

SYBASE SQL Server™ Utility Programs for UNIX

SYBASE SQL Server Release 10.0

Document ID: 30475-01-1000-04

Change Level: 1

Last Revised: February 1, 1994

Principal authorship: Server Publications Group

Document ID: 30475-01-1000

This publication pertains to SYBASE SQL Server Release 10.0 of the SYBASE database management software and to any subsequent release until otherwise indicated in new editions or technical notes. Information in this document is subject to change without notice. The software described herein is furnished under a license agreement, and it may be used or copied only in accordance with the terms of the agreement.

Document-Back Guarantee

Sybase welcomes corrections and comments on its documents. If you mark typographical errors, formatting errors, errors of fact, or areas that need clarification in any Sybase user's manual and send copies of marked-up pages to us, we will send you a clean copy of the manual, absolutely free.

Send pages to the Publications Operations Department at the address below. Please include your Site ID number.

Sybase, Inc.

Document Orders

Customers may purchase additional copies of any document or the right to make photocopies of documentation for their in-house use.

To order additional documents or photocopy rights, U.S. and Canadian customers should call Customer Fulfillment at (800) 685-8225, fax (617) 229-9845.

Customers in other countries with a U.S. license agreement may contact Customer Fulfillment via the fax number. All other international customers should contact their Sybase subsidiary or local distributor.

Upgrades are provided only at regularly scheduled software release dates.

© Copyright Sybase, Inc., 1989, 1994. All rights reserved.

No part of this publication may be reproduced, transmitted, or translated in any form or by any means, electronic, mechanical, manual, optical or otherwise, without prior written permission of Sybase, Inc.

Sybase Trademarks

SYBASE, the SYBASE logo, APT-FORMS, Data Workbench, DBA Companion, Deft, Gain*Momentum*, SA Companion, SQL Debug, SQL Solutions, SQR, Transact-SQL, and VQL are registered trademarks of Sybase, Inc. ADA Workbench, Adaptable Windowing Environment, Application Manager, Applications from Models, APT Workbench, APT-Build, APT-Edit, APT-Execute, APT-Translator, APT-Library, Build *Momentum*, Camelot, Client/Server Architecture for the Online Enterprise, Client/Server for the Real World, Configurator, DataServer, Data Workbench, Database Analyzer, DB-Library, Deft Analyst, Deft Designer, Deft Educational, Deft Professional, Deft Trial, Developers Workbench, Easy SQR, Embedded SQL, Enterprise Builder, Enterprise Client/Server, Enterprise Meta Server, Enterprise Modeler, Enterprise *Momentum*, Gain, Gain*Exposure*, Insight, Mainframe Access Products (MAP), *Momentum*, Movedb, Navigation Server, Net-Gateway, Net Library, Object *Momentum*, OmniSQL Gateway, Omni SQL Server, OmniSQL Access Module, Open Client, Open Gateway, Open Server, Open Solutions, PC APT-Execute, PC DB-Net, PC Net Library, Report Workbench, Report Execute, Open Server, Partnerships that Work, Replication Server, Resource Manager, RW-Display Lib, RW-Library, SA Monitor, Secure SQL Server, Secure SQL Toolset, SQL Code Checker, SQL Edit/TPU, SQL Edit, SQL Monitor, SQL Server, SQL Toolset, SQL Server/CFT, SQL Server/DBM, SQL Station, SQR Toolset, SQR Developers Kit, SQR Workbench, SYBASE Client/Server Interfaces, SYBASE Gateways, SYBASE SQL Lifecycle, Sybase Synergy Program, SYBASE Virtual Server Architecture, SYBASE User Workbench System 10, Tabular Data Stream, and The Enterprise Client/Server Company are trademarks of Sybase, Inc.

All other company and product names used herein may be the trademarks or registered trademarks of their respective companies.

Restricted Rights Legend

Use, duplication or disclosure by the Government is subject to restrictions set forth in subparagraph (c)(1)(ii) of DFARS 52.227-7013 for the DOD and as set forth in FAR 52.227-19(a)-(d) for civilian agencies.

<i>isql</i>	1-28
<i>langinstall</i>	1-35
<i>showserver</i>	1-37
<i>startserver</i>	1-38

2. Using *bcp* to Transfer Data to and from SQL Server

Introduction	2-1
About Importing and Exporting Data	2-1
Requirements for Using <i>bcp</i>	2-2
Permissions Needed for Copying Data	2-2
<i>bcp</i> Performance Issues	2-2
Bulk Copying Data with Indexes and Triggers	2-3
Steps for Copying Data	2-5
Using the <i>bcp</i> Options	2-5
Using the Default Formats	2-5
Native Format	2-6
Character Format	2-6
Changing Terminators for Character Format	2-7

Changing the Defaults: Interactive <i>bcp</i>	2-7
File Storage Type	2-8
Prefix Length	2-9
Storage Length	2-10
Field and Row Terminators	2-11
Using Format Files	2-12
Elements of the Format File	2-13
Version	2-13
Number of Columns	2-13
Columns in the Format File	2-14
Host File Column Order	2-14
Host File Datatype	2-14
Prefix Length	2-14
Host File Data Length	2-15
Terminator	2-15
Server Column Order	2-15
Server Column Name	2-15
Examples: Copying out Data Interactively	2-16
Copying out Data with Field Lengths	2-16
Copying out Data with Delimiters	2-18
Examples: Copying Data in Interactively	2-20
Copying in Data with Field Lengths	2-20
Copying in Data with Delimiters	2-22
Copying in Data with a Format File	2-22
Using <i>bcp</i> with Alternate Languages	2-23
Batch Files and Copy in	2-23
Specifying a Network Packet Size	2-24
Copying out <i>text</i> and <i>image</i> Data	2-25
Error Files and Copy in	2-25
Error Files and Copy out	2-26
Data Integrity: Defaults, Rules, and Triggers	2-26
Bulk Copy Distinguished from Other SQL Server Facilities	2-26

3. Using *isql*: Additional Information

Introduction	3-1
Changing the Command Terminator	3-1
Performance Statistics Interaction with Command Terminator Values	3-2
Setting the Network Packet Size	3-2
Input and Output Files	3-3
UNIX Command Line Redirection	3-3

Preface

SQL Server Utility Programs for UNIX is a guide to the SQL Server utility commands available on all UNIX platforms. Utility programs are commands that you invoke directly from the operating system.

Audience

This manual is for anyone using Transact-SQL® and System 10 SQL Server™. It is a reference manual, and assumes that you have basic knowledge of how to use the UNIX operating system and SQL Server.

How to Use This Book

This manual includes the following chapters:

- Chapter 1, “SQL Server Utility Programs for UNIX,” consists of alphabetized reference pages for all of the available utility commands.
- Chapter 2, “Using bcp to Transfer Data to and from SQL Server,” discusses bcp in detail.
- Chapter 3, “Using isql: Additional Information,” discusses using the interactive SQL utility.

The examples in this book are based on the *pubs2* sample database. Ask your System Administrator how to get a clean copy of *pubs2*.

Related Documents

Other manuals that you may find useful are:

- *System Administration Guide for SQL Server*, which contains in-depth information about SQL Server administration issues.
- *System Administration Guide Supplement* for your platform, which documents operating-system specific system administration tasks.
- *Open Client DB-Library/C Reference Manual*, a collection of manual pages and code samples for the SQL Server interface library, Open Client DB-Library.

- The *SQL Server Installation Guide*, which describes the installation procedures for SQL Server.
- *SQL Server Reference Manual Vol. 1 and Vol. 2*, which contains detailed information on all of the commands and system procedures discussed in this manual.

Conventions Used in This Manual

The following paragraphs detail the typographic conventions used in this manual.

Font and Syntax Conventions

The font and syntax conventions in this reference are as follows:

Element	Example
Command names, command option names, utility names, utility flags, and other keywords are bold .	select
Database names, datatypes, filenames and pathnames are in <i>italics</i> .	<i>master</i> database
Variables, or words that stand for values that you fill in, are in <i>italics</i> .	select <i>column_name</i> from <i>table_name</i> where <i>search_conditions</i>
Parentheses are to be typed as part of the command.	compute <i>row_aggregate</i> (<i>column_name</i>)
Curly braces indicate that you must choose at least one of the enclosed options. Do not type the braces.	{cash, check, credit}
Brackets mean choosing one or more of the enclosed options is optional. Do not type the brackets.	[anchovies]
The vertical bar means you may select only one of the options shown.	{die_on_your_feet live_on_your_knees live_on_your_feet}
The comma means you may choose as many of the options shown as you like, separating your choices with commas to be typed as part of the command.	[extra_cheese, avocados, sour_cream]

Element	Example
An ellipsis (...) means that you can repeat the last unit as many times as you like.	<pre>buy thing = price [cash check credit] [, thing = price [cash check credit]]...</pre> <p>You must buy at least one thing and give its price. You may choose a method of payment: one of the items enclosed in square brackets. You may also choose to buy additional things: as many of them as you like. For each thing you buy, give its name, its price, and (optionally) a method of payment.</p>

- Syntax statements (displaying the syntax and all options for a command) appear as follows:

```
showserver parameter
```

or, for a command with more options:

```
buildmaster [-d physicalname] [-c cntrltype]
[-s size] [-r] [-m]
```

In syntax statements, commands are in normal font and options are in lowercase: normal font for flags, italics for user-supplied values.

- Examples showing utility commands appear in bold, as follows:

```
bcp -v
```

- Examples of output from the computer appear as follows:

```
pub_id  pub_name                city                state
-----  -
0736    New Age Books           Boston              MA
0877    Binnet & Hardley        Washington          DC
1389    Algodata Infosystems   Berkeley            CA
```

```
(3 rows affected)
```

If You Need Help

Help with your SYBASE software is available in the form of documentation and the Technical Support Center.

Each SYBASE installation has a designated person who may contact Technical Support. If you cannot resolve your problem using the manuals, ask the designated person at your site to contact SYBASE Technical Support.

1

SQL Server Utility Programs for UNIX

Introduction

This chapter consists of reference pages for the utility commands listed below.

The UNIX system shell interprets the utility commands. Place characters with special meaning to the shell, such as the backslash (\), asterisk (*), slash (/), and spaces, in quotes. You can precede some special characters with the backslash (\) to “escape” them. This prevents the shell from interpreting the special characters.

Command	Description
backupserver	Executable form of the Backup Server program
bcp	Copies a database table to or from an operating system file in a user-specified format
buildmaster	Builds the master device and creates the <i>master</i> , <i>model</i> , and <i>tempdb</i> databases on the device
dataserver	Executable form of the SQL Server program
defncopy	Copies definitions for specified views, rules, defaults, triggers, procedures, or reports from a database to an operating system file or from an operating system file to a database
isql	Interactive SQL parser to SQL Server
langinstall	Installs one new language on the SQL Server
showserver	Shows SQL Servers and Backup Servers that are currently running on the local machine
startserver	Starts a SQL Server and/or a Backup Server

Table 1-1: Utility Commands for UNIX

backupserver

Function

The executable form of the Backup Server program.

Syntax

```
backupserver [-Cserver_connections] [-Sb_servername]
             [-Iinterface_filename] [-eerror_log_file]
             [-Msybmultbuf_binary] [-Nnetwork_connections]
             [-Ttrace_value] [-LSybase_language_name]
             [-JSybase_character_set_name]
```

or

```
backupserver [-v]
```

Parameters

-Cserver_connections – specifies the number of server connections for the Backup Server. The Backup Server requires:

- Two connections for each dump session
- One connection for each load session
- One connection for volume change messages

Allow a maximum of three times the number of expected concurrent dump and load sessions. The default value is 20 server connections.

-Sb_servername – specifies the name of the Backup Server to start. The default is SYB_BACKUP. This entry must specify the name of a Backup Server in the interfaces file.

-Iinterfaces_file – specifies the name and location of the interfaces file to search when connecting to Backup Server. If **-I** is omitted, **backupserver** looks for a file named *interfaces* in the directory pointed to by your SYBASE environment variable.

-eerror_log_file – specifies the name and location of the Backup Server error log file used to report Open Server internal errors, *sybmultbuf* errors, errors that halt the Backup Server, and errors for disconnected sessions. All other errors are sent to the notify destination specified in the dump database, dump transaction, load database, and load transaction commands.

- Msybmultbuf_binary* – specifies the full path name of the *sybmultbuf* executable. Use this option only when starting Backup Server from a directory other than the */bin* directory of the SYBASE installation tree, or when using a diagnostic version of *sybmultbuf*.
- Nnetwork_connections* – specifies the number of total network connections (DBPROCESSES) that the master Backup Server can originate. The default value is 25.
- Ttrace_value*– interprets *trace_value* as a bit mask (base-2 number). The 1 bits in *trace_value* correspond to Open Server trace flags to turn on. If you specify more than one -T option on the command line, the final -T value overrides the values from earlier -T options. The *trace_value* must be a positive integer.
- LSybase_language_name* – specifies the default language for Backup Server. If not specified, Backup Server uses the locale specified by the LC_ALL or LANG environment variables. If these variables are not set, Backup Server searches for the “default” entry in *locales.dat*.
- JSybase_character_set_name* – specifies the default character set for Backup Server. If not specified, Backup Server uses the locale specified by the LC_ALL or LANG environment variables. If these variables are not set, Backup Server searches for the “default” entry in *locales.dat*.
- v – prints the version number and copyright message of the backupserver software, then exits.

Comments

- Start Backup Server with the *startserver* command rather than by directly executing the *backupserver* program. If you need to change any of the default values, edit the *RUN_servername* file in your SYBASE installation directory. See the *startserver* manual page for details.
- The default name of a Backup Server is SYB_BACKUP. The value of the environment variable *DSLISTEN* overrides the default value, and the -S option overrides the default and the value in *DSLISTEN*.
- Whenever possible, the Backup Server and any SQL Servers that dump or load directly through the Backup Server should share

the same interfaces file. The interfaces file that Backup Server uses must contain entries for:

- The Backup Server.
- Any other Backup Servers with which this Backup Server communicates.
- Trace flags cause the Backup Server to print information regarding its operation while it is running, for debugging problems in the Backup Server. See the *Open Server Server-Library/C Reference Manual* for more details on trace flags. The UNIX Backup Server does not support use of the Open Server-defined SRV__TR symbols for -T.
- If Backup Server cannot find the *locales* and *charsets* directories specified by the -L and -J options, or if these options specify an incorrect language and character set combination, Backup Server issues an error message and uses the default language and character set.

See Also

startserver

bcp

Function

Copies a database table to or from an operating system file in a user-specified format.

Syntax

```
bcp [[database_name.]owner.]table_name {in | out}
    datafile
    [-m maxerrors] [-f formatfile] [-e errfile]
    [-F firstrow] [-L lastrow] [-b batchsize]
    [-T text_or_image_size] [-n] [-c]
    [-t field_terminator] [-r row_terminator]
    [-U username] [-P password] [-I interfaces_file]
    [-S server] [-a display_charset]
    [-q datafile_charset] [-J client_charset]
    [-z language] [-v] [-A size] [-E] [-X]
```

Parameters

database_name – is optional if the table being copied is in your default database or in *master*. Otherwise, you must specify a database name.

owner – is optional if you or the Database Owner own the table being copied. If you do not specify an owner, *bcp* looks first for a table of that name owned by you. Then it looks for one owned by the Database Owner. If another user owns the table, you must specify the owner's name or the command fails.

table_name – is the name of the database table to copy. The table name cannot be a Transact-SQL reserved word.

in / out – is the direction of the copy. *in* indicates a copy from a file into the database table, while *out* indicates a copy to a file from the database table.

datafile – is the full path name of an operating system file. The path name can be from 1 to 255 characters in length.

-m max_errors – is the maximum number of errors permitted before *bcp* aborts the copy. *bcp* throws out each row that it cannot build, counting it as one error. If you do not include this option, *bcp* uses a default value of 10.

- f *format_file* – is the full path name of a file with stored responses from a previous use of **bcp** on the same table. After you answer **bcp**'s format questions, it asks you if you want to save your answers in a format file; creation of the format file is optional. The default file name is *bcp.fmt*. The **bcp** program can refer to a format file when copying data, so that you do not have to duplicate your previous format responses interactively. Use this option only when you previously created a format file that you want to use now for a copy in or out. If this option is not used, **bcp** queries you for format information interactively.
- e *errfile* – is the full path name of an error file where **bcp** stores any rows that it was unable to transfer from the file to the database. Error messages from the **bcp** program appear on your terminal. **bcp** creates an error file only when you specify this option. If you specify this option and **bcp** does not encounter any error, it does not create the error file.
- F *firstrow* – is the number of the first row to copy (default is the first row).
- L *lastrow* – is the number of the last row to copy (default is the last row).
- b *batchsize* – is the number of rows per batch of data copied (the default is to copy all the rows in one batch). Batching applies only when bulk copying in; it has no effect on bulk copying out.
- T *text_or_image_size* – allows you to specify, in bytes, the maximum length of *text* or *image* data that SQL Server sends. The default is 32K. If a *text* or *image* field is larger than the value of -T or the default, **bcp** does not send the overflow.
- n – performs the copy operation using native (operating system) formats. This option does not prompt for each field. Files in native data format are not human-readable.
- c – performs the copy operation with *char* datatype as the default. This option does not prompt for each field; it uses *char* as the default storage type, no prefixes, \t (tab) as the default field terminator, and \n (newline) as the default row terminator.
- t *field_terminator* – specifies the default field terminator.
- r *row_terminator* – specifies the default row terminator.

► **Note**

When specifying terminators from the command line with the `-t` or `-r` options, you must escape characters that have special significance to the UNIX operating system (see Example 1 on page 1-10). Either place a backslash in front of the special character or enclose it in quotes. This is not necessary when `bcp` prompts you (interactive mode).

`-U username` – specifies a SQL Server login name. If you do not specify *username*, `bcp` uses the current user's operating system login name.

`-P password` – specifies a SQL Server password. If you do not specify `-P password`, `bcp` prompts for a password. If your password is NULL, place the `-P` flag at the end of the command line by itself.

`-S server` – specifies the name of the SQL Server to connect to. If you specify `-S` with no argument, `bcp` uses the server that your `DSQUERY` environment variable specifies.

`-I interfaces_file` – specifies the name and location of the interfaces file to search when connecting to SQL Server. If you do not specify `-I`, `bcp` looks for a file named *interfaces* in the directory that your `SYBASE` environment variable specifies.

`-J client_charset` – specifies the character set to use on the client. `bcp` uses a filter to convert input between *client_charset* and the SQL Server character set.

`-J client_charset` requests that SQL Server convert to and from *client_charset*, the character set used on the client.

`-J` with no argument sets character set conversion to NULL. No conversion takes place. Use this if the client and server use the same character set.

Omitting **-J** sets the character set to a default for the platform. Table 1-2 lists platform defaults.

Platform	Default Character Set
Sun, DEC, Pyramid, NCR, Alpha, others	iso_1
HP	roman8
RS6000/aix, OS/2	cp850
Macintosh	mac

Table 1-2: Default Character Sets for Different Platforms

The default may not necessarily be the character set that the client is using. (See the *System Administration Guide for SYBASE SQL Server* and the *System Administration Guide Supplement* for more information about character sets and the associated flags.)

-a *display_charset* – allows you to run **bcp** from a terminal where the character set differs from that of the machine on which **bcp** is running. (See the *System Administration Guide* for more information about changing character sets.) **-a** in conjunction with **-J** specifies the character set translation file (*.xlt* file) required for the conversion. Use **-a** without **-J** only if the client character set is the same as the default character set.

-q *datafile_charset* – allows you to run **bcp** to copy character data to or from a file system that uses a character set different from the client character set. **-q** in conjunction with **-J** specifies the character set translation file (*.xlt* file) required for the conversion.

In Japanese language environments, the **-q** flag translates Hankaku Katakana (half-width characters) into Zenkaku Katakana (full-width characters). Use with the argument “zenkaku” and with the **-J** flag to indicate the client’s Japanese character set (sjis or eucjis). The *zenkaku.xlt* file was designed to translate **only** from terminal display to SQL Server, **not** from SQL Server to the terminal.

► *Note*

The `ascii_7` character set is compatible with all character sets. If either the SQL Server's or client's character set is set to `ascii_7`, any 7-bit ASCII character is allowed to pass between client and server unaltered. Other characters produce conversion errors. Character set conversion issues are covered more thoroughly in the *System Administration Guide*.

-z *language* – is the official name of an alternate language that the server uses to display `bcp` prompts and messages. Without the `-z` flag, `bcp` uses the server's default language. Add languages to a SQL Server at installation, or afterwards with the utility `langinstall` or the stored procedure `sp_addlanguage`.

-v – displays the version number of `bcp` and a copyright message and returns to the operating system.

-A *size* – specifies the network packet size to use for this `bcp` session. For example:

```
bcp -A 2048
```

sets the packet size to 2,048 bytes for this `bcp` session. *size* must be between the values of the `default network packet size` and `maximum network packet size` configuration variables, and it must be a multiple of 512.

Use larger-than-default network packet sizes to improve the performance of large bulk copy operations.

-E – explicitly specifies the value of a table's `IDENTITY` column.

By default, when you bulk copy data into a table with an `IDENTITY` column, `bcp` assigns each row a temporary `IDENTITY` column value of 0. As `bcp` inserts each row into the table, the server assigns the row a unique, sequential `IDENTITY` column value, beginning with the value 1. If you specify the `-E` flag when copying data into a table, `bcp` prompts you to enter an explicit `IDENTITY` column value for each row. If the number of inserted rows exceeds the maximum possible `IDENTITY` column value, SQL Server returns an error.

By default, when you bulk copy data from a table with an `IDENTITY` column, `bcp` excludes all information about the column from the output file. If you specify the `-E` flag, `bcp` copies the existing `IDENTITY` column values into the output file.

- X – when connecting to the server, **bcp** initiates the login with client-side password encryption. **bcp** (the client) specifies to the server that password encryption is desired. The server sends back an encryption key, which **bcp** uses to encrypt your password, and the server uses the key to authenticate your password when it arrives.

If **bcp** crashes, the system creates a core file which contains your password. If you did not use the encryption option, the password appears in plain text in the file. If you used the encryption option, your password is not readable.

Examples

1. In the following example, the **-c** option copies data out of the *publishers* table in character format (using *char* for all fields). The **-t** *field_terminator* option ends each field with a comma, and the **-r** *row_terminator* option ends each line with a Return. **bcp** prompts only for a password. The first backslash before the final “r” escapes the second so that one backslash prints.

```
bcp pubs2..publishers out pub_out -c -t , -r \\r
```

2. In the following example, **bcp** copies data from the *publishers* table to a file named *pub_out* for later reloading into SQL Server. Pressing Return accepts the defaults that the prompts specify. The same prompts appear when copying data into the *publishers* table.

```
bcp pubs2..publishers out pub_out
```

```
Password:
```

```
Enter the file storage type of field pub_id [char]:
```

```
Enter prefix length of field pub_id [0]:
```

```
Enter length of field pub_id [4]:
```

```
Enter field terminator [none]:
```

```
Enter the file storage type of field pub_name [char]:
```

```
Enter prefix length of field pub_name [1]:
```

```
Enter length of field pub_name [40]:
```

```
Enter field terminator [none]:
```

```
Enter the file storage type of field city [char]:
```

```
Enter prefix length of field city [1]:
```

```
Enter length of field city [20]:
```

```
Enter field terminator [none]:
```

```
Enter the file storage type of field state [char]:
```

```

Enter prefix length of field state [1]:
Enter length of field state [2]:
Enter field terminator [none]:

Do you want to save this format information in a
file? [Y-n] y
Host filename [bcp.fmt]: pub_form

```

```
Starting copy...
```

```

3 rows copied.
Clock Time (ms.): total = 300   Avg = 100   (10.00
rows per sec.)

```

3. To copy this data back into SQL Server using the saved format file, *pub_form*, use the following command:

```
bcp pubs2..publishers in pub_out -f pub_form
```

4. To see examples of datatypes, enter “?” at the prompt:

```

Enter the file storage type of field 'pub_id'
['char']:?
Invalid column type. Valid types are:
<cr>: same type as SQL Server column.
  c : char
  T : text
  i : int
  s : smallint
  t : tinyint
  f : float
  m : money
  b : bit
  d : datetime
  x : binary
  I : image
  D : smalldatetime
  r : real
  M : smallmoney
  n : numeric
  e : decimal

```

Enter the single letter exactly as it appears above.

5. The following example copies a data file created with a character set used on a VT200 terminal into the *pubs2..publishers* table. The *-q* flag translates it. The *-z* flag displays bcp messages in French.

```
bcp pubs2..publishers in vt200_data -J iso_1 -q
vt200 -z french
```

6. The following example specifies that you are using a Macintosh, running `bcp` on a workstation that is using `roman8`, with the file system on another machine that uses `iso_1`:

```
bcp pubs2..publishers in -a mac -J roman8 -q iso_1
```

7. The following example specifies that SQL Server send 40K of *text* or *image* data using a packet size of 4096:

```
bcp pubs2..publishers out -T 40960 -A 4096
```

Comments

- See Chapter 2, “Using `bcp` to Transfer Data to and from SQL Server” for a more in-depth discussion of `bcp`.
- `bcp` provides a convenient and high-speed method for transferring data between a database table and an operating system file. It is capable of reading or writing files in a wide variety of formats. When copying in from a file, `bcp` appends data to an existing database table; when copying out to a file, `bcp` overwrites any previous contents of the file.
- Upon completion, `bcp` informs you of the number of rows of data successfully copied, the number of rows (if any) that it could not copy, the total time the copy took, the average amount of time that it took to copy one row (in milliseconds), and the number of rows copied per second.

Copying Tables with Indexes or Triggers

- The `bcp` program is optimized to load data into tables that do not have indexes or triggers associated with them. It loads data into tables without indexes or triggers at the fastest possible speed, with a minimum of logging. Page allocations are logged, but the insertion of rows is not.

When you copy data into a table that has one or more indexes or triggers, a slower version of `bcp` is automatically used, which logs row inserts. This includes indexes implicitly created using the unique integrity constraint of a `create table` statement.

However, `bcp` does not enforce the other integrity constraints defined for a table.

Because the fast version of `bcp` inserts data without logging it, the System Administrator or Database Owner must first set the `select into/bulkcopy` option on with the system procedure `sp_dboption`. If the option is not set on, and you try to copy data into a table that has no indexes or triggers, SQL Server generates an error

message. You do not need to set this option in order to copy data out to a file, or in order to copy data in to a table that contains indexes or triggers.

► **Note**

Because **bcp** logs inserts into a table that has indexes or triggers, the log can grow very large. You can truncate the log with **dump transaction** after the bulk copy completes, after you have backed up your database with **dump database**.

- While the **select into/bulkcopy** option is on, you cannot dump the transaction log. Issuing **dump transaction** produces an error message instructing you to use **dump database** instead.

◆ **WARNING!**

Be certain that you dump your database before you turn off the select into/bulkcopy flag. If you insert unlogged data into your database, and then perform a dump transaction before you perform a dump database, you will not be able to recover your data.

- Unlogged **bcp** runs more slowly while a **dump database** is taking place.
- Table 1-3 shows which version **bcp** uses when copying in, the necessary settings for the **select into/bulkcopy** option, and whether the transaction log is kept and dumpable.

	select into/bulkcopy	
	on	off
fast bcp (no indexes or triggers on target table)	OK dump transaction prohibited	bcp prohibited
slow bcp (one or more indexes or triggers)	OK dump transaction prohibited	OK dump transaction OK

Table 1-3: Comparing Fast and Slow **bcp**

- By default, the **select into/bulkcopy** option is off in newly created databases. To change the default situation, turn this option on in the *model* database.

► *Note*

The performance penalty for copying data into a table that has indexes or triggers in place can be severe. If you are copying in a very large number of rows, it may be faster to drop all the indexes and triggers first with **drop index** (or **alter table** for indexes created as a unique constraint) and **drop trigger**, set the database option, copy the data into the table, recreate the indexes and triggers, and then dump the database. Remember to allocate disk space for the construction of indexes and triggers—about 2.2 times the amount of space needed for the data for a clustered index.

Responding to bcp Prompts

When you copy data in or out using the **-n** (native format) or **-c** (character format) option, **bcp** only prompts you for your password, unless you supplied it with the **-P** option. If you don't supply either the **-n** or **-c** options, **bcp** prompts you for information for each field in the table.

- Each prompt displays a default value, in brackets, which you can accept by pressing Return. The prompts include:
 - The file storage type, which can be character or any valid SQL Server datatype
 - The prefix length, which is an integer indicating the length in bytes of the following data
 - The storage length of the data in the file
 - The field terminator, which can be any character string

The row terminator is the field terminator of the last field in the table or file.

- The bracketed defaults represent reasonable values for the datatypes of the field in question. For the most efficient use of space when copying out to a file:
 - Use the default prompts
 - Copy all data in their table datatypes
 - Use prefixes as indicated
 - Do not use terminators
 - Accept the default lengths

The following table shows the defaults and possible alternate responses:

Prompt	Default Provided	Possible Responses
File Storage Type	Use database storage type for most fields except: <i>char</i> for <i>varchar</i> <i>binary</i> for <i>varbinary</i>	<i>char</i> to create or read a human-readable file; any SQL Server datatype where implicit conversion is supported.
Prefix Length	0 for fields defined with <i>char</i> datatype (not storage type) and all fixed-length datatypes 1 for most other datatypes 2 for <i>binary</i> and <i>varbinary</i> saved as <i>char</i> 4 for <i>text</i> and <i>image</i>	0 if no prefix is desired; defaults are recommended in all other cases.
Storage Length	For <i>char</i> and <i>varchar</i> , use defined length. For <i>binary</i> and <i>varbinary</i> saved as <i>char</i> , use double the defined length. For all other datatypes, use maximum length needed to avoid truncation or data overflow.	Default values, or greater, are recommended.
Field or Row Terminator	none	Up to 30 characters, or one of the following: \t tab \n newline \r carriage return \0 null terminator \ backslash

Table 1-4: *bcp* Prompts, Their Defaults and Responses

- **bcp** can copy data out to a file either as its native (database) datatype, or as any datatype for which implicit conversion is supported for the datatype in question. **bcp** copies user-defined datatypes as their base datatype or as any datatype for which implicit conversion is supported. For more information on datatype conversions, see **dbconvert** in the *Open Client DB-Library/C Reference Manual*.

► **Note**

Be careful copying data in native format from different versions of SQL Servers because they do not always have the same datatypes.

- A prefix length is a 1-, 2-, or 4-byte integer that represents the length of each data value in bytes. It immediately precedes the data value in the host file.
- If fields are stored as *char* (except *char*, *nchar*, and *binary* fields) instead of their database datatypes, they take less file storage space with the default length and prefix or a terminator. *bcp* can use either a terminator or a prefix to determine the most efficient use of storage space. *bcp* suggests the maximum amount of storage space required for each field as the default. For *char* or *varchar* data, *bcp* accepts any length.

- Fields defined in the database as *char*, *nchar*, and *binary* are always padded with spaces (null bytes for binary) to the full length defined in the database. *timestamp* data is treated as *binary(8)*.

If data in *varchar* and *varbinary* fields is longer than the length you specify for copy out, *bcp* silently truncates the data in the file at the specified length.

- A field terminator string can be up to 30 characters long; the most common terminators are a tab (entered as “\t” and used for all columns except the last one), and a newline (entered as “\n” and used for the last field in a row). Other terminators are: “\0” (the null terminator), “\” (backslash), and “\r” (Return). When choosing a terminator, be sure that its pattern does not appear in any of your character data. For example, if you use tab terminators with a string that contains a tab, *bcp* would not know which tab represents the end of the string. Since *bcp* always looks for the first possible terminator, in this case it would find the wrong one.

When a terminator or prefix is present, it affects the actual length of data transferred. If the length of an entry being copied out to a file is less than the storage length, it is followed immediately by the terminator, or the prefix for the next field. The entry is not padded to the full storage length (*char*, *nchar*, and *binary* data is returned from SQL Server already padded to the full length).

When copying in from a file, data is transferred until either the number of bytes indicated in the “Length” prompt have been copied or the terminator is encountered. Once a number of bytes equal to the specified length has been transferred, the rest of the data is flushed until the terminator is encountered. When no terminator is used, the table storage length is strictly observed.

- The following tables show the interaction of prefix lengths, terminators, and field length on the information in the file. “P”

indicates the prefix in the stored table. “T” indicates the terminator, and dashes (-) show appended spaces. An ellipsis (...) indicates that the pattern repeats for each field. The field length is 8 for each column, and “string” represents the 6-character field each time.

	Prefix length = 0	Prefix length 1, 2 or 4
No terminator	string--string--...	Pstring--Pstring--...
Terminator	string--Tstring--T...	Pstring--TPstring--T...

Table 1-5: SQL Server char Data

	Prefix length = 0	Prefix length 1, 2 or 4
No terminator	string--string--...	PstringPstring...
Terminator	stringTstringT...	PstringTPstringT...

Table 1-6: Other Datatypes Converted to char Storage

- Note that the file storage type and length of a column do not have to be the same as the type and length of the column in the database table. (If types and formats copied in are incompatible with the structure of the database table, the copy fails.)
- File storage length is generally the maximum amount of data to be transferred for the column, plus terminators and/or prefixes.
- When copying data into a table, **bcp** observes any defaults defined for columns and user-defined datatypes. However, **bcp** ignores rules in order to load data at the fastest possible speed.
- Because **bcp** considers any data column that can contain null values to be variable length, use either a length prefix or terminator to denote the length of each row of data.
- Data written to a host file in its native format preserves all of its precision. *datetime* and *float* values preserve all of their precision even when they are converted to character format. SQL Server stores *money* values to a precision of one ten-thousandth of a monetary unit. However, when *money* values are converted to character format, their character format values are recorded only to the nearest two places.

- Before copying data that is in character format from a file into a database table, check the datatype entry rules in the “Datatypes” section of the *SQL Server Reference Manual*. Character data that is being copied into the database with `bcp` must conform to those rules. Note especially that dates in the undelimited *(yy)yyymmdd* format may result in overflow errors if the year is not specified first.
- When you send host data files to sites that use terminals different from your own, inform them of the *datafile_charset* that you used to create the files.
- You cannot use named pipes to `bcp` files in or out.

Messages

Error in attempting to determine the size of a pair of translation tables.: 'stat' utility failed.

The character translation file(s) named with the `-a` or `-q` parameter is missing, or you mistyped the name(s).

See Also

Chapter 2, “Using `bcp` to Transfer Data to and from SQL Server”.

buildmaster

Function

Builds the master device and creates the *master*, *model*, and *tempdb* databases on the device.

Syntax

```
buildmaster [-d physicalname] [-c cntrltype]  
            [-s size] [-r] [-m] [-x]
```

Parameters

- d *physicalname* – is the physical name of the raw disk partition or operating system file where the master device resides.
- c *cntrltype* – is the controller number for the master device. Together, *cntrltype* and *physicalname* specify the device. The default value for *cntrltype* is 0. Do not change this value unless instructed to do so.
- s *size* – is the size of the master device in 2K blocks. For example, a *size* of “5120” creates a 10 megabyte master device. **buildmaster** verifies that the value you specify for this parameter does not exceed the space available to the master device, unless you use the -m or -r option.
- r – rewrites the configuration block that contains the system startup parameters with the default values without disturbing anything else on the database device. This option changes the configuration variables to their default values without rebuilding the *master* database. Use this option when the value of a configuration variable is set so high that SQL Server cannot start.
- m – rewrites only the *master* database, without changing the configuration block or initializing the master device. Use this option when the *master* database is corrupted but the other databases on the master device are undamaged. If you use both -m and -r, then **buildmaster** rewrites the configuration block that contains the system start parameters (as derived from the system tables *sysconfigures* and *syscurconfigs*) and the *master* database without initializing the rest of the master device.
- x – rewrites only the *model* database, without changing the configuration block or initializing the master device. Use this option when the *model* database is corrupted and you cannot load

it successfully from a backup. If you modified *model*, you must restore it from a backup after reinitializing it with this option.

Examples

1. `buildmaster -d /dev/rsd1f -s8704`

Initializes the raw device */dev/rsd1f* as a 17 Mb master device, and creates the system databases *master*, *model*, and *tempdb* on the device.

Comments

- The `buildmaster` program initializes the specified device (database device) as a SQL Server master device, and builds the *master* and *model* databases on it. `buildmaster` also provides options for recovery from configuration errors and other disasters.
- The `sybinit` installation program runs `buildmaster` and builds an initial *master* database on the database device you specify in answer to the program's prompts.
- If you run `buildmaster` with no options, it prompts for the information listed below. **You must enter a response for each prompt.**

```
master disk name?
master disk controller number?
master disk size?
configuration only?(y or n) (same as -r)
databases only? (y or n) (same as -m)
```

- If you rebuild the *model* database, you must run the `installmodel` script, located in `$$SYBASE/scripts`. `installmodel` sets up the necessary permissions for the *model* database. To run the script enter the following series of commands:

```
cd $$SYBASE/scripts
setenv DSQUERY server_name
isql -Usa -P -Sserver_name < installmodel
```
- If you rebuild the *master* database, and do not have a database dump, or cannot load the dump, you must:
 1. Start the server using `startserver`.
 2. If your *sybystemprocs* database is undamaged, run `disk reinit` and `disk refit` to restore the system tables entries. Otherwise, create a *sybystemprocs* database on any device or on an operating system file. This database should be at least 10 Mb. If you do not have a

sybserverprocs database, the next step tries to install the system procedures in the *master* database.

3. Run the *installmaster* script. To run the script, use the following commands:

```
cd $SYBASE/scripts
setenv DSQUERY server_name
isql -Usa -P -Sserver_name < installmaster
```

The *installmaster* script installs the system stored procedure tables such as *spt_values* in the master database and creates the system procedures in *sybserverprocs*. If *sybserverprocs* does not exist, *installmaster* creates the procedures in *master*.

- The password to the default “sa” account reverts to NULL after you run *buildmaster -m*, and the account is unlocked. Loading a backup of the master database restores the password and lock state from when the dump was taken.

dataserver

Function

The executable form of the SQL Server program.

Syntax

```
dataserver -ddevicename [-errorlogfile] [-m]
           [-rmastermirror] [-Msharedmem_directory]
           [-pssso_login_name]
```

Parameters

- ddevicename – is the full path name of the *master* database device. The *master* database device must be writable by the user who starts SQL Server. The default *master* database device name is *d_master*.
- errorlogfile – is the full path name of the error log file for SQL Server system-level error messages.
- m – starts SQL Server in single user mode.
- rmastermirror – starts the mirror of the *master* database device. Use this option to start SQL Server if the *master* database device has been damaged.
- Msharedmem_directory – places shared memory files in the specified directory instead of in the default location, *\$\$SYBASE*. If *sharedmem_directory* starts with “/”, the directory name is assumed to be absolute. Otherwise, the directory name is interpreted relative to *\$\$SYBASE*.
- p – specifies the login name of a System Security Officer when starting SQL Server, for the purposes of getting a new password for that account. SQL Server generates a random password, displays it, encrypts it, and saves it in *master..syslogins* as that account’s new password.

Comments

- Start SQL Server with the *startserver* command rather than by directly executing the *dataserver* program.
- SQL Server derives its running environment from values in the *sysconfigures* system table. Run the system procedure *sp_configure* to see configuration values; use *sp_configure* and *reconfigure* to change configuration.

- Because SQL Server passwords are encrypted, you cannot recover forgotten passwords. If all System Security Officers lose their passwords, the `-p` option generates a new password for a System Security Officer account. Start SQL Server with `-p`, immediately log into SQL Server with the new random password and execute `sp_password` to reset your password to a more secure one.
- After you have finished running the `sybinit` installation program, be sure to set the file permissions on the `dataserver` executable to limit who can execute it.

defncopy

Function

Copies definitions for specified views, rules, defaults, triggers, or procedures from a database to an operating system file or from an operating system file to a database.

► Note

The `defncopy` utility cannot copy table definitions or reports created with Report Workbench.

Syntax

```
defncopy [-U username][-P password] -S server [-v]
        [-I interfaces_file] [-a display_charset]
        [-J client_charset] [-z language] [-X]
        {in filename dbname | out filename dbname
         [owner.]objectname [[owner.]objectname]....}
```

Parameters

- U *username* – allows you to specify a login name. Login names are case-sensitive. If you do not specify *username*, `defncopy` uses the current user's operating system login name.
- P *password* – allows you to specify your password. If you do not specify -P, `defncopy` prompts for your password.
- S *server* – allows you to specify the name of the SQL Server to connect to. If you specify -S with no argument, `defncopy` looks for a server named SYBASE. If you do not specify -S, `defncopy` uses the server specified by your DSQUERY environment variable.
- v – displays the version and copyright message of `defncopy` and returns to the operating system.
- I *interfaces_file* – allows you to specify the name and location of the interfaces file to search when connecting to SQL Server. If you do not specify -I, `defncopy` looks for a file named *interfaces* in the directory that your SYBASE environment variable specifies.
- a *display_charset* – allows you to run `defncopy` from a terminal whose character set differs from that of the machine on which `defncopy` is running. -a in conjunction with -J specifies the character set

translation file (.xlt file) required for the conversion. Use -a without -J only if the client character set is the same as the default character set.

In Japanese language environments, the -q flag is required to translate Hankaku Katakana (half-width characters) into Zenkaku Katakana (full-width characters). Use with the argument “zenkaku” and with the -J flag to indicate the client’s Japanese character set (sjis or eucjis). The *zenkaku.xlt* file was designed to translate **only** from terminal display to SQL Server, **not** from SQL Server to the terminal.

► **Note**

The `ascii_7` character set is compatible with all character sets. If either the SQL Server’s or client’s character set is set to `ascii_7`, any 7-bit ASCII character is allowed to pass between client and server unaltered. Other characters produce conversion errors. (Character set conversion issues are covered more thoroughly in the *System Administration Guide*.)

-J *client_charset* – specifies the character set to use on the client. A filter converts input between *client_charset* and the SQL Server character set.

-J *client_charset* requests that SQL Server convert to and from *client_charset*, the client’s character set.

-J with no argument sets character set conversion to NULL. No conversion takes place. Use this if the client and server are using the same character set.

Omitting -J sets the character set to a default for the platform. The default may not necessarily be the character set that the client is using. (See the *System Administration Guide* and the *System Administration Guide Supplement* for your platform for more information about character sets and the associated flags.)

-z *language* – is the official name of an alternate language that the server uses to display `defncopy` prompts and messages. Without the -z flag, `defncopy` uses the server’s default language. Add languages to a SQL Server at installation, or afterwards with the utility `langinstall` or the stored procedure `sp_addlanguage`.

-X – specifies that in this connection to the server, initiate the login with client-side password encryption. `defncopy` (the client) specifies to the server that password encryption is desired. The

server sends back an encryption key, which defncopy uses to encrypt your password, and the server uses the key to authenticate your password when it arrives.

If defncopy crashes, the system creates a core file which contains your password. If you did not use the encryption option, the password appears in plain text in the file. If you used the encryption option, your password is not readable.

in | out – specifies the direction of definition copy.

filename – specifies the name of the operating system file destination or source for the definition copy. The copy out overwrites any existing file.

dbname – specifies the name of the database to copy the definitions from or to.

objectname – specifies name(s) of database object(s) for defncopy to copy out. Do not use *objectname* when copying definitions in.

Comments

- Invoke the defncopy program directly from the operating system. defncopy provides a non-interactive way of copying out definitions (create statements) for views, rules, defaults, triggers, or procedures from a database to an operating system file. Alternatively, it copies in all the definitions from a specified file.

You must have select permission on the *sysobjects* and *syscomments* tables to copy out definitions; you do not need permission on the object itself.

- You must have the appropriate create permission for the type of object you are copying in. Objects copied in belong to the copier. A System Administrator copying in definitions on behalf of a user must log in as that user to give the user proper access to the reconstructed database objects.
- The *in filename* or *out filename* and the database name are required and must be unambiguously stated. For copying out, use file names that reflect both the object's name and its owner.
- defncopy ends each definition that it copies out with the comment

```
/* ### DEFNCOPY: END OF DEFINITION */
```

Definitions you create as text must end with this comment, or defncopy cannot copy them in successfully.

- Enclose values specified to defncopy in quotation marks if they contain characters that could be significant to the shell.

◆ ***WARNING!***

Long comments (>100 characters) placed before a create statement may cause defncopy to fail.

isql

Function

Interactive SQL parser to SQL Server.

Syntax

```
isql [-e] [-F] [-g] [-p] [-n] [-v] [-X] [-Y]
      [-a display_charset] [-c cmdend] [-E editor]
      [-h headers] [-H hostname] [-i inputfile]
      [-I interfaces_file] [-J client_charset]
      [-l login_timeout] [-m errorlevel]
      [-o outputfile] [-P password] [-s colseparator]
      [-S server] [-t timeout] [-U username]
      [-w columnwidth] [-y sybase_directory]
      [-z language] [-A size]
```

To terminate a command: **go**

To clear the query buffer: **reset**

To call the editor: **vi**

To execute an operating system command: **!! *command***

To exit from isql: **quit** or **exit**

Parameters

-e – echoes input.

-F – enables the FIPS flagger. With this option, the server flags any non-ANSI standard commands sent.

-p – prints out performance statistics.

-n – removes numbering and the prompt symbol (>) from input lines.

-v – prints the version and copyright of the isql software that you are using, and exits.

-X – initiates the login connection to the server with client-side password encryption. isql (the client) specifies to the server that password encryption is desired. The server sends back an encryption key, which isql uses to encrypt your password, and the server uses the key to authenticate your password when it arrives.

If isql crashes, the system creates a core file which contains your password. If you did not use the encryption option, the

password appears in plain text in the file. If you used the encryption option, your password is not readable.

-Y – tells the SQL Server to use chained transactions.

-a *display_charset* – allows you to run `isql` from a terminal whose character set differs from that of the machine on which `isql` is running. **-a** in conjunction with **-J** specifies the character set translation file (*.xlt* file) required for the conversion. Use **-a** without **-J** only if the client character set is the same as the default character set.

In Japanese language environments, the **-q** flag is required to translate Hankaku Katakana (half-width characters) into Zenkaku Katakana (full-width characters). Use with the argument “zenkaku” and with the **-J** flag to indicate the client’s Japanese character set (`sjis` or `ujis`). The *zenkaku.xlt* file was designed to translate **only** from terminal display to SQL Server, **not** from SQL Server to the terminal.

► **Note**

The `ascii_7` character set is compatible with all character sets. If either the SQL Server’s or client’s character set is set to `ascii_7`, any 7-bit ASCII character is allowed to pass between client and server unaltered. Other characters produce conversion errors. See the *System Administration Guide* for more information on character set conversion.

-c *cmdend* – resets the command terminator. By default, terminate commands and send them to SQL Server by entering “go” on a line by itself. When you reset the command terminator, do not use SQL reserved words or control characters.

-E *editor* – specifies an editor other than your default editor.

-h *headers* – specifies how many rows to print between column headings. The default prints headings only once for each set of query results.

-H *hostname* – sets the client hostname.

-i *inputfile* – specifies the name of an operating system file to use for input to `isql`. The file must contain command terminators (“go” by default).

Specifying the parameter as follows:

-i *inputfile*

is equivalent to:

< *inputfile*

If you use **-i** and do not specify your password on the command line, **isql** prompts you for it.

If you use **< *inputfile*** and do not specify your password on the command line, you must specify your password as the first line of the input file.

-l *interfaces_file* – specifies the name and location of the interfaces file to search when connecting to SQL Server. Without **-l**, **isql** looks for a file named *interfaces* in the directory specified by your SYBASE environment variable.

-J *client_charset* – specifies the character set to use on the client. **-J *client_charset*** requests that SQL Server convert to and from *client_charset*, the character set used on the client. A filter converts input between *client_charset* and the SQL Server character set.

-J with no argument sets character set conversion to NULL. No conversion takes place. Use this if the client and server use the same character set.

Omitting **-J** sets the character set to a default for the platform. The default may not necessarily be the character set that the client is using. (See the *System Administration Guide* and the *System Administration Guide Supplement* for your platform for more information about character sets and the associated flags.)

-l *login_timeout* – specifies the maximum timeout value allowed when connecting to SQL Server.

-m *errorlevel* – customizes the error message display. For errors of the severity level specified or higher only the message number, state, and error level display; no error text appears. For error levels lower than the specified level, nothing appears.

-o *outputfile* – specifies the name of an operating system file to store the output from **isql**. Specifying the parameter as follows:

-o *outputfile*

is similar to:

> *outputfile*

- P *password* – specifies your current SQL Server password. If you do not specify the -P flag, isql prompts for a password. If your password is NULL, use the -P flag at the end of the command line without any password.
- s *colseparator* – resets the column separator character, which is blank by default. To use characters that have special meaning to the operating system (for example, “|”, “;”, “&”, “<”, “>”), enclose them in quotes or precede them with a backslash.
- S *server* – specifies the name of the SQL Server to connect to. isql looks this name up in the interfaces file. If you specify -S with no argument, isql looks for a server named SYBASE. Without -S, isql looks for the server specified by your DSQUERY environment variable.
- t *timeout* – specifies the number of seconds before a SQL command times out. If you do not specify a timeout, a command runs indefinitely. This affects commands issued from within isql, not the connection time. The default timeout for logging into isql is 60 seconds.
- U *username* – specifies a login name. Logins are case-sensitive.
- w *columnwidth* – sets the screen width for output. The default is 80 characters. When an output line reaches its maximum screen width, it breaks into multiple lines.
- y *sybase_directory* – specifies a SYBASE directory other than the default \$SYBASE directory.
- z *language* – is the official name of an alternate language to display isql prompts and messages. Without -z, isql uses the server’s default language. Add languages to a SQL Server at installation, or afterwards with the utility langinstall or the stored procedure sp_addlanguage.
- A *size* - specifies the network packet size to use for this isql session For example:

```
isql -A 2048
```

sets the packet size to 2,048 bytes for this isql session. *size* must be between the values of the default network packet size and maximum network packet size configuration variables, and must be a multiple of 512.

Examples

1. isql

Password:

```
1>select *
2>from authors
3>where city = "Oakland"
4>go
```

Executes the command.

2. isql -Ujoe -Pabracadabra

```
1>select *
2>from authors
3>where city = "Oakland"
4>vi
```

Puts you in a text file where you can edit the query. When you write and save the file, you are returned to isql. The query is displayed. Type go to execute it.

3. isql -U alma

Password:

```
1>select *
2>from authors
3>where city = "Oakland"
4>reset
5>quit
```

reset clears the query buffer. quit returns you to the operating system.

4. isql -a mac -J roman8

Specifies that you are running isql from a Macintosh against a server that is using the roman8 character set.

Comments

- To use isql interactively, give the command isql (and any of the optional flags) at your operating system prompt. The isql program accepts SQL commands and sends them to SQL Server. The results are formatted and printed on standard output. Exit isql with quit or exit.
- Terminate a command by typing a line beginning with the default command terminator go. You may follow the command terminator with an integer to specify how many times to run the

command. For example, to execute this command 100 times, type:

```
select x = 1
go 100
```

The results display once at the end of execution.

- If you enter an option more than once on the command line, isql uses the last value. For example, if you enter the following command:

```
isql -c"." -csend
```

“send”, the second value for -c, overrides “.”, the first value. This enables you to override any aliases you set up.

- To call an editor on the current query buffer, enter its name as the first word on a line. Define your preferred callable editor by specifying it with the EDITOR environment variable. If EDITOR is undefined, the default is vi.

Execute operating system commands by starting a line with “!” followed by the command. Call alternate editors this way, without defining EDITOR.

- To clear the existing query buffer, type reset on a line by itself. isql discards any pending input. You can also enter Ctrl-c anywhere on a line; this cancels the current query and returns the user to the isql prompt.
- Read in an operating system file containing a query for execution by isql as follows:

```
isql -U alma -P***** < input_file
```

The file must include command terminator(s). The results appear on your terminal. Read in an operating system file containing a query and direct the results to another file as follows:

```
isql -U alma -P***** < input_file > output_file
```

- Case is significant for the isql flags.
- isql displays only six digits of *float* or *real* data after the decimal point, rounding off the remainder.
- When using isql interactively, read an operating system file into the command buffer with the command:

```
:r filename
```

Do not include a command terminator in the file; enter the terminator interactively once you have finished editing.

- You can include comments in a Transact-SQL statement submitted to SQL Server by isql. Open a comment with “/*”. Close it with “*/”. Comments can be nested. For example:

```
select au_lname, au_fname
/*retrieve authors' last and first names*/
from authors, titles, titleauthor
where authors.au_id = titleauthor.au_id
and titles.title_id = titleauthor.title_id
/*this is a three-way join that links authors
**to the books they have written.**/
```

sp_droplanguage, sp_helplanguage in the *SQL Server Reference Manual*,
Volume 2.

langinstall

Function

Installs one new language on SQL Server.

Syntax

```
langinstall [-S server] [-I interfaces_file]  
            [-P password] [-R release_number] [-v]  
            language character_set
```

Parameters

- S *server* – specifies the name of the SQL Server to connect to. If you do not specify -S, langinstall uses the server specified by your DSQUERY environment variable. If DSQUERY is not set, langinstall attempts to connect to a server named SYBASE.
- I *interfaces_file* – specifies the name and location of the interfaces file that langinstall searches when connecting to SQL Server. If you do not specify -I, langinstall uses the *interfaces* file in the directory that your SYBASE environment variable specifies. If SYBASE is not set, langinstall looks for the default SYBASE home directory.
- P *password* – specifies the System Administrator's password. Only the System Administrator can run langinstall. If you omit -P, langinstall prompts for the System Administrator's password.
- language* – is the official name of the language to install. You must specify a language.
- character_set* – is the name of SQL Server's default character set. *character_set* indicates the directory name of the localization files for the language. The *common.loc* and *server.loc* localization files for an official language reside in the character set directory *\$\$SYBASE/locales/language/character_set*. You must specify a character set.
- R *release_number* – specifies the release number, in the format *n.n.n.*, to use to upgrade messages in *master.sysmessages*. Use -R only in failure conditions, such as if langinstall fails or in case of user error, when you think that messages in *sysmessages* are out of date.
- v – prints the version number and copyright message for langinstall, and exits.

Comments

- **sybinit** runs **langinstall** automatically for a new installation as well as for customers who are upgrading from a previous release.
- **langinstall** does the following:
 - Adds the specified language-specific information to *master.syslanguages* using the **sp_addlanguage** stored procedure. If the language already exists, **langinstall** updates the appropriate row in *syslanguages*.
 - Adds to, updates, and deletes error messages as necessary from *master.sysmessages*.
 - Updates *syslanguages.update*, inserting the new release number.
- **langinstall** validates the entries found in the localization file sections that it uses. If anything is missing, **langinstall** prints an error message and does not add the language to *syslanguages*.
- **langinstall** compares the version numbers of each of the localization files that it uses, *common.loc* and *server.loc*. If they are not the same it prints a warning message. *syslanguages.upgrade* is always set according to the version number in *server.loc*.
- The **-R** option forces **langinstall** to collect messages from a release previous to the most current one. **langinstall** compares the existing messages with the ones to be installed and replaces any that have changed.

For example, if the most current release is 4.9 but you think that *sysmessages* may not be correct, specify the messages added before the release in the *syslanguages.upgrade* column (4.9 in this case) with **-R 4.8**. **langinstall** then installs all messages from Release 4.8 and earlier.

Permissions

Only System Administrators can run **langinstall**.

Tables Used

master.dbo.syslanguages, *master.dbo.sysmessages*

See Also

showserver

Function

Shows SQL Servers and Backup Servers currently running on the local machine.

Syntax

```
showserver
```

Comments

- `showserver` prints process information about SQL Server or Backup Server. If no servers are running, only the header appears.

startserver

Function

Starts a SQL Server and/or a Backup Server.

Syntax

```
startserver [[-f runserverfile] [-m]] ...
```

Parameters

-f *runserverfile* – specifies the name of a runserver file that is used as a reference each time you restart a SQL Server or Backup Server. By default, the runserver file is named *RUN_servername*. If you start a second SQL Server on the same machine, a new runserver file named *RUN_servername* is created.

The startserver command creates SQL Server's error log file (named *errorlog*) in the directory where you start the server, and adds this information as part of the -e option on the SQL Server executable line in the runserver file. If a second SQL Server is started on the same machine, a new error log named *errorlog_servername* is created; this information is added to that server's runserver file. The user must have execute permission on the specified runserver file.

-m – starts SQL Server in single user mode, allowing only one System Administrator to log in, and turns the *allow updates* configuration variable on. Use this mode to restore the *master* database. The System Administrator can use the *dbo use only* option of *sp_dboption* for system administration activities that require more than one process, such as bulk copying or using the data dictionary. startserver normally starts up only one server per node.

The -m option creates a *m_RUNSERVER* file and overwrites any existing *m_RUNSERVER* file.

Examples

1. **startserver**

Starts a SQL Server named SYBASE.

2. **startserver -f RUN_MYSERVER -f RUN_SYB_BACKUP**

Starts a SQL Server named MYSERVER and a Backup Server named SYB_BACKUP.

3. startserver -f RUN_SYB_BACKUP

Starts only the Backup Server SYB_BACKUP.

Comments

- The master device must be writable by the user who starts SQL Server.
- You may specify more than one runserver file, as shown in Example 2. You may specify -m after each -f *runserverfile*.
- If the *master* database device has been damaged, use the *dataserver -r* option to start the mirror of the device. See *dataserver* for information.
- SQL Server derives its running environment from values in the *sysconfigures* system table. Run the system procedure *sp_configure* and the Transact-SQL command *reconfigure* to see or to change configuration.
- To ensure the integrity of your SQL Server, it is important that you apply appropriate operating system protections to the *startserver* executable file.

Using *bcp* to Transfer Data to and from SQL Server

Introduction

This chapter explains how to use *bcp* to move data between SQL Server and an operating system file. There are two ways to move data:

- The bulk copy utility (*bcp*), used as a stand-alone program from the operating system
- Open Client DB-Library routines from inside an application program

This chapter discusses *bcp* in detail. See “*bcp*” on page 1-5 for the full command syntax and descriptions of the parameters.

For information about transferring data using Open Client DB-Library, see the *Open Client and Open Server Common Libraries Reference Manual*.

About Importing and Exporting Data

There are no Transact-SQL commands for the bulk transfer of data. Use the bulk copy utility (*bcp*) from the operating system.

bcp is most frequently used to import data previously associated with another program (such as another database management system). Use the dump facilities from the other program to put the data to be transferred into an operating system file.

You can also use the bulk copy facilities for moving tables between SQL Servers, or almost any data source that can produce an operating system file.

SQL Server’s bulk copy utility can also transfer data for use with other programs—for example, with spreadsheet programs. *bcp* moves the data from SQL Server into an operating system file or onto disk; from there the other program can import the data. When you are through using your data with the other program, transfer it back into an operating system file or onto disk, and then back onto SQL Server with the bulk copy facilities.

SQL Server can accept data in any character or binary format, as long as you can describe the terminators (the characters used to separate columns) or the length of the fields in the data file. The table structures need not be identical. When importing from a file, *bcp*

appends data to an existing database table; when exporting to a file, **bcp** overwrites any previous contents of the file.

Requirements for Using *bcp*

In general, you must supply the following information for transferring data to and from SQL Server:

- Name of the database and table
- Name of the operating system file
- Direction of the transfer (in or out)

In addition, you can optionally modify the datatype, file storage length, and terminator for each column.

When the transfer is complete, the program reports the number of rows successfully copied and some performance information.

Permissions Needed for Copying Data

In order to use **bcp**, you must have a SQL Server account and the appropriate permissions on the database tables and operating system files that you will use. To copy data into a table, you must have insert permission on the table.

To copy a table out to an operating system file, the user must have select permission on the following tables:

- The table being copied
- *sysobjects*
- *syscolumns*
- *sysindexes*

bcp Performance Issues

When using **bcp** to copy data into a target table, you must make some choices between performance and recoverability. The choices you make depend on the size of the table into which you are copying, the amount of data you are copying in or out, the number of indexes on the table, and the amount of spare database device space that you have for recreating indexes should you decide to remove them.

These issues are discussed in detail in the following section. Here is a summary of the main considerations:

- **Fast bcp:** You can remove any indexes and triggers on the target table and use “fast” bcp. Inserts are not logged and cannot be recovered from a log backup created using `dump transaction`. Also, you need to allocate resources to recreate the indexes when you are finished copying in—for a clustered index, this is typically about 2.2 times the amount of disk space needed for the data.
- **Slow bcp:** You can retain the indexes and triggers on the table and use “slow” bcp. Every insert is logged, which can cause the transaction log to fill very quickly. If you are copying a large number of rows, the performance penalty and log space requirements for using slow bcp can be severe.

Bulk Copying Data with Indexes and Triggers

For copying data in, bcp is fastest if your database table has no indexes or triggers, because “fast” bcp does not log data inserts in the transaction log.

When you copy into a table that has indexes or triggers, bcp automatically uses a slower version, which logs data inserts in the transaction log. This can cause the transaction log to become very large, but dumping the log to a backup device with `dump transaction` assures that the database is fully recoverable in the event of a failure. Also, after backing up your database with `dump database`, you can truncate the transaction log with `dump transaction with truncate_only`.

bcp does not fire the triggers on the target table, if any exist.

► **Note**

To allow any user to copy in data using the fast version of bcp, a System Administrator or the Database Owner must first use the `sp_dboption` system procedure to set the `select into/bulkcopy` option to `on` for the database containing the target table(s). If the option is not set to `on` and a user tries to copy data into a table that does not have indexes, SQL Server generates an error message.

You don't need to set this database option in order to copy data out, or in order to run bcp on a table that does have indexes or triggers. Tables with indexes or triggers are always copied with the slower version, and all inserts are logged.

If you have made unlogged data inserts with fast bcp, you cannot dump the transaction log because changes are not in the log, and therefore are not recoverable from such a dump. In this situation, issuing `dump transaction` produces an error message instructing you to use `dump database` instead. This restriction remains in force until a `dump database` successfully completes.

The following table shows which version of bcp is used when copying in, the necessary settings for the `select into/bulkcopy` option, and whether the transaction log is kept and dumpable.

	select into/bulkcopy	
	on	off
fast bcp (no indexes or triggers on target table)	OK dump transaction prohibited	bcp prohibited
slow bcp (one or more indexes or triggers)	OK dump transaction prohibited	OK dump transaction OK

Table 2-1: Fast and Slow bcp with select into/bulkcopy

By default, the `select into/bulkcopy` option is off in newly created databases. To change the default setting, turn this option on in the *model* database.

If you are copying a very large number of rows, it may be faster to drop all the indexes and triggers beforehand with `drop index` and `drop trigger`, set the database option, copy the data into the table, recreate the indexes and triggers, and then dump the database. Remember to allocate 2.2 times the amount of space needed for the data to reconstruct a clustered index. If you don't have enough space to sort the data and build the index(es), use "slow" bcp.

Steps for Copying Data

Table 2-2 summarizes the steps to copy data into SQL Server.

Steps	Notes	Who Can Do It
Use <code>sp_dboption</code> to set <code>select into/bulkcopy</code> to true, and then run <code>checkpoint</code> in the database that was changed		System Administrator
Drop the indexes on the table	Check to be sure that you have enough space to recreate!	Table owner
Be sure that you have <code>insert</code> permission on the table		Granted by the table owner
Perform the copy with <code>bcp</code>		Any user with <code>insert</code> permission
Re-create the indexes		
Reset <code>sp_dboption</code> , if desired, and run <code>checkpoint</code> in the database that was changed		System Administrator or Database Owner
Use <code>dump database</code> to back up the newly inserted data		System Administrator, Operator, or Database Owner
Run stored procedures or queries to check to see if any of the newly loaded data violates rules		Table owner or stored procedure owner

Table 2-2: Steps for Copying Data

Using the *bcp* Options

See the reference page in Chapter 1 for `bcp`'s syntax and a full discussion of the available options. The following sections detail some of the more complex options.

Using the Default Formats

`bcp` provides two command line options that automatically create files with frequently used default formats. These options provide the easiest way to copy data in and out of SQL Server. The `-n` option uses "native" (or operating system) formats. The `-c` option uses "character" (*char* datatype) for all columns, providing tabs between fields on a row, and a newline at the end of each row.

If you are using the native or character options, **bcp** operates non-interactively and does not ask you for any information except your SQL Server password.

Native Format

The **-n** option creates files using “native” (operating-system-specific) formats. Native format usually creates a more compact operating system file. For example, the following commands copy the *publishers* table to the file called *pub_out*, using native data format:

```
bcp pubs2..publishers out pub_out -n
```

Here are the contents of *pub_out*:

```
0736^MNew Age Books^FBoston^BMA0877^PBinnet & Hardley^J
Washington^BDC1389^TAlgodata Infosystems^HBerkeley^BCA
```

bcp prefixed each field (except the *pub_id*, which is a *char(4)* datatype) with an ASCII character equivalent to the length of the data in the field. For example, “New Age Books” is 13 characters, and ^M (Ctrl-M) is ASCII 13. All of the data in this table is *char* or *varchar* data, and so is human-readable. In a table with numeric data, **bcp** writes the information to the file in the operating system’s data representation format and may not be human-readable.

► **Note**

Be careful copying native format data from different versions of SQL Servers because they do not always have the same datatypes.

Character Format

Character format uses “character” (the *char* datatype) for all columns. It inserts tabs between fields on each row, and a newline at the end of each row.

For example, the following commands copy the *publishers* file out in character format:

```
bcp pubs2..publishers out pub_out -c
```

This is the output:

```
0736      New Age Books           Boston      MA
0877      Binnet & Hardley             Washington  DC
1389      Algodata Infosystems        Berkeley    CA
```

Changing Terminators for Character Format

The row terminator is the field terminator of the last field in the table or file.

Use the `-t field_terminator` and `-r row_terminator` command line options with the character format option to change the terminators. The following example uses the comma as the field terminator and Return (`\r`) as the row terminator (remember to “escape” the backslash if necessary for your operating system command shell):

```
bcp pubs2..publishers out pub_out -c -t , -r \r
```

This produces:

```
0736,New Age Books,Boston,MA
0877,Binnet & Hardley,Washington,DC
1389,Algodata Infosystems,Berkeley,CA
```

You can also use the `-t` and `-r` options to change the default terminators without the character option.

Changing the Defaults: Interactive *bcp*

If you do not use the native or character options, `bcp` enters interactive mode and prompts you for the storage type, prefix length, and terminator for each column of data to copy. For fields that are to be stored as *char* or *binary*, `bcp` also prompts for a field length.

The default values for these four prompts (presented along with the prompts) produce exactly the same results as using the native option, and provide a simple means for copying data out of a database for later reloading into SQL Server. If you are copying data to or from SQL Server for use with other programs, base your answers to the prompts on the format that the other software requires.

Your responses to these four prompts provide an extremely flexible system that allows you to read files from other software, or to create a file that requires little or no editing to conform to many other data formats. The next sections discuss each of these prompts and the ways that they interact to affect the data. Remember that the default responses to these prompts provide the fastest and easiest method to copy data to and from SQL Server. Other responses create custom data formats.

File Storage Type

The file storage type describes how to store the data in the file. You can copy data into a file either as its database table type, as a character string, or as any datatype for which implicit conversion is supported. User-defined datatypes are copied as their base types.

Table 2-3 shows the storage types that can be used with `bcp`, the defaults for each SQL Server datatype, and the legal abbreviations. For the most compact storage, use the default value; for character files, use *char*. In the table, brackets ([]) indicate that you may use the initial character or the beginning characters of the word; for example, for *bit* you can use *b*, *bi*, or *bit*. *timestamp* data is treated as *binary(8)*. The *date* storage type is the SQL Server internal storage format of *datetime*, not the host operating system format of the date.

Table Datatype	Storage Type
<i>char</i>	c[har]
<i>varchar</i>	c[har]
<i>text</i>	T[ext]
<i>binary</i>	x
<i>varbinary</i>	x
<i>image</i>	I[mage]
<i>int</i>	i[nt]
<i>smallint</i>	s[mallint]
<i>tinyint</i>	t[inyint]
<i>float</i>	f[loat]
<i>bit</i>	b[it]
<i>money</i>	m[oney]
<i>datetime</i>	d[atetime]
<i>timestamp</i>	x
<i> smalldatetime</i>	D
<i>real</i>	r
<i>smallmoney</i>	M
<i>numeric</i>	n
<i>decimal</i>	e

Table 2-3: File Storage Datatypes for `bcp`

To see this list while using `bcp` interactively, type a question mark in response to the “Enter the file storage type” prompt.

The suggested values that appear in the prompts are the defaults. Remember that your response determines how the data is stored in the output file; you need not indicate the column’s type in the database.

bcp fails if you enter a type that is not either implicitly convertible or *char*. For example, you may not be able to use *smallint* for *int* data (you may get overflow errors), but you can use *int* for *smallint*.

When storing non-character datatypes as their database types, **bcp** writes the data to the file in the operating system's data representation format, rather than in human-readable form.

Prefix Length

By default, **bcp** precedes each field that has a variable storage length with a string of one or more characters indicating the length of the field. This provides the most compact file storage. The default values in the prompts indicate the most efficient prefix length.

For fixed-length fields, the prefix length should be 0.

For fields of 255 characters or less, the default prefix length is 1. For *text* or *image* datatypes, the default prefix length is 4. When *binary* and *varbinary* datatypes are being converted to *char* storage types, the default prefix length is 2, since each byte of table data requires 2 bytes of storage.

► **Note**

Any data column that can contain null values is considered variable length for **bcp** purposes. This includes columns with integer datatypes that might ordinarily be considered fixed length. Use a length prefix (other than 0) or terminator to denote the length of each row's data.

To store data with no prefix before its column, use a prefix length of 0. **bcp** pads each stored field with spaces to the full length specified at the next prompt, "length," unless you supply a terminator.

Note that since length prefixes consist of "native" format integers, they will cause the resulting host file to contain non-printable characters. This causes problems if you try to print out the host file, or try to transmit it using a communications program that cannot handle characters that are not human-readable.

Storage Length

► **Note**

“Length” and “storage length” in this discussion always refer to the operating system file, not to SQL Server field lengths.

In almost all cases, accept the `bcp` default value for the storage length while copying data out. If you are making a file to later reload into SQL Server, the default prefixes and length keep the storage space needed to a minimum. If you are creating a human-readable file, use the default length to ensure that you won't truncate the data or create overflow errors that cause `bcp` to fail.

However, it is possible to change the default length by supplying another value. If you are copying character data in from other software, carefully examine the source file before choosing length values.

If the storage type is non-character, `bcp` stores the data in the operating system's native data representation and does not prompt for a length.

When `bcp` converts non-character data to character storage, it suggests a default field length large enough to store the data without truncating *datetime* data or causing overflow of numeric data. The default lengths are the number of bytes needed to display the longest value for the SQL Server datatype. Table 2-4 lists the default field lengths.

Datatype	Default Size
<i>int</i>	12 bytes
<i>smallint</i>	6 bytes
<i>tinyint</i>	3 bytes
<i>decimal</i>	33 bytes
<i>numeric</i>	33 bytes
<i>float</i>	25 bytes
<i>money</i>	24 bytes
<i>datetime</i>	26 bytes
<i>bit</i>	1 byte
<i>real</i>	25 bytes
<i>smallmoney</i>	24 bytes
<i>smalldatetime</i>	26 bytes

Table 2-4: Default Field Lengths in `bcp`

If you specify a field length that is too short for numeric data when copying data out, `bcp` prints an overflow message and does not copy the data.

The default length for *binary* and *varbinary* fields is twice the length defined for the column, since each byte of the field requires 2 bytes of storage.

If you accept the default storage length, the actual amount of storage space allocated depends on whether or not you specify a prefix length and/or terminators:

- If you specify a prefix length of 1, 2 or 4, `bcp` uses a storage space of the actual length of the data plus the length of the prefix, plus any terminators.
- If you specify a prefix length of 0 and no terminator, `bcp` allocates the maximum amount of space shown in the prompt, which is the maximum space that may be needed for the datatype in question. In other words, `bcp` treats the field as if it were fixed length to determine where one field ends and the next begins. For example, if the field is defined as *varchar*(30), `bcp` uses 30 characters for each value, even if some of the values are only one character long. Because `bcp` does not know how large any one data value will be before copying all the data, `bcp` always pads *char* datatypes to their full specified length.

Field and Row Terminators

A terminator can be used to mark the end of a column or row, separating one from the next. The default is no terminator. Field terminators separate table columns; the row terminator is the field terminator of the last field in the table or file.

Terminators are very useful for dealing with character data because you can choose human-readable terminators. The `bcp` character option, which uses tabs between each column with a newline at the end of each row, is an example of using terminators that enhance the readability of a data file.

When you prepare data for use with other programs, and when you want to use `bcp` to prepare tabular data, supply your own terminators. The available terminators are:

- Tabs, indicated by `\t`
- Newlines, indicated by `\n`
- Carriage returns, indicated by `\r`

- Backslash, indicated by \
- Null terminators (no visible terminator), indicated by \0
- Any printable character (*, A, t, |, etc.)
- Strings of up to ten printable characters, including some or all of the terminators listed earlier (for example, `**\t**`, `end, !!!!!!!!!!`, or `\t--\n`).

► *Note*

Control characters (ASCII 0–25) are not printable.

Choose terminators with patterns that do not appear in any of the data. For example, using a tab terminator with a string of data that contains a tab creates an ambiguity: which tab represents the end of the string? `bcp` always looks for the first possible terminator, which in this case would be incorrect, since the first tab it would encounter would be the one that is part of the data string.

Data in “native” format can also conflict with terminators. Given a column that contains a four-byte integer in native format, if the values of these integers are not strictly limited, it will be impossible to choose a terminator that is guaranteed not to appear inside the data. Use `bcp`'s native format option for data in native format.

Note that “no terminator” is different from a “null terminator,” which is an invisible but real character.

Using Format Files

After gathering information about each field in the table, `bcp` asks if you want to save a format file, and then prompts for the file name. Use this format file to copy the data back into SQL Server, or to copy data out from the table at another time. When you are copying data in or out using an existing format file, `bcp` does not prompt for information; the format file provides the information needed.

The following diagram illustrates the format of the `bcp` format files. It shows the *publishers* table from the *pubs2* database, with all the host file columns in character format, no prefix, the default data length, a

newline at the end of the final column of a row, and tabs as terminators for all other columns.

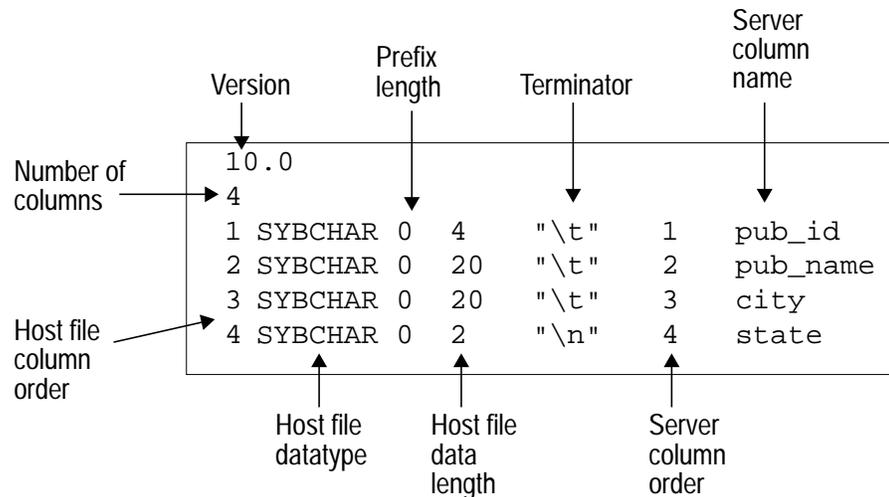

Figure 2-1: A bcp Format File

Format file columns are separated by tabs, except that the host file datatype and the prefix length are separated by a space.

The bcp version is always the first line of the file, followed by the number of columns on the second line. These are followed by one line for each column in the table.

Elements of the Format File

The format file consists of the **version**, **number of columns**, and a set of columns. These elements are explained in the following sections.

Version

The **version** is the bcp version number. This is a literal string without quotation marks. In Figure 2-1 the version is 10.0.

Number of Columns

Number of columns refers to the number of records in the format file, not including lines 1 and 2. Each column in the host table has one line.

Columns in the Format File

The columns in the format file are:

Host File Column Order

The **host file column order** is the sequential number of the field in the host data file, starting with 1.

Host File Datatype

The **host file datatype** refers to the storage format of the field in the host data file, **not** the corresponding database table column datatype. Valid storage formats are:

Storage Format	SQL Server Datatype
SYBCHAR	<i>char/ varchar (ASCII)</i>
SYBTEXT	<i>text</i>
SYBBINARY	<i>binary</i>
SYBIMAGE	<i>image</i>
SYBINT1	<i>tinyint</i>
SYBINT2	<i>smallint</i>
SYBINT4	<i>int</i>
SYBFLT8	<i>float</i>
SYBREAL	<i>real</i>
SYBBIT	<i>bit</i>
SYBMONEY	<i>money</i>
SYBMONEY4	<i>smallmoney</i>
SYBDATETIME	<i>datetime</i>
SYBDATETIME4	<i>smalldatetime</i>

Table 2-5: Host File Datatype Storage Format

Prefix Length

Prefix length indicates the number of bytes in the field length prefix. The length prefix is a 0-, 1-, 2- or 4-byte unsigned integer value embedded in the host data file specifying the actual length of data contained in the field. Some fields may have a length prefix while others do not.

Table 2-6 shows the allowable prefix length values.

No. of Bytes	Range
0	NO PREFIX
1	2^8-1 ; 0-255
2	$2^{16}-1$; 0-65535
4	$2^{32}-1$; 0-4,294,967,295

Table 2-6: Allowable Prefix Length Values

Host File Data Length

Host file data length refers to the maximum number of bytes to copy for the field. **bcp** uses either the maximum field length, the length prefix (if any), or the field terminator string (if any) to decide how much data to copy in or out. If more than one method of field length specification is given, **bcp** chooses the one that copies the least amount of data.

Terminator

The **terminator** can be up to 30 characters enclosed in quotation marks (" "). The terminator designates the end of data for the host data file field.

Server Column Order

The **host file column order** and the **server column order** together map host data file fields to the database table columns. The value in this field must equal either the *colid* of the table column into which the host data file column is to be loaded, or 0 if the host file field will not be loaded into any table column.

Server Column Name

The **server column name** is the name of the database table column into which this field is loaded. This is optional.

Examples: Copying out Data Interactively

By changing the default values of the prompts to `bcp`, you can prepare data for use with other software. To create a human-readable file, respond to the `bcp` prompts as follows:

- *char* storage type
- 0 prefix length
- Default field length
- Terminator depends on the software you plan to use. Choose between delimited fields or fixed length fields. Always use “\n”, the newline character, to terminate the last field.

For fixed-length fields, use no terminator. Each field has a fixed length, with spaces to pad the fields. Adjacent fields where the data completely fills the first field seem to run together, since there are no field separators on each line of output. See the example below.

For comma-delimited output, use a comma as the terminator for each field. To create tabular output, use the tab character, “\t”. See the examples on pages 18 and 19.

Copying out Data with Field Lengths

The following example uses fixed-length fields to create output in the personal computer format called SDF or “system data format.” This format can be easily read or produced by other software.

```
bcp pubs2..sales out sal_out
Password:

Enter the file storage type of field stor_id [char]:
Enter prefix-length of field stor_id [0]:
Enter length of field stor_id [4]:
Enter field terminator [none]:

Enter the file storage type of field ord_num [char]:
Enter prefix-length of field ord_num [1]: 0
Enter length of field ord_num [20]:
Enter field terminator [none]:

Enter the file storage type of field date [datetime]: char
Enter prefix-length of field date [1]: 0
Enter length of field date [26]:
Enter field terminator [none]: \n
```

Do you want to save this format information in a file? [Y/n] **y**

The contents of the format file *sal_fmt* is as follows:

```

10.0
3
1  SYBCHAR 0  4  ""  1  stor_id
2  SYBCHAR 0 20  ""  2  ord_num
3  SYBCHAR 0 26  ""  3  date

```

Copying out Data with Delimiters

In the following examples, `bcp` interactively copies data from the *publishers* table to a file.

The first example creates an output file with commas between all fields in a row and a newline at the end of each row. This example creates a format file (*pub_fmt*) which you can later use to copy the same or similar data back into SQL Server.

```
bcp pubs2..publishers out pub_out
```

```
Password:
```

```
Enter the file storage type of field pub_id [char]:
```

```
Enter prefix length of field pub_id [0]:
```

```
Enter length of field pub_id [4]:
```

```
Enter field terminator [none]:,
```

```
Enter the file storage type of field pub_name [char]:
```

```
Enter prefix length of field pub_name [1]: 0
```

```
Enter length of field pub_name [40]:
```

```
Enter field terminator [none]:,
```

```
Enter the file storage type of field city [char]:
```

```
Enter prefix length of field city [1]:0
```

```
Enter length of field city [20]:
```

```
Enter field terminator [none]:,
```

```
Enter the file storage type of field state [char]:
```

```
Enter prefix length of field state [1]:0
```

```
Enter length of field state [2]:
```

```
Enter field terminator [none]:\n
```

```
Do you want to save this format information in a file? [Y/n] y
```

```
Host filename [bcp.fmt]: pub_fmt
```

```
Starting copy...
```

```
3 rows copied.
```

```
Clock Time (ms.): total = 0   Avg = 0   (3.00 rows per sec.)
```

These are the results in *pub_out*:

```
0736,New Age Books,Boston,MA
```

```
0877,Binnet & Hardley,Washington,DC
```

```
1389,Algodata Infosystems,Berkeley,CA
```

The contents of *pub_out* is as follows:

```

10.0
4
1  SYBCHAR 0 4      ", "      1  pub_id
2  SYBCHAR 0 40     ", "      2  pub_name
3  SYBCHAR 0 20     ", "      3  city
4  SYBCHAR 0 2      "\n"     4  state

```

Similarly, the following example creates tab-delimited output from the table *pubs2..publishers* in the file *pub_out*.

```
bcp pubs2..publishers out pub_out
```

```
Password:
```

```
Enter the file storage type of field pub_id [char]:
Enter prefix-length of field pub_id [0]: 0
Enter length of field pub_id [4]:
Enter field terminator [none]: \t
```

```
Enter the file storage type of field pub_name [char]:
Enter prefix-length of field pub_name [1]: 0
Enter length of field pub_name [40]:
Enter field terminator [none]: \t
```

```
Enter the file storage type of field city [char]:
Enter prefix-length of field city [1]: 0
Enter length of field city [20]:
Enter field terminator [none]: \t
```

```
Enter the file storage type of field state [char]:
Enter prefix-length of field state [1]: 0
Enter length of field state [2]:
Enter field terminator [none]: \n
```

```
Do you want to save this format information in a file? [Y/n] y
Host filename [bcp.fmt]: pub_fmt
```

```
Starting copy...
```

```
3 rows copied.
Clock Time (ms.): total = 120 Avg = 40 (25.00 rows per sec.)
```

The contents of *pub_out* is as follows:

```

0736  New Age Books          Boston      MA
0877  Binnet & Hardley         Washington DC
1389  Algodata Infosystems    Berkeley   CA

```

The contents of the format file *pub_fmt* are as follows:

```
10.0
4
1 SYBCHAR 0 4 "\t" 1 pub_id
2 SYBCHAR 0 40 "\t" 2 pub_name
3 SYBCHAR 0 20 "\t" 3 city
4 SYBCHAR 0 2 "\n" 4 state
```

Examples: Copying Data in Interactively

To copy data successfully into a table from a file, you must know what the terminators in the file are, or what the field lengths are, and specify them when you use *bcp*. The following examples show how to copy data (either with fixed field lengths or with delimiters) in using *bcp*, with or without a format file.

Copying in Data with Field Lengths

In the following example, *bcp* copies data from the file *salesnew* into the table *pubs2..sales*. In the *salesnew* file, there are 3 fields: the first is 4 characters long, the second is 20, and the third is 26 characters long. Each row ends with a newline (\n), as follows:

```
5023ZS-731-AAB-780-2B9 May 24 1993 12:00:00:000AM
5023XC-362-CFB-387-3Z5 May 24 1993 12:00:00:000AM
6380837206 May 24 1993 12:00:00:000AM
6380838441 May 24 1993 12:00:00:000AM
```

Since *salesnew* is all character data, you can use the character command line flag, as follows:

```
bcp pubs2..sales in salesnew
```

The system responds as follows:

```
Password:
Enter the file storage type of field stor_id [char]:
Enter prefix-length of field stor_id [0]:
Enter length of field stor_id [4]:
Enter field terminator [none]:

Enter the file storage type of field ord_num [char]:
Enter prefix-length of field ord_num [1]: 0
Enter length of field ord_num [20]:
Enter field terminator [none]:
```

```

Enter the file storage type of field date [datetime]: char
Enter prefix-length of field date [1]: 0
Enter length of field date [26]:
Enter field terminator [none]: \n

Do you want to save this format information in a file? [Y/n] y
Host filename [bcp.fmt]: salesin_fmt

```

Starting copy...

4 rows copied.

Clock Time (ms.): total = 45 Avg = 11 (88.89 rows per sec.)

When you log on to SQL Server and access *publishers*, you'll see the following data from *newpubs* appended to the table:

```
select * from sales
```

stor_id	ord_num	date
5023	AB-123-DEF-425-1Z3	Oct 31 1985 12:00AM

8042	91-A-7	Mar 20 1991 12:00AM
8042	91-V-7	Mar 20 1991 12:00AM

(34 rows affected)

Since there is a unique clustered index on the *stor_id* and *ord_num* columns of *sales*, the new rows were sorted into order. Had there been any violations of the unique index on the columns in the data being copied from the file, *bcp* would have discarded the entire batch that contained a violating row. (A batch size of 1 evaluates each row individually, but loads more slowly.) If the types copied in are incompatible with the database types, the entire copy fails.

The format file *salesin_fmt* is the same as the format file created when copying out the data and giving the same responses.

Copying in Data with Delimiters

In the following example, *bcp* copies data from the file *newpubs* into the table *pubs2..publishers*. In the *newpubs* file, each field in a row ends with a tab character (`\t`); each row ends with a newline (`\n`), as follows:

1111	Stone Age Books	Boston	MA
2222	Harley & Davidson	Washington	DC
3333	Infodata Algosystems	Berkeley	CA

Since *newpubs* is all character data, we can use the character command line flag, and specify the terminators with command line options, as follows:

```
bcp pubs2..publishers in newpubs -c -t \t -r \n
```

Copying in Data with a Format File

To copy data back into SQL Server using the saved format file *pub_fmt*, use the following command:

```
bcp pubs2..publishers in pub_out -f pub_fmt
```

You can use the *pub_fmt* file to copy any data with the same format into SQL Server. If you have a similar data file with different delimiters, you can change the delimiters in the format file.

Similarly, you can edit the format file to reflect any changes to the field lengths, so long as all fields have the same length. For example, the file *moresales* contains the following:

```
804213-L-9 Jan 21 1993 12:00AM
804255-N-8 Mar 12 1993 12:00AM
804291-T-4 Mar 23 1993 12:00AM
804291-W-9 Mar 23 1993 12:00AM
```

Edit the format file *sal_fmt* to read as follows:

```
10.0
3
1 SYBCHAR 0 4 "" 1 stor_id
2 SYBCHAR 0 7 "" 2 ord_num
3 SYBCHAR 0 21 "\n" 3 date
```

Then enter the following command:

```
bcp pubs2..sales in moresales -f sal_fmt
```

The system responds as follows:

```
Starting copy...
4 rows copied.
Clock Time (ms.): total = 28 Avg = 7 (142.86 rows per sec.)
```

Using *bcp* with Alternate Languages

SQL Server stores its data using a default character set, which varies by platform. If your terminal does not support that default character set, it may send confusing characters to *bcp* when you respond to prompts by typing or by using host file scripts.

Omitting all character set options sets the character set to a default for the platform. Note that the default may not necessarily be the character set that the client is using. (See the *System Administration Guide* for more information about character sets and the associated flags.)

Batch Files and Copy in

Batching applies only to bulk copying in; it has no effect when copying out. By default, SQL Server copies all the rows specified in one batch. SQL Server considers each batch to be a separate *bcp*

operation. `bcp` copies each batch in a single insert transaction, and if the server rejects any row in the batch, the entire insert rolls back. `bcp` then continues to the next batch. Only fatal errors roll back the insert.

You can break large input files into smaller units for better recoverability. For example, if 300,000 rows are bulk copied in with a batch size of 100,000 rows, and there is a fatal error after row 200,000, the first two batches—200,000 rows—will have been successfully copied into SQL Server. If batching had not been used, no rows would have been copied into SQL Server.

When using slow `bcp`, the log entry for the transaction is available for truncation after the batch completes. If you copy in to a database that has `trunc log on chkpt` set on, the next automatic checkpoint removes the log entries for completed batches. This breaks up large `bcp` operations and keeps the log from filling.

You can even set the `batchsize` to 1, which causes only the defective row to be rejected. This allows you to identify exactly which row failed. Since `bcp` sends rows to SQL Server in batches, it cannot save copies of rows that SQL Server rejects in an error file (for example, when SQL Server encounters a duplicate row for a table that has a unique index). SQL Server generates error messages on a batch-by-batch basis, instead of row-by-row, and rejects each entire batch in which it finds an error. Error messages appear on your terminal.

Specifying a Network Packet Size

You may want to use larger-than-default network packet sizes to improve the performance of large bulk copy operations. The `-A size` option specifies the network packet size to use for this `bcp` session. `size` must be between the values of the default network packet size and maximum network packet size configuration variables, and it must be a multiple of 512. The new packet size is in effect for that `bcp` session only.

For example:

```
bcp pubs2..authors out -A 2048 -T 40960
```

specifies that SQL Server send 40K of *text* or *image* data using a packet size of 2048 for this `bcp` session.

Copying out *text* and *image* Data

When you copy out *text* or *image* data, by default SQL Server copies the first 32K of data in a *text* or *image* field. The `-T` flag allows you to specify a different value. For example, if the *text* field to copy out contains 40K of data, copy out all 40K with the following command:

```
bcp pubs2..publishers out -T 40960
```

If a *text* or *image* field is larger than the given value or the default, the overflow is not sent.

Error Files and Copy in

When you specify the `-e` flag with `copy in`, `bcp` stores certain rows that it cannot copy into SQL Server in the specified error file.

The error file stores a line indicating which row failed and what error occurred, and a line which is an exact copy of the row from the host file. `bcp` overwrites any file of the same name. If `bcp` does not encounter any errors, it does not create the file.

`bcp in` detects two types of errors:

- Data conversion errors
- Errors in building the row, such as attempts to insert a NULL into columns that don't accept them, or illegal data formats (such as a 3-byte integer)

Error messages appear on your terminal. The following example loads the *newpubs* file into the *publishers* database, storing any error rows in the file *pub_err*:

```
bcp pubs2..publishers in newpubs -e pub_err
```

`bcp` only stores rows when `bcp` itself detects the error. Since `bcp` sends rows to SQL Server in batches, it cannot save copies of rows that SQL Server rejects (for example, when SQL Server encounters a duplicate row for a table that has a unique index). SQL Server generates error messages on a batch-by-batch basis, instead of row-by-row, and rejects the entire batch if it finds an error.

It is not considered an error for SQL Server to reject duplicate rows if `allow_dup_row` or `ignore_dup_key` was set when a table's index was created. The copy proceeds normally, and the duplicate rows are not stored in the `bcp` error file.

Error Files and Copy out

When you use the `-e` flag with `copy out`, `bcp` stores the rows that it cannot copy out in the specified error file. As with `copy in`, `bcp` overwrites any file of the same name, and does not create the file if no errors occurred.

There are two possible cases that log rows in the error file during a copy out:

- A data conversion error in one of the row's columns
- An I/O error in writing to the host file

`bcp` logs rows in the error file in the default character format. All data values print as characters, with tabs between the columns, and a newline at the end of each row.

Data Integrity: Defaults, Rules, and Triggers

When copying data into a table, `bcp` observes any defaults defined for the columns and datatypes. That is, if there is a null field in the data in a file, `bcp` loads the default value instead during the copy. For example, here are two rows in a file to load into *authors*:

```
409-56-7008,Bennet,Abraham,415 658-9932,6223 Bateman St.,Berkeley,CA,USA,94705
213-46-8915,Green,Marjorie,,309 63rd St. #411,Oakland,CA,USA,94618
```

Commas separate the fields; a newline separates the rows. Note that there is no phone number for Marjorie Green. If the *phone* column of the *titles* table has a default of "unknown," the rows in the loaded table look like this:

```
409-56-7008,Bennet,Abraham,415 658-9932,6223 Bateman St.,Berkeley,CA,USA,94705
213-46-8915,Green,Marjorie,unknown,309 63rd St. #411,Oakland,CA,USA,94618
```

However, `bcp` ignores rules and triggers in order to load data at the maximum speed. To find any rows that violate rules and triggers, copy the data into the table and run queries or stored procedures that test the rule or trigger conditions.

Bulk Copy Distinguished from Other SQL Server Facilities

The bulk copy facilities, which copy entire tables or portions of a single table, are distinct from several other commands and options

that also move data from one place to another. These other commands are:

- The SQL commands **dump database**, **load database**, **dump transaction**, and **load transaction**. These are used for backup purposes only. Unlike the bulk copy facilities, the dump facilities create a physical image of the entire database. Data dumped with **dump database** or **dump transaction** can be read only by using **load database** or **load transaction**. (See the *System Administration Guide* or the *SQL Server Reference Manual* for details.)
- The data modification commands **insert**, **update**, and **delete**. Use these to add new rows, change existing rows, or remove rows in a table or view. (See the *SQL Server Reference Manual* or *Transact-SQL User's Guide* for details.)

The **insert** command can also be used with a **select** statement in order to move data from one table to another. The **select** statement with an **into** clause can create a new table, based on the columns in the **select** statement and the tables in the **from** clause, and copy the rows specified in the **where** clause. (See the *SQL Server Reference Manual* or *Transact-SQL User's Guide* for details.)

3

Using *isql*: Additional Information

Introduction

This chapter discusses some details about *isql*: changing the command terminator, the interaction of the performance option and command terminator values, and input and output files.

Changing the Command Terminator

If you include the command terminator argument (-c) you can choose your own terminator symbol. “go” is the default value for this option. For example, to use a period as the command terminator, invoke *isql* as follows:

```
isql -c.
```

A sample *isql* session with this command terminator looks like this:

```
1> select name from sysusers
2> .

name
-----
sandy
kim
leслиe

(3 rows affected)
```

Using the *isql* command terminator option with scripts requires advance planning:

- All SQL Server-supplied scripts, such as *installmaster*, use “go”. Do not change the command terminator for any session which uses these scripts.
- Your own scripts may already have “go” in them. Remember to update any of your own scripts to include the terminator you plan to use.

Performance Statistics Interaction with Command Terminator Values

isql provides a performance statistics option (-p). For example:

```
isql -p
1> select * from sysobjects
2> go
```

returns the following statistics:

```
1 xact:
Clock Time (ms.): total = 35000 avg = 35000 (0.03 xacts per sec.)
```

This means that a single transaction took 3000 milliseconds, and the average is 1 transaction per 3000 milliseconds. The clock time value reflects the entire transaction, which starts when Client Library builds the query and ends when Client Library returns the information from SQL Server.

You can gather performance statistics based on executing one or more transactions. To gather statistics on more than one transaction, specify a number after the command terminator (`go`, by default). For example:

```
isql -p
1> select * from sysobjects
2> go 3
```

This tells SQL Server to execute three `select *` transactions and report the performance statistics. SQL Server returns:

```
3 xacts:
Clock Time (ms.): total = 41000 avg = 13666 (0.07 xacts per sec.)
```

Setting the Network Packet Size

The `-A size` option specifies the network packet size to use for this `isql` session. For example:

```
isql -A 2048
```

sets the packet size to 2,048 bytes for this `isql` session. To check, type:

```
select * from sysprocesses
```

The value appears under the `network_pktsz` heading.

`size` must be between the values of the default network packet size and maximum network packet size configuration variables, and must be a multiple of 512. SQL Server uses the closest available packet size which is a multiple of 512 if there is not enough memory available.

Use larger-than-default packet sizes to perform I/O-intensive operations, such as `readtext` or `writetext` operations.

Setting or changing SQL Server's packet size does not affect remote procedure call's packet size.

Input and Output Files

You can specify input and output files on the command line with the `-i` and `-o` options.

`isql` does not provide formatting options for the output. However, you can use the `-n` option to eliminate the `isql` prompts, and use other tools to reformat the output.

If you use the `-e` option, `isql` echoes the input to output. The resulting output file contains both the queries and their results.

UNIX Command Line Redirection

The UNIX redirection symbols, “<” and “>”, provide a similar mechanism to the `-i` and `-o` options, as follows:

```
isql -Usa -Ppassword < input > output
```

You can direct `isql` to take input from the terminal, as in the following example:

```
isql -Usa -Ppassword << EOF > output
select * from table
go
EOF
```

The `<<EOF` instructs `isql` to take input from the terminal until the string `EOF`. You can replace `EOF` with any character string.

Similarly, the following example signals the end of input with `Ctrl-d`:

```
isql -Usa -Ppassword << > output
```

Index

The index is divided into two sections:

- Symbols
Indexes each of the symbols used in SYBASE SQL Server documentation.
- Subjects
Indexes subjects alphabetically.

Page numbers in **bold** are primary references.

Symbols

!! (exclamation points) operating system commands prefix (isql) 1-28, 1-33
" " (quotation marks) for enclosing special characters 1-1
:r (interactive isql) 1-33

 - Spaces, character 2-9
 - Speed (SQL Server), bcp fast or slow 2-2 to 2-3
 - Spreadsheet programs 2-1
 - SQL parser utility. *See* isql utility command
 - SQL Server
 - dataserver command 1-22
 - isql SQL parser to 1-28 to 1-34
 - restarting with startserver 1-38
 - showserver information on 1-37
 - starting with startserver 1-38
 - startserver utility command **1-38 to 1-39**
 - dataserver and 1-22
 - Statistics
 - isql 1-28, 3-2
 - showserver 1-37
 - Storage format of data 2-14
 - Storage lengths, bcp file 2-10 to 2-11
 - Stored procedures, copying with defncopy 1-24 to 1-27
 - SYB storage types 2-14
 - sybinit installation program
 - buildmaster and 1-20
 - langinstall and 1-36
 - sybmultbuf executable 1-3
 - sybsystemprocs table 1-21
 - Symbols, field terminator (bcp) 2-11, 2-12
 - Syntax conventions xii to xiii
 - sysconfigures table
 - buildmaster and 1-19
 - dataserver and 1-22
 - syscurconfigs table, buildmaster and 1-19
 - syslanguages table, and langinstall 1-36
 - sysmessages table, langinstall and 1-36
 - System data format (SDF) and bcp 2-16
 - System procedures, installmaster and 1-21
 - System Security Officer account 1-23
- T**
- Tab data field terminator, bcp 1-16, 2-12
 - Table rows. *See* Rows, table
 - Tables without indexes, bcp and 2-3
 - Tabular data, copying 2-11 to 2-12
 - Tabular output 2-16, 2-19
 - tempdb database, buildmaster creation of 1-19

Terminator, command. *See* Command terminator (isql)

Terminators (bcp)

changing 2-7

field and row 2-11

invisible 2-12

specifying 1-7

text datatype, copying with bcp 1-6, 2-9, 2-25

Text, defncopy copying definitions as 1-27

Timeout option, isql 1-31

Trace values 1-3

Transaction logs, size 2-3

Transferring data. *See* bcp (bulk copy utility)

Triggers

bcp copying and 1-12, 2-3 to 2-4

copying data into tables and 2-26

copying with defncopy 1-24 to 1-27

dropping before using bcp 1-14

Truncation, data, bcp copying and 1-16

U

Unlogged transactions 2-4

V

Version number

backupsrvr 1-3

bcp 1-9

bcp, in format file 2-13

defncopy 1-24

isql 1-28

langinstall 1-35

localization files and langinstall 1-36

vi default editor 1-28, 1-33

Views, copying with defncopy 1-24 to 1-27

W

with truncate_only option, dump transaction command 2-3
