
- Specify a VPRN BGP peer group.
- Specify a VPRN BGP neighbor with which to peer.
- Specify a VPRN BGP peer-AS that is associated with the above peer.

VPRN BGP is administratively enabled upon creation. Minimally, to enable VPRN BGP in a VPRN instance, you must associate an autonomous system number and router ID for the VPRN service, create a peer group, neighbor, and associate a peer AS number. There are no default VPRN BGP groups or neighbors. Each VPRN BGP group and neighbor must be explicitly configured.

All parameters configured for VPRN BGP are applied to the group and are inherited by each peer, but a group parameter can be overridden on a specific basis. VPRN BGP command hierarchy consists of three levels:

- the global level
- the group level
- the neighbor level

For example:

CLI Syntax: `config>service>vprn>bgp#(global level)`
 `group (group level)`
 `neighbor (neighbor level)`

The local-address must be explicitly configured if two systems have multiple BGP peer sessions between them for the session to be established.

For more information about the BGP protocol, refer to the Router Configuration Guide.

Configuring VPRN BGP Group and Neighbor Parameters

A group is a collection of related VPRN BGP peers. The group name should be a descriptive name for the group. Follow your group, name, and ID naming conventions for consistency and to help when troubleshooting faults.

All parameters configured for a peer group are applied to the group and are inherited by each peer (neighbor), but a group parameter can be overridden on a specific neighbor-level basis.

After a group name is created and options are configured, neighbors can be added within the same autonomous system to create IBGP connections and/or neighbors in different autonomous systems to create EBGP peers. All parameters configured for the peer group level are applied to each neighbor, but a group parameter can be overridden on a specific neighbor basis.

Configuring Route Reflection

Route reflection can be implemented in autonomous systems with a large internal BGP mesh to reduce the number of IBGP sessions required. One or more routers can be selected to act as focal points, for internal BGP sessions. Several BGP-speaking routers can peer with a route reflector. A route reflector forms peer connections to other route reflectors. A router assumes the role as a route reflector by configuring the **cluster** *cluster-id* command. No other command is required unless you want to disable reflection to specific peers.

If you configure the cluster command at the global level, then all subordinate groups and neighbors are members of the cluster. The route reflector cluster ID is expressed in dotted decimal notation. The ID should be a significant topology-specific value. No other command is required unless you want to disable reflection to specific peers.

If a route reflector client is fully meshed, the **disable-client-reflect** command can be enabled to stop the route reflector from reflecting redundant route updates to a client.

Configuring BGP Confederations

A VPRN can be configured to belong to a BGP confederation. BGP confederations are one technique for reducing the degree of IBGP meshing within an AS. When the confederation command is in the configuration of a VPRN the type of BGP session formed with a VPRN BGP neighbor is determined as follows:

- The session is of type IBGP if the peer AS is the same as the local AS.
- The session is of type confed-EBGP if the peer AS is different than the local AS AND the peer AS is listed as one of the members in the confederation command.
- The session is of type EBGP if the peer AS is different than the local AS AND the peer AS is not listed as one of the members in the confederation command.

VPRN BGP CLI Syntax

Use the CLI syntax to configure VPRN BGP parameters.

The following example displays a VPRN BGP configuration:

```
*A:ALA-1>config>service# info
-----
...
    vprn 1 customer 1 create
        vrf-import "vrfImpPolCust1"
        vrf-export "vrfExpPolCust1"
        ecmp 8
        autonomous-system 10000
        route-distinguisher 10001:1
        auto-bind-tunnel
            resolution filter
            resolution-filter ldp
        vrf-target target:10001:1
        interface "to-cel" create
            address 11.1.0.1/24
            sap 1/1/10:1 create
                ingress
                    scheduler-policy "SLA2"
                    qos 100
                exit
                egress
                    scheduler-policy "SLA1"
                    qos 1010
                    filter ip 6
                exit
            exit
        exit
    static-route 6.5.0.0/24
        next-hop 10.1.1.2
    bgp
        router-id 10.0.0.1
        group "to-cel"
            export "vprnBgpExpPolCust1"
            peer-as 65101
            neighbor 10.1.1.2
            exit
        exit
    spoke-sdp 2 create
    exit
    no shutdown
    exit
...
-----
*A:ALA-1>config>service#
```

3.8.3.4.3 Configuring VPRN Protocols - RIP

PE routers which attach to a particular VPN need to know, for each of that VPN's sites, which addresses in that VPN are at each site. There are several ways that a PE router can obtain this set of addresses. The Routing Information Protocol (RIP) sends routing update messages that include entry changes. The routing table is updated to reflect the new information. This functionality applies only to the 7450 ESS and 7750 SR.

RIP can be used as a PE/CE distribution technique. PE and CE routers may be RIP peers, and the CE may use RIP to tell the PE router the set of address prefixes which are reachable at the CE router's site. When RIP is configured in the CE, care must be taken to ensure that address prefixes from other sites (i.e., address prefixes learned by the CE router from the PE router) are never advertised to the PE. Specifically, if a PE router receives a VPN-IPv4 route, and as a result distributes an IPv4 route to a CE, then that route must not be distributed back from that CE's site to a PE router (either the same router or different routers).

In order to enable a VPRN RIP instance, the RIP protocol must be enabled in the **config>service> >vprn>rip** context of the VPRN. VPRN RIP is administratively enabled upon creation. Configuring other RIP commands and parameters are optional.

Caution: Careful planning is essential to implement commands that can affect the behavior of VPRN RIP global, group, and neighbor levels. Because the RIP commands are hierarchical, analyze the values that can disable features on a particular level.

The parameters configured on the VPRN RIP global level are inherited by the group and neighbor levels. Many of the hierarchical VPRN RIP commands can be modified on different levels. The most specific value is used. That is, a VPRN RIP group-specific command takes precedence over a global VPRN RIP command. A neighbor-specific statement takes precedence over a global VPRN RIP and group-specific command. For example, if you modify a VPRN RIP neighbor-level command default, the new value takes precedence over VPRN RIP group- and global-level settings. There are no default VPRN RIP groups or neighbors. Each VPRN RIP group and neighbor must be explicitly configured.

The minimal parameters that should be configured for a VPRN instance are:

- Specify a VPRN RIP peer group.
- Specify a VPRN RIP neighbor with which to peer.
- Specify a VPRN RIP peer-AS that is associated with the above peer.

VPRN RIP command hierarchy consists of three levels:

- The global level
- The group level
- The neighbor level

For example:

CLI Syntax: config>service>vprn>rip#(global level)
 group(group level)
 neighbor (neighbor level)

VPRN RIP CLI Syntax

The following example displays a VPRN RIP configuration:

```
*A:ALA-1>config>service# info
-----
...
    vprn 1 customer 1 create
        vrf-import "vrfImpPolCust1"
        vrf-export "vrfExpPolCust1"
        ecmp 8
        autonomous-system 10000
        route-distinguisher 10001:1
        auto-bind-tunnel
            resolution filter
            resolution-filter ldp
        vrf-target target:10001:1
        interface "to-cel" create
            address 11.1.0.1/24
            sap 1/1/10:1 create
                ingress
                    scheduler-policy "SLA2"
                    qos 100
                exit
                egress
                    scheduler-policy "SLA1"
                    qos 1010
                    filter ip 6
                exit
            exit
        exit
    static-route 6.5.0.0/24 next-hop 10.1.1.2
    bgp
        router-id 10.0.0.1
        group "to-cel"
            export "vprnBgpExpPolCust1"
            peer-as 65101
            neighbor 10.1.1.2
            exit
        exit
    exit
```

```

        rip
        export "vprnRipExpPolCust1"
        group "cel"
            neighbor "to-cel"
        exit
    exit
exit
spoke-sdp 2 create
exit
no shutdown
exit
...
-----
*A:ALA-1>config>service# info

```

For more information about the RIP protocol, refer to the Router Configuration Guide.

3.8.3.4.4 Configuring VPRN Protocols - OSPF

Each VPN routing instance is isolated from any other VPN routing instance, and from the routing used across the backbone. OSPF can be run with any VPRN, independently of the routing protocols used in other VPRNs, or in the backbone itself. For more information about the OSPF protocol, refer to the Router Configuration Guide.

CLI Syntax: config>service>vprn>ospf#

VPRN OSPF CLI Syntax

Refer to [OSPF Commands](#) for CLI syntax to configure VPRN parameters.

The following example displays the VPRN OSPF configuration shown above:

```

*A:ALA-48>config>service# info
-----
vprn 2 customer 1 create
    interface "test" create
    exit
    no shutdown
exit
    area 0.0.0.0
        virtual-link 1.2.3.4 transit-area 1.2.3.4
        hello-interval 9
        dead-interval 40
    exit
exit
-----
*A:ALA-48>config>service#

```

For more information about the OSPF protocol, refer to the Router Configuration Guide.

3.8.3.4.5 Configuring TMS Parameters

The following example displays a VPRN TMS configuration for the 7750 SR:

```
configure
  service
    customer 1 create
      description "Default customer"
    exit
    vprn 1 customer 1 create
      ecmp 16
      router-id 0.0.3.1
      autonomous-system 1
      route-distinguisher 1.1.1.3:1
      auto-bind-tunnel
  resolution filter
    resolution-filter ldp
    vrf-target target:1:1
    tms-interface "mda-1-1" create
      address 20.12.0.43/32
      description "tms-1-1"
      port 1/1
      password "password=arbor zone-secret=admin"
    exit
    tms-interface "mda-2-1" create
      address 20.12.0.44/32
      description "tms-2-1"
      port 2/1
      password "password=arbor zone-secret=admin"
    exit
    tms-interface "mda-2-2" create
      address 20.12.0.45/32
      description "tms-2-2"
      port 2/2
      password "password=arbor zone-secret=admin"
    exit
    tms-interface "mda-3-1" create
      address 20.12.0.46/32
      description "tms-3-1"
      port 3/1
      password "password=arbor zone-secret=admin"
    exit
    no shutdown
  exit
exit
exit

configure service vprn 1
  tms-interface "mda-1-1" create
    address 20.12.0.43/32
    description "tms-1-1"
    port 1/1
```

```

        password "password=arbor zone-secret=admin"
    exit
exit

configure router
    interface "itfToArborCP"
        address 10.12.0.1/24
        port 3/2/4
    exit
exit

```

Configuration Notes:

- Use the mda-type isa-tms parameter for this configuration
- The tms-interface address 20.12.0.43/32 should be configured on the ArborSP via "Administration> Peakflow Appliances"
- The port is the card/mda
- The tms-interface address 20.12.0.43/32 results in a static route in the Base instance

```

*A:Dut-C# show router route-table 20.12.0.43/32
=====
Route Table (Router: Base)
=====
Dest Prefix[Flags]                                Type   Proto   Age           Pref
Next Hop[Interface Name]                          Metric
-----
20.12.0.43/32                                     Remote Static   00h08m49s     5
vprnl:mda-1-1                                     1
-----

```

- The tms-interface zone-secret=admin should match with the zone-secret used on the ArborSP
- The tms-interface password=arbor should be used as password during ssh/telnet to tms
- The tms-interface ipv6. This is a prerequisite for adding IPv6 TMS routes and scrubbing IPv6 traffic
- The connectivity SR/ArborSP goes via port 3/2/4 interface itfToArborCP (10.12.0.1) to an interface (10.12.0.2) of the ArborSP.
- On the ArborSP, to reach the TMS, a static route like this is needed: 20.12.0.0/24 with next-hop 10.12.0.1
- On the SR, to reach the ArborSP a static route like this is needed (with 138.203.71.202 the mgmt ip address of the ArborSP (eth0)):

```

static-route-entry 138.203.71.202/32
    next-hop 10.12.0.2

```

- Use the same ntp server on both SR/ArborSP and enable ntp-server (because CPM is ntp server for isa-tms's)
- A policy (in this example "exporttmsgtr") is needed to leak tms routes to bgp
- If you want to telnet/ping to tms, then you should enable first following services:
ssh 127.1.mda.slot -l admin router management

```
ip access add ping all 0.0.0.0/0
ip access add telnet all 0.0.0.0/0
ip access commit
services telnet start
config write
```

- On the ArborSP
- Use a TMS cluster which holds the relevant isa-tms's Administration> Mitigation> TMS-ISA Clusters
- Put the TMS cluster in a TMS group Administration> Mitigation> TMS Groups
- Use the TMS Group in the mitigation rule (Mitigation> Threat Management> Add> TMS Appliances)

3.8.3.4.6 Configuring a VPRN Interface

Interface names associate an IP address to the interface, and then associate the IP interface with a physical port. The logical interface can associate attributes like an IP address, port, Link Aggregation Group (LAG) or the system.

There are no default interfaces.

You can configure a VPRN interface as a loopback interface by issuing the loopback command instead of the **sap** *sap-id* command. The loopback flag cannot be set on an interface where a SAP is already defined and a SAP cannot be defined on a loopback interface.

When using mtrace/mstat in a Layer 3 VPN context then the configuration for the VPRN should have a loopback address configured which has the same address as the core instance's system address (BGP next-hop).

Refer to [OSPF Commands](#) for CLI commands and syntax.

The following example displays a VPRN interface configuration:

```
*A:ALA-1>config>service>vprn# info
-----
...
vprn 1 customer 1 create
vrf-import "vrfImpPolCust1"
vrf-export "vrfExpPolCust1"
ecmp 8
```

```
autonomous-system 10000
route-distinguisher 10001:1
auto-bind-tunnel
  resolution filter
  resolution-filter ldp
vrf-target target:10001:1
interface "to-cel" create
  address 11.1.0.1/24
  exit
exit
static-route 6.5.0.0/24
  next-hop 10.1.1.2
spoke-sdp 2 create
exit
no shutdown
exit
...
-----
*A:ALA-1>config>service#
```

3.8.3.4.7 Configuring Overload State on a Single SFM

A 7450 ESS or 7750 SR system with a single SFM installed has a system multicast throughput that is only a half of a system with dual SFMs installed. For example, in a mixed environment in which IOM1s, IOM2s, and IOM3s are installed in the same system (chassis mode B or C), system multicast throughput doubles when redundant SFMs are used instead of a single SFM. If the required system multicast throughput is between 16G and 32G (which means both SFMs are being actively used), when there is an SFM failure, multicast traffic needs to be rerouted around the node.

Some scenarios include:

- there is only one SFM installed in the system
- one SFM (active or standby) failed in a dual SFM configuration
- the system is in the ISSU process

You can use an overload state in IGP on a 7450 ESS or 7750 SR to trigger the traffic reroute by setting the overload bit or setting the metric to maximum in OSPF. Since PIM uses IGP to find out the upstream router, a next-hop change in IGP will cause PIM to join the new path and prune the old path, which effectively reroutes the multicast traffic downstream. When the problem is resolved, the overload condition is cleared, which will cause the traffic to be routed back to the router.

3.8.3.4.8 Configuring a VPRN Interface SAP

A SAP is a combination of a port and encapsulation parameters which identifies the service access point on the interface and within the SR. Each SAP must be unique within a router. A SAP cannot be defined if the interface **loopback** command is enabled.

When configuring VPRN interface SAP parameters, a default QoS policy is applied to each ingress and egress SAP. Additional QoS policies and scheduler policies must be configured in the **config>qos** context. Filter policies are configured in the **config>filter** context and must be explicitly applied to a SAP. There are no default filter policies.

VPRN interface ATM SAP parameters on a 7750 SR can only be configured on ATM-type MDAs and ATM-configured ports. The **periodic-loopback** command can only be enabled when the **config>system>atm>oam** context is enabled. See the Basic System Configuration Guide.

Refer to [OSPF Commands](#) for CLI commands and syntax.

The following example displays a VPRN interface SAP configuration:

```
*A:ALA-1>config>service# info
-----
...
    vprn 1 customer 1 create
        vrf-import "vrfImpPolCust1"
        vrf-export "vrfExpPolCust1"
        ecmp 8
        autonomous-system 10000
        route-distinguisher 10001:1
        auto-bind-tunnel
            resolution filter
            resolution-filter ldp
        vrf-target target:10001:1
        interface "to-cel" create
            address 11.1.0.1/24
            sap 1/1/10:1 create
                ingress
                    scheduler-policy "SLA2"
                    qos 100
                exit
                egress
                    scheduler-policy "SLA1"
                    qos 1010
                    filter ip 6
                exit
            exit
        exit
    static-route 6.5.0.0/24
        next-hop 10.1.1.2
    spoke-sdp 2 create
    exit
no shutdown
```

```

        exit
    ...
    -----
    *A:ALA-1>config>service#

```

3.8.4 Configuring IPSec Parameters

The following output displays service with IPSec parameters configured.

```

    *A:ALA-49>config# info
    -----
    ...
        service
            ies 100 customer 1 create
                interface "ipsec-public" create
                    address 10.10.10.1/24
                    sap ipsec-1.public:1 create
                exit
            exit
            no shutdown
        exit
    vprn 200 customer 1 create
        ipsec
            security-policy 1 create
                entry 1 create
                    local-ip 172.17.118.0/24
                    remote-ip 172.16.91.0/24
                exit
            exit
        exit
    route-distinguisher 1:1
        interface "ipsec-private" tunnel create
            sap tunnel-1.private:1 create
            ipsec-tunnel "remote-office" create
                security-policy 1
                local-gateway-address 10.10.10.118 peer 10.10.7.91 delivery-
service 100
            dynamic-keying
                ike-policy 1
                pre-shared-key "humptydumpty"
                transform 1
            exit
            no shutdown
        exit
    exit
    exit
    interface "corporate-network" create
        address 172.17.118.118/24
        sap 1/1/2 create
    exit
    exit
    static-route-entry 172.16.91.0/24
        ipsec-tunnel "remote-office"
        no shutdown
    exit

```

```

        exit
    ...
-----
*A:ALA-49>config#

```

3.8.5 Service Management Tasks

This section discusses the following service management tasks:

- [Modifying VPRN Service Parameters](#)
- [Deleting a VPRN Service](#)

3.8.5.1 Modifying VPRN Service Parameters

Use the CLI syntax to modify VPRN parameters ([VPRN Service Configuration Commands](#)).

The following example displays the VPRN service creation output.

```

*A:ALA-1>config>service# info
-----
...
vprn 1 customer 1 create
    shutdown
    vrf-import "vrfImpPolCust1"
    vrf-export "vrfExpPolCust1"
    ecmp 8
    maximum-routes 2000
    autonomous-system 10000
    route-distinguisher 10001:1
    interface "to-cel" create
        address 10.1.1.1/24
        sap 1/1/10:1 create
        exit
    exit
    static-route 6.5.0.0/24
        next-hop 10.1.1.2
    bgp
        router-id 10.0.0.1
        group "to-cel"
            export "vprnBgpExpPolCust1"
            peer-as 65101
            neighbor 10.1.1.2
            exit
        exit
    exit
    spoke-sdp 2 create
    exit
exit

```

```
...
-----
*A:ALA-1>config>service>vprn#
```

3.8.5.2 Deleting a VPRN Service

An VPRN service cannot be deleted until SAPs and interfaces are shut down and deleted. If protocols and/or a spoke-SDP are defined, they must be shut down and removed from the configuration as well.

Use the following CLI syntax to delete a VPRN service:

CLI Syntax:

```
config>service#
[no] vprn service-id [customer customer-id]
      shutdown
[no] interface ip-int-name
      shutdown
      [no] sap sap-id
[no] bgp
      shutdown
[no] rip
      shutdown
[no] spoke-sdp sdp-id
      [no] shutdown
```

3.8.5.3 Disabling a VPRN Service

A VPRN service can be shut down without deleting any service parameters.

CLI Syntax:

```
config>service#
vprn service-id [customer customer-id]
      shutdown
```

Example:

```
config>service# vprn 1
config>service>vprn# shutdown
config>service>vprn# exit
```

```
*A:ALA-1>config>service# info
-----
...
vprn 1 customer 1 create
      shutdown
      vrf-import "vrfImpPolCust1"
      vrf-export "vrfExpPolCust1"
      ecmp 8
```

```

autonomous-system 10000
route-distinguisher 10001:1
auto-bind-tunnel
    resolution filter
    resolution-filter ldp
vrf-target target:10001:1
interface "to-cel" create
    address 11.1.0.1/24
    sap 1/1/10:1 create
        ingress
            scheduler-policy "SLA2"
            qos 100
        exit
        egress
            scheduler-policy "SLA1"
            qos 1010
            filter ip 6
        exit
    exit
exit
static-route 6.5.0.0/24
    next-hop 10.1.1.2
bgp
    router-id 10.0.0.1
    group "to-cel"
        export "vprnBgpExpPolCust1"
        peer-as 65101
        neighbor 10.1.1.2
    exit
exit
rip
    export "vprnRipExpPolCust1"
    group "cel"
        neighbor "to-cel"
    exit
exit
spoke-sdp 2 create
exit
exit
...
-----
*A:ALA-1>config>service#

```

3.8.5.4 Re-enabling a VPRN Service

To re-enable a VPRN service that was shut down.

CLI Syntax:

```

config>service#
vprn service-id [customer customer-id]
no shutdown

```

3.9 VPRN Service Configuration Commands

### 3.9.1.10 Router Advertisement Commands

```

config
 — service
 — vpn
 — [no] router-advertisement
 — [no] dns-options
 — server ipv6-address
 — no server
 — rdnss-lifetime {seconds | infinite}
 — no rdnss-lifetime
 — [no] interface ip-int-name
 — current-hop-limit number
 — no current-hop-limit
 — [no] dns-options
 — server ipv6-address
 — no server

```

- **rdnss-lifetime** *seconds*
- **no rdnss-lifetime**
- **[no] include-dns**
- **[no] managed-configuration**
- **max-advertisement-interval** *seconds*
- **no max-advertisement-interval**
- **min-advertisement-interval** *seconds*
- **no min-advertisement-interval**
- **mtu** *mtu-bytes*
- **no mtu**
- **[no] other-stateful-configuration**
- **prefix** [*ipv6-prefix/prefix-length*]
- **no prefix**
  - **[no] autonomous**
  - **[no] on-link**
  - **preferred-lifetime** {*seconds* | **infinite**}
  - **no preferred-lifetime**
  - **valid-lifetime** {*seconds* | **infinite**}
  - **no valid-lifetime**
- **reachable-time** *milli-seconds*
- **no reachable-time**
- **retransmit-time** *milli-seconds*
- **no retransmit-time**
- **router-lifetime** *seconds*
- **no router-lifetime**
- **[no] shutdown**
- **[no] use-virtual-mac**

### 3.9.1.11 NTP Commands

The **ntp-server** command is not supported in the **vprn ntp** context. Then NTP is configured in a VPRN service, the NTP server mode is assumed and is not optional.

```

config
 — service
 — vprn
 — [no] ntp
 — [no] authenticate
 — [no] authentication-check
 — authentication-key key-id key [hash | hash2] type {des | message-digest}
 — no authentication-key key-id
 — [no] broadcast [router router-name] {interface ip-int-name} [key-id key-id] [version version] [ttd ttl]

```

### 3.9.1.12 NAT Commands

```

config

```

```

— service
 — vpn service-id [customer customer-id]
 — no vpn service-id
 — [no] nat
 — inside
 — [no] destination-prefix ip-prefix/length
 — dual-stack-lite
 — [no] address ipv6-address
 — tunnel-mtu mtu-bytes
 — no tunnel-mtu
 — [no] shutdown
 — subscriber-prefix-length prefix-length
 — no subscriber-prefix-length
 — l2-aware
 — [no] address ip-address/mask
 — nat-policy nat-policy-name
 — no nat-policy
 — redundancy
 — peer ip-address
 — no peer
 — steering-route ip-prefix/length
 — no steering-route
 — outside
 — pool nat-pool-name [nat-group nat-group-id type pool-type [no-allocate] [create]]
 — no pool nat-pool-name
 — address-range start-ip-addr end-ip-addr [create]
 — no address-range start-ip-address end-ip-address
 — description description-string
 — no description
 — [no] drain
 — description description-string
 — no description
 — mode {auto | n apt}
 — no mode
 — port-forwarding-range range-end
 — no port-forwarding-range
 — port-reservation blocks num-blocks
 — port-reservation ports num-ports
 — no port-reservation
 — redundancy
 — export ip-prefix/length
 — no export
 — follow router router-instance pool name
 — no follow
 — monitor ip-prefix/length
 — no monitor
 — [no] shutdown
 — subscriber-limit limit
 — no subscriber-limit
 — watermarks high percentage-high low percentage-low
 — no watermarks

```

### 3.9.1.13 Subscriber Interface Commands

```

config

```

**Description** This command administratively disables an entity. When disabled, an entity does not change, reset, or remove any configuration settings or statistics.

The operational state of the entity is disabled as well as the operational state of any entities contained within. Many objects must be shut down before they may be deleted.

Services are created in the administratively down (**shutdown**) state. When a **no shutdown** command is entered, the service becomes administratively up and then tries to enter the operationally up state. Default administrative states for services and service entities is described below in Special Cases.

The **no** form of this command places the entity into an administratively enabled state.

If the AS number was previously changed, the BGP AS number inherits the new value.

**Special Cases** **Service Admin State** — Bindings to an SDP within the service will be put into the out-of-service state when the service is shutdown. While the service is shutdown, all customer packets are dropped and counted as discards for billing and debugging purposes.

A service is regarded as operational providing that one IP Interface SAP and one SDP is operational.

**VPRN BGP and RIP** — This command disables the BGP or RIP instance on the given IP interface. Routes learned from a neighbor that is shutdown are immediately removed from the BGP or RIP database and RTM. If BGP or RIP is globally shutdown, then all RIP group and neighbor interfaces are shutdown operationally. If a BGP or RIP group is shutdown, all member neighbor interfaces are shutdown operationally. If a BGP or RIP neighbor is shutdown, just that neighbor interface is operationally shutdown.

## description

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Description</b> | This command creates a text description stored in the configuration file for a configuration context.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

The **description** command associates a text string with a configuration context to help identify the content in the configuration file.

The **no** form of this command removes the string from the configuration.

|                   |                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>This command creates or edits a Virtual Private Routed Network (VPRN) service instance.</p> <p>If the <i>service-id</i> does not exist, a context for the service is created. If the <i>service-id</i> exists, the context for editing the service is entered.</p> <p>VPRN services allow the creation of customer-facing IP interfaces in the same routing instance used for service network core routing connectivity. VPRN services require that the IP addressing scheme used by the subscriber must be unique between it and other addressing schemes used by the provider and potentially the entire Internet.</p> <p>IP interfaces defined within the context of an VPRN service ID must have a SAP created as the access point to the subscriber network.</p> <p>When a service is created, the <b>customer</b> keyword and <i>customer-id</i> must be specified and associates the service with a customer. The <i>customer-id</i> must already exist having been created using the customer command in the service context. When a service is created with a customer association, it is not possible to edit the customer association. The service must be deleted and re-created with a new customer association.</p> <p>When a service is created, the use of the <b>customer</b> <i>customer-id</i> is optional to navigate into the service configuration context. If attempting to edit a service with the incorrect <i>customer-id</i> results in an error.</p> |

Multiple VPRN services are created to separate customer-owned IP interfaces. More than one VPRN service can be created for a single customer ID. More than one IP interface can be created within a single VPRN service ID. All IP interfaces created within an VPRN service ID belongs to the same customer.

The **no** form of the command deletes the VPRN service instance with the specified *service-id*. The service cannot be deleted until all the IP interfaces and all routing protocol configurations defined within the service ID have been shutdown and deleted.

|                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |                     |                 |                   |                       |

| <b>Description</b> | This command creates an aggregate route.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Use this command to automatically install an aggregate in the routing table when there are one or more component routes. A component route is any route used for forwarding that is a more-specific match of the aggregate.

The use of aggregate routes can reduce the number of routes that need to be advertised to neighbor routers, leading to smaller routing table sizes.

Overlapping aggregate routes may be configured; in this case a route becomes a component of only the one aggregate route with the longest prefix match. For example if one aggregate is configured as 10.0.0.0/16 and another as 10.0.0.0/24, then route 10.0.128/17 would be aggregated into 10.0.0.0/16, and route 10.0.0.128/25 would be aggregated into 10.0.0.0/24. If multiple entries are made with the same prefix and the same mask the previous entry is overwritten.

A standard 4-byte BGP community may be associated with an aggregate route in order to facilitate route policy matching.

By default aggregate routes are not installed in the forwarding table, however there are configuration options that allow an aggregate route to be installed with a black-hole next hop or with an indirect IP address as next hop.

The **no** form of the command removes the aggregate.

|            |                                                                                              |
|------------|----------------------------------------------------------------------------------------------|
| Default    | no aggregate                                                                                 |
| Parameters | <i>ip-prefix</i> — the destination address of the aggregate route in dotted decimal notation |

Values

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| ipv4-prefix        | a.b.c.d (host bits must be 0)                                                                 |
| ipv4-prefix-length | 0 to 32                                                                                       |
| ipv6-prefix        | x:x:x:x:x:x:x (eight 16-bit pieces)<br>x:x:x:x:x:d.d.d.d<br>x: [0 to FFFF]H<br>d: [0 to 255]D |
| ipv6-prefix-length | 0 to 128                                                                                      |

the ipv6-prefix and ipv6-prefix-length apply only to the 7750 SR and 7950 XRS

the mask associated with the network address expressed as a mask length

**Values:** 0 to 32

**summary-only** — This optional parameter suppresses advertisement of more specific component routes for the aggregate.

To remove the **summary-only** option, enter the same aggregate command without the **summary-only** parameter.

**as-set** — This optional parameter is only applicable to BGP and creates an aggregate where the path advertised for this route will be an AS\_SET consisting of all elements contained in all paths that are being summarized. Use this feature carefully as it can increase the amount of route churn due to best path changes.

**aggregator as-number:ip-address** — This optional parameter specifies the BGP aggregator path attribute to the aggregate route. When configuring the aggregator, a two-octet AS number used to form the aggregate route must be entered, followed by the IP address of the BGP system that created the aggregate route.

**community** *comm-id* — This configuration option associates a BGP community with the aggregate route. The community can be matched in route policies and is automatically added to BGP routes exported from the aggregate route.

|                 |                                              |
|-----------------|----------------------------------------------|
| <b>Values</b>   |                                              |
| comm-id         | asn:comm-val   well-known-comm               |
| asn             | 0 to 65535                                   |
| comm-val        | 0 to 65535                                   |
| well-known-comm | no-advertise, no-export, no-export-subconfed |

**black-hole** — This optional parameter installs the aggregate route, when activated, in the FIB with a black-hole next-hop; where packets matching this route are discarded.

**indirect ip-address** — This configuration option specifies that the aggregate route should be installed in the FIB with a next-hop taken from the route used to forward packets to ip-address.

|               |                                     |
|---------------|-------------------------------------|
| <b>Values</b> |                                     |
| ipv4-prefix   | a.b.c.d                             |
| ipv6-prefix   | x:x:x:x:x:x:x (eight 16-bit pieces) |
|               | x:x:x:x:x:d.d.d.d                   |
|               | x: [0 to FFFF]H                     |
|               | d: [0 to 255]D                      |

The ipv6-prefix applies only to the 7750 SR and 7950 XRS.

**description** *description-text* — specifies a text description stored in the configuration file for a configuration context

| <b>Description</b> | <p>This command causes the vrf-export and vrf-target functions of the VPRN to include BGP-VPN routes installed in the VPRN route table. For split-horizon reasons, these routes are normally not re-advertisable as VPN-IP routes.</p> <p>When a BGP-VPN route is re-exported, the route-distinguisher and label values are rewritten per the configuration of the re-exporting VPRN.</p> |

**Caution:** Ensure that routing updates do not loop back to the source when this command is used, otherwise the routes could become unstable.

---

**Default**    no allow-export-bgp-vprn

## auto-bind-tunnel

**Syntax**    **auto-bind-tunnel**

**Context**    config>service>vprn

**Description**    This command enables the context to configure automatic binding of a VPRN service using tunnels to MP-BGP peers.

The **auto-bind-tunnel** node is simply a context to configure the binding of VPRN routes to tunnels. The user must configure the **resolution** option to enable auto-bind resolution to tunnels in TTM. If the **resolution** option is explicitly set to **disabled**, the auto-binding to tunnel is removed.

If **resolution** is set to **any**, any supported tunnel type in VPRN context will be selected following TTM preference. If one or more explicit tunnel types are specified using the **resolution-filter** option, then only these tunnel types will be selected again following the TTM preference.

The following tunnel types are supported in a VPRN context in order of preference: RSVP, LDP, Segment Routing (SR), and GRE. The BGP tunnel type is not explicitly configured and is thus implicit. It is always preferred over any other tunnel type enabled in the **auto-bind-tunnel** context.

The **ldp** value instructs BGP to search for an LDP LSP with a FEC prefix corresponding to the address of the BGP next-hop.

The **rsvp** value instructs BGP to search for the best metric RSVP LSP to the address of the BGP next-hop. This address can correspond to the system interface or to another loopback used by the BGP instance on the remote node. The LSP metric is provided by MPLS in the tunnel table. In the case of multiple RSVP LSPs with the same lowest metric, BGP selects the LSP with the lowest tunnel-id.

When the **sr-isis (sr-ospf)** value is enabled, a SR tunnel to the BGP next-hop is selected in the TTM from the lowest numbered ISIS (OSPF) instance.

The **sr-te** value instructs BGP to search for the best metric SR-TE LSP to the address of the BGP next-hop. The LSP metric is provided by MPLS in the tunnel table. In the case of multiple SR-TE LSPs with the same lowest metric, BGP selects the LSP with the lowest tunnel-id.

The user must set **resolution** to **filter** to activate the list of tunnel-types configured under **resolution-filter**.

When an explicit SDP to a BGP next-hop is configured in a VPRN service (**configure>service>vprn>spoke-sdp**), it overrides the **auto-bind-tunnel** selection for that BGP next-hop only. There is no support for reverting automatically to the **auto-bind-tunnel** selection if the explicit SDP goes down. The user must delete the explicit spoke-sdp in the VPRN service context to resume using the **auto-bind-tunnel** selection for the BGP next-hop.

---

| <b>Context</b>     | config>service>vprn>auto-bind-tunnel                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Description</b> | <p>This command configures the subset of tunnel types which can be used in the resolution of VPRN prefixes within the automatic binding of VPRN service to tunnels to MP-BGP peers.</p> <p>The following tunnel types are supported in a VPRN context in order of preference: RSVP, LDP, Segment Routing (SR), and GRE. The BGP tunnel type is not explicitly configured and is thus implicit. It is always preferred over any other tunnel type enabled in the <b>auto-bind-tunnel</b> context.</p> |
| <b>Parameters</b>  | <b>gre</b> — selects the GRE tunnel type<br><b>ldp</b> — selects the LDP tunnel type<br><b>rsvp</b> — selects the RSVP-TE tunnel type<br><b>sr-isis</b> — selects the Segment Routing (SR) tunnel type programed by an IS-IS instance in TTM<br><b>sr-ospf</b> — selects the SR-OSPF tunnel type<br><b>sr-te</b> — selects the SR-TE tunnel type                                                                                                                                                     |

| <b>Description</b> | This command enables the computation and use of a backup path for IPv4 and/or IPv6 BGP-learned prefixes belonging to the base router or a particular VPRN. Multiple paths must be received for a prefix in order to take advantage of this feature. When a prefix has a backup path and its primary path(s) fail the affected traffic is rapidly diverted to the backup path without waiting for control plane re-convergence to occur. When many prefixes share the same primary path(s), and in some cases also the same backup path, the time to failover traffic to the backup path is independent of the number of prefixes. In some cases prefix independent convergence may require use of FP2 or later IOMs/IMMs/XMAs. |
|                    | By default, IPv4 and IPv6 prefixes do not have a backup path installed in the IOM.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <b>Default</b>     | no backup-path                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## carrier-carrier-vpn

|                    |                                                                                                                                                      |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] carrier-carrier-vpn</b>                                                                                                                      |
| <b>Context</b>     | config>service>vprn                                                                                                                                  |
| <b>Description</b> | This command configures a VPRN service to support a Carrier Supporting Carrier model. It should be configured on a network provider's CSC-PE device. |

This command cannot be applied to a VPRN unless it has no SAP or spoke-SDP interfaces. Once this command has been entered one or more MPLS-capable CSC interfaces can be created in the VPRN.

The **no** form of the command removes the Carrier Supporting Carrier capability from a VPRN.

**Default** no carrier-carrier-vpn

## confederation

**Syntax** **confederation** *confed-as-num* **members** *as-number* [*as-number...*(up to 15 max)]  
**no confederation** *confed-as-num* **members** *as-number* [*as-number...*(up to 15 max)]  
**no confederation**

**Context** config>service>vpn

**Description** This command configures the VPRN BGP instance to participate in a BGP confederation. BGP confederations can be used to reduce the number of IBGP sessions required within an AS.

When a VPRN BGP instance is part of a confederation, it can form confederation-EBGP sessions with CE router peers in a different sub-autonomous systems of the same confederation as well as regular EBGP sessions with CE router peers outside the confederation. A VPRN BGP instance that is part of a confederation cannot import or export its routes to the base router instance (as VPN-IP routes).

The **no** form of the command deletes the specified member AS from the confederation. When members are not specified in the no statement, the entire list is removed and confederations is disabled. When the last member of the list is removed, confederations is disabled.

**Default** No confederations are defined.

**Parameters** *confed-as-num* — the confederation AS number defined as a decimal value

**Values** 1 to 4294967295

**members** *as-number* — The AS number(s) that are members of the confederation, each expressed as a decimal integer. Configure up to 15 members per confed-as-num.

**Values** 1 to 4294967295

## dns

**Syntax** [**no**] dns

**Context** config>service>vpn

**Description** This command enables the context to configure domain name servers.

The **no** form of the command disables DNS for this service.

## ipv4-source-address

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Description</b> | <p>This command enables equal-cost multipath (ECMP) and configures the number of routes for path sharing. For example, the value of 2 means that 2 equal cost routes will be used for cost sharing.</p> <p>ECMP groups form when the system routes to the same destination with equal cost values. Routing table entries can be entered manually (as static routes), or they can be formed when neighbors are discovered and routing table information is exchanged by routing protocols. The system can balance traffic across the groups with equal costs.</p> <p>ECMP can only be used for routes learned with the same preference and same protocol. See the discussion on preferences in the <a href="#">application6</a> command.</p> |

When more ECMP routes are available at the best preference than configured by the `max-ecmp-routes` parameter, then the lowest next-hop IP address algorithm is used to select the number of routes configured.

The **no** form of the command disables ECMP path sharing. If ECMP is disabled and multiple routes are available at the best preference and equal cost, the newly updated route is used.

**Default** no ecmp

**Parameters** *max-ecmp-routes* — specifies the maximum number of routes for path sharing

**Values** 0 to 32

## export-grt

**Syntax** **export-grt** *plcy-or-long-expr* [*plcy-or-expr* [*plcy-or-expr*... (up to 4 max)]]  
**no export-grt**

**Context** config>service>vprn

**Description** This command is used to specify route policies that control how routes are exported from the local VRF route table to the base router (GRT) route table. The leaked routes show as protocol VPN-Leak in the GRT and allow traffic to ingress on a GRT interface and egress on a VPRN interface.

The **export-grt** command can reference up to 5 objects, where each object is either a policy logical expression or the name of a single policy. The objects are evaluated in the specified order to determine final action to accept or reject the route.

Only one of the 5 objects referenced by the **export-grt** command can be a policy logical expression consisting of policy names (enclosed in square brackets) and logical operators (AND, OR, NOT). The first of the 5 objects has a maximum length of 255 characters while the remaining 4 objects have a maximum length of 64 characters each.

When multiple **export-grt** commands are issued, the last command entered overrides the previous command.

The **no** form of the command removes all route policy names from the **export-grt** list.

**Default** no export-grt

**Parameters** *plcy-or-long-expr* — the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long)

*plcy-or-expr* — the route policy name (up to 64 characters long) or a policy logical expression (up to 255 characters long)

| <b>Context</b>     | config>service>vprn                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>Description</b> | <p>This command allows the best BGP route learned by a VPRN to be exported as a VPN-IP route even when that BGP route is inactive in the route table due to the presence of a preferred BGP-VPN route from another PE. In order for the BGP route to be exported, it must be accepted by the VRF export policy.</p> <p>This “best-external” type of route advertisement is useful in active/standby multi-homing scenarios because it can ensure that all PEs have knowledge of the backup path provided by the standby PE.</p> <p>By default, an inactive BGP route cannot be exported from a VPRN.</p> |
| <b>Default</b>     | no export-inactive-bgp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## fib-priority

|                    |                                                                                                                             |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>fib-priority {high   standard}</b>                                                                                       |
| <b>Context</b>     | config>service>vprn                                                                                                         |
| <b>Description</b> | This command specifies the FIB priority for VPRN.                                                                           |
| <b>Parameters</b>  | <p><b>high</b> — specifies high FIB priority for VPRN</p> <p><b>standard</b> — specifies standard FIB priority for VPRN</p> |

## flowspec

|                    |                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>flowspec</b>                                                                                               |
| <b>Context</b>     | config>service>vprn                                                                                           |
| <b>Description</b> | This command enables the context to configure flowspec-related parameters for the specified routing instance. |

## ip-filter-max-size

| <b>Syntax</b>  | <b>ip-filter-max-size {value   default}</b> |
| <b>Context</b> | config>service>vprn>flowspec                |

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | <p>This command configures the maximum number of flowspec routes or rules that can be embedded into an ingress IP filter policy for a specified routing instance. Flowspec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between the embedding offset and “offset + ip-filter-max-size – 1”.</p> <p>The sum of the <b>ip-filter-max-size</b> <i>value</i> parameter and the highest offset in any IPv4 filter that embeds IPv4 flowspec rules from this routing instance (excluding filters that embed at offset 65536) must not exceed 65536.</p> <p>The <b>ip-filter-max-size</b> configuration can be adjusted up or down at any time. If the number of IPv4 flowspec rules that are currently installed is <i>M</i>, and the new limit is <i>N</i>, where <math>N &lt; M</math>, then the last set of rules from <i>N</i> to <i>M</i> (by flowspec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.</p> |
| <b>Default</b>     | ip-filter-max-size default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| <b>Description</b> | <p>This command configures the maximum number of IPv6 flowspec routes or rules that can be embedded into an ingress IPv6 filter policy for a specified routing instance. Flowspec filter entries embedded in a filter policy in this routing instance will use filter entries from the range between the embedding offset and “offset + ip-filter-max-size – 1”.</p> <p>The sum of the <b>ip-filter-max-size</b> <i>value</i> parameter and the highest offset in any IPv6 filter that embeds IPv6 flowspec rules from this routing instance (excluding filters that embed at offset 65536) must not exceed 65536.</p> <p>The <b>ip-filter-max-size</b> configuration can be adjusted up or down at any time. If the number of IPv6 flowspec rules that are currently installed is <i>M</i>, and the new limit is <i>N</i>, where <math>N &lt; M</math>, then the last set of rules from <i>N</i> to <i>M</i> (by flowspec order) are immediately removed, but are retained in the BGP RIB. If the limit is increased, new rules are programmed only as they are received again in new BGP updates.</p> |
| <b>Default</b>     | ipv6-filter-max-size default                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| <b>Description</b> | <p>This command enables the functions required for looking up routes in the Global Route Table (GRT) when the lookup in the local VRF fails. If this command is enabled without the use of a <b>static-route</b> option (as subcommand to this parent), a lookup in the local VRF is preferred over the GRT. When the local VRF returns no route table lookup matches, the result from the GRT is preferred.</p> <p>The <b>no</b> form of this command disables the lookup in the GRT when the lookup in the local VRF fails.</p> |
| <b>Default</b>     | no enable-grt                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| <b>Description</b> | <p>Enables the support of specific management protocols over VPRN interfaces that terminate on Base routing context IPv4 and IPv6 interface addresses, including Base loopback and system addresses. Global Routing Table (GRT) leaking is used to enable visibility/access of the Base interface addresses in the VPRN. The supported protocols are Telnet, FTP, SNMP, and SSH (including applications that ride over SSH such as scp, sftp, and NETCONF).</p> <p>Ping and traceroute responses from the Base router interfaces are supported and are not configurable.</p> |

The **allow-local-management** command does not control the support for management protocols terminating on VPRN interfaces directly. See the **configure>service>vprn>snmp>access** CLI command for SNMP support on VPRN interface addresses.

Configuring a range of 1-1000 will limit the number of routes to the specified value.</p> <p>The <b>no</b> form of the command sets the export-limit to a default of 5.</p> |
| <b>Default</b>     | export-v6-limit 5                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>num-routes</i> — specifies maximum number of routes that can be exported                                                                                                                                                                                                                                                                                                                                                                                                 |
| <b>Values</b>      | 0 to 1000                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## gsmp

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>gsmp</b>                                                                                |
| <b>Context</b>     | config>service>vprn                                                                        |
| <b>Description</b> | This command enables the context to configure GSMP connections maintained in this service. |
| <b>Default</b>     | not enabled                                                                                |

## group

|                    |                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] group</b> <i>name</i>                                                                                                |
| <b>Context</b>     | config>service>vprn>gsmp                                                                                                     |
| <b>Description</b> | This command specifies a GSMP name. A GSMP group name is unique only within the scope of the service in which it is defined. |
| <b>Parameters</b>  | <i>name</i> — specifies the group name up to 32 characters in length                                                         |

## ancp

|                    |                                                              |
|--------------------|--------------------------------------------------------------|
| <b>Syntax</b>      | <b>ancp</b>                                                  |
| <b>Context</b>     | config>service>vprn>gsmp>group                               |
| <b>Description</b> | This command configures ANCP parameters for this GSMP group. |

## dynamic-topology-discover

|                    |                                                                                                                                      |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] dynamic-topology-discover</b>                                                                                                |
| <b>Context</b>     | config>service>vprn>gsmp>group>ancp                                                                                                  |
| <b>Description</b> | This command enables the ANCP dynamic topology discovery capability.<br><br>The <b>no</b> form of this command disables the feature. |

## oam

|                    |                                                                                                                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] oam</b>                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>gsmp>group>ancp                                                                                                                                                        |
| <b>Description</b> | This command specifies whether or not the GSMP ANCP OAM capability should be negotiated at startup of the GSMP connection.<br><br>The <b>no</b> form of this command disables the feature. |

## hold-multiplier

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hold-multiplier</b> <i>multiplier</i><br><b>no hold-multiplier</b>                      |
| <b>Context</b>     | config>service>vprn>gsmp>group                                                             |
| <b>Description</b> | This command configures the hold-multiplier for the GSMP connections in this group.        |
| <b>Parameters</b>  | <i>multiplier</i> — specifies the GSMP hold multiplier value<br><br><b>Values</b> 1 to 100 |

## idle-filter

|                    |                                                                                                                      |
|--------------------|----------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>idle-filter</b><br><b>no idle-filter</b>                                                                          |
| <b>Context</b>     | config>service>vpls>gsmp<br>config>service>vprn>gsmp                                                                 |
| <b>Description</b> | This command when applied will filter out new subscriber's ANCP messages from subscriber with "DSL-line-state" IDLE. |
| <b>Default</b>     | no idle-filter                                                                                                       |

## keepalive

|                    |                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>keepalive</b> <i>seconds</i><br><b>no keepalive</b>                                        |
| <b>Context</b>     | config>service>vprn>gsmp>group                                                                |
| <b>Description</b> | This command configures keepalive values for the GSMP connections in this group.              |
| <b>Parameters</b>  | <i>seconds</i> — specifies the GSMP keepalive timer value in seconds<br><b>Values</b> 1 to 25 |

## neighbor

|                    |                                                                         |
|--------------------|-------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] neighbor</b> <i>ip-address</i>                                  |
| <b>Context</b>     | config>service>vprn>gsmp>group                                          |
| <b>Description</b> | This command adds or removes a neighbor in this group.                  |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP address in dotted decimal notation |

## local-address

|                    |                                                                                            |
|--------------------|--------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-address</b> <i>ip-address</i><br><b>no local-address</b>                          |
| <b>Context</b>     | config>service>vprn>gsmp>group>neighbor                                                    |
| <b>Description</b> | This command configures the source ip-address used in the connection towards the neighbor. |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP address in dotted decimal notation                    |

## priority-marking

|                    |                                                                                                                                  |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>priority-marking dscp</b> <i>dscp-name</i><br><b>priority-marking prec</b> <i>ip-prec-value</i><br><b>no priority-marking</b> |
| <b>Context</b>     | config>service>vprn>gsmp>group>neighbor                                                                                          |
| <b>Description</b> | This command configures the type of priority marking to be used.                                                                 |

---

|                   |                                                                                                                                                                                                                                                                                                                                                                             |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>dscp dscp-name</i> — specifies the DSCP code-point to be used                                                                                                                                                                                                                                                                                                            |
| <b>Values</b>     | be, cp1, cp2, cp3, cp4, cp5, cp6, cp7, cs1, cp9, af11, cp11, af12, cp13, af13, cp15, cs2, cp17, af21, cp19, af22, cp21, af23, cp23, cs3, cp25, af31, cp27, af32, cp29, af33, cp31, cs4, cp33, af41, cp35, af42, cp37, af43, cp39, cs5, cp41, cp42, cp43, cp44, cp45, ef, cp47, nc1, cp49, cp50, cp51, cp52, cp53, cp54, cp55, nc2, cp57, cp58, cp59, cp60, cp61, cp62, cp63 |
|                   | <i>prec ip-prec-value</i> — specifies the precedence value to be used                                                                                                                                                                                                                                                                                                       |
| <b>Values</b>     | 0 to 7                                                                                                                                                                                                                                                                                                                                                                      |

|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>persistency-database</b><br><b>no persistency-database</b>                                                                                                                                                       |
| <b>Context</b>     | config>service>vpls <service id>gsmp<br>config>service>vprn<service id>gsmp                                                                                                                                         |
| <b>Description</b> | This command enables the system to store DSL line information in memory. If the GSMP connection terminates, the DSL line information will remain in memory and accessible for Radius authentication and accounting. |
| <b>Default</b>     | no persistency-database                                                                                                                                                                                             |

### 3.9.2.3 Router L2TP Commands

## l2tp

|                    |                                                                                                                                                                                                             |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>l2tp</b><br><b>no l2tp</b>                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn                                                                                                                                                                                         |
| <b>Description</b> | This command enables the context to configure L2TP parameters. L2TP extends the PPP model by allowing Layer 2 and PPP endpoints to reside on different devices interconnected by a packet-switched network. |

## avp-hiding

|               |                                                                            |
|---------------|----------------------------------------------------------------------------|
| <b>Syntax</b> | <b>avp-hiding</b> <i>sensitive</i>   <i>always</i><br><b>no avp-hiding</b> |
|---------------|----------------------------------------------------------------------------|

---

|                    |                                                                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                                                                                                                                                                                          |
| <b>Description</b> | <p>This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as clear text in an AVP.</p> <p>The <b>no</b> form of the command returns the value to <b>never</b> allow AVP hiding.</p>                                               |
| <b>Default</b>     | no avp-hiding                                                                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <p><i>avp-hiding</i> — Specifies the method to be used for the authentication of the tunnels in this L2TP group.</p> <p><b>Values</b></p> <ul style="list-style-type: none"> <li>sensitive — AVP hiding is used only for sensitive information (such as username/password)</li> <li>always — AVP hiding is always used</li> </ul> |

## calling-number-format

|                    |                                                                                                                                           |                    |                                                                  |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>calling-number-format</b> <i>ascii-spec</i><br><b>no calling-number-format</b>                                                         |                    |                                                                  |
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                  |                    |                                                                  |
| <b>Description</b> | This command what string to put in the Calling Number AVP, for L2TP control messages related to a session in this L2TP protocol instance. |                    |                                                                  |
| <b>Parameters</b>  | <i>ascii-spec</i> — specifies the L2TP calling number AVP                                                                                 |                    |                                                                  |
|                    | <b>Values</b>                                                                                                                             |                    |                                                                  |
|                    | ascii-spec                                                                                                                                | char-specification | ascii-spec                                                       |
|                    |                                                                                                                                           | char-specification | ascii-char   char-origin                                         |
|                    |                                                                                                                                           | ascii-char         | a printable ASCII character                                      |
|                    |                                                                                                                                           | char-origin        | %origin                                                          |
|                    | origin                                                                                                                                    | S   c   r   s   l  |                                                                  |
|                    |                                                                                                                                           | S                  | - system name, the value of TIMETRA-CHASSIS-MIB::tmnxChassisName |
|                    |                                                                                                                                           | c                  | - Agent Circuit Id                                               |
|                    |                                                                                                                                           | r                  | - Agent Remote Id                                                |
|                    |                                                                                                                                           | s                  | - SAP ID, formatted as a character string                        |
|                    |                                                                                                                                           | l                  | - Logical Line ID                                                |

## challenge

|               |                                                          |
|---------------|----------------------------------------------------------|
| <b>Syntax</b> | <b>challenge</b> {always   never}<br><b>no challenge</b> |
|---------------|----------------------------------------------------------|

|                    |                                                                                                                                                                    |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                           |
| <b>Description</b> | This command configures the use of challenge-response authentication.<br><br>The <b>no</b> form of the command reverts to the default <b>never</b> value.          |
| <b>Default</b>     | no challenge                                                                                                                                                       |
| <b>Parameters</b>  | <b>always</b> — Specifies that challenge-response authentication is always used.<br><b>never</b> — Specifies that challenge-response authentication is never used. |

## destruct-timeout

|                    |                                                                                                                                                                                                         |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>destruct-timeout</b> <i>destruct-timeout</i><br><b>no destruct-timeout</b>                                                                                                                           |
| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                                                                |
| <b>Description</b> | This command configures the period of time that the data of a disconnected tunnel will persist before being removed.<br><br>The <b>no</b> form of the command removes the value from the configuration. |
| <b>Default</b>     | no destruct-timeout                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>destruct-timeout</i> — specifies the automatic removal of dynamic L2TP sessions, in seconds, that are no longer active<br><br><b>Default</b> no destruct-timeout<br><b>Values</b> 60 to 86400        |

## exclude-avps

|                    |                                                                     |
|--------------------|---------------------------------------------------------------------|
| <b>Syntax</b>      | <b>exclude-avps</b> <i>calling-number</i><br><b>no exclude-avps</b> |
| <b>Context</b>     | config>service>vprn>l2tp                                            |
| <b>Description</b> | This command configures the L2TP AVPs to exclude.                   |

## ipcp-subnet-negotiation

|                |                                                                                                           |
|----------------|-----------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>[no] ipcp-subnet-negotiation</b>                                                                       |
| <b>Context</b> | config>router>l2tp>group>ppp<br>config>router>l2tp>group>tunnel>ppp<br>config>service>vprn>l2tp>group>ppp |

```
config>service>vprn>l2tp>group>tunnel>ppp
```

**Description** Enables IPCP negotiation for PPPoE hosts. If not enabled (default setting), the current behavior will apply even if subnet is allocated to the host. Enables IPCP negotiation for PPPoE hosts. If not enabled (default setting), the current behavior will apply even if subnet is allocated in the host.

## peer-address-change-policy

**Syntax** **peer-address-change-policy** {**accept** | **ignore** | **reject**}

**Context** config>service>vprn>l2tp

**Description** This command configures the reaction to a change of tunnel peer address in this router.

## receive-window-size

**Syntax** **receive-window-size** *window-size*  
**no receive-window-size**

**Context** config>service>vprn>l2tp

**Description** This command configures the L2TP receive window size.

**Parameters** *window-size* — specifies the window size

**Values** 4 to 1024

## session-limit

**Syntax** **session-limit** *session-limit*  
**no session-limit**

**Context** config>service>vprn>l2tp

**Description** This command configures the L2TP session limit of this router.

**Parameters** *session-limit* — specifies the session limit

**Values** 1 to 131071

## group

**Syntax** **group** *tunnel-group-name* [**create**]  
**no group** *tunnel-group-name*

**Context** config>service>vprn>l2tp

---

|                    |                                                                                                                                                                                                                                                                                                          |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command configures an L2TP tunnel group.                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>tunnel-group-name</i> — specifies a name string to identify a L2TP group up to 63 characters in length<br><br><b>create</b> — This keyword is mandatory when creating a tunnel group name. The <b>create</b> keyword requirement can be enabled/disabled in the <b>environment&gt;create</b> context. |

## session-limit

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

| <b>Context</b>     | config>service>vprn>l2tp                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command configures the L2TP session limit for the router. L2TP is connection-oriented. The L2TP Network Server (LNS) and LAC maintain state for each call that is initiated or answered by an LAC. An L2TP session is created between the LAC and LNS when an end-to-end PPP connection is established between a remote system and the LNS. Datagrams related to the PPP connection are sent over the tunnel between the LAC and LNS. There is a one to one relationship between established L2TP sessions and their associated calls. |
| <b>Default</b>     | no session-limit                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| <b>Parameters</b>  | <i>session-limit</i> — specifies the number of sessions allowed<br><br><b>Values</b> 1 to 131071                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## avp-hiding

|                    |                                                                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>avp-hiding</b> <i>sensitive</i>   <i>always</i><br><b>no avp-hiding</b>                                                                                                                                                                                                      |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as clear text in an AVP.<br><br>The <b>no</b> form of the command returns the value to <b>never</b> allow AVP hiding.    |
| <b>Default</b>     | no avp-hiding                                                                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>avp-hiding</i> — specifies the method to be used for the authentication of the tunnels in this L2TP group<br><br><b>Values</b> <i>sensitive</i> — AVP hiding is used only for sensitive information (such as username/password)<br><i>always</i> — AVP hiding is always used |

| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                                                                                               |
| <b>Description</b> | This command configures the time interval between two consecutive tunnel Hello messages. The Hello message is an L2TP control message sent by either peer of a LAC-LNS control connection. This control message is used as a keepalive for the tunnel.<br><br>The <b>no</b> form of the command removes the interval from the configuration. |

---

|                   |                                                                                                                |
|-------------------|----------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no hello-interval                                                                                              |
| <b>Parameters</b> | <i>hello-interval</i> — specifies the time interval, in seconds, between two consecutive tunnel Hello messages |
| <b>Values</b>     | 60 to 3600                                                                                                     |
| <b>Default</b>    | 60                                                                                                             |

## idle-timeout

|                    |                                                                                                                                                                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>idle-timeout</b> <i>idle-timeout</i><br><b>no idle-timeout</b>                                                                                                                                                                                                                                               |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the period of time that an established tunnel with no active sessions will persist before being disconnected.<br><br>Enter the <b>no</b> form of the command to maintain a persistent tunnel.<br><br>The <b>no</b> form of the command removes the idle timeout from the configuration. |
| <b>Default</b>     | no idle-timeout                                                                                                                                                                                                                                                                                                 |
| <b>Parameters</b>  | <i>idle-timeout</i> — specifies the idle timeout value, in seconds until the group is removed                                                                                                                                                                                                                   |
| <b>Values</b>      | 0 to 3600                                                                                                                                                                                                                                                                                                       |

## l2tpv3

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>l2tpv3</b>                                                    |
| <b>Context</b>     | config>service>vprn>l2tp<br>config>service>vprn>l2tp>group       |
| <b>Description</b> | This command enables the context to configure L2TPv3 parameters. |
| <b>Default</b>     | n/a                                                              |

## cookie-length

|                    |                                                                          |
|--------------------|--------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>cookie-length</b> {4   8   none}<br><b>no cookie-length</b>           |
| <b>Context</b>     | config>service>vprn>l2tp>l2tpv3<br>config>service>vprn>l2tp>group>l2tpv3 |
| <b>Description</b> | This command configures the length of the optional cookie field.         |

The **no** form of the command returns the **cookie-length** to a default of **none**.

|                   |                                                                                                                                                                           |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Default</b>    | no cookie-length                                                                                                                                                          |
| <b>Parameters</b> | <b>4</b> — Specifies the cookie length as 4 bytes<br><b>8</b> — Specifies the cookie length as 8 bytes<br><b>none</b> — Specifies that no cookie field should be included |

## digest-type

|                    |                                                                                                                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>digest-type {none   md5   sha1}</b><br><b>no digest-type</b>                                                                                                                         |
| <b>Context</b>     | config>service>vprn>l2tp>l2tpv3<br>config>service>vprn>l2tp>group>l2tpv3                                                                                                                |
| <b>Description</b> | This command configures the hashing algorithm used to calculate the message digest.<br><br>The <b>no</b> form of the command returns the <b>digest-type</b> to <b>none</b> .            |
| <b>Default</b>     | no digest-type                                                                                                                                                                          |
| <b>Parameters</b>  | <b>none</b> — Specifies that no digest should be used<br><b>md5</b> — Specifies that the MD5 algorithm should be used<br><b>sha1</b> — Specifies that the SHA1 algorithm should be used |

## nonce-length

|                    |                                                                                                                                                                                                                   |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>nonce-length {length   none}</b><br><b>no nonce-length</b>                                                                                                                                                     |
| <b>Context</b>     | config>service>vprn>l2tp>l2tpv3<br>config>service>vprn>l2tp>group>l2tpv3                                                                                                                                          |
| <b>Description</b> | This command configures the length for the local L2TPv3 nonce (random number) value used in the Nonce AVP.<br><br>The <b>no</b> form of the command returns the <b>nonce-length</b> to a default of <b>none</b> . |
| <b>Default</b>     | no nonce-length                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>length</i> — Specifies the length of the Nonce AVP value<br><br><b>Values</b> 16 to 64<br><br><b>none</b> — Specifies that no Nonce AVP is included                                                            |

## rem-router-id

|                    |                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rem-router-id</b> <i>ip-addr</i><br><b>no rem-router-id</b>                                                                                                                  |
| <b>Context</b>     | config>service>vprn>l2tp>group>l2tpv3                                                                                                                                           |
| <b>Description</b> | <p>This command configures the IP address that should be used within the Remote Router-ID AVP.</p> <p>The <b>no</b> form of this command removes the configured IP address.</p> |
| <b>Default</b>     | no rem-router-id                                                                                                                                                                |
| <b>Parameters</b>  | <i>ip-addr</i> — Specifies an IP address to be used within the Remote Router-ID AVP                                                                                             |

## pw-cap-list

|                    |                                                                                                                                                                                                                                                                                                           |

| <b>Syntax</b>      | <b>[no] track-password-change</b>                                                                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>l2tp>group>l2tpv3                                                                                                                                                                                                                                        |
| <b>Description</b> | <p>This command enables tracking of password changes, allowing password tunnel passwords to be changed without bringing down active tunnels or sessions. This is only supported with L2TPv3.</p> <p>The <b>no</b> form of the command disables password change tracking.</p> |
| <b>Default</b>     | no track-password-change                                                                                                                                                                                                                                                     |

## transport-type

|                    |                                                                                                                                                                                                                                |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>transport-type ip</b><br><b>no transport-type</b>                                                                                                                                                                           |
| <b>Context</b>     | config>service>vprn>l2tp>l2tpv3<br>config>service>vprn>l2tp>group>l2tpv3                                                                                                                                                       |
| <b>Description</b> | This command configures the transport type to be used to carry the L2TPv3 tunnel. Currently, only IP transport is supported.<br><br>The <b>no</b> form of this command returns the <b>transport-type</b> to the default value. |
| <b>Default</b>     | no transport-type                                                                                                                                                                                                              |
| <b>Parameters</b>  | <b>ip</b> — Specifies that IP should be used as the transport type for the L2TPv3 tunnel                                                                                                                                       |

## lns-group

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>lns-group</b> <i>lns-group-id</i><br><b>no lns-group</b>                  |
| <b>Context</b>     | config>service>vprn>l2tp>group                                               |
| <b>Description</b> | This command configures the ISA LNS group.                                   |
| <b>Parameters</b>  | <i>lns-group-id</i> — specifies the LNS group ID<br><br><b>Values</b> 1 to 4 |

## local-address

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-address</b> <i>ip-address</i><br><b>no local-address</b>            |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                        |
| <b>Description</b> | This command configures the local address.                                   |
| <b>Parameters</b>  | <i>ip-address</i> — specifies the IP address used during L2TP authentication |

## local-name

|                |                                                                         |
|----------------|-------------------------------------------------------------------------|
| <b>Syntax</b>  | <b>local-name</b> <i>host-name</i><br><b>no local-name</b>              |
| <b>Context</b> | config>service>vprn>l2tp>group<br>config>service>vprn>l2tp>group>tunnel |

---

|                    |                                                                                                                                                                                                                                                                                   |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command creates the local host name used by this system for the tunnels in this L2TP group during the authentication phase of tunnel establishment. It can be used to distinguish tunnels.<br><br>The <b>no</b> form of the command removes the name from the configuration. |
| <b>Default</b>     | no local-name                                                                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>host-name</i> — specifies the host name, up to 64 characters in length, that the router will use to identify itself during L2TP authentication                                                                                                                                 |

## max-retries-estab

|                    |                                                                                                                                                                                                                                 |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>max-retries-estab</b> <i>max-retries</i><br><b>no max-retries-estab</b>                                                                                                                                                      |

| <b>Description</b> | This command configures the password between L2TP LAC and LNS<br><br>The <b>no</b> form of the command removes the password.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| <b>Default</b>     | no password                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>password</i> — Configures the password used for challenge/response calculation and AVP hiding. The maximum length can be up to 20 characters if unhashed, 32 characters if hashed, 54 characters if the hash2 keyword is specified.<br><br><b>hash</b> — Specifies the key is entered in an encrypted form. If the <b>hash</b> or <b>hash2</b> parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> or <b>hash2</b> parameter specified<br><br><b>hash2</b> — Specifies the key is entered in a more complex encrypted form that involves more variables than the key value alone, meaning that the <b>hash2</b> encrypted variable cannot be copied and pasted. If the <b>hash</b> or <b>hash2</b> parameter is not used, the key is assumed to be in an unencrypted, clear text form. For security, all keys are stored in encrypted form in the configuration file with the <b>hash</b> or <b>hash2</b> parameter specified. |

## ppp

|                    |                                                        |
|--------------------|--------------------------------------------------------|
| <b>Syntax</b>      | <b>ppp</b>                                             |
| <b>Context</b>     | config>service>vprn>l2tp>group                         |
| <b>Description</b> | This command configures PPP for the L2TP tunnel group. |

## authentication

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication</b> { <b>chap</b>   <b>pap</b>   <b>pref-chap</b>   <b>pref-pap</b> } |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                      |
| <b>Description</b> | This command configures the PPP authentication protocol to negotiate.                   |

## authentication-policy

|                    |                                                                                                  |
|--------------------|--------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>authentication-policy</b> <i>auth-policy-name</i><br><b>no authentication-policy</b>          |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                               |
| <b>Description</b> | This command configures the authentication policy.                                               |
| <b>Parameters</b>  | <i>auth-policy-name</i> — specifies the authentication policy name<br><b>Values</b> 32 chars max |

## default-group-interface

|                    |                                                                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>default-group-interface</b> <i>ip-int-name</i> <b>service-id</b> <i>service-id</i><br><b>no default-group-interface</b>                                                                                                                                             |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                                                                                                                                                                                                     |
| <b>Description</b> | This command configures the default group interface.                                                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>ip-int-name</i> — specifies the interface name<br><b>Values</b> 32 chars max<br><i>service-id</i> — specifies the service ID<br><b>Values</b> 1 to 2147483648<br><i>svc-name</i> — specifies the service name (instead of service ID)<br><b>Values</b> 64 chars max |

## keepalive

|                    |                                                                                                                                                       |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>keepalive</b> <i>seconds</i> [ <b>hold-up-multiplier</b> <i>multiplier</i> ]<br><b>no keepalive</b>                                                |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                                                                                    |
| <b>Description</b> | This command configures the PPP keepalive interval and multiplier.                                                                                    |
| <b>Parameters</b>  | <i>seconds</i> — specifies in seconds the interval<br><b>Values</b> 10 to 300<br><i>multiplier</i> — specifies the multiplier<br><b>Values</b> 1 to 5 |

## mtu

|                    |                                                                  |
|--------------------|------------------------------------------------------------------|
| <b>Syntax</b>      | <b>mtu</b> <i>mtu-bytes</i><br><b>no mtu</b>                     |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                               |
| <b>Description</b> | This command configures the maximum PPP MTU size.                |
| <b>Parameters</b>  | <i>mtu-bytes</i> — specifies, in bytes, the maximum PPP MTU size |
| <b>Values</b>      | 512 to 9212                                                      |

## proxy-authentication

|                    |                                                                                   |
|--------------------|-----------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-authentication</b>                                                  |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                |
| <b>Description</b> | This command configures the use of the authentication AVPs received from the LAC. |

## proxy-lcp

|                    |                                                                              |
|--------------------|------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] proxy-lcp</b>                                                        |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                           |
| <b>Description</b> | This command configures the use of the proxy LCP AVPs received from the LAC. |

## user-db

|                    |                                                                                         |
|--------------------|-----------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>user-db</b> <i>local-user-db-name</i><br><b>no user-db</b>                           |
| <b>Context</b>     | config>service>vprn>l2tp>group>ppp                                                      |
| <b>Description</b> | This command configures the local user database to use for PPP PAP/CHAP authentication. |
| <b>Parameters</b>  | <i>local-user-db-name</i> — specifies the local user database name                      |
| <b>Values</b>      | 32 chars max                                                                            |

## session-assign-method

|               |                                                                                                               |
|---------------|---------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b> | <b>session-assign-method</b> {existing-first   weighted   weighted-random}<br><b>no session-assign-method</b> |
|---------------|---------------------------------------------------------------------------------------------------------------|

---

|                    |                                                                                                                                                                                                                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                                                                                                    |
| <b>Description</b> | This command specifies how new sessions are assigned to one of the set of suitable tunnels that are available or could be made available.                                                                                                                                                                                                         |
| <b>Default</b>     | session-assign-method existing-first                                                                                                                                                                                                                                                                                                              |
| <b>Parameters</b>  | <b>existing-first</b> — All new sessions are placed by preference in existing tunnels<br><b>weighted</b> — Enables weighted preference to tunnels in the group<br><b>weighted-random</b> — Enhances the weighted algorithm so that when there are multiple tunnels with an equal number of sessions (equal weight), LAC randomly selects a tunnel |

## session-limit

|                    |                                                                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>session-limit</b> <i>session-limit</i><br><b>no session-limit</b>                                                                                                                                                                   |
| <b>Context</b>     | config>service>vprn>l2tp>group<br>config>service>vprn>l2tp>group>tunnel                                                                                                                                                                |
| <b>Description</b> | <p>This command configures the session limit. The value controls how many L2TP session will be allowed within a given context (system, group, tunnel).</p> <p>The no form of the command removes the value from the configuration.</p> |
| <b>Default</b>     | no session-limit                                                                                                                                                                                                                       |
| <b>Parameters</b>  | <i>session-limit</i> — specifies the allowed number of sessions within the given context<br><b>Values</b> 1 to 131071                                                                                                                  |

### 3.9.2.3.1 Router L2TP Tunnel Commands

## tunnel

|                    |                                                                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>tunnel</b> <i>tunnel-name</i> [create]<br><b>no tunnel</b> <i>tunnel-name</i>                                                                                                                                                                                          |
| <b>Context</b>     | config>service>vprn>l2tp>group                                                                                                                                                                                                                                            |
| <b>Description</b> | This command configures an L2TP tunnel. A tunnel exists between a LAC-LNS pair and consists of a Control Connection and zero or more L2TP sessions. The tunnel carries encapsulated PPP datagrams and control messages between the LAC and the L2TP Network Server (LNS). |

**Parameters** *tunnel-name* — specifies a valid string to identify a L2TP up to 32 characters in length  
**create** — mandatory while creating a new tunnel

## auto-establish

**Syntax** **[no] auto-establish**  
**Context** config>service>vprn>l2tp>group>tunnel  
**Description** This command specifies if this tunnel is to be automatically set up by the system.  
**Default** no auto-establish

## avp-hiding

**Syntax** **avp-hiding {never | sensitive | always}**  
**no avp-hiding**  
**Context** config>service>vprn>l2tp>group>tunnel  
**Description** This command configures Attribute Value Pair (AVP) hiding. This capability can be used to avoid the passing of sensitive data, such as user passwords, as clear text in an AVP.

**Caution:** Nokia recommends that sensitive information not be sent in clear text.

The **no** form of the command removes the parameter of the configuration and indicates that the value on group level will be taken.

**Default** no avp-hiding  
**Parameters** *avp-hiding* — specifies the method to be used for the authentication of the tunnel  
**Values** never — AVP hiding is not used  
sensitive — AVP hiding is used only for sensitive information (such as username/password)  
always — AVP hiding is always used

## challenge

**Syntax** **challenge {always | never}**  
**no challenge**  
**Context** config>service>vprn>l2tp>group>tunnel

---

|                    |                                                                                                                                                                                                                        |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Description</b> | This command configures the use of challenge-response authentication.<br><br>The <b>no</b> form of the command removes the parameter from the configuration and indicates that the value on group level will be taken. |
| <b>Default</b>     | no challenge                                                                                                                                                                                                           |
| <b>Parameters</b>  | <b>always</b> — Specifies that challenge-response authentication should always be used for the tunnel.<br><br><b>never</b> — Specifies that challenge-response authentication should never be used for the tunnel      |

## hello-interval

|                    |                                                                                                                                                                                                                           |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>hello-interval</b> <i>hello-interval</i><br><b>hello-interval infinite</b><br><b>no hello-interval</b>                                                                                                                 |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                                     |
| <b>Description</b> | This command configures the number of seconds between sending Hellos for a L2TP tunnel.<br><br>The <b>no</b> form removes the parameter from the configuration and indicates that the value on group level will be taken. |
| <b>Parameters</b>  | <i>hello-interval</i> — specifies the time interval, in seconds, between two consecutive tunnel Hello messages<br><br><b>Values</b> 60 to 3600<br><br><b>infinite</b> — specifies that no Hello messages are sent         |

## idle-timeout

|                    |                                                                                                                                                                                                                                    |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>idle-timeout</b> <i>idle-timeout</i><br><b>idle-timeout infinite</b><br><b>no idle-timeout</b>                                                                                                                                  |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                                              |
| <b>Description</b> | This command configures the idle timeout to wait before being disconnect.<br><br>The <b>no</b> form indicates that the parameter will be removed from the configuration and that the value specified on group level will be taken. |
| <b>Parameters</b>  | <i>idle-timeout</i> — specifies the idle timeout, in seconds<br><br><b>Values</b> 0 to 3600<br><br><b>infinite</b> — specifies that the tunnel will not be closed when idle                                                        |

## peer

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>peer</b> <i>ip-address</i><br><b>no peer</b>                                                                                          |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                    |
| <b>Description</b> | This command configures the peer address.<br><br>The <b>no</b> form of the command removes the IP address from the tunnel configuration. |
| <b>Default</b>     | no peer                                                                                                                                  |
| <b>Parameters</b>  | <i>ip-address</i> — sets the LNS IP address for the tunnel                                                                               |

## preference

|                    |                                                                                                                                                                                                                                                        |
|--------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>preference</b> <i>preference</i><br><b>no preference</b>                                                                                                                                                                                            |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                                                                                                                                  |
| <b>Description</b> | This command configures a preference number that indicates the relative preference assigned to a tunnel when using a weighted session assignment.<br><br>The <b>no</b> form of the command removes the preference value from the tunnel configuration. |
| <b>Default</b>     | no preference                                                                                                                                                                                                                                          |
| <b>Parameters</b>  | <i>preference</i> — specifies the tunnel preference number with its group. The value 0 corresponds to the highest preference<br><br><b>Values</b> 0 to 16777215                                                                                        |

## remote-name

|                    |                                                                                                                                                   |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>remote-name</b> <i>host-name</i><br><b>no remote-name</b>                                                                                      |
| <b>Context</b>     | config>service>vprn>l2tp>group>tunnel                                                                                                             |
| <b>Description</b> | This command configures a string to be compared to the host name used by the tunnel peer during the authentication phase of tunnel establishment. |
| <b>Parameters</b>  | <i>host-name</i> — specifies a remote host name for the tunnel up to 64 characters in length                                                      |

### 3.9.2.4 Router DHCP Configuration Commands

#### dhcp

|                    |                                                                |
|--------------------|----------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp</b>                                                    |
| <b>Context</b>     | config>service>vprn                                            |
| <b>Description</b> | This command enables the context to configure DHCP parameters. |

#### dhcp6

|                    |                                                                 |
|--------------------|-----------------------------------------------------------------|
| <b>Syntax</b>      | <b>dhcp6</b>                                                    |
| <b>Context</b>     | config>service>vprn                                             |
| <b>Description</b> | This command enables the context to configure DHCP6 parameters. |

#### local-dhcp-server

|                    |                                                                                                                                                                                                                         |
|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>local-dhcp-server</b> <i>server-name</i> [ <b>create</b> ]<br><b>no local-dhcp-server</b> <i>server-name</i>                                                                                                         |
| <b>Context</b>     | config>service>vprn>dhcp<br>config>service>vprn>dhcp6<br>config>service>vprn>if<br>config>service>vprn>nw-if                                                                                                            |
| <b>Description</b> | This command instantiates a local DHCP server. A local DHCP server can serve multiple interfaces but is limited to the routing context it was which it was created.                                                     |
| <b>Default</b>     | n/a                                                                                                                                                                                                                     |
| <b>Parameters</b>  | <i>server-name</i> — specifies the name of local DHCP server<br><b>create</b> — Creates the server name. The <b>create</b> keyword requirement can be enabled/<br>disabled in the <b>environment&gt;create</b> context. |

#### failover

|                    |                                                                    |
|--------------------|--------------------------------------------------------------------|
| <b>Syntax</b>      | <b>failover</b>                                                    |
| <b>Context</b>     | config>service>vprn>dhcp                                           |
| <b>Description</b> | This command enables the context to configure failover parameters. |

---

## ignore-mclt-on-takeover

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| <b>Description</b> | <p>With this flag enabled, the 'remote' IP address/prefix can be taken over immediately upon entering the PARTNER-DOWN state of the intercommunication link, without having to wait for the MCLT to expire. By setting this flag, the lease times of the existing DHCP clients, while the intercommunication link is in the PARTNER-DOWN state, will still be reduced to the MCLT over time and all new lease times will be set to MCLT ? this behavior remain the same as originally intended for MCLT.</p> <p>Some deployments require that the 'remote' IP address/prefix range starts delegating new IP addresses/prefixes upon the failure of the intercommunication link, without waiting for the intercommunication link to transition from the COMM-INT state into the PARTNER-DOWN state and the MCLT to expire while in PARTNER-DOWN state.</p> <p>This can be achieved by enabling the ignore-mclt-on-takeover flag and by configuring the partner-down-delay to 0.</p> <p>Enabling this functionality must be exercised with caution. One needs to keep in mind that the partner-down-delay and MCLT timers were originally introduced to prevent IP address duplication in cases where DHCP redundant nodes transition out-of-sync due to the failure of intercommunication link. These timers (partner-down-delay and MCLT) would ensure that during their duration, the new IP addresses/prefixes are delegated only from one node – the one with local IP address-range/prefix. The drawback is of course that the new IP address delegation is delayed and thus service is impacted.</p> <p>But if one could ensure that the intercommunication link is always available, then the DHCP nodes would stay in sync and the two timers would not be needed. This is why it is of utmost importance that in this mode of operation, the intercommunication link is well protected by providing multiple paths between the two DHCP nodes. The only event that should cause intercommunication link to fail is the entire nodal failure. This failure is acceptable since in this case only one DHCP node is available to provide new IP addresses/prefixes.</p> |
| <b>Default</b>     | no ignore-mclt-on-takeover                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

**Description** The maximum-client-lead-time (MCLT) is the maximum time that a DHCP server can extend client's lease time beyond the lease time currently known by the DHCP partner node. In dual-homed environment, the initial lease time for all DHCP clients is by default restricted to MCLT. Consecutive DHCP renewals are allowed to extend the lease time beyond the MCLT.

The MCLT is a safeguard against IP address/prefix duplication in cases of a lease synchronization failure when local-remote failover model is deployed

Once the intercommunication link failure between the redundant DHCP servers is detected, the DHCP IP address range configured as remote will not be allowed to start delegating new leases until the MCLT + partner-down-delay intervals expire. This is to ensure that the new lease that was delegated from the 'local' IP address-range/prefix on one node, but was never synchronized due to the intercommunication link failure, will expire before the same IP address/prefix is allocated from the remote IP address-range/prefix on the other node.

However, the already existing (and synchronized) lease times can be renewed from the remote IP address range at any time, regardless of the state of the intercommunication link (operational or failed).

Lease synchronization failure can be caused either by a node failure, or a failure of the link over which the DHCP leases are synchronized (intercommunication link). Synchronization failure detection can take up to 3 seconds.

During the failure, the DHCP lease time for the new clients will be restricted to MCLT while for the existing clients the lease time will over time (by consecutive DHCP renewals) be gradually reduced to the MCLT.

**Default** 10 minutes

**Parameters** **hrs** *hours* — specifies the hour parameter of the MCLT

**Values** 1 to 23

**min** *minutes* — specifies the minute parameter of the MCLT

**Values** 1 to 59

**sec** *seconds* — specifies the seconds parameter of the MCLT

**Values** 1 to 59

## partner-down-delay

**Syntax** **partner-down-delay** [**hrs** *hours*] [**min** *minutes*] [**sec** *seconds*]  
**no partner-down-delay**

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| <b>Description</b> | <p>Since the DHCP lease synchronization failure can be caused by the failure of the intercommunication link (and not necessary the entire node), there is a possibility the redundant DHCP servers become isolated in the network. In other words, they can serve DHCP clients but they cannot synchronize the lease. This can lead to duplicate assignment of IP addresses, since the servers have configured overlapping IP address ranges but they are not aware of each other's leases.</p> <p>The purpose of the partner-down-delay is to prevent the IP lease duplication during the intercommunication link failure by not allowing new IP addresses to be assigned from the remote IP address range. This timer is intended to provide the operator with enough time to remedy the failed situation and to avoid duplication of IP addresses/prefixes during the failure.</p> <p>During the partner-down-delay time, the prefix designated as remote will be eligible only for renewals of the existing DHCP leases that have been synchronized by the peering node. Only after the sum of the partner-down-delay and the maximum-client-lead-time will the prefix designated as remote be eligible for delegation of the new DHCP leases. When this occurs, we say that the remote IP address range has been taken over.</p> <p>It is possible to expedite the takeover of a remote IP address range so that the new IP leases can start being delegated from that range shortly after the intercommunication failure is detected. This can be achieved by configuring the partner-down-delay timer to 0 seconds, along with enabling the ignore-mclt-on-takeover CLI flag. Caution must be taken before enabling this functionality. It is safe to bypass safety timers (partner-down-delay + MCLT) only in cases where the operator is certain that the intercommunication between the nodes has failed due to the entire node failure and not due to the intercommunication (MCS) link failure. Failed intercommunication due to the nodal failure would ensure that only one node is present in the network for IP address delegation (as opposed to two isolated nodes with overlapping IP address ranges where address duplication can occur). For this reason, the operator <b>MUST</b> ensure that there are redundant paths between the nodes to ensure uninterrupted synchronization of DHCP leases.</p> <p>In access-driven mode of operation, partner-down-delay has no effect.</p> |
| <b>Default</b>     | 23 hours, 59 minutes, and 59 seconds.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| <b>Description</b> | <p>DHCP leases can be synchronized per DHCP server of DHCP pool. The pair of synchronizing servers or pools is identified by a tag. The synchronization information is carried over the Multi-Chassis Synchronization (MCS) link between the two peers. MCS link is a logical link (IP, or MPLS).</p> <p>MCS runs over TCP, port 45067 and it is using either data traffic or keepalives to detect failure on the communication link between the two nodes. In the absence of any MCS data traffic for more than 0.5sec, MCS will send its own keepalive to the peer. If a reply is NOT received within 3sec, MCS will declare its operation state as DOWN and the DB Sync state as out-of-sync. MCS will consequently notify its clients (DHCP Server being one of them) of this. It can take up to 3 seconds before the DHCP client realizes that the inter-chassis communication link has failed.</p> <p>The inter-chassis communication link failure does not necessarily assume the same failed fate for the access links. In other words the two redundant nodes can become isolated from each other in the network. This would occur in cases where only the intercommunication (MCS) link fails. It is of utmost importance that this MCS link be highly redundant.</p> |
| <b>Parameters</b>  | <p><i>ip-address</i> — specifies the IPv4 address of the peer</p> <p><b>sync-tag</b> <i>sync-tag</i> — specifies a synchronization tag to be used while synchronizing DHCP server or pools</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

**startup-wait-time**

|                    |                                                                                                                                                                                                                                                                |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] startup-wait-time</b> [ <i>min minutes</i> ] [ <i>sec seconds</i> ]                                                                                                                                                                                    |
| <b>Context</b>     | config>service>vprn>dhcp6>server>failover<br>config>service>vprn>dhcp6>server>pool<br>config>router>dhcp6>server>failover<br>config>router>dhcp6>server>pool                                                                                                   |
| <b>Description</b> | This command enables startup-wait-time during which each peer waits after the initialization process before assuming the active role for the prefix designated as local or access-driven. This is to avoid transient issues during the initialization process. |
| <b>Default</b>     | 2 minutes                                                                                                                                                                                                                                                      |

---

|                   |                                                                                              |
|-------------------|----------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <b>min</b> <i>minutes</i> — specifies the minute parameter of the startup wait time feature  |
| <b>Values</b>     | 1 to 10                                                                                      |
|                   | <b>sec</b> <i>seconds</i> — specifies the seconds parameter of the startup wait time feature |
| <b>Values</b>     | 1 to 59                                                                                      |

## force-renews

|                    |                                                                                                                                                                 |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>[no] force-renews</b>                                                                                                                                        |
| <b>Context</b>     | config>service>vprn>dhcp>server                                                                                                                                 |
| <b>Description</b> | <p>This command enables the sending of sending force-renew messages.</p> <p>The <b>no</b> form of the command disables the sending of force-renew messages.</p> |

**Default** no force-renews

## pool

**Syntax** **pool** *pool-name* [**create**]  
**no pool** *pool-name*

**Context** config>service>vprn>dhcp>server

**Description** This command configures a DHCP address pool on the router.

**Default** n/a

**Parameters** *pool name* — Specifies the name of this IP address pool. Allowed values are any string up to 32 characters long composed of printable, 7-bit ASCII characters.

**create** — Keyword used to create the entity. The **create** keyword requirement can be enabled/disabled in the **environment>create** context.

## max-lease-time

**Syntax** **max-lease-time** [**days** *days*] [**hrs** *hours*] [**min** *minutes*] [**sec** *seconds*]  
**no max-lease-time**

**Context** config>service>vprn>dhcp>server>pool

**Description** This command configures the maximum lease time.

The **no** form of the command returns the value to the default.

**Default** 10 days

**Parameters** *time* — specifies the maximum lease time

### Values

|          |           |
|----------|-----------|
| days :   | 0 to 3650 |
| hours    | 0 to 23   |
| minutes: | 0 to 59   |
| seconds  | 0 to 59   |

## min-lease-time

**Syntax** **min-lease-time** [**days** *days*] [**hrs** *hours*] [**min** *minutes*] [**sec** *seconds*]  
**no min-lease-time**

**Context** config>service>vprn>dhcp>server>pool

---

**Description** This command configures the minimum lease time.

The **no** form of the command returns the value to the default.

**Default** 10 minutes

**Parameters** *time* — specifies the minimum lease time

**Values**

|          |           |
|----------|-----------|
| days :   | 0 to 3650 |
| hours    | 0 to 23   |
| minutes: | 0 to 59   |
| seconds  | 0 to 59   |

## minimum-free

**Syntax** **minimum-free** *minimum-free* [**percent**] [**event-when-depleted**]  
**no minimum-free**

**Context** config>service>vprn>dhcp>server>pool

**Description** This command configures the minimum number of free addresses.

The **no** form of the command reverts to the default.

**Default** 1

**Parameters** *minimum-free* — Specifies the desired minimum number of free addresses in this pool. If the actual number of free addresses in this pool falls below this configured minimum, a notification is generated.

**Values** 0 to 255

**percent** — indicates the value indicates a percentage

**event-when-depleted** — enables a system-generate event when all available addresses in the pool/subnet of local DHCP server are depleted

## offer-time

**Syntax** **offer-time** [**min** *minutes*] [**sec** *seconds*]  
**no offer-time**

**Context** config>service>vprn>dhcp>server>pool

**Description** This command configures the offer time.

The **no** form of the command returns the value to the default.

**Default** 1 minute

---

|                   |                                        |
|-------------------|----------------------------------------|
| <b>Parameters</b> | <i>time</i> — specifies the offer time |
| <b>Values</b>     | minutes: 0 to 10<br>seconds: 0 to 59   |

## options

|                    |                                                                                                                                                               |
|--------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>options</b>                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>dhcp>server>pool                                                                                                                          |
| <b>Description</b> | This command enables the context to configure pool options. The options defined here can be overruled by defining the same option in the local user database. |
| <b>Default</b>     | n/a                                                                                                                                                           |

## custom-option

|                    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| <b>Context</b>     | config>service>vprn>dhcp>server>pool>options                                                                                                                                                                                                         |
| <b>Description</b> | This command configures the IP address of the DNS server.                                                                                                                                                                                            |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                                  |
| <b>Parameters</b>  | <i>ip-address</i> — The IP address of the DNS server. This address must be unique within the subnet and specified in dotted decimal notation. Allowed values are IP addresses in the range 1.0.0.0 to 223.255.255.255 (with support of /31 subnets). |

## domain-name

|                    |                                                                                                                                                                                                                                               |
|--------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>domain-name</b> <i>domain-name</i><br><b>no domain-name</b>                                                                                                                                                                                |
| <b>Context</b>     | config>service>vprn>dhcp>server>pool>options                                                                                                                                                                                                  |
| <b>Description</b> | This command configures the default domain for a DHCP client that the router uses to complete unqualified hostnames (without a dotted-decimal domain name).<br><br>The <b>no</b> form of the command removes the name from the configuration. |
| <b>Default</b>     | n/a                                                                                                                                                                                                                                           |
| <b>Parameters</b>  | <i>domain-name</i> — specifies the domain name for the client<br><br><b>Values</b> Up to 127 characters                                                                                                                                       |

## renew-timer

|                    |                                                                                                                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>renew-timer</b> [ <b>days</b> <i>days</i> ][ <b>hrs</b> <i>hours</i> ] [ <b>min</b> <i>minutes</i> ] [ <b>sec</b> <i>seconds</i> ]<br><b>no renew-timer</b>                                                                           |
| <b>Context</b>     | config>service>vprn>dhcp6>server>pool>prefix                                                                                                                                                                                             |
| <b>Description</b> | This command configures the renew-timer (T1), the time at which the client contacts the server from which the addresses in the IA_NA or IA_PD were obtained to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 1800                                                                                                                                                                                                                                     |

|                   |                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Parameters</b> | <i>seconds</i> — Specifies the time duration relative to the current time, expressed in units of seconds. A value of zero leaves the renew-time at the discretion of the client. |
| <b>Values</b>     | 0-604,800                                                                                                                                                                        |

## rebind-timer

|                    |                                                                                                                                                                                        |
|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>rebind-timer</b> [ <b>days</b> <i>days</i> ][ <b>hrs</b> <i>hours</i> ] [ <b>min</b> <i>minutes</i> ] [ <b>sec</b> <i>seconds</i> ]<br><b>no rebind-timer</b>                       |
| <b>Context</b>     | config>service>vpn>dhcp6>server>pool>prefix                                                                                                                                            |
| <b>Description</b> | This command configures the rebind-timer (T2), the time at which the client contacts any available server to extend the lifetimes of the addresses or prefixes assigned to the client. |
| <b>Default</b>     | 2880                                                                                                                                                                                   |
| <b>Parameters</b>  | <i>seconds</i> — T2 is a time duration relative to the current time. A value of zero leaves the rebind-time at the discretion of the client.                                           |
| <b>Values</b>      | 0 to 1209600                                                                                                                                                                           |
|                    | <b>[days days][hrs hours] [min minutes] [sec seconds]</b> — Specifies the rebind timer.                                                                                                |
| <b>Values</b>      |                                                                                                                                                                                        |
|                    | days 0 to 3650                                                                                                                                                                         |

|                    | minutes 0 to 59                                                                                                                                                                        |
|                    | seconds 0 to 59                                                                                                                                                                        |

## prefix

|                    |                                                                                                                                                                                                                                                                                                                              |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Syntax</b>      | <b>prefix</b> <i>ipv6-address/prefix-length</i> [ <b>failover</b> { <b>local</b>   <b>remote</b>   <b>access-driven</b> }] [ <b>pd</b> ] [ <b>wan-host</b> ]<br>[ <b>create</b> ]<br><b>no prefix</b> <i>ipv6-address/prefix-length</i>                                                                                      |
| <b>Context</b>     | config>router>dhcp6>server>pool<br>config>service>vpn>dhcp6>server>pool                                                                                                                                                                                                                                                      |
| <b>Description</b> | This command allows a list of prefixes (using the prefix command multiple times) to be routed to hosts associated with this pool. Each prefix will be represented in the associated FIB with a reference to the pool. Prefixes are defined as being for prefix delegation (pd) or use on a WAN interface or host (wan-host). |
| <b>Default</b>     | failover local                                                                                                                                                                                                                                                                                                               |
| <b>Parameters</b>  | <i>ipv6-address</i> — specifies the 128-bit IPv6 address                                                                                                                                                                                                                                                                     |
| <b>Values</b>      | 128-bit hexadecimal IPv6 address in compressed form                                                                                                                                                                                                                                                                          |

*prefix-length* — specifies the length of any associated aggregate prefix

**Values** 32 to 63

**failover** — This command designates a IPv6 prefix as local, remote or access-driven. This is used when multi-chassis synchronization is enabled.

**local** — An IPv6 prefix designated as local is used for new lease grants or to renew the existing lease grants. Local prefix designation should be always paired with the remote designation of the same prefix on the peering node.

The IPv6 prefix configured as local on one node can only be configured as remote on the other node. No other combination is allowed between the two nodes for an IPv6 prefix that is configured as local.

The dhcpv6 relay could point to both IPv6 DHCP server addresses— the one hosting the local IPv6 prefix and the one hosting the corresponding remote IPv6 prefix. Under normal circumstances the new lease will always be allocated from the local IPv6 prefix while the leases can be renewed from either IPv6 prefix (local or remote). Under network failure, the remote IPv6 prefix can be taken over according to the intercommunication link state transitions and associated timers.

**remote** — An IPv6 prefix designated as remote is used only to renew the existing DHCP leases. The new leases will be delegated from it only after the maximum-client-lead-time + partner-down-delay time elapses. At that point we say that the remote IPv6 prefix has been taken over.

To ensure faster takeover, the partner-down-delay can be set to 0 and the MCLT time can be ignored. Extra caution should be exercised when enabling this mode of operation, as described in the configuration guides.

The IPv6 prefix configured as remote on one node can only be configured as local on the other node. No other combination is allowed between the two nodes for an IP address ranges that is configured as remote.

**access-driven** — An IPv4 prefix designated as access-driven is used for new lease grants or to renew the existing lease grants regardless of the state of the intercommunication link (operational or failed). In this mode of operation the IPv6 prefix is actively shared between the two DHCPv6 server nodes. This can be used on both DHCPv6 servers only in cases where the access protection mechanism (SRRP or MC-LAG) will ensure that there is only a single active path for DHCPv6 clients using the same IPv6 prefix available to one of the redundant DHCPv6 nodes.

The IPv6 prefix configured as access-driven on one node can only be configured as access-driven on the other node. No other combination is allowed between the two nodes for an IPv6 prefix that is configured as access-driven.

There MUST be no crosslinks between the DHCPv6 servers that have IPv6 address ranges configured in access-driven failover mode. In other words, each node must have the dhcp-relay pointing to the IPv6 address of the local DHCPv6 server. This IPv6 address must be the same on both nodes. For example, both DHCPv6 servers should have a loopback address configured with the same IPv6 address (IPv4 or IPv6) and a DHCPv6 server associated with this loopback address. Those IPv6 addresses MUST not be advertised outside of each box. The DHCPv6 relay in each node would point to its local DHCPv6 server via this loopback IPv6 address.

**pd** — specifies that this aggregate is used by IPv6 ESM hosts for DHCPv6 prefix-delegation

**wan-host** — specifies that this aggregate is used by IPv6 ESM hosts for local addressing or by a routing gateway's WAN interface

## preferred-lifetime

|                    |                                                                                                                                                                                |           |  |
