| 2305 (j)   | Any      | Download Test (#581)         | MAJOR       | OFF          | reset packet-control C     |

Notes:

- a. This error occurs when maintenance software resets the Packet Control circuit pack due to an in-line error or certain test failures. Once a threshold number of these errors occur, maintenance places the Packet Control circuit pack into an out-of-service state, and a major on-board alarm is raised on the Packet Control circuit pack.
- b. This error occurs due to certain in-line errors and test failures. This error is very serious, and when it occurs maintenance software immediately escalates testing to the destructive reset test (#586).

- c. This error indicates that a loss of communication was detected between the SPE software and the Packet Control circuit pack. No alarm is raised. However, if this error occurs repeatedly, software testing escalates to the Reset Test (#586) so that the health of the Packet Control circuit pack can be determined.
- d. This error occurs when the Packet Control Loop Around Test (#585) fails because a link cannot be established or because the Packet Control circuit pack cannot send and receive data correctly. No alarm is raised. However, if this error occurs repeatedly, software testing escalates to the Reset Test (#586) so that the health of the Packet Control circuit pack can be determined.
- e. This error occurs when the Packet Control Parity Circuitry Test (#584) fails, thus indicating a possible fault with the parity circuitry in detecting Packet Bus parity errors. If this error occurs a number of times exceeding a defined threshold, a minor on-board alarm is raised.
- f. This error occurs when a certain circuit pack-level diagnostic test fails, thus indicating a transient fault (which has been recovered) existed on the Packet Control/Packet Bus interface. No alarm is raised because the error does not isolate the fault to the Packet Control circuit pack. However, if the error occurs repeatedly, software testing escalates to the Reset Test (#586) so that the health of the Packet Control circuit pack can be determined.
- g. This error occurs when a certain circuit pack-level diagnostic test fails, indicating there is a fault on the Packet Control/Packet Bus interface. No alarm is raised because the Packet Bus may be the source of problem. When this error occurs, Packet Bus maintenance is notified, thereby causing appropriate tests to run.
- h. This error occurs when a parity error is detected by the Packet Control circuit pack, indicating some data sent over the Packet Bus is corrupted. No alarm is raised against the Packet Control circuit pack because the problem may be associated with the Packet Bus. When this error occurs, Packet Bus maintenance is notified, thereby causing appropriate tests to run.
- i. This error occurs when the Packet Control circuit pack receives a threshold number of frames with invalid address. No alarm is raised because there is no direct indication of a Packet Control fault. The frames may be corrupted by the sending side or by the Packet Bus. No maintenance activity is triggered by this error. No action is required.
- j. This error occurs when the Packet Control Download Test (#581) fails. Once a threshold number of these errors occur, a major off-board alarm is raised. Maintenance software retries the download test repeatedly until it passes. Since the **reset packet-control C** command causes the firmware to be downloaded and provides additional diagnostics on this error type, this command should be used when a download failure has occurred.

- k. If the specified Packet Control circuit pack is in the active SPE, it must first be busied-out via the **busyout packet-control C** command. After testing has been completed, the Packet Control circuit pack should be released from the busyout state via the **release packet-control C** command.

System Technician-Demanded Tests:  
Descriptions and Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors in the order they are presented in the tables below. By clearing error codes associated with the *Packet Control Parity Circuitry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-321. Active PKT-CTRL

| Order of Investigation                                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------------|---------------------|--------------------|-------------------|
| Packet Control Reset Test (#586)                        |                     |                    | D                 |
| Packet Control Parity Circuitry Test (#584)             |                     | X                  | ND                |
| Packet Control Loop Around Test (#585)                  | X                   | X                  | ND                |
| Packet Control Error Counter Read and Clear Test (#583) |                     | X                  | ND                |

Table 10-322. Standby PKT-CTRL

| Order of Investigation                                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------------|---------------------|--------------------|-------------------|
| Packet Control Reset Test (#586)                        | X                   | X                  | ND                |
| Packet Control Loop Around Test (#585)                  | X                   | X                  | ND                |
| Packet Control Error Counter Read and Clear Test (#583) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Packet Control Error Counter Read and Clear Test  
(#583)

This test involves reading and clearing the error counters on the Packet Control circuit pack. The test is performed by sending multiple maintenance requests to the Packet Control circuit pack and waiting for the response to each of the "read and clear" commands from the circuit pack.

Table 10-323. TEST #583 Packet Control Error Counter Read/Clear Test

| Error Code                                                                                                   | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Packet Control Parity Circuitry Test (#584)

This test checks the error detection capability of the Packet Control circuit pack’s circuitry by verifying that it correctly identifies frames on the Packet Bus with parity errors.

 **NOTE:**  
This test aborts in a High or Critical Reliability system, or in a system with an alarmed PPN Packet Bus.

Table 10-324. TEST #584 Packet Control Parity Circuitry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                |

Packet Control Loop Around Test (#585)

This test checks whether the Packet Control circuit pack can send and receive data correctly. The test performs the following major functions:

- 1. Establishes an LAPD link from the Packet Control circuit pack to itself.  
(See [Figure 10-80](#).)
- 2. Transmits and receives test data over the testing link.

Figure 10-80. Test Configuration

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1-3        | FAIL        | Maintenance was unable to establish a loop around link from the Packet Control circuit pack back to itself, or was unable to receive the data that was sent out over one side of the loop around link.<br><br>1. Issue <b>test packet-control C short</b> command to retry the test.<br><br>2. If the same error code is observed, maintenance software automatically escalates the testing. No specific action is required. |
|            | PASS        | The Packet Control circuit pack can send and receive data correctly.                                                                                                                                                                                                                                                                                                                                                         |

Packet Control Reset Test (#586)

This test resets the Packet Control circuit pack, downloads Packet Control circuit pack firmware form tape, and then causes the Packet Control circuit pack to begin operation.

 **WARNING:**

*This test is destructive and disrupts service when run on the Packet Control circuit pack in the Active SPE. This test is not destructive when run on the Packet Control circuit pack in the Standby SPE of a High or Critical Reliability system. When this test is run on the Packet Control circuit pack on the Active SPE, the "busyout packet-control C" command must be executed first. Once testing has been completed, a busied-out Packet Control should be released via the release packet-control C command.*

| 1152                                                                                                         | ABORT       | The Packet Control circuit pack hardware was successfully reset and the circuit pack was successfully put back into service. However, a new image of Packet Control circuit pack firmware was not able to be downloaded from the tape, because the tape was unavailable. Nonetheless, the existing firmware on the circuit pack is valid, and there is no need to repeat this test. |

| 5          | FAIL        | <p>The SPE could not communicate with the Packet Control circuit pack. This indicates that either the Packet Control circuit pack is not installed or that it has failed.</p> <ol style="list-style-type: none"><li>1. Examine the appropriate carrier to determine if there is a Packet Control circuit pack in the correct slot. If there is, go to the next step. If there isn't, the problem is that the Packet Control circuit pack is administered (that is, the "Packet Bus Activated?" field on the Maintenance-Related System Parameters Form is set to "y") but the circuit pack isn't installed. If the system is supposed to have a Packet Control circuit pack, the system must be upgraded appropriately (see upgrade documentation). If the system is not supposed to have a Packet Control circuit pack, then the Packet Control circuit pack should be unadministered by setting the "Packet Bus Activated?" field on the Maintenance-Related System Parameters Form to "n." Refer to the "Maintenance-Related System Parameters Form" section in <a href="#">Chapter 5, "Routine Maintenance Procedures"</a> for more information on the "Packet Bus Activated?" field.</li><li>2. Retry the command.</li><li>3. If it fails again with the same error code, replace the Packet Control circuit pack.</li></ol> |

If the test still fails with this error code, then replace the Packet Control circuit pack.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 10-326. TEST #586 Packet Control Reset Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2102       | FAIL        | <p>As the Packet Control circuit pack firmware was being downloaded from system tape, a block of data could not be read from the tape. This indicates a problem with the tape unit, and not with the Packet Control circuit pack.</p> <ol style="list-style-type: none"><li>1. Test the TAPE with the long option and with a repeat option of 3. If any of the tests fail, or if there are any tape alarms, refer to the TAPE Maintenance documentation and follow the recommended repair procedures. If a tape problem is detected and then fixed, then retry the reset command.</li><li>2. If no tape problem was detected in the previous step, then there may be a problem with the area on the tape where the Packet Control circuit pack firmware resides. Replace the tape cartridge and then retry the reset command.</li></ol> |
| 2500       | FAIL        | <p>Internal system error</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals a maximum of 5 times.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|            | PASS        | <p>The reset command passed and the Packet Control circuit pack is operational. If the Packet Control circuit pack was busied-out, it needs to be released (via the <b>release packet-control C</b> command) before it can be considered in service.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## PMS-LINK (Property Management System Link)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO |
|------------------------------------|-------------|------------------------------------------|-----------------|
| PMS-LINK                           | MINOR       | test pms l                               | PMS Link        |
| PMS-LINK                           | WARNING     | test pms                                 | PMS Link        |

Property Management System (PMS) is a stand-alone computer system that a hotel/motel-type and a hospital-type environment use for services such as reservations, registration, messaging, housekeeping, night audit, billing, and inventory. The PMS Link provides a communications channel between DEFINITY Generic 1 or Generic 3iV2 and a customer-owned PMSs so that the PMS can interrogate the system about the information related to the following features:

- Message Waiting Notification
- Controlled Restriction
- Housekeeping Status
- Check-in/Check-out
- Room Change/Room Swap

Refer to *DEFINITY Communications System Generic 3 Feature Description*, 555-230-204 for details on the PMS feature. The PMS Link is administered to a data extension that provides a standard EIA 232C interface to the PMS. A PMS can be connected through a data module (PDM, MPDM, DTDM) and a port on the TN754 or TN754B Digital Line circuit pack, or through an ADU and a port on the TN726 Digital Line circuit pack.

PMS Link Maintenance provides a strategy for maintaining the link between DEFINITY Generic 1 and Generic 3iV2 and a PMS device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Link Maintenance uses a "try-and-wait" mechanism for maintaining the PMS Link. If a PMS Link is torn down due to an error, PMS Link Maintenance attempts to bring up the link immediately. If the trial of "Link Setup" fails, PMS Link Maintenance waits for five minutes before the next retry. If the number of retries reaches the value of a threshold (12), a Minor alarm is raised for service attention.

PMS Link Maintenance does not cover the maintenance of the elements composing the PMS physical link [the external PMS device, Data Module (PDM/MPDM/DTDM), and Digital Line Port of TN754 or TN754B Digital Line circuit pack, ADU and Data Line Port of TN726 Data Link circuit pack, and Data Channels on TN777 Network Control circuit pack]. If PMS Link Maintenance cannot restore the PMS Link, then the maintenance tests of these individual

components of the PMS Link must be executed to diagnose faults. If system technician-demanded **test pms-link** command fails, no alarm is generated.

## **Procedures for Restoring the PMS Link**

---

1. Determine the status of the PMS Link.

Enter **status pms** command and make sure that the PMS Link is not busied out for maintenance. If the link is "down," then continue with the next step.

2. Where does the PMS Link connect?

Enter **display system hospitality** and find out the destinations of the PMS Link.

3. Determine the status of the data extension.

Enter **status data <extension>** command and verify whether the data extension is in in-service/idle state. If the data extension is NOT available, then look for the extension number in Alt Name field of Hardware Error Log. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for resolutions.

4. Is a data channel on Network Control circuit pack in in-service/idle state?

Enter **list data** command and find out the extension numbers of data channels on Network Control circuit pack. Enter **status data <extension>** command and make sure that at least one data channel is in in-service/idle state. If no data channel is available, then look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If present, refer to the DATA-BD (Network Control Circuit Pack) Maintenance documentation; if not present, escalate the error.

5. Is the external PMS device available?

Make sure that the PMS device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the PMS device.

It is recommended that you busy out the PMS Link before executing maintenance tests over objects composing the PMS Link. If the PMS Link is busied out, then all PMS Link maintenance actions are deactivated. The interference to tests of other MO is off.

Hardware Error Log Entries and Test to Clear Values

| PMS Link Maintenance Error Log Entries |                                                          |                        |                             |              |                                   |

- 
- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
  - Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.
  - Is any integer.

Notes:

- 
- a.

The PMS Link has been busied out for system technician-demanded maintenance via the **busyout pms-link** command. The link is torn down. Enter the **release pms-link** command to restore the link.

Page 10-1110

- b. The Link Retry Test (#215) fails. The Aux Data field contains either the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04) or an Error Type of 99 indicating no data channels are available for setting up the link, or an Error Type of 255 for the internal system error generated upon initialization or power-up. Refer to the ["Procedures for Restoring the PMS Link"](#) section for resolution.
- c. The PMS physical link is down due to the following causes: cable to the PMS device is disconnected; the PMS device is powered off; or the data extension to which the PMS device connects has been busied out. The Aux Data field contains the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04) or an Error Type of 255 for the internal system error generated upon initialization or power-up. Check the connectivity of wire and cable among wall jacket, data module, and the PMS device. Enter **status data <extension>** and verify that the data extension of the PMS device is in in-service/idle state. If the data extension is not available, then refer to the ["Procedures for Restoring the PMS Link"](#) section for recommended repair strategy.
- d. No communication between DEFINITY Generic 1 or Generic 3iV2 and PMS for a period of time (the time is specified in "system hospitality" administration). The PMS Link is torn down. To clear this error, refer to the ["Procedures for Restoring the PMS Link"](#) section.
- e. The link was taken down because the switch could not receive an incoming message from the PMS. The message from the PMS repeatedly had corrupted data or the switch received requests for acknowledgment but never received a message to be processed. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.
- f. The link was taken down because the switch could not send an outgoing message. The message, which was sent but not acknowledged, was flushed. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.
- g. The PMS has been busied out for maintenance at the request of the PMS. The PMS Link is torn down. The reason code (N), if present, is that supplied by the PMS in the request message. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.
- h. PBX buffer overflows due to either heavy call traffic or PMS protocol message rate being faster than the PMS/PBX protocol specifications allow. The PMS Link is torn down. PMS Link maintenance software waits

for five minutes before attempting to set up the link again. If this error type recurs frequently (that is, more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log (see Note).

 **NOTE:**

The PMS should be checked for adherence to message rate defined in the PMS/PBX protocol specifications. No alarm is raised against this error.

- i. The attempt to swap the database between PBX and PMS failed three times consecutively due to excessive PMS/PBX protocol violations, buffer overflows, or PMS Link outages. The PMS Link is NOT torn down. If this error type recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. No alarm is raised against this error.
- j. The PMS Link has been busied out for system technician-demanded maintenance via the **busyout pms-link** command or has been brought down via the **test pms-link long** command. The PMS Link is torn down, and PMS Link maintenance stops attempting to reestablish the link in the case where the **busyout pms-link** command has been used. When the **test pms-link long** command has been used, PMS Link maintenance continues to try to reset the link. To restore the PMS Link after use of the **busyout pms-link** command, issue the **release pms-link** command. To restore the PMS Link after use of the **test pms-link long** command, issue the **test pms-link** command.
- k. The PMS Link is physically established, but the protocol has not been started by the PMS before the protocol timer expires. The PMS Link is NOT torn down. If this error type recurs frequently (that is, more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

 **NOTE:**

The PMS should be checked to make sure that it attempts to start the protocol according to the PMS/PBX protocol specifications. No alarm is raised against this error.

I. Error Type 2817:

Aux values of concern:

- 10x The PMS violated the application protocol. The first message after a request to initiate a database exchange was not the start of a database exchange. The message is processed. If this error type with this aux data value recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. See Note.
- 20x The PMS violated the application protocol. The start of a database exchange was received in a state in which it was not expected. The message is ignored. If this error type with this Aux data value recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log. See the next Note.
- 30x The PMS violated the application protocol. The end of a database exchange was received when no exchange was in progress. The message is ignored. If this error type with this Aux Data value recurs frequently (that is, more than once a month), then advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Hardware Error Log.

**NOTE:**

The PMS should be assessed for adherence to the PMS/PBX protocol specifications. No alarm is raised against this error.

- m. The link was taken down by the switch because the threshold for application protocol violations has been exceeded by the PMS. The protocol never started and messages were received and/or messages were received in a state in which they were not expected. (Refer to Error Type 2817 for recommended strategy.)
- n. Link was taken down by the switch because the threshold for link protocol violations has been exceeded by the PMS. PMS is sending "garbage" to the switch.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------|---------------------|--------------------|-------------------|
| Link Tear Down Test (#213) |                     | X                  | D                 |
| Link Retry Test (#215)     | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external PMS device. If the link has been disconnected already, then this test just returns "PASS." All resources allocated for a PMS Link are released after this test.

Table 10-327. TEST #213 Link Tear Down Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                            |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 40<br>50   | ABORT       | Internal System Error.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                                    |
| 1010       | ABORT       | The PMS Link has been busied out and placed in the out-of-service state.<br><br>1. Enter <b>release pms-link</b> command to release the PMS Link from busyout state.<br><br>2. Retry <b>test pms long</b> command to execute the test. |

Continued on next page

Table 10-327. TEST #213 Link Tear Down Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                         |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | Internal System Error.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem. |
|            | PASS        | The PMS Link is torn down.                                                                                                                                          |

Link Retry Test (#215)

This test sends a message to the PMS software process to make a data call to the extension where the PMS device connects. If the PMS Link is already up, then this test passes without making any data call.

Table 10-328. TEST #215 Link Retry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                       |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10<br>20   | ABORT       | Internal System Error.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                               |
| 30         | ABORT       | Internal System Error.<br><br>1. Refer back to the <a href="#">“Procedures for Restoring the PMS Link”</a> section for resolution.                                                                                                |
| 1010       | ABORT       | The PMS Link has been busied out and placed in the out-of-service state.<br><br>1. Enter <b>release pms-link</b> command to release the PMS Link from busyout state.<br><br>2. Retry <b>test pms</b> command to execute the test. |

**Table 10-328. TEST #215 Link Retry Test — Continued**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                 |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | The PMS Link CANNOT be established.<br><br>1. Refer back to the <a href="#">“Procedures for Restoring the PMS Link”</a> section for restoring the PMS Link. |
|            | PASS        | The PMS Link is up.                                                                                                                                         |

## PMS-PRNT/JNL-PRNT (PMS Printer Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run               | Full Name of MO              |
|------------------------|-------------|--------------------------------------|------------------------------|
| PMS-PRNT/JNL-PRNT      | MINOR       | test journal<br>pms-log/wakeup-log l | PMS Printer/ Journal Printer |
| PMS-PRNT/JNL-PRNT      | WARNING     | test journal<br>pms-log/wakeup-log   | PMS Printer/ Journal Printer |

**⇒ NOTE:**  
PMS-PRNT stands for the pms-log printer. JNL-PRNT stands for the wakeup-log printer. Since the maintenance strategy for the both the JNL-PRNT and PMS-PRNT MOs is the same, both of these MOs are described in this section.

In DEFINITY Generic 1 and Generic 3iV2, there are up to two journal printers. They are identified as the wakeup-log printer which is shared between the Automatic Wakeup feature and the Emergency Access to Attendant feature to print scheduled reports and log of events, and the pms-log printer which is used as a backup of the PMS output device to print the audit trail data of all PMS transactions executed by the system and the PMS Housekeeping Status Change events while the PMS Printer Link is not available. The journal printer link is administered to a data extension that provides a standard EIA 232C interface to the printer. The printer can be connected through a data module (PDM, MPDM, DTDM) and a port on the TN754 or TN754B Digital Line circuit pack, or through an ADU and a port on the TN726 Data Line circuit pack.

PMS Printer Link Maintenance provides a strategy in the system for maintaining the link between the system and a PMS device (an external Journal Printer device). The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Printer Link Maintenance uses a try-and-wait mechanism for maintaining the PMS Printer Link. If a PMS Printer Link is torn down due to an error, PMS Printer Link Maintenance intends to bring the link up immediately. If the trial of Link Setup fails, PMS Link Maintenance waits for five minutes before the next retry. If the number of retries reaches the value of a threshold (15), a Minor alarm is raised for service attention.

PMS Printer Link Maintenance does not cover the maintenance of the elements composing the journal printer physical link, for instance, the external printer device, Data Module (PDM/MPDM/DTDM) and Digital Line Port of TN754 or TN754B Digital Line circuit pack, ADU and Data Line Port of TN726 Data Line circuit pack, and Data Channels on TN777 Network Control circuit pack. If PMS Printer Link Maintenance cannot restore the PMS Printer Link, then the maintenance tests of these individual components of the PMS Link must be executed to diagnose faults.

## Procedures for Restoring the PMS Printer Link

1. Determine the status of the PMS Printer Link.

Enter **status journal-printer wakeup-log|pms-log** command and make sure that the journal printer link is not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the journal printer link connect?

Enter **display system hospitality** and find out the destinations of the PMS Printer Link.

3. Determine the status of the data extension.

Enter **status data extension** command and verify whether the data extension is in the in-service/idle state. If the data extension is NOT available, then look for the extension number in Alt Name field of Hardware Error Log. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for resolutions.

4. Is a data channel on Network Control circuit pack in the in-service/idle state?

Enter **list data** command and find out the extension numbers of data channels on Network Control circuit pack. Enter **status data extension** command and make sure that at least one data channel is in the in-service/idle state. If no data channel is available, look for DATA-CHL/DATA-CON/DATA-BD errors in the Error Log. If present, refer to "DATA-BD".

5. Is the external printer device available?

Make sure that the printer device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the printer device.

It is recommended that you busyout the PMS Printer Link before executing maintenance tests over objects composing the PMS Printer Link. If the PMS Printer Link is busied out, then all PMS Printer Link maintenance actions are deactivated. The interference to tests of other MOs is off.

Error Log Entries and Test to Clear Values

Table 10-329. PMS-PRNT/JNL-PRNT Link Maintenance Error Log Entries

| Error Type     | Aux Data            | Associated Test                           | Alarm Level                    | On/Off Board | Test to Clear Value                   |
|----------------|---------------------|-------------------------------------------|--------------------------------|--------------|---------------------------------------|
| 0 <sup>1</sup> | 0                   | Any                                       | Any                            | Any          | test journal<br>wakeup-log pms-log sh |
| 18 (a)         | 0                   | busyout journal<br>wakeup-log/<br>pms-log | WARNING                        | OFF          | release journal<br>wakeup-log pms-log |
| 257 (b)        | 0,<br>3 to 6<br>255 | Link Retry Test<br>(#215)                 | MINOR/<br>WARNING <sup>2</sup> | OFF          | test journal<br>wakeup-log pms-log 1  |
| 513 (c)        | 0,<br>3 to 6<br>255 |                                           |                                |              | test journal<br>wakeup-log pms-log    |
| 769 (d)        |                     |                                           |                                |              |                                       |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- Both PMS Printer and Journal Printer are administered to the same extension, and the printer is not connected. Refer to the [“Procedures for Restoring the PMS Printer Link”](#) section for resolution.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. System Technician busied out the Journal Printer Link. The link is torn down. Enter **release** command to restore the link.
- b. Link Retry Test (#215) fails. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. The Aux Data field contains the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04), an Error Code 255 for the Internal system error, or 0 which indicates that the data module connected to the PMS Printer Link is out-of-service. Refer to [“Procedures for Restoring the PMS Printer Link”](#) section for resolution.
- c. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. The PMS Printer Link physical link is down due to the following causes: cable to the printer device is disconnected, the printer device is powered off, or the data extension where the printer device connects to has been busied out. The Aux Data field contains the Channel ID of Data Channels on Network Control circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04). Check the connectivity of wire and cable among wall jacket,

data module, and the printer device. Enter **status data <extension>** and verify that the data extension of the printer device is in the in-service/idle state. If the data extension is not available, then refer to the [“Procedures for Restoring the PMS Printer Link”](#) section for resolution.

- d. Link idle timer; link comes down. This error indicates that the printer device is in an off-line state, for example, paper jam or paper out for a printer device. Check the printer device and act promptly to put it back to on-line state. Enter **test journal wakeup-log|pms-log** command to set up the printer link.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------|---------------------|--------------------|-------------------|
| Link Tear Down Test (#213) |                     | X                  | D                 |
| Link Retry Test (#215)     | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Link Tear Down Test (#213)

This test is destructive.

This test disconnects the existing link between the system and the external printer device. If the link has been disconnected already, this test just returns PASS. All resources allocated for a PMS Printer Link are released after this test.

Table 10-330. TEST #213 Link Tear Down Test

| Error Code | Test Result | Description/ Recommendation                                                              |
|------------|-------------|------------------------------------------------------------------------------------------|
| 40         | ABORT       | Internal system error                                                                    |
| 50         | ABORT       | Internal system error<br>1. Retry the command at 1minute intervals a maximum of 5 times. |

Table 10-330. TEST #213 Link Tear Down Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                     |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1010       | ABORT       | The link has been busied out to out-of-service.<br><br>1. Enter <b>release journal wakeup-log pms-log</b> command to release the link from busyout state.<br><br>2. Retry <b>test journal wakeup-log pms-log l</b> command to execute the test. |
|            | FAIL        | Internal system error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                   |
|            | PASS        | The link is torn down.                                                                                                                                                                                                                          |

Link Retry Test (#215)

This test sends a message to the journal printer management software process to make a data call to the extension where the printer device connects to. If the journal printer link is already up, this test passes without making any data call.

Table 10-331. TEST #215 Link Retry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                 |

# POWER (Battery & Battery Charger) for AC-Powered Systems

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO           |
|------------------------------------|-------------|-------------------------------------------------------|---------------------------|
| POWER                              | MINOR       | test environment P                                    | Battery & Battery Charger |

1. Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

Generic 1 and Generic 3iV2 offer two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configuration may be powered by either an external AC or DC power source.

**NOTE:**  
For environment maintenance, PPN or EPN cabinet configuration aspects for a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate section(s).

- For a single-carrier cabinet system, refer to the DC-POWER (Single-Carrier Cabinet Power) Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following Maintenance documentation sections: AC-POWER (AC Power) for AC-Powered Systems, CARR-POW (Carrier Port Power Unit) for AC-Powered Systems, or POWER (Battery & Battery Charger) for AC-Powered Systems.
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following Maintenance documentation sections: AC-POWER (AC Power) for DC-Powered Systems, CARR-POW (Carrier Port Power Unit) for DC-Powered Systems, or POWER (Battery & Battery Charger) for DC-Powered Systems.

The G3iV1.1-286 or G3iV2-386 multicarrier cabinet is equipped with rechargeable batteries that can span short AC power outages. In a multicarrier PPN system with High or Critical Reliability, the cabinet can be powered for 10 seconds from the batteries. After this time, all port carrier power is shed and the control carrier is powered for another 10 minutes. In a High or Critical Reliability PPN system, these times are cut to five seconds and five minutes, respectively. In an EPN multicarrier cabinet, the entire cabinet can be powered for 15 seconds from the batteries, after which time the entire cabinet is powered down.

In a multicarrier cabinet system, the POWER (Battery & Battery Charger) MO represents the battery charger and the battery which are located in the lower left corner of the cabinet. Should anything go wrong with the battery or charger, they must be replaced using the procedure described in "[Replacing the Battery and Battery Charger](#)" below. The system detects one of the following three problems with the batteries or charger:

1. Reserve Fault—The charger has detected a problem within itself or the batteries and has notified the system.
2. High Charge Rate—The batteries are charging at a high charge rate. This means that batteries with a low charge are being recharged or that a problem may exist with the batteries or the charger.
3. Prepare to Disconnect (Low Battery)—The batteries are in danger of being drained to a point where the batteries would be damaged. This warning often occurs after multiple power failures.

The batteries take 30 hours to fully charge after being drained. A fully charged battery pack should bridge two power failures without causing a low battery warning to occur.

## Replacing the Battery and Battery Charger

Use the procedure below to replace the Battery and Battery Charger:

1. Move the power switch on the battery charger to OFF.

### **WARNING:**

*Always turn off the battery charger before replacing the batteries. Failure to do so results in damage to the 397B battery charger.*

2. Disconnect the cord from the outlet on the front of the battery charger.
3. Remove the screw at the top left of the cover and open the cover to access the charger.
4. Check the battery voltages at the test points. The test points on the CE Distribution Unit check all 3 batteries wired in series (the voltages should read 144 volts, 3X48 volts = 144 volts) .

### **NOTE:**

An ordinary voltmeter can be used to check battery voltages at the test points, but it may not produce valid results. If the battery voltage readings are below 48 volts (the voltages at test points should read 144 volts, 3X48 volts = 144 volts), the battery is probably defective. However, a normal voltage reading does not necessarily mean the battery is good; under load, a defective battery with a normal reading on the voltmeter may discharge rapidly.

5. Check the battery dates and replace the batteries if they are more than four years old or if a POWER alarm is present.

**⇒ NOTE:**  
If any defective batteries are found, replace all of them. Batteries are ordered in sets of three and should be replaced as such.

6. If no defective batteries are found, replace the entire charger.
7. Close the cover and secure it with the screw.
8. Reconnect the cord and move the power switch to ON.

Hardware Error Log Entries and Test to Clear Values

Battery & Battery Charger Error Log Entries

| Error Type     | Aux Data     | Associated Test                                          | Alarm Level | On/Off Board | Test to Clear Value       |
|----------------|--------------|----------------------------------------------------------|-------------|--------------|---------------------------|
| 0 <sup>1</sup> | 0            | Any                                                      | Any         | Any          | test environment P sh r 1 |
| 1              | Any          | Battery & Battery Charger Query Test (#5) (Error Code 8) | MINOR       | ON           | test environment P sh r 1 |
| 257            | Any          | Battery & Battery Charger Query Test (#5) (Error Code 4) | MINOR       | ON           | test environment P sh r 1 |
| 769            | Any          | Battery & Battery Charger Query Test (#5) (Error Code 2) | MINOR       | ON           | test environment P sh r 1 |
| 3840           | 1005 or 1028 | Battery & Battery Charger Query Test (#5)                |             | ON           | test environment P sh r 1 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- a. Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors

generated from other tests in the testing sequence. During this test, the status LED on the battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| Battery & Battery Charger Query Test (#5)            | X                   | X                  | ND                |
| AC Power Query Test (#78) (a)                        | X                   | X                  | ND                |
| Power Unit Query Test (carrier E) (#127) (b)         | X                   | X                  | ND                |
| Power Unit Query Test (carrier D) (#127) (b)         | X                   | X                  | ND                |
| Power Unit Query Test (carrier A) (#127) (b)         | X                   | X                  | ND                |
| Power Unit Query Test (carrier B) (#127) (b)         | X                   | X                  | ND                |
| Power Unit Query Test (carrier C) (#127) (b)         | X                   | X                  | ND                |
| Emergency Transfer Query Test (#124) (c)             | X                   | X                  | ND                |
| Cabinet Sensors Query Test (#122) (d)                | X                   | X                  | ND                |
| External Alarm Lead Query Test (#120) (e)            | X                   | X                  | ND                |
| Analog Ring Generator Initialization Test (#117) (f) | X                   | X                  | ND                |
| Analog Ring Generator Query Test (#118) (f)          | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.
- b. Refer to CARR-POW (Carrier Port Power Unit) Maintenance documentation for a description of this test
- c. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.
- d. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.
- e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.
- f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

 **NOTE:**

This test only shows up in the test sequence if there is a Tone-Clock circuit pack in the port network being tested.

**Battery & Battery Charger Query Test (#5)**

This test queries the Maintenance/Tape Processor in a multicarrier cabinet PPN system without High or Critical Reliability, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN for the status of the battery pack and battery charger, and reports the result. During this test, the status LED battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

**Table 10-332. TEST #5 Battery & Battery Charger Query Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | System resources required to run this test are not available.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                    |
| 1005       | ABORT       | Battery Charger is not connected.<br><br>1. If the system has a UPS supplying the power, ignore this error since the UPS supplies the power, not the battery and battery charger.<br><br>2. The batteries probably need charging and may be drained if there were power outages. Reconnect the battery charger to allow the batteries to recharge. If Test #5 is run before the batteries are completely charged, the test fails.<br><br>3. Wait 24 hours and rerun the test. |

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2          | FAIL        | <p>The system is in nominal power holdover, and the battery is currently so low that the system disconnects power very shortly.</p> <ol style="list-style-type: none"><li>1. If power returns, the port carriers in the PPN should power up again. All the circuit packs should be reinserted, and the system should continue to operate normally. There will probably be a Minor alarm against Battery &amp; Battery Charger because the batteries are recharging.</li><li>2. If power does not return, the system shuts down to prevent damage to the batteries. If power is restored, the system reboots. <b>No manual intervention is required.</b></li><li>3. Rerun the test. If the test still fails, the PR-MAINT (Maintenance/Tape Processor) in a multicarrier cabinet PPN system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a PPN for a system with High or Critical Reliability, or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. Resolve all alarms on these MOs and rerun the test. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that ARE NOT be detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If the test still fails, follow normal escalation procedures.</li></ol> |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8          | FAIL        | <div> <b>NOTE:</b><br/>For a Global AC MCC (J58890CH) use the procedures outlined in step 3.</div> <p>There is a reserve power fault. A problem exists with the battery charger (more probable) or the battery (less probable).</p> <div><div>1.</div><div>Replace the battery charger or the battery. The fault should disappear. However, the test fails with Error Code 4 if the battery is charging.</div></div> <div> <b>WARNING:</b><br/><i>Always turn off the battery charger before replacing the batteries.</i></div> <div><div>2.</div><div>Rerun the test. If the test still fails with an error code other than 4 (that is, there is something wrong besides the battery needing charging), the PR-MAINT (Maintenance/Tape Processor) in a multicarrier cabinet PPN system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a PPN for a High or Critical Reliability, or the EPN MAINT (Maintenance) circuit pack in an EPN could be reporting this condition incorrectly. Resolve all alarms on these MOs and rerun the test. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that ARE NOT be detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If the test still fails, then follow normal escalation procedures.</div></div> |

Table 10-332. TEST #5 Battery & Battery Charger Query Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10         | FAIL        | This indicates that Error Codes 2 and 8 have occurred. Refer to these descriptions. Also, refer to the description for Error Code 14 for this test.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 12         | FAIL        | This indicates that Error Codes 4 and 8 have occurred. Refer to these descriptions. Also, refer to the description for Error Code 14 for this test.                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 14         | FAIL        | <p>This indicates that Error Codes 2, 4, and 8 have occurred. Refer to these descriptions.</p> <p> <b>NOTE:</b></p> <p>This could also indicate that the detection logic on the DUPINT (Duplication Interface), PR-MAINT (Maintenance/Tape Processor), or EPN MAINT (Maintenance) circuit pack is defective. Such an error will not be detected by the respective maintenance. If many environment tests are failing, replace the suspect circuit pack (depending on system configuration).</p> |
|            | PASS        | The Maintenance/Tape Processor in a multicarrier cabinet PPN system without High or Critical Reliability, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN have reported that the status of Battery & Battery Charger is good.                                                                                                                                                                                                                                                           |

# POWER (Battery & Battery Charger for DC-Powered Systems

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO           |
|------------------------|-------------|-------------------------------------|---------------------------|
| POWER                  | MINOR       | test environment P                  | Battery & Battery Charger |

1. Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.

 **NOTE:**

For environment maintenance, the PPN or EPN cabinet configuration aspects for a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Refer to the DC-POWER (DC Power) Maintenance documentation for environment maintenance strategy.

In a DC-powered cabinet, the POWER MO still exists, but serves no functional purpose. Because the system cannot determine the type of powering provided, all POWER tests should always pass or abort. Since the tests should never fail, POWER alarms should not be raised.

## Error Log Entries and Test to Clear Values

Table 10-333. Power Error Log Entries

| Error Type     | Aux Data | Associated Test                                          | Alarm Level | On/Off Board | Test to Clear Value       |
|----------------|----------|----------------------------------------------------------|-------------|--------------|---------------------------|
| 0 <sup>1</sup> | 0        | Any                                                      | Any         | Any          | test environment P sh r 1 |
| 1              | Any      | Battery & Battery Charger Query Test (#5) (Error Code 8) | MINOR       | ON           | test environment P sh r 1 |
| 257            | Any      | Battery & Battery Charger Query Test (#5) (Error Code 4) | MINOR       | ON           | test environment P sh r 1 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

- a. This error occurs only in a multi-carrier cabinet and can be ignored but not cleared for DC-powered systems.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| Battery & Battery Charger Query Test (#5)            | X                   | X                  | ND                |
| AC Power Query Test (#78) (a)                        | X                   | X                  | ND                |
| Emergency Transfer Query Test (#124) (c)             | X                   | X                  | ND                |
| Cabinet Sensors Query Test (#122) (d)                | X                   | X                  | ND                |
| External Alarm Lead Query Test (#120) (e)            | X                   | X                  | ND                |
| Analog Ring Generator Initialization Test (#117) (f) | X                   | X                  | ND                |
| Analog Ring Generator Query Test (#118) (f)          | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to “AC-POWER” (AC Power) for a description of this test.
- b. Refer to “EMG-XFER” (Emergency Transfer) for a description of this test.
- c. Refer to “CABINET” (Cabinet Sensors) for a description of this test.
- d. Refer to “EXT-DEV” (External Alarm) for a description of this test.
- e. Refer to “RING-GEN” for a description of this test.

 **NOTE:**  
This test shows up in the test sequence only if there is a TN768 or TN780 Tone-Clock circuit pack in the port network being tested.

**Battery & Battery Charger Query Test (#5)**

This test queries the Maintenance/Tape Processor in a standard PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN for the status of the battery pack and battery charger, and reports the result. In a DC-powered system, this test should never fail. During this test, the status LED on the battery charger is lit and extinguished if the status of the battery charger is reported as normal. This event is a result of checking that the battery charger is connected.

**Table 10-334. TEST #5 Battery & Battery Charger Query Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                             |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | System resources required to run this test are not available.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                       |
| 1005       | ABORT       | Battery charger is not connected since the system uses DC power and the battery charger and battery are for AC-powered systems.<br>1. Ignore this error in DC-powered systems.                                                                                          |
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                         |
| 2028       | ABORT       | Internal system error prevented the extinguishing of the Battery Charger status LED.<br>1. Although this test is not relevant for DC-powered systems, this error should trigger close monitoring of the system as this error means that internal system problems exist. |
| 2029       | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                               |

Table 10-334. TEST #5 Battery & Battery Charger Query Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| any        | FAIL        | The Duplication Interface circuit pack in a PPN for a high or critical reliability system is incorrectly reporting a problem with power. If this test fails, the problem is with the circuit pack and not with POWER.<br><br>1. The suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. |
|            | PASS        | All that can be inferred is that the DUPINT (Duplication Interface) circuit pack in a PPN for a high or critical reliability system is working properly.                                                                                                                                                                                |

PR-MAINT (Maintenance Processor  
[TN790 RISC Systems])

| MO Name (in Alarm Log) | Alarm Level      | Initial Command to Run  | Full Name of MO       |
|------------------------|------------------|-------------------------|-----------------------|
| PR-MAINT               | MIN <sup>1</sup> | test processor a/b sh/l | Maintenance Processor |

1. Alarms on the PROCR and PR-MAINT maintenance objects are indicated by the red LED on the Processor circuit pack.

The TN790 Processor circuit pack is comprised of the RISC Processor (PROCR), the Maintenance Processor (PR-MAINT), and the Memory (PR-MEM). PR-MAINT is responsible for monitoring the sanity of the RISC Processor.

PR-MAINT contains the hardware required for controlling the environmental conditions. The Maintenance/Tape Processor provides the serial interfaces for the administration terminal and DCE port. The Maintenance Processor also provides the communications interface to INADS for alarm reporting and remote maintenance capability. INADS connectivity is through the internal or external modem. The external modem is connected to the DCE port. When the external modem is the administered modem option the internal modem is disabled.

The TN790 has a higher speed 9600 baud internal modem or can support an external modem connected to the DCE port.

Error Log Entries and Test to Clear Values

Table 10-335. PR-MAINT Error Log Entries

| Error Type     | Aux Data | Associated Test                    | Alarm Level | On/Off Board | Test to Clear Value <sup>1</sup> |
|----------------|----------|------------------------------------|-------------|--------------|----------------------------------|

| 2049(h)    | Any      | External Modem Present Test (#230) | MIN         | OFF          | test processor a/b r 2           |

Continued on next page

- 
1. The MTP Reset Test (#101) logs you off. The MTP Dual Port Ram Test (#104) can also log you off. Manually repeat the command with the “long” option for the designated number of times when testing from the PPN SAT.
  2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- 
- a.

The MTP Reset Test (#101) has failed.
- b.

The MTP Sanity Handshake Test (#106) has failed.
- c.

The MTP Analog Loop Around Test (#103) has failed.
- d.

The MTP Dual Port Ram Test (#104) has failed. An error of 769 with an aux data of 5 indicates a hardware problem and testing cannot clear it. Replace the circuit pack.
- e.

The MTP Outputse Relay Test (#102) has failed.
- f.

The MTP SAT Loop Around Test (#228) has failed.
- g.

The MTP Aux Loop Around Test (#229) has failed.
- h.

The External Modem Present Test (#230) has failed.

 **NOTE:**  
Refer to the FAIL section of each test that fails for further instructions.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *MTP Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence. The following table is for the TN790 [RISC] System.

| Order of Investigation                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------|---------------------|--------------------|-------------------|
| Processor Cache Test (#895)(a)                 |                     | X                  | ND                |
| Processor Cache Audit (#896)(a)                | X                   | X                  | ND                |
| Processor Bus Time-out Exception Test (#82)(a) | X                   | X                  | ND                |
| Processor BOOTPROM Checksum Test (#80)(a)      | X                   | X                  | ND                |
| Processor Write Buffer Test (#900)(a)          | X                   | X                  | ND                |
| Memory Burst Read Test (#908)(a)               | X                   | X                  | ND                |
| Read All Memory Test (#85)(a)                  |                     | X                  | ND                |
| Memory Parity Error Detection Test (#87)(a)    | X                   | X                  | ND                |
| Flash Memory Checksum Test (#86)(a)            |                     | X                  | ND                |
| Memory Functional Test (#332) (b)(c)           |                     | X                  | D                 |
| MTP Outpulse Relay Test (#102)(d)              | X                   | X                  | ND                |
| External Modem Present Test (#230)(d)(e)       | X                   | X                  | ND                |
| MTP Analog Loop Around Test (#103)(d)          | X                   | X                  | ND                |
| MTP Sanity Handshake Test (#106)               | X                   | X                  | ND                |
| MTP SAT Loop Around Test (#228)                | X                   | X                  | ND                |
| MTP Aux Loop Around Test (#229)                | X                   | X                  | ND                |
| MTP Reset Test (#101)                          |                     | X                  | D                 |
| MTP Dual Port Ram Test (#104)(d)               |                     | X                  | D                 |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to PROCRA (TN790 RISC Processor) for a description of these tests.
- b. Refer to PR-MEM (TN790 RISC Memory) for a description of these tests.
- c. This test is run only on the standby SPE in a high or critical reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

- d. This test only runs on the active SPE.
- e. This test aborts if an external modem is not administered.

MTP Reset Test (#101)

This test is destructive.

The test resets the Maintenance Processor. The destructive nature of this test causes the following:

- System Access Terminal to log off
- DCE port to terminate data transmission
- Any current memory card access to terminate and also to tear down any remote access INADS connection

Table 10-336. TEST #101 MTP Reset Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                              |

MTP Outpulse Relay Test (#102)

This test is a nondestructive test. When the internal modem is administered, the test validates the correct operation of the remote access CO trunk used by INADS. The MTP first goes off-hook, then on-hook on this trunk. If the loop current is detected, the test passes. If the external modem is administered the MTP sends an AT command sequence that will cause the external modem to go OFF-HOOK and wait for dial-tone. If the modem detects dial-tone, the test passes. This test is not allowed if the remote access line is in use.

MTP Analog Loop Around Test (#103)

This test is a nondestructive test. The test does a loop around by using the MTP INADS channel. Test data is sent through the modem out toward the INADS trunk. The data is looped around before the actual trunk, and it comes back into the on-board modem. The data is then verified for integrity. The internal modem is tested when the internal modem is selected. The external modem is tested when the external modem is selected.

When an external modem is administered in place of the internal modem, the test loops data in the MTP DUART ahead of the connection to the external modem. This test also causes the MTP DUART to verify that **Clear-To-Send (CTS)** is being supplied by the modem.

**⇒ NOTE:**  
The test does not send any data onto the INADS trunk. However, to pass, the test does require the trunk to be present

|            | FAIL        | MTP reported test failure. The system is not able to reliably contact INADS with alarm data. However, the system continues to provide good service.<br><br>1. For an internal modem:<br><br>a. If MTP Outpulse Relay Test (#102) is also failing, check for the presence of the INADS trunk, and resolve any INADS trunk problems.<br><br>b. If Test #102 passes, the fault is on the Processor circuit pack. The circuit pack should be replaced.<br><br>2. For an external modem:<br><br>a. Check the power to the modem.<br><br>b. Check the RS-232 cable connections from the DCE terminal on the switch to the DTE connector on the modem. Transmit, Receive, RTS, and CTS signals must be communicating between the MTP DUART hardware and the modem hardware<br><br>c. The MTP DUART or related circuitry on the processor circuit pack may have failed. The circuit pack should be changed at your convenience. |
|            | PASS        | For an internal modem—MTP detected correct data through the loop back connection.<br><br>For an external modem—The test detected correct data through the loop back in the MTP DUART hardware ahead of the RS232 connection to the modem, and received a CTS signal from the external modem.<br><br>1. If the system cannot call INADS, or if INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct.                                                                                                                                                                                                                                                                                                                                                                                                                      |

MTP Dual Port Ram Test (#104)

This test is destructive.

The test terminates any PPN SAT session, and it is a coordinated test of the MTP dual port ram (DPR). The DPR is a section of memory that is shared by the MTP and by the RISC Processor circuit pack. Control messages and data are passed through the DPR. The test forces both sides to read and write the DPR simultaneously in alternate locations.

The DPR test causes the PPN SAT to log off before the test result is displayed. The test result is determined according to the terminal from which the test is run. If the test is run from the PPN SAT, system technician should log back in and examine the Error Log for an error against PR-MAINT, with Error Type 769, no Aux Data. This error entry indicates that the MTP DPR Test failed and that the Processor circuit pack should be replaced.

**⇒ NOTE:**  
If the test is being run from a terminal other than the PPN SAT (for example, EPN SAT, remote access, etc.), the test results are displayed on the screen.

**⇒ NOTE:**  
A dial-up (through the INADS port) does not display the results discussed in the previous paragraph. However, a dial-up through data channels does display these results.

If the test continues to fail, replace the Processor circuit pack. |
|            | PASS        | Dual port RAM is functioning. Communication exists between the Processor circuit pack and the MTP.                                                                                                                                                                                                                                                                |

MTP Sanity Handshake Test (#106)

This test is a nondestructive test. The MTP Sanity Handshake Test is simply a query from a maintenance process to the MTP. The MTP must reply for the test to pass.

Table 10-340. TEST #106 MTP Sanity Handshake Test

| Error Code                                                            | Test Result | Description/ Recommendation                                                                                                                                                    |

MTP SAT Loop Around Test (#228)

This test is a nondestructive test. The test places the SAT channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. Although the test is nondestructive, it causes loss of keyboard input from the PPN SAT.

Table 10-341. TEST #228 MTP SAT Loop Around Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                |

MTP Auxiliary Loop Around Test (#229)

This test is a nondestructive test. The test places the Auxiliary channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. The Auxiliary channel is used as the CDR output port

Table 10-342. TEST #229 MTP Auxiliary Loop Around Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                               |

|                                                                                      | FAIL        | The Auxiliary channel failed the Loop Back Test. The AUX port may not be sending any auxiliary data to the auxiliary collection device.<br><br>1. Repeat the command at 1-minute intervals a maximum of 5 times.<br><br>2. If test continues to fail, replace the Processor circuit pack. |
|                                                                                      | PASS        | The Auxiliary channel passed the Loop Back Test. The auxiliary port is functioning correctly.<br><br>1. If no auxiliary data is being recorded, check the auxiliary collection device, and verify that it has been set up and connected correctly.                                        |

MTP External Modem Present Test (#230)

This test is a nondestructive test on the remote access line, and will run only if the channel is idle. The test validates the presence of an external modem with a firmware invoked AT command. The test will pass if the modem responds with "OK" to the AT command.

Table 10-343. TEST #230 External Modem Present Test

| Error Code   | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                |

If all MTP tests are aborting, execute the <b>test processor a/b long</b> command in order to reset MTP, and examine the results of the MTP Reset Test (#101).                                                                        |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2500       | ABORT       | Internal System software Error<br><br>1. Retry at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|            | FAIL        | MTP reported test failure. The system is not able to reliably contact INADS with alarm data. However, the system continues to provide good service. The MTP did not receive an <b>OK</b> response after sending the <b>AT</b> command to the modem.<br><br>1. If test #103 failed, follow the external modem recommendations for that test failure.<br><br>2. If Test #103 passes:<br><br>a. Check the RS-232 connections from the DCE terminal on the switch to the DTE terminal on the modem. RTS and CTS signals are being communicated between the MTP DUART hardware and the modem hardware. Transmit and receive signals may not be communicated correctly.<br><br>b. Check the modem administration using the <b>change system-parameters maintenance</b> command, especially changes from default parameters.<br><br>c. Check the modem settings, especially changes from factory defaults.<br><br> <b>CAUTION:</b><br><i>The fault may be on the Processor circuit pack. The circuit pack should be replaced.</i> |
|            | PASS        | MTP detected correct data from the external modem. The MTP received an <b>OK</b> response after sending the <b>AT</b> command to the modem.<br><br>1. If the system cannot call INADS, or if INADS cannot contact the system, check with the local Central Office for problems with the INADS trunk, and verify that the INADS number is correct. If an external modem is being used instead of the internal MTP modem, modem settings may be wrong. Approved external modems with factory default settings are expected to work if administered correctly using the <b>change system-parameters maintenance</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## PR-MAINT (Maintenance Processor)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run  | Full Name of MO                         |
|------------------------|-------------|-------------------------|-----------------------------------------|
| PR-MAINT               | MIN         | test processor a/b sh/l | Maintenance/Tape Processor <sup>1</sup> |

1. The full Name of the MO in a 386 system is Maintenance Processor.

**NOTE:**

For systems with a TN790 Processor Circuit Pack use maintenance object PR-MAINT (MainTenance Processor TN790 RISC Systems).

The 80386 Processor, Memory, and MainTenance Processor comprise the TN786B Processor circuit pack [386 systems].

The TN786B Processor circuit pack is comprised of the 80386 Processor (PROCR), the MainTenance Processor (PR-MAINT), and the Memory (MEMORY). On the TN786B circuit pack, PR-MAINT is responsible for monitoring the sanity of the 80386 Processor.

The major difference between the two circuit packs is that on the TN786B circuit pack, there is no tape for PR-MAINT to control and Memory is on the circuit pack. The rest of the functionality is the same. On both circuit packs, PR-MAINT contains the hardware required for controlling the environmental conditions. The Maintenance/Tape Processor provides the serial interfaces for the administration terminal and CDR ports. The Maintenance/Tape Processor also provides the communications interface to INADS for alarm reporting and remote maintenance capability.

Error Log Entries and Test to Clear Values

Table 10-344. Maintenance/Tape Processor Error Log Entries

| Error Type     | Aux Data | Associated Test                       | Alarm Level | On/Off Board | Test to Clear Value <sup>1</sup> |
|----------------|----------|---------------------------------------|-------------|--------------|----------------------------------|
| 0 <sup>2</sup> | 0        | Any                                   | Any         | Any          | test processor a/b sh r 1        |
| 1 (a)          | Any      | MTP Reset Test (#101)                 | MIN         | ON           | test processor a/b l r 3         |
| 257 (b)        | Any      | MTP Sanity Handshake Test (#106)      |             |              | test processor a/b r 2           |
| 513 (c)        | Any      | MTP Analog Loop Around Test (#103)    | MIN         | ON           | test processor a/b r 8           |
| 769 (d)        | Any      | MTP Dual Port Ram Test (#104)         | MIN         | ON           | test processor a/b l r 3         |
| 1025 (e)       | Any      | MTP Outpulse Relay Test (#102)        | MIN         | OFF          | test processor a/b r 5           |
| 1537 (f)       | Any      | MTP Manager I Loop Around Test (#228) | MIN         | ON           | test processor a/b r 3           |
| 1793 (g)       | Any      | MTP Aux Loop Around Test (#229)       | MIN         | ON           | test processor a/b r 3           |

1. You must manually repeat the command with the "long" option the designated number of times from the administration terminal or from a remote administration terminal because the Sanity Timer Test (#83) logs you off.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The MTP Reset Test (#101) has failed.
- b. The MTP Sanity Handshake Test (#106) has failed.
- c. The MTP Analog Loop Around Test (#103) has failed.
- d. The MTP Dual Port Ram Test (#104) has failed. An error of 769 with an aux data of 5 indicates a hardware problem and testing will not clear it. The circuit pack should be replaced.
- e. The MTP Outpulse Relay Test (#102) has failed.
- f. The MTP Manager I Loop Around Test (#228) has failed.
- g. The MTP Aux Loop Around Test (#229) has failed.

 **NOTE:**  
Refer to the FAIL section of each test that fails for further instructions.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *MTP Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|-------------------|
| Processor Software Initiated Interrupt Test (#77) (a) | X                   | X                  | ND                |
| Processor ROM Checksum Test (#80) (a)                 | X                   | X                  | ND                |
| Processor Non-maskable Interrupt Test (#82) (a)       | X                   | X                  | ND                |
| Processor Sanity Timer Test (#83) (a)                 |                     | X                  | D                 |
| MTP Reset Test (#101)                                 |                     | X                  | D                 |
| MTP Dual Port Ram Test (#104)                         |                     | X                  | D                 |
| MTP Sanity Handshake Test (#106)                      | X                   | X                  | ND                |
| MAP Manager I Loop Around Test (#228)                 | X                   | X                  | ND                |
| MTP Analog Loop Around Test (#103)                    | X                   | X                  | ND                |
| MTP Outpulse Relay Test (#102)                        | X                   | X                  | ND                |
| MTP Aux Loop Around Test (#229)                       | X                   | X                  | ND                |
| Read All Memory Test (#85)(b)                         |                     | X                  | ND                |
| Memory Error Detection Test (#87)(b)                  | X                   | X                  | ND                |
| Text Checksum Test (#86)(b)                           |                     | X                  | ND                |
| Memory Functional Test (#332) (b)                     |                     | X                  | D                 |
| Memory Board Check Test (#631) (b)                    | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

- Notes:
- a. Refer to PROCR for a description of these tests.
  - b. Refer to MEMORY [386 systems only] for a description of these tests.

MTP Reset Test (#101)

**This test is destructive.** The test resets the Maintenance/Tape Processor. The destructive nature of this test causes the following:

- Administration terminal to log off
- CDR port to terminate data transmission
- Any current tape access to terminate and also to tear down any remote access INADS connection

Table 10-345. TEST #101 MTP Reset Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

|            | PASS        | The Maintenance/Tape Processor was reset, and it passed initialization correctly. The other MTP tests should be examined to verify that the MTP is functioning correctly.<br><br>1. Enter <b>test processor a/b</b> and verify that the MTP is functioning correctly. |

MTP Outpulse Relay Test (#102)

This test is a nondestructive test. The test validates the correct operation of the remote access CO trunk used by INADS. The MTP first goes off-hook, then on-hook on this trunk. If the loop current is detected, the test passes. This test is not allowed if the remote access line is in use.

MTP Analog Loop Around Test (#103)

This test is a nondestructive test. The test does an on-board loop around by using the MTPINADS channel. Test data is sent through the on-board modem out toward the INADS trunk. The data is looped around before the actual trunk, and it comes back into the on-board modem. The data is then verified for integrity.

 **NOTE:**  
The test does not send any data onto the INADS trunk. However, in order to pass, the test does require the trunk to be present.

MTP Dual Port Ram Test (#104)

This test is destructive.

The test terminates any PPN Manager I session, and it is a coordinated test of the MTP dual port ram (DPR). The DPR is a section of memory that is shared by the MTP and by the 80286/386 Processor circuit pack. Control messages and data are passed through the DPR. The test forces both sides to read and write the DPR simultaneously in alternate locations.

The DPR test causes the PPN Manager I to log off before the test result is displayed. The test result is determined according to the terminal from which the test is run. If the test is run from the PPN Manager I terminal, system technician should log back in and examine the Error Log for an error against PR-MAINT, with Error Type 769, no Aux Data. This error entry indicates that the MTPDPR Test failed and that the Processor circuit pack should be replaced.

 **WARNING:**

*If the TN786B circuit pack must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.*

If the test is being run from a terminal other than the PPN Manager I (for example, EPN Manager I, remote access, and so forth), the test results are displayed on the screen.

**⇒ NOTE:**  
A dial-up (through the INADS port) does not display the results discussed in the previous paragraph. However, a dial-up through data channels does display these results.

MTP Sanity Handshake Test (#106)

This test is a nondestructive test. The MTP Sanity Handshake Test is simply a query from a maintenance process to the MTP. The MTP must reply for the test to pass.

Table 10-349. TEST #106 MTP Sanity Handshake Test

| Error Code                                                                           | Test Result    | Description/ Recommendation                                                                                                                                                            |

MTP Auxiliary Loop Around Test (#229)

This test is a nondestructive test. The test places the Auxiliary channel of the MTP into a loop around mode, and it verifies the data integrity of the channel. The Auxiliary channel is used as the CDR output port.

Table 10-350. TEST #229 MTP Auxiliary Loop Around Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                           |

If test continues to fail, replace the Processor circuit pack. |
|                                                                                      | PASS        | The Auxiliary channel passed the Loop Back Test. The auxiliary port is functioning correctly.<br>1. If no auxiliary data is being recorded, check the auxiliary collection device, and verify that it has been set up and connected correctly.                                        |

## PR-MEM (TN790 RISC Memory)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO   |
|------------------------|-------------|------------------------|-------------------|
| PR-MEM <sup>1</sup>    | MAJOR       | test memory a/b lo c   | TN790 RISC Memory |
| PR-MEM <sup>1</sup>    | MINOR       | test memory a/b sh c   | TN790 RISC Memory |

1. The MO is “PR-MEM” because all of the Memory used by the Processor is on the TN790 Processor circuit pack.

The TN790 RISC Memory contains the DEFINITY software and firmware. The Processor circuit pack is the most critical component in the system.

For testing purposes, the circuit pack is logically separated into PR-MAINT, PROCR, and PR-MEM. This means that a memory problem requires that the Processor be replaced. These systems contain two types of memory: Flash ROM and DRAM. Flash ROM is memory that contains the boot image, part of the low-level maintenance firmware, PI firmware, and PACCON firmware. This type of memory is not erased during circuit pack resets. It can be reprogrammed via the **upgrade software** command or a Reset System 4/5 using a software memory card.

One section of the Flash ROM (BOOTPROM) containing the system initialization functions and the low-level diagnostic programs is programmed at the factory and is not reprogrammed by the **upgrade software** command. DRAM is used for software data storage, and it changes constantly. Both types of memory are present on the Processor circuit pack. The diagnostics run appropriate tests on both memories.

DRAM is replaceable and installed in 3 Single In-line Memory Module (SIMM) sockets on this circuit pack. Replacement of these SIMMs is described in "Install the SIMM on the TN790 Processor Circuit Pack" in [Chapter 5, “Routine Maintenance Procedures”](#).

For all system activity, the Processor must be able to access the Memory. If the Processor cannot do this, the system goes into SPE-down mode. In SPE-down mode, fatal Memory errors may show up as Processor errors. This merely indicates that the Processor and the Memory are very closely linked as a matter of course.

If the initialization diagnostics fail, refer to the "Procedure for SPE-Down Mode" section in [Chapter 4, “Initialization and Recovery”](#).

Error Log Entries and Test to Clear Values

Table 10-351. Memory Error Log Entries

| Error Type     | Aux Data   | Associated Test                          | Alarm Level | On/Off Board | Test to Clear Value   |
|----------------|------------|------------------------------------------|-------------|--------------|-----------------------|
| 0 <sup>1</sup> | 0          | Any                                      | Any         | Any          | test memory a/b l r 1 |
| 1              | Any        | Flash Memory Checksum Test (#86)         | MAJOR       | ON           | test memory a/b l r 5 |
| 3(a)           | Any        | Flash Memory Checksum Test (#86)         | MAJOR       | ON           | test memory a/b l r 5 |
| 1025           | Any        | Memory Parity Error Detection Test (#87) | MINOR       | ON           | test memory a/b r 3   |
| 1281           | Any        | Memory Burst Read Test (#908)            | MAJOR       | ON           | test memory a/b l r 2 |
| 1793           | Any (b)(c) | Read All Memory (#85)                    | MAJOR       | ON           | test memory a/b l r 1 |
| 2049(d)        | Any (b)(c) | Memory Functional Test (#332)            | MAJOR       | ON           | test memory a/b l r 1 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error (3) indicates that a software patch has been applied and either the software patch is bad or was installed incorrectly.
  - 1.Back out the software patch and run the **test memory UUCS long** command to verify that the problem has been cleared.
  - 2.If the PBX system is equipped with High Reliability or Critical Reliability option (i.e. with duplicated SPEs), and this error occurs, a SPE interchange will occur if the health of the standby SPE permits the interchange.
- b. The following Aux Data indicate SIMM Failures
  - 1.SIMM A
  - 2.SIMM B
  - 3.SIMM A & SIMM B
  - 4.SIMM C
  - 5.SIMM A & SIMM C
  - 6.SIMM B & SIMM C
  - 7.SIMM A, SIMM B, & SIMM C

- c. Aux Data of 100 is an LMM Flash Checksum initialization failure.
- d. There are Functional Memory Test errors against the Processor circuit pack. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate errors in the order in which they are presented in the table that follows when you are inspecting errors in the system. By clearing error codes associated with the *Read All Memory Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------|---------------------|--------------------|-------------------|
| Processor Cache Test (#895)(a)                 |                     | X                  | ND                |
| Processor Cache Audit (#896)(a)                | X                   | X                  | ND                |
| Processor Bus Time-out Exception Test (#82)(a) | X                   | X                  | ND                |
| Processor BOOTPROM Checksum Test (#897)(a)     | X                   | X                  | ND                |
| Processor Write Buffer Test (#900)(a)          | X                   | X                  | ND                |
| Memory Burst Read Test (#908)                  | X                   | X                  | ND                |
| Read All Memory Test (#85)                     |                     | X                  | ND                |
| Memory Parity Error Detection Test (#87)       | X                   | X                  | ND                |
| Flash Memory Checksum Test (#86)               |                     | X                  | ND                |
| Memory Functional Test (#332) (b)              |                     | X                  | D                 |
| MTP Outpulse Relay Test (#102) (c)             | X                   | X                  | ND                |
| MTP External Modem Present Test (#230) (c)     | X                   | X                  | ND                |
| MTP Analog Loop Around Test (#103) (c)         | X                   | X                  | ND                |
| MTP Sanity Handshake Test (#106) (c)           | X                   | X                  | ND                |
| MTP SAT Loop Around Test (#228) (c)            | X                   | X                  | ND                |
| MTP Aux Loop Around Test (#229) (c)            | X                   | X                  | ND                |
| MTP Reset Test (#101) (c)                      |                     | X                  | D                 |
| MTP Dual Port Ram Test (#104) (c)              |                     | X                  | D                 |

1. D = Destructive; ND = Nondestructive

- Notes:
- a. Refer to PROCR (TN790 RISC Processor) Maintenance documentation for a description of these tests.
  - b. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.
  - c. Refer to PR-MAINT (MainTenance Processor) Maintenance documentation for a description of these tests.

Read All Memory Test (#85)

This test is a nondestructive test. The test reads every memory location in memory. A failure of this test indicates a DRAM failure in the Processor circuit pack. DRAM is replaceable and installed in 3 Single Inline Memory Module (SIMM) sockets on this circuit pack. Replacement of these SIMMs is described in the "Circuit Pack Replacement Procedure" section.

| 1 - 7      | FAIL        | <p>If the system can still provide service, this indicates that the Processor circuit pack has a problem with memory or the RISC processor, but can still function.</p> <p>At the customers convenience run the destructive "<b>reset system 4</b>" command to boot the system and write to all of the memory locations. This will clear transient parity errors and test for permanent parity errors. This complete memory testing during initialization will cause "SPE DOWN" if a parity error is detected and the PROCR circuit pack should be replaced.</p> <p>If parity errors reoccur within several weeks, record the error code information indicating which memory modules failed, together with the extended interval between failures. After recording the information and at the customers convenience replace the PROCR circuit pack.</p> |
|            | PASS        | The Memory is healthy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Flash Memory Checksum Test (#86)

This test is a nondestructive test. The test computes the checksum of the DEFINITY Generic 3 software and firmware loaded from the Software Memory Card (SOFTWARE MEM-CARD). A failure of this test indicates corruption of the Flash Memory. However, this failure does NOT always indicate a hardware problem. **DO NOT REPLACE** the Processor circuit pack when this is the only error. A system restart via the **reset system 4** command starting with inserting the Software Memory Card for this system followed by re-inserting the Translation Memory Card memory card should be implemented at the customer's earliest convenience.

In a High or Critical Reliability system, an **upgrade software** command can be used with the Software Memory Card for the system followed by re-inserting the Translation Memory Cards as directed by this upgrade procedure. This command performs the same operation as the **reset system 4** command but is much less service-disruptive.

Memory Parity Error Detection Test (#87)

This test is a nondestructive test. The test is run on a few reserved locations in memory. A failure of this test indicates a failure on the Processor circuit pack.

This test determines if the parity circuitry is working. Accordingly, the test determines if parity errors can be detected. The parity circuitry is used to detect DRAM memory failures.

Table 10-354. TEST #87 Memory Parity Error Detection Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                   |

Memory Functional Test (#332)

This test is destructive.

This test ensures that every DRAM memory location can be accessed and changed independently. Running this test wipes out all data in DRAM memory. This test is performed during a **reset system 4** or **reset system 5**. If the test fails during a **reset system** command, refer to the "Procedure for SPE-Down Mode" in the [Chapter 4, "Initialization and Recovery"](#) for the recommended maintenance strategy. This test can be run as a long demand test on the standby SPE.

Table 10-355. TEST #332 Memory Functional Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                               |

| 100                                                                                  | ABORT       | The test did not complete within the allowable time period.<br>1. Retry the command.                                                                                                                      |
| 1000                                                                                 | ABORT       | System resources required to run this test are not available.<br>1. Retry the command at 1-minute intervals a maximum of 3 times.                                                                         |
| 1029<br>2014<br>2015<br>2016<br>2017<br>2018<br>2020<br>2022<br>2024<br>2025<br>2051 | ABORT       | Refer to STBY-SPE Maintenance documentation for a description of these error codes.                                                                                                                       |
| 1 - 7                                                                                | FAIL        | The Standby SPE Processor circuit pack is defective.<br>1. Repeat the command at 1-minute intervals a maximum of five times.<br>2. If the test still shows a failure, replace the Processor circuit pack. |
|                                                                                      | PASS        | The Standby SPE Processor circuit pack is healthy.                                                                                                                                                        |

Memory Burst Read Test (#908)

This test verifies that the Memory Burst Read function works properly on the Processor circuit pack.

Table 10-356. TEST #908 Memory Burst Read Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                            |
|--------------------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------|
| 100                                                                                  | ABORT       | The test did not complete within the allowable time period.<br>1. Retry the command.                                   |
| 1022<br>1335<br>2500                                                                 | ABORT       | Internal system error<br>1. Retry the command.                                                                         |
| 1029<br>2014<br>2015<br>2016<br>2017<br>2018<br>2020<br>2022<br>2024<br>2025<br>2051 | ABORT       | Refer to STBY-SPE Maintenance documentation for a description of these error codes.                                    |
| 1 - 7                                                                                | FAIL        | The Burst Read circuit is not functioning properly.<br>1. If the test fails, replace the Processor and retry the test. |
|                                                                                      | PASS        | The Burst Read portion of the Processor circuit pack is operating correctly.                                           |

PRI-CDR/SEC-CDR (PRI-CDR Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run            | Full Name of MO |
|------------------------|-------------|-----------------------------------|-----------------|
| PRI-CDR/SEC-CDR        | MINOR       | test cdr-link primary/secondary I | CDR Link        |
| PRI-CDR/SEC-CDR        | WARNING     | test cdr-link primary/secondary   | CDR Link        |

The CDR feature records detailed call information on all incoming and outgoing calls on specified trunk groups and sends this information to an CDR output device. The two physical links can be administered for connecting external CDR output devices to the system. They are identified as the primary CDR (PRI-CDR) link and the secondary CDR (SEC-CDR) link. The CDR link can be administered to a data extension or the EIA port on the system TN773 Processor circuit pack which provides a standard EIA-232C interface. The external CDR output devices are:

- 94A Local Storage Unit (LSU)
- TELESEER CDR Unit
- Call Accounting System (CAS)
- Call Detail Recording Unit (CDRU)
- Printer
- Host computer
- Personal computer (PC)
- Customer-provided equipment

Refer to *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*, for details of the CDR feature.

CDR Link Maintenance provides a strategy for maintaining the link between the system and an external CDR output device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. CDR Link Maintenance uses a try-and-wait mechanism for maintaining the CDR link. If the CDR link is torn down due to an error, CDR Link Maintenance intends to bring the CDR link up. If the Link Setup trial fails, CDR Link Maintenance waits 30 seconds before the next retry. If the number of retries reaches the value of a threshold (two), a Minor alarm is raised for service attention.

The following physical configurations are supported for the CDR link:

- From the EIA port of Processor circuit pack to an CDR output device through the standard EIA-232C interface.

- From a data channel on TN777 Network Control circuit pack to a data extension where the CDR output device connects via the standard EIA 232C interface.

The data extension can be a PDM, MPDM, DTDM, or ADU. The PDM, MPDM, and DTDM connect to a Digital Line Port of TN754 or TN754B Digital Line circuit pack; ADU connects to a Data Line Port of TN726 Data Link circuit pack.

**NOTE:**

In duplicated systems it is possible for a failure on one of the processor circuit packs to bring down the CDR link even if it is the standby processor. This problem can not be resolved by interchanging processors because the CDR ports on each of the processor circuit packs are connected via WIRE-OR.

CDR Link Maintenance does not cover the maintenance of the elements composing the CDR physical link, which are as follows:

- External CDR output device
- EIA port on Processor circuit pack
- Data Module (PDM/MPDM/DTDM) and Digital Line Port of TN754 or TN754B Digital Line circuit pack
- ADU and Data Line Port of TN726 Data Link circuit pack
- Data Channels on TN777 Network Control circuit pack

If CDR Link Maintenance cannot restore the CDR link, then the maintenance tests of these individual components of the CDR link must be executed to diagnose faults.

## **Procedures for Restoring the CDR Link**

1. Get the status of CDR links.

Enter **status cdr-link** command and make sure that the CDR links are not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the CDR link connect to?

Enter **display system feature** and find out the destinations of CDR links. Continue to the next step.

3. Is the destination an extension or the EIA port?

If the destination is an extension number, then enter the **status data extension** command and verify whether the data extension is in the in-service/idle state. If the data extension is NOT available, then look for

the extension number in Alt Name field of Hardware Error Log and refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for resolutions.

If the destination is "eia," then look for PR-MAINT errors in the Hardware Error Log. If present, refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation.

4. Is a data channel on TN777 Network Control circuit pack in the in-service/idle state?

Enter **list data** command and find out the extension numbers of data channels on TN777 Network Control circuit pack. Enter **status data extension** command and make sure that at least one data channel is in the in-service/idle state. If no data channel is available, then look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If present, refer to DATA-BD (Network Control Circuit Pack).

5. Is the external CDR output device available?

Make sure that the CDR output device is on-line and ready for service. Check the physical connectivity between Data Module and the CDR output device or between the EIA port on backplane of the switch and the CDR output device.

It is recommended to busy out the CDR link before executing maintenance tests over the CDR link. If the CDR link is busied out, then all CDR link maintenance actions are deactivated. The interference to tests of other MO is off.

Error Log Entries and Test to Clear Values

Table 10-357. CDR Link Maintenance Error Log Entries

| Error Type     | Aux Data                      | Associated Test        | Alarm Level                    | On/Off Board | Test to Clear Value                |
|----------------|-------------------------------|------------------------|--------------------------------|--------------|------------------------------------|
| 0 <sup>1</sup> | 0                             | Any                    | Any                            | Any          | test cdr-link primary secondary sh |
| 18 (a)         | 0                             | busy out cdr           | WARNING                        | OFF          | release cdr-link primary secondary |
|                |                               | primary secondary      |                                |              |                                    |
| 25 (b)         | 0<br>3 to 6<br>9<br>99<br>255 | Link Retry Test (#215) | MINOR/<br>WARNING <sup>2</sup> | OFF          | test cdr-link primary secondary l  |
| 513 (c)        | 0<br>3 to 6<br>9              |                        |                                |              | test cdr-link primary secondary    |
| 1025 (d)       |                               |                        |                                |              |                                    |
| 1281 (e)       |                               |                        |                                |              |                                    |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. System Technician has busied out the CDR link to out-of-service state. The CDR link is torn down.
- b. Link Retry Test (#215) fails. The Aux Data field contains either the Channel ID of Data Channels on the TN777 circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04, and 9 for EIA port) or an Error Code of 99 indicating that no data channels are available for setting up the link, or an Error Type of 255 indicating an internal system error. Refer to the preceding ["Procedures for Restoring the CDR Link"](#) for resolution.
- c. The CDR physical link is down due to the following causes: cable to the CDR output device is disconnected; CDR output device is powered off, the data extension where the CDR output device connects to has been busied out or there is a scheduled daily interchange. The Aux Data field contains the Channel ID of Data Channels on the TN777 circuit pack (that is, 3 for Channel 01, 4 for Channel 02, 5 for Channel 03, 6 for Channel 04, and 9 for EIA port). Check the connectivity of wire and cable among wall jacket, data module, and the CDR output device. Enter **status data**

**extension** and verify that the data extension of the CDR output device is in the in-service/idle state. If the data extension is not available, then refer to the preceding [“Procedures for Restoring the CDR Link”](#) for resolution. Issue the **display system-parameters-maintenance** command to see the start time of daily maintenance. If the error occurs and is resolved during the interval of daily maintenance, then the error can be ignored.

- d. This error indicates that the CDR output device is in an off-line state, for example, paper jam or paper out for a printer device. The CDR link is torn down. Check the CDR output device and act promptly to put it back to on-line state. Enter **test cdr-link primary|secondary** command to set up the CDR link.
- e. Software detects an overflow of CDR records generated in the switch due to the heavy trunk traffic and low speed CDR output device. If both primary and secondary links are ON, the secondary link is torn down temporarily for two minutes to speed up the output process to the primary link. No action is necessary for this error type.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------|---------------------|--------------------|-------------------|
| Link Tear Down Test (#213) |                     | X                  | D                 |
| Link Retry Test (#215)     | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

**Link Tear Down Test (#213)**

**This test is destructive.**

This test disconnects the existing link between the system and the external CDR output device. If the link has been disconnected already, this test just returns PASS. All resources allocated for an CDR link are released after this test.

Table 10-358. TEST #213 Link Tear Down Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| 50         | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                  |
| 1010       | ABORT       | The CDR link has been busied out to out-of-service.<br>1. Enter the <b>release cdr-link primary secondary</b> command to release the CDR link from busyout state.<br>2. Retry the <b>test cdr-link primary secondary long</b> command to execute the test. |
|            | FAIL        | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                  |
|            | PASS        | The CDR link is torn down.                                                                                                                                                                                                                                 |

Link Retry Test (#215)

This test sends a message to the CDR software process to make a data call to the extension where the CDR output device connects to or opens the EIA port to the CDR output device. If the CDR link is already up, this test is passed without making any data call or opening the EIA port.

Table 10-359. TEST #215 Link Retry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                               |

## PROC-SAN (Process Sanity Audits)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO       |
|------------------------|-------------|------------------------|-----------------------|
| PROC-SAN               | none        | none                   | Process Sanity Audits |

The Process Sanity Audits MO is responsible for monitoring the sanity of software processes in the system. If the Process Sanity Audits MO detects that a process has gone insane (does not respond to a sanity message within an allotted time period), the process is restarted. If the Process Sanity Audits MO detects that multiple processes (or a single key process) do not respond to sanity messages within an allotted time period, a system recovery action is initiated.

The Process Sanity Audits MO has no alarms and no tests. Certain errors are logged to the Hardware Error Log for information purposes only.

### Error Log Entries and Test to Clear Values

Table 10-360. Process Sanity Audits Error Log Entries

| Error Type     | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-----------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any             | Any         | Any          | none                |
| 10 (a)         | 0        | none            | none        | none         | none                |
| 204 (a)        | any      | none            | none        | none         | none                |

- 
1. Look for other errors of the same type and deal with them accordingly.

Notes:

- a. These errors indicate that a system recovery action has been taken because one or more software processes failed to respond to a sanity audit in a timely fashion. As a result of the recovery action, the system may have temporarily suspended service for a period of time surrounding the error.

## PROCR (Processor Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run    | Full Name of MO        |
|------------------------|-------------|---------------------------|------------------------|
| PROCR                  | MAJOR       | test processor a/b sh r/c | Processor Circuit Pack |

**NOTE:**  
For systems with a TN790 RISC Processor circuit pack see maintenance object [“PROCR \(TN790 RISC Processor Circuit Pack\)”](#).

**NOTE:**  
Alarms on the MEM-BD [386 systems only], PROCR and PR-MAINT maintenance objects (MOs) are indicated by the red LED on the Processor circuit pack.

The TN786B has an 80386 processor that uses on-board flash ROM and DRAM memory. The TN786B Processor circuit pack is comprised of the 80386 Processor (PROCR), the MainTenance Processor (PR-MAINT) and Memory (MEM-BD).

The TN786B Processor circuit pack is responsible for the execution of the DEFINITY software. This includes all of the call processing, maintenance, and administration functions. The Processor circuit pack is the most critical component to proper operation of the system.

The PR-MAINT is responsible for monitoring the sanity of the Processor circuit pack as well as the environmental conditions. The PR-MAINT provides the serial interfaces for the administration terminal and for the Call Detail Recording (CDR) ports. The PR-MAINT also provides the communications interface to INADS for alarm reporting and remote maintenance capability.

In High and Critical Reliability systems, the PR-MAINT is part of the communications path between the Active Processor Element and the Standby Processor Element.

Error Log Entries and Test to Clear Values

Table 10-361. 80286/386 Processor Circuit Pack Error Log Entries

| Error Type     | Aux Data | Associated Test                             | Alarm Level | On/Off Board | Test to Clear Value <sup>1</sup> |
|----------------|----------|---------------------------------------------|-------------|--------------|----------------------------------|
| 0 <sup>2</sup> | 0        | Any                                         | Any         | Any          | test processor a/b r 1           |
| 1 (a)          | 0        | Software Initiated Interrupt Test (#77)     | MAJOR       | ON           | test processor a/b r 3           |
| 769 (b)        | 0        | ROM Checksum Test (#80)                     | MAJOR       | ON           | test processor a/b r 5           |
| 1025 (c)       | 0        | Processor Non-maskable Interrupt Test (#82) | MAJOR       | ON           | test processor a/b r 2           |
| 1281 (d)       | 0        | Processor Sanity Timer Test (#83)           | MAJOR       | ON           | test processor a/b l r 2         |

1. Software does not accept the repeat option on the TN773 circuit pack [G3iV1.1-286]. The repeat option is valid only on the TN786B circuit pack. You must manually repeat the command with the long option the designated number of times from the administration terminal and from a remote SAT because the Sanity Timer Test (#83) logs you off. In G3iV1.1-286, if the **test processor long** System Technician command is executed six times back-to-back, the system goes into SPE-DOWN mode.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The Software Initiated Interrupt Test (#77) failed. Refer to the FAIL condition of this test for further action.
- b. The ROM Checksum Test (#80) failed. Refer to the FAIL condition of this test for further action.
- c. The Processor Non-maskable Interrupt Test (#82) failed. Refer to the FAIL condition of this test for further action.
- d. The Processor Sanity Timer Test (#83) failed. Refer to the FAIL condition of this test for further action.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *Processor Non-maskable Interrupt Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------|---------------------|--------------------|-------------------|
| Processor Non-maskable Interrupt Test (#82)       | X                   | X                  | ND                |
| Processor ROM Checksum Test (#80)                 | X                   | X                  | ND                |
| Processor Software Initiated Interrupt Test (#77) | X                   | X                  | ND                |
| Processor Sanity Timer Test (#83)                 |                     | X                  | D                 |
| MTP Outpulse Relay Test (#102) (a)                | X                   | X                  | ND                |
| MTP Analog Loop Around Test (#103) (a)            | X                   | X                  | ND                |
| MTP Sanity Handshake Test (#106) (a)              | X                   | X                  | ND                |
| MTPSAT Loop Around Test (#228) (a)                | X                   | X                  | ND                |
| MTP Aux Loop Around Test (#229) (a)               | X                   | X                  | ND                |
| MTP Reset Test (#101) (a)                         |                     | X                  | D                 |
| MTP Dual Port Ram Test (#104) (a)                 |                     | X                  | D                 |
| Read All Memory Test (#85)(b)                     |                     | X                  | ND                |
| Memory Error Detection Test (#87)(b)              | X                   | X                  | ND                |
| Text Checksum Test (#86)(b)                       |                     | X                  | ND                |
| Memory Functional Test (#332) (c)(b)              |                     | X                  | D                 |
| Memory Board Check Test (#631) (b)                | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation for a description of these tests.
- b. Refer to MEMORY [386 systems only] Maintenance documentation for a description of these tests.

Processor Software Initiated Interrupt Test (#77)

This test is a nondestructive test. The test verifies if the 80286/386 Processor can exercise the three types of software-initiated interrupts:

- Divide by zero
- Single step
- One byte interrupt instruction.

Table 10-362. TEST #77 Processor Software Initiated Interrupt Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|                                                                                      | FAIL        | <p>The processor did not detect the software interrupt condition. As a result, the processor executed the incorrect interrupt vector. The system may or may not continue to operate correctly.</p> <ol style="list-style-type: none"><li>1. Repeat the command at 1-minute intervals a maximum of 5 times.</li><li>2. If the test continues to fail, the Processor circuit pack should be replaced.</li></ol> <p> <b>WARNING:</b></p> <p><i>If the TN786B circuit pack [386 systems only] must be replaced, and if there is a blank in the Expansion Memory circuit pack slot (that is, in the slot immediately to the right of the TN786B circuit pack), remove the blank before removing the circuit pack. Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.</i></p> |
|                                                                                      | PASS        | The processor detected the software interrupt condition, and it executed the correct interrupt vector. The system continues to operate correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Processor ROM Checksum Test (#80)

This test is a nondestructive test. The test computes the checksum of the processor’s bootstrap ROM, and it compares this checksum to a predetermined value stored within the ROM. A failure of this test indicates corruption of the ROM.

Table 10-363. TEST #80 Processor ROM Checksum Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Processor Non-maskable Interrupt Test (#82)

This test is a nondestructive test. The test is used to verify that the 80286/386 Processor can detect and respond to non-maskable interrupts. For example, the processor intentionally causes a BUS TIMEOUT EXCEPTION (BTE) and then verifies if it vectors to the correct interrupt routine. This is basically a test of the internal operation of the 80286/386 CPU chip.

Table 10-364. TEST #82 Processor Non-maskable Interrupt Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

If replacement of the Processor circuit pack still results in test failure, the following circuit packs should be replaced, one at a time in the order provided: TN770 Memory [G3iV1.1-286 only] Expansion Memory [G3iV2-386 only] TN765 Processor Interface, TN777B Network Control, TN778 Packet Control, and TN772 Duplication Interface circuit packs. The test should then be repeated.</li><li>4. If the test still fails after you replace all the circuit packs discussed in the previous step, the problem must be in the control carrier, and the carrier should be replaced.</li></ol> |
|                                                                                      | PASS        | The interrupt was correctly detected. The 80286/386 CPU chip is functioning correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Processor Sanity Timer Test (#83)

This test is destructive.

This test causes service to be disrupted for about seven seconds on the TN773 and for about one second on the TN786B. During this time, the system does not respond to any user action.

This test checks to see if the 80286/386 processor watch-dog sanity timer is functioning correctly. The processor intentionally allows the sanity timer to time out. If the processor detects itself being reset, the test passes, and the processor continues to execute normally. If the processor does not detect a reset, the test has failed. If this test continues to fail, the processor pack should be replaced as soon as possible. The sanity timer is not critical to system operation, but it is needed for processor recovery if the processor stops functioning.

Table 10-365. TEST #83 Processor Sanity Timer Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                      |

Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                      |
| 1029<br>2014<br>2015<br>2016<br>2017<br>2018<br>2020<br>2022<br>2024<br>2025<br>2051 | ABORT       | Refer to STBY-SPE Maintenance documentation for a description of these error codes.                                                                                                                                                                                                                                                                                                                              |
|                                                                                      | FAIL        | The sanity timer did not time out as expected. The system continues to function normally. If the processor gets into an infinite loop, the reset CANNOT be detected, and the system DOES NOT reboot itself to clear the problem.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If test continues to fail, the Processor circuit pack should be replaced as soon as possible. |
|                                                                                      | PASS        | The sanity timer went off as expected. The system continues to function normally. If the processor gets into an infinite loop, the reset IS detected, and the system reboots itself to clear the problem.                                                                                                                                                                                                        |

## PROCR (TN790 RISC Processor Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run    | Full Name of MO                   |
|------------------------|-------------|---------------------------|-----------------------------------|
| PROCR                  | MAJOR       | test processor a/b lo r/c | TN790 RISC Processor Circuit Pack |
| PROCR                  | MINOR       | test processor a/b sh r/c | TN790 RISC Processor Circuit Pack |

**⇒ NOTE:**  
For systems with the TN786B Processor circuit pack, see maintenance object, [“PROCR \(Processor Circuit Pack\)”](#).

**⇒ NOTE:**  
Alarms on the PR-MEM, PROCR and PR-MAINT maintenance objects (MOs) are indicated by the red LED on the Processor circuit pack.

This section applies to the TN790. The TN790 has a RISC processor (PROCR) that uses on-board Flash ROM and DRAM memory (PR-MEM). This circuit pack also contains the MainTenance Processor (PR-MAINT).

The RISC Processor circuit pack portion is responsible for the execution of the DEFINITY Generic 3 software package. This includes all of the call processing, maintenance, and administration functions. The RISC Processor circuit pack is the most critical component to the correct operation of the system.

The PR-MAINT (MainTenance Processor for RISC systems) is responsible for monitoring the sanity of the RISC Processor circuit pack and the environmental conditions. The PR-MAINT provides the serial interfaces for the SAT and for the Digital Communications Equipment (DCE) ports. The PR-MAINT also provides the communications interface to INADS for alarm reporting and remote maintenance capability.

In High and Critical Reliability systems, the PR-MAINT is part of the communications path between the Active Processor Element and the Standby Processor Element.

Error Log Entries and Test to Clear Values

Table 10-366. RISC Processor Circuit Pack Error Log Entries

| Error Type     | Aux Data | Associated Test                             | Alarm Level | On/Off Board | Test to Clear Value <sup>1</sup> |
|----------------|----------|---------------------------------------------|-------------|--------------|----------------------------------|
| 0 <sup>2</sup> | 0        | Any                                         | Any         | Any          | test processor a/b r 1           |
| 1(a)           | Any      | BOOTPROM Checksum Test (#80)                | MAJOR       | ON           | test processor a/b r 5           |
| 513            |          | Processor Write Buffer Test (#900)          | MAJOR       | ON           | test processor a/b r 1           |
| 1025(b)        | Any      | Processor Cache Audit (#896)                | MINOR       | ON           | test processor a/b r 2           |
| 1281           | Any      | Processor Cache Test(#895)                  | MAJOR       | ON           | test processor a/b r 1           |
| 1793(c)        |          | Processor Bus Time-out Exception Test (#82) | MAJOR       | ON           | test processor a/b r 2           |
| 2049(d)(e)     | Any      | Processor Sanity Timer Test                 | MINOR       | ON           | test processor a/b l c           |
| 2305(d)(f)     | Any      | Address Matcher Test                        | none        | ON           | test processor a/b l c           |

1. The MTP Reset Test (#101) logs you off. The MTP Dual Port Ram Test (#104) can also log you off.
2. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The BOOTPROM Checksum Test (#80) failed. Refer to the FAIL condition of this test for further action.
- b. A parity error was detected in the processor's data cache or instruction cache. Aux Data indicates the difference in the number of parity errors since the last report.
- c. The Processor Bus Time-out Test (#82) failed. Refer to the FAIL condition of this test for further action.
- d. Aux Data of 100 is an LMM initialization failure.
- e. The Processor Sanity Timer Test failed during a reset level 4 or 5 initialization. reset system 4 at the customers convenience and if the alarm occurs again, replace the processor circuit pack. The system runs with this failure, but it is not protected if the system software has a sanity problem. The test processor a/b long clear command clears this alarm, but the sanity timer is only tested during initialization so the alarm occurs again and the system is not protected against insane software.

- f. The Address Matcher Test failed during a reset level 4 or 5 initialization. This is not alarmed because the address matcher is only used for high level debugging. Replace the processor circuit pack if the Address Matcher is needed for troubleshooting.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Processor Bus Time-out Exception Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                      | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------|---------------------|--------------------|-------------------|
| Processor Cache Test (#895)                 |                     | X                  | ND                |
| Processor Cache Audit (#896)                | X                   | X                  | ND                |
| Processor Bus Time-out Exception Test (#82) | X                   | X                  | ND                |
| Processor BOOTPROM Checksum Test (#80)      | X                   | X                  | ND                |
| Processor Write Buffer Test (#900)          | X                   | X                  | ND                |
| Memory Burst Read Test (#908)(a)            | X                   | X                  | ND                |
| Read All Memory Test (#85)(a)               |                     | X                  | ND                |
| Memory Parity Error Detection Test (#87)(a) | X                   | X                  | ND                |
| Flash Memory Checksum Test (#86)(a)         |                     | X                  | ND                |
| Memory Functional Test (#332) (a) (b)       |                     | X                  | D                 |
| MTP Outpulse Relay Test (#102) (c)          | X                   | X                  | ND                |
| MTP External Modem Present Test (#230) (c)  | X                   | X                  | ND                |
| MTP Analog Loop Around Test (#103) (c)      | X                   | X                  | ND                |
| MTP Sanity Handshake Test (#106) (c)        | X                   | X                  | ND                |
| MTP SAT Loop Around Test (#228) (c)         | X                   | X                  | ND                |
| MTP Aux Loop Around Test (#229) (c)         | X                   | X                  | ND                |
| MTP Reset Test (#101) (c)                   |                     | X                  | D                 |
| MTP Dual Port Ram Test (#104) (c)           |                     | X                  | D                 |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to “PR-MEM” for a description of these tests.
- b. There are Functional Memory Test errors against the Processor circuit pack. This test is run only on the Standby SPE in a high or critical reliability system. On other systems or on the Active SPE, the test is run only via a reset system 4 command or a reset system 5 command.
- c. Refer to “PR-MAINT” for a description of these tests.

Processor BOOTPROM Checksum Test (#80)

This test is a nondestructive test. This test computes the checksum of the Processor's bootstrap BOOTPROM. A failure indicates the BOOTPROM is corrupt.

Table 10-367. Test #80 Processor BOOTPROM Checksum Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                    |
|--------------------------------------------------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 100                                                                                  | ABORT       | The test did not complete within the allowable time period.<br><br>1. Retry the command.                                                                                                                                                                       |

|                                                                                      | FAIL        | The computed checksum did not match the BOOTPROM checksum. The system may not continue to operate correctly. The system may fail at some future date when the corrupted area the bootstrap BOOTPROM is accessed.<br><br>1. Replace the Processor circuit pack. |
|                                                                                      | PASS        | The computed checksum matched the BOOTPROM checksum. This part of the Processor will continue to operate normally.                                                                                                                                             |

Processor Bus Time-out Exception Test (#82)

This test is a nondestructive test. The test is used to verify that the RISC Processor can intentionally cause a BUS TIMEOUT EXCEPTION (BTE) and then verifies if it vectors to the correct interrupt routine. This is basically a test of the internal operation of the RISC Processor chip and the bus time-out circuitry.

Table 10-368. Test #82 Processor Bus Time-out Exception Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| 2500                                                                                 | ABORT       | Internal system error<br>1. Retry the command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|                                                                                      | FAIL        | The interrupt was not detected or acted upon.<br>1. Repeat the command at 1-minute intervals a maximum of 5 times.<br>2. If the test continues to fail, the Processor circuit pack should be replaced. The replacement must have enough memory for this system.<br>3. If replacement of the Processor circuit pack still results in test failure, the following circuit packs should be replaced, one at a time in the order provided: TN765 Processor Interface, TN777B Network Control, TN778 Packet Control, and TN772 Duplication Interface circuit packs. The test should then be repeated. |
|                                                                                      | PASS        | The interrupt was correctly detected. The RISC Processor is functioning correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Processor Cache Test (#895)

This test is a nondestructive test. This test overwrites the contents in the Instruction and Data Caches, requiring them to be refilled during normal execution.

This test verifies that the Processor Instruction and Data Caches are functional. Some errors in the caches will simply reduce performance by forcing instructions or data to be read from memory more often than would normally be necessary. In any case, cache problems are serious and the Processor circuit pack must be replaced as soon as possible if they are detected.

Table 10-369. Test #895 Processor Cache Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                             |

|                                                                                      | FAIL        | The Processor cache is not functioning correctly.<br>1. Replace the Processor circuit pack immediately. |
|                                                                                      | PASS        | The cache portion of the Processor circuit pack is operating correctly.                                 |

Processor Cache Audit (#896)

This nondestructive audit checks the state of the Cache Parity bit maintained by the RISC CPU. If this bit is set, there may be problems with either the CPU, the Instruction, or Data Cache. An indication of bad cache parity won't itself mean that the system won't operate, but minor to severe performance degradation may be present. For example, a single bad bit in either cache could cause this bit to be set. If the faulty word is seldom accessed, the impact will be small. If the bit is accessed frequently, there could be serious problems with much, or all, of the cache (stuck data bit) with the only direct indication again being the cache parity error or cache test error.

Table 10-370. Test #896 Processor Cache Audit

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                       |

## RING-GEN (Analog Ring Generator)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO       |
|------------------------------------|-------------|-------------------------------------------------------|-----------------------|
| RING-GEN                           | MAJOR       | test environment P                                    | Analog Ring Generator |

1.
- Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.

All analog phones in DEFINITY Generic 1 cabinets must be provided with a voltage that allows them to ring. The Analog Ring Generator MO represents the device that provides the ringing voltage for analog phones in a multicarrier or single carrier cabinet system. In a multicarrier cabinet system, the Analog Ring Generator resides in the PDU. [Figure 10-81](#) shows the position of the PDU and illustrates that fuse F9 is used for the Analog Ring Generator. [Figure 10-82](#) shows the position of the fuses on the PDU and describes how to replace a fuse. In a single carrier cabinet system, the Analog Ring Generator is part of the WP-91153 power unit, and each carrier in the single carrier cabinet contains its own Analog Ring Generator. A ringing voltage generator failure means that no ringing will occur on analog phones; however, ringing on digital and hybrid phones will still occur.

The ringing voltage is monitored by the Tone-Clock circuit pack. In a port network with duplicated Tone-Clocks, it is the active Tone-Clock that performs this function. In an EPN made up of single-carrier cabinets, the Tone-Clock monitors only the ringing voltage in the carrier that contains the tone clock.

Also, if the TN2182 Tone-Clock is installed in the Processor Interface slot, the ringing voltage is not monitored.

The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins.

Figure 10-81. Multicarrier Cabinet Environment Components

Hardware Error Log Entries and Test to Clear Values

| Analog Ring Generator Error Log Entries |          |                                         |             |              |                         |
|-----------------------------------------|----------|-----------------------------------------|-------------|--------------|-------------------------|
| Error Type                              | Aux Data | Associated Test                         | Alarm Level | On/Off Board | Test to Clear Value     |
| 0 <sup>1</sup>                          | 0        | Any                                     | Any         | Any          | test environment UU     |
| 1                                       |          | Analog Ring Generator Query Test (#118) | MAJOR       | ON           | test environment UU r 3 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Analog Ring Generator Initialization Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Multicarrier Cabinet                             |                     |                    |                   |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
| Analog Ring Generator Initialization Test (#117) | X                   | X                  | ND                |
| Analog Ring Generator Query Test (#118)          | X                   | X                  | ND                |
| Battery & Battery Charger Query Test (#5) (a)    | X                   | X                  | ND                |
| AC Power Query Test (#78) (b)                    | X                   | X                  | ND                |
| Power Unit Query Test (Carrier E) (#127) (c)     | X                   | X                  | ND                |
| Power Unit Query Test (Carrier D) (#127) (c)     | X                   | X                  | ND                |
| Power Unit Query Test (Carrier A) (#127) (c)     | X                   | X                  | ND                |
| Power Unit Query Test (Carrier B) (#127) (c)     | X                   | X                  | ND                |
| Power Unit Query Test (Carrier C) (#127) (c)     | X                   | X                  | ND                |
| Emergency Transfer Query Test (#124) (d)         | X                   | X                  | ND                |
| Cabinet Sensors Query Test (#122) (e)            | X                   | X                  | ND                |
| External Alarm Lead Query Test (#120) (f)        | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes

- a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.
- b. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.
- c. Refer to CARR-POW (Carrier Port Power Unit) for AC- and DC-Powered Systems Maintenance documentation for a description of this test.
- d. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.
- e. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.
- f. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

| Single-Carrier Cabinet                           |                     |                    |                   |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
| Analog Ring Generator Initialization Test (#117) | X                   | X                  | ND                |
| Analog Ring Generator Query Test (#118)          | X                   | X                  | ND                |
| Single-Carrier Power Query Test (#79) (a)        | X                   | X                  | ND                |
| Emergency Transfer Query Test (#124) (b)         | X                   | X                  | ND                |
| External Alarm Lead Query Test (#120) (c)        | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to DC-POWER (Power) Maintenance documentation for a description of this test.
- b. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.
- c. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.

Analog Ring Generator Initialization Test (#117)

The TN768, or TN780 will report an error to the system software if the ringing voltage falls to low (only if system software has made a request to the TN768, or TN780 to monitor the voltage). The Analog Ring Generator Initialization Test sends a request to the TN768, or TN780. If there are redundant tone/clock circuit packs in the port network, then the request is sent only to the active tone/clock.

Table 10-372. TEST #117 Analog Ring Generator Initialization Test

| Error Code                                        | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                |
|---------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1<br>1000<br>1001<br>1003<br>1115<br>2012<br>2100 | ABORT       | <p>The system software is unable to determine the active tone/clock circuit pack, unable to allocated the resources necessary to run the test, or unable to send a down link message.</p> <p>1. Wait for the green LED on the active tone/clock to go out; use the <b>status port-network</b> command to determine the active Tone/Clock circuit pack.</p> <p>2. Rerun the test. If the test aborts again, refer to TDM-CLK Maintenance documentation.</p> |
| 2000                                              | ABORT       | <p>Response to the request was not received within the allowable time period.</p> <p>1. Look for TDM-CLK errors and alarms. Resolve all other Tone/Clock problems first.</p> <p>2. Rerun the test.</p>                                                                                                                                                                                                                                                     |
| 1005                                              | ABORT       | <p>The tone/clock is unable to read the analog ringing voltage level when the tone/clock is in the Processor Interface slot. This test is not available for the Processor Port Network in this configuration.</p>                                                                                                                                                                                                                                          |
|                                                   | PASS        | <p>The active Tone/Clock has successfully been enabled to monitor the ringing voltage level.</p>                                                                                                                                                                                                                                                                                                                                                           |

Analog Ring Generator Query Test (#118)

This test requests the Active Tone-Clock circuit pack to check the ringing voltage. The tone/clock circuit pack replies with PASS if the ringing voltage is adequate to ring the analog phones. If not, the active tone/clock circuit pack replies with a FAIL. The Analog Ring Generator Query Test then reports the result.

Table 10-373. TEST #118 Analog Ring Generator Query Test

| Error Code                                        | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------------------------------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Error Code | Test Result       | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL<br>(cont'd.) | <div><div>5. If the test passes, then the Analog Ring Generator is healthy, and one of the Analog circuit packs is defective. Replace the Analog circuit packs one at a time, and rerun the test to determine which circuit pack is causing the problem. When the defective Analog circuit pack is found, replace it. Rerun the test. If the test still fails, proceed with Step 6.</div><div>6. Since the test still fails, the Analog Ring Generator is defective. Replace the Analog Ring Generator as follows:<div><div>a. Open the PDU compartment door. The door is hinged on the right and has a magnetic latch on the left.</div><div>b. If the reset button on the Analog Ring Generator is out, press it in.</div><div>c. Originate calls to several analog stations on different port circuit packs in different carriers in the affected port network.</div><div>d. If called stations ring, the fault is cleared. Proceed to Step f. If no stations ring, replace the Analog Ring Generator. To replace the Analog Ring Generator, first disconnect the output (P6) and input (P7) connectors from the Analog Ring Generator and then remove the two screws at the base of the Analog Ring Generator.</div><div>e. Replace the Analog Ring Generator, secure it with the two screws at the base, and replace the P6 and P7 connectors (P6 goes on top).</div><div>f. Rerun the test. If the test still fails, proceed to Step 7.</div></div></div><div>7. The active tone/clock may be faulty and incorrectly reporting the level of the ringing voltage. Replace the Active tone/clock and rerun the test. Refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details on replacing the tone/clock. Rerun the test. If the test still fails, escalate the problem.</div></div> |

| S-SYN-PT                                 | WARNING        | test port PCSSpp sh                                         | Speech Synthesis Port |

1. Where P is the port network number (1 for PPN and 2 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The TN725 Speech Synthesis circuit pack provides four independent Speech Synthesis Ports which may be connected to any of the voice time slots on the TDM Bus. Each Speech Synthesis Port consists of a speech synthesizer device (SSD) and is managed by a custom-coded programmable speech synthesizer (PSS) controller. The PSS controller is, in turn, controlled by the on-board microprocessor via a command interface specifically designed for this application. The PSS controller's main function is the orderly transfer of encoded speech from the speech vocabulary read-only memory (ROM) to the SSDs. The SSDs decode it and produce 64 kb/s 5-255 PCM (Pulse Code Modulation) speech. The encoded speech is stored in up to 512K bytes of on-board read-only memory (ROM). In addition, each Speech Synthesis Port has an associated dual-tone multifrequency (DTMF) receiver to receive touch-tone digits from a station set connected to the port via a voice time slot. The station set may be connected to the Speech Synthesis Port through either a line or trunk circuit.

When there is an incoming call to a port, the "listen" network time slot is connected to the DTMF receiver input and the "talk" network time slot is connected to the SSD output. This enables the Speech Synthesis Port to support speech synthesis features or touch-tone input with voice response features. Some of the features that use the Speech Synthesis Port's capabilities include Leave Word Calling, Automatic Circuit Assurance, Automatic Wakeup (hotel-motel), and do Not Disturb (hotel-motel).

The Speech Synthesis circuit pack should not be confused with the Announcement circuit pack as different voice features are supported by each circuit pack.

Hardware Error Log Entries and Test to Clear Values

| Speech Synthesis Port Error Log Entries |          |                                                    |             |              |                         |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. An in-line failure of the on-board microprocessor/PSS handshake has occurred. Refer to Test #168 for repair procedures.
- b. This error type indicates that the circuit pack been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- c. A transient error that does not cause an alarm can occasionally occur during a SPE, TDM BUS, or Tone Clock interchange. Test the port and follow the instructions for conference Test (#7).
- d. This error is not service-affecting and no action is required.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                             | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------|---------------------|--------------------|-------------------|
| Speech Synthesis PSS Handshake Test (#168)         | X                   | X                  | ND                |
| NPE Crosstalk Test (#6)                            |                     | X                  | ND                |
| Conference Circuit Test (#7)                       |                     | X                  | ND                |
| Speech Synthesis DTMF Receiver Test (#163)         |                     | X                  | ND                |
| Speech Synthesis Memory Test (#166)                | X                   | X                  | ND                |

| Speech Synthesis SSD Inquiry Test (#167)           | X                   | X                  | ND                |
| Speech Synthesis DTMF Receiver Inquiry Test (#164) | X                   | X                  | ND                |
| Speech Synthesis Parameter Update Test (#169)      | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may occur. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                          |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Any        | FAIL        | The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections.<br><br>1. Replace the circuit pack.                  |
|            | PASS        | The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining the Error Log. |

**Conference Circuit Test (#7)**

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

|            | PASS        | The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and examining the Error Log. |

Speech Synthesis DTMF Receiver Test (#163)

A series of DTMF tones are conferenced from the TDM Bus into the port's DTMF receiver and checked to see if the correct tones have been detected during the correct intervals. If all the DTMF tones were detected correctly, the test passes. If any of the tones were not detected correctly, the test fails.

Speech Synthesis DTMF Receiver Inquiry Test  
(#164)

This test determines the sanity of the port's DTMF receiver. The on-board microprocessor tests the port's DTMF receiver and determines if it is in a sane (test passes) or insane (test fails) condition.

Table 10-377. TEST #164 Speech Synthesis DTMF Receiver Inquiry Test

Speech Synthesis DSP Tone Test (#165)

The digital signal processor (DSP) associated with each port can generate a 440-Hz tone whose presence can be detected by TN748 General Purpose Tone Detector circuit packs. A 440-Hz tone is generated for 500 msec on a specified time slot which is being listened to by the detector circuit. If the detector determines the tone is present on the time slot, the test passes; otherwise, it fails.

Table 10-378. TEST #165 Speech Synthesis DSP Tone Test

If the test fails again, verify all Tone Detector circuit packs in the system are functioning correctly by checking the Error Log and using the <b>test board PCSS long</b> command. Replace any faulty Tone Detector circuit packs and repeat the test.<br><br>2. If the test fails again, replace the Speech Synthesis circuit pack. |
|            | PASS        | The 440-Hz tone has been detected correctly. User-reported troubles should be investigated using other tests and verifying other ports on this circuit pack are working correctly.                                                                                                                                                                                                                               |

Speech Synthesis Memory Test (#166)

The encoded speech for the Speech Synthesis circuit pack is stored in on-board read-only memory. A checksum is computed for each 32K speech memory block and compared against a known checksum value. If all computed checksum values are successfully compared against the stored checksum values, the test passes. If, while testing the speech complex memory, the on-board microprocessor finds a memory error, the test is terminated and a failure is reported. This type of failure may affect other ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

**Speech Synthesis SSD Inquiry Test (#167)**

This test determines the sanity of the specified port's Speech Synthesis Device (SSD). The on-board microprocessor tests the port's SSD and determines if it is in a sane (test passes) or insane (test fails) condition. Other ports on the Speech Synthesis circuit pack continue to function correctly during this type of failure.

**Speech Synthesis PSS Handshake Test (#168)**

This test verifies control functionality between the on-board microprocessor and PSS controller. A failure occurs if either of the following events occur:

- The on-board microprocessor times out while waiting for the PSS controller to respond.
- An invalid command is received by the on-board microprocessor from the PSS controller.

This type of failure affects all four ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

Table 10-381. TEST #168 Speech Synthesis PSS Handshake Test

|            | PASS        | The DTMF interdigit time-out parameter has been updated.<br><br>1. User-reported troubles should be investigated using other tests and by verifying that other ports on this circuit pack are working correctly.                                                                                                                                                                               |

## SEC-CDR (SEC-CDR Link Maintenance)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run            | Full Name of MO |
|------------------------|-------------|-----------------------------------|-----------------|
| PRI-CDR/SEC-CDR        | MINOR       | test cdr-link primary/secondary I | CDR Link        |
| PRI-CDR/SEC-CDR        | WARNING     | test cdr-link primary/secondary   | CDR Link        |

The SEC-CDR (SEC-CDR Link) maintenance strategy is covered in the PRI-CDR/SEC-CDR (PRI-CDR Link) Maintenance documentation.

# SHDW-CIR (Common Shadow Circuit)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO       |
|------------------------|-------------|------------------------|-----------------------|
| SHDW-CIR <sup>1</sup>  | MAJOR       | test duplication 1C sh | Common Shadow Circuit |

- Determine the carrier to test via the Port field from the Alarm or Error Log.

The Common Shadow Circuit is that portion of the Duplication Interface circuit pack that is responsible for memory shadowing in a High or Critical Reliability system. All memory writes on the active SPE are detected by the Common Shadow Circuit on the active Duplication Interface circuit pack via the Memory Bus (M-BUS—bus used by control complex circuit packs to write/read memory and to communicate with one another). The write information is then passed to the Common Shadow Circuit on the Standby Duplication Interface circuit pack via the ICC which then executes the write into the Standby Memory circuit pack via the Standby M-BUS. In this way, the Standby SPE is kept up-to-date with the Active SPE and, as a result, is always ready to take over for the Active SPE.

Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation for a detailed description of SPE-to-SPE connectivity and STBY-SPE (Standby SPE) Maintenance documentation for a description of how the Standby SPE is maintained.

Error Log Entries and Test to Clear Values

Table 10-383. Common Shadow Circuit Error Log Entries

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation for description of this test.
- b. Refer to SPE-SELEC (SPE Select Switch) Maintenance documentation for description of this test.

Common Shadow Circuit Loop Back Test (#283)

This test allows maintenance to loop data through the common shadow circuit and examine the results. The test is designed to test the shadow data and shadow address portions of the common shadow circuit. The test is done entirely on the Duplication Interface circuit pack.

The Common Shadow Circuit is put into Maintenance Mode before the test is run. Maintenance software writes data into an address in the maintenance address space. This data is routed through the common shadow circuit and put into the FIFO bank of the common shadow circuit. Maintenance reads the contents of the FIFO bank and compares them with the value written to the maintenance address space. The test is repeated with another address in the maintenance address space.

This test does not disable the common shadow circuit and can be run with no disruption in service. The test must be executed from control carrier B to test the

Duplication Interface B Common Shadow Circuit and from control carrier A to test the Duplication Interface A Common Shadow Circuit.

Common Shadow Circuit Address Decoder Test  
(#284)

This test verifies the operation of the shadow address decoder portion of the common shadow circuit. Software writes data into memory locations that should not be shadowed. The maintenance register of the common shadow circuit is examined to determine if the shadow address decoder permitted the write to be shadowed. The test fails if the writes were shadowed. This test is run only when

demanded by maintenance software and can be run on both Duplication Interface circuit pack A and Duplication Interface circuit pack B. The same addresses used in the Common Shadow Circuit Circuit Loop Back Test (#283) are used.

Common Shadow Circuit M-BUS Time-Out  
Query Test (#285)

An M-BUS time-out occurs when the Common Shadow Circuit on the Standby SPE attempts a memory write to the Memory circuit pack via the M-BUS and the write fails. The Common Shadow Circuit M-BUS Time-Out Query first tries to refresh the Standby SPE memory and then queries the Common Shadow Circuit on the Standby Duplication Interface circuit pack for the number of M-BUS time-outs. If there were any M-BUS time-outs, the test fails.

# SHDW-LNK (Memory Shadowing Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO       |
|------------------------|-------------|------------------------|-----------------------|
| SHDW-LNK               | MAJOR       | test shadow-link       | Memory Shadowing Link |

A High or Critical Reliability system contains two SPEs. One is known as the Active SPE and is the SPE that is currently responsible for all call processing, administration, and maintenance activities being performed by the system. The other SPE is known as the Standby SPE. The role of the Standby SPE is to be ready to take over as the Active SPE in the event that the current Active SPE fails.

The Standby SPE is usually in a mode known as Standby Mode in which it is ready to assume the role of the Active SPE. To do this, Standby SPE Memory (MEM-BD) must be an up-to-date reflection of Active SPE Memory. This is accomplished via the memory shadowing mechanism described below.

The SHDW-CIR (Common Shadow Circuit) on the Active SPE Duplication Interface circuit pack (DUPINT, TN772) detects all memory writes that the Active SPE Processor (PROCR) makes to Active SPE Memory. The Active SPE Common Shadow Circuit sends this information to the Common Shadow Circuit on the Standby SPE Duplication Interface circuit pack via the Inter-Carrier Cable (ICC). The Common Shadow Circuit on the Standby SPE Duplication Interface circuit pack then writes the data to Standby SPE Memory. This logical connection between Active SPE Memory and Standby SPE Memory is known as the SHDW-LNK (Memory Shadowing Link).

Although most of the components comprising the Memory Shadowing Link (that is, Active SPE Memory, both sets of Common Shadow Circuit, and Standby SPE Memory) may be tested individually, it is useful to test the integrity of the entire logical connection to verify that the shadowing mechanism is functional and that Standby SPE Memory is the same as Active SPE Memory. Therefore, this testing is done under the guise of the Memory Shadowing Link.

The logical connection between the Memory circuit packs of the two SPEs of a High or Critical Reliability system is shown in [Figure 10-83](#). This connection includes the A carrier memory bus, the A carrier TN772 Duplication Interface circuit pack, the shadow extension in the ICC, the B carrier TN772 Duplication Interface circuit pack, and the B carrier memory bus. The dotted lines in [Figure 10-83](#) represent important logical connections between components. The following abbreviations are used in [Figure 10-83](#):

- DUPINT for Duplication Interface Circuit Pack
- PR MAINT for Maintenance/Tape Processor
- PROCR for 80386 Processor Circuit Pack

- NETCON for Network Control Circuit Pack
- PACKET BUS for Packet Control Pack
- TN CLK for Tone-Clock Circuit Pack
- TDM-BUS for Time Division Multiplexing Bus
- M-BUS for Memory Bus
- ICC for Inter-Carrier Cable

Please refer to the DUPINT, SHDW-CIR, MEM-BD, PROCR, PR-MAINT, and STBY-SPE Maintenance documentation for more detailed descriptions of these components.

Error Log Entries and Test to Clear Values

Table 10-387. Standby SPE Error Log Entries

| Error Type     | Aux Data | Associated Test         | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-------------------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any                     | Any         | Any          | test shadow-link    |
| 2047           |          | Shadow Link Test (#318) | MAJOR       | OFF          | test shadow-link    |
| 2048           |          | Shadow Link Test (#318) | MAJOR       | OFF          | test shadow-link    |
| 2049           |          | Shadow Link Test (#318) | MAJOR       | OFF          | test shadow-link    |
| 2050           |          | Shadow Link Test (#318) | MAJOR       | OFF          | test shadow-link    |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below . By clearing error codes associated with the *Shadow Link Test*, for example, you may also clear errors generated from other tests in the testing sequence.

The Short and Long Test Sequences for Memory Shadowing Link are identical. Only one test (Test #318) tests the Memory Shadowing Link.

| Order of Investigation  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------|---------------------|--------------------|-------------------|
| Shadow Link Test (#318) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Shadow Link Test (#318)

Interactions

One interaction with the Standby SPE that results when testing the Memory Shadowing Link is as follows:

If the Standby SPE is in Maintenance Mode because a previous test command on a Standby SPE component was issued within the last three minutes, the Active SPE takes the Standby SPE out of Maintenance Mode and puts it in Standby Mode when the Shadow Link Test is run. Therefore, issuing another test

command on a Standby SPE component requires that the Standby SPE be put into Maintenance Mode again before the test is run. Thus, the user notices a 1- to 20-minute delay when running another Standby SPE test after executing the Shadow Link Test.

**⇒ NOTE:**

In most cases, the delay lasts only one to two minutes. However, a 20-minute delay is possible.

Another interaction that the Memory Shadowing Link has with the Standby SPE is that if the Shadow Link Test fails, an error of type 67 is logged, and an alarm is raised against the STBY-SPE (Standby SPE). This is because the failure of the Shadow Link Test implies that Standby SPE Memory may not be an up-to-date reflection of Active SPE Memory and, therefore, that the Standby SPE may not be ready to take over as the Active SPE. Refer to "Hardware Error Log Entries and Test to Clear Values" section of STBY-SPE (Standby SPE) Maintenance documentation for more details.

**Test Description**

Because of the number and nature of steps that it performs, the Shadow Link Test takes from 1 to 5 minutes to run, depending on the load that the system is experiencing at the time. The Shadow Link Test performs the following activities to verify the integrity of the Memory Shadowing Link:

For a 286 based system:

- Disables shadowing from Active SPE Memory (MEM-BD) to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor (PR-MAINT) to release the Standby SPE processor (PROCR) for the Standby SPE Processor to clear Standby SPE Memory (zero all memory locations).
- Waits for Standby SPE Processor to report that Standby SPE Memory was successfully cleared.
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).
- Disables shadowing from Active SPE Memory to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor to release the Standby SPE Processor for the Standby SPE Processor to perform a RAM checksum test on Standby SPE Memory (just updated by the refresh operation).
- Waits for Standby SPE Processor to report the results of the RAM checksum test.

- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE Processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).

For a flash-based system:

- Disables shadowing from Active SPE Memory (MEM-BD) to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor (PR-MAINT) to release the Standby SPE processor (PROCR) for the Standby SPE Processor to clear a magic area in Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).
- Disables shadowing from Active SPE Memory to Standby SPE Memory.
- Requests the Standby SPE Maintenance/Tape Processor to release the Standby SPE Processor for the Standby SPE Processor to perform a verification on the magic area in Standby SPE Memory (just updated by the refresh operation).
- Requests the Standby SPE Maintenance/Tape Processor to hold the Standby SPE Processor reset.
- Enables shadowing from Active SPE Memory to Standby SPE Memory and causes all of Active SPE Memory to be written to Standby SPE Memory (a refresh operation).

#### NOTE:

The shadowing verification method used for 80386 systems does not do a complete RAM checksum. It only clears a special magic area in the Standby SPE's memory and then updates that area by shadowing. It then verifies the value in that magic area based on the Active SPE's value. Thus, the test is not as comprehensive in terms of testing the memory aspect of shadowing as is the 80286 method. The reason for this is the inability to shadow flash memory.

### Management Terminal Message Line Errors

In addition to Shadow Link Test (#318) Error Codes, the following Manager I (G1) or G3MT message line errors may be displayed when attempting to run this test. They are:

- "Standby SPE not available; for information use status system"

This message line error corresponds to Error Code 2020. It is displayed if the Shadow Link Test is attempted within the first five minutes of a restart of the Active SPE (that is, prior to the Active SPE holding the Standby SPE reset and refreshing it).

- "Standby SPE busy with another task; for information use status system"

This message line error corresponds to Error Code 2018. It is displayed if the Shadow Link Test is attempted while the Active SPE is performing some Maintenance Mode activity on the Standby SPE other than system technician-demanded maintenance.

- "Cannot interrupt Standby SPE while entering maintenance mode; please try later"

This message line error is displayed when **test shadow-link** has been issued and subsequently canceled and then **refresh spe-standby** is issued while maintenance software is in the process of performing the Shadow Link Test. Allow up to three minutes for the Shadow Link Test to complete before issuing the **refresh spe-standby** command again.

In either case, the following actions should be taken:

1. Issue the **refresh spe-standby** command to put the Standby SPE in Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more.
2. Repeat the command.
3. Issue the **test spe-standby long** command.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2049       | FAIL        | <p>The Standby SPE Maintenance/Tape Processor released the Standby SPE processor with a request to perform the RAM Checksum Test on Standby SPE Memory. The RAM checksum was correct; however, a significant discrepancy was detected between two special Standby SPE Memory locations that should contain the same time stamp value as the one shadowed over from the Active SPE. This indicates that a problem exists with one or more components that make up the Memory Shadowing Link such that Active SPE Memory was not accurately shadowed to Standby SPE Memory.</p> <ol style="list-style-type: none"><li>1. Check for both Active SPE and Standby SPE Common Shadow Circuit errors and alarms. Refer to SHDW-CIR (Common Shadow Circuit) Maintenance documentation and follow the prescribed procedures.</li><li>2. Check for Standby SPE Memory errors and alarms. Refer to MEM-BD (Memory) Maintenance documentation and follow the prescribed procedures.</li><li>3. Check the Inter-Carrier Cable to see if it is loose or disconnected. Also if intermittent problems are occurring inspect the Inter-Carrier Cable for cuts or broken leads. If so, follow the repair procedures for reconnecting the Inter-Carrier Cable described in Chapter 6.</li><li>4. If all problems found in Steps 1, 2, or 3 have now been repaired, proceed with Step 9. If no problems were found in Steps 1, 2, or 3, proceed with Step 5.</li><li>5. Issue the <b>display errors</b> command and check to see if an Error Type 80 is logged against STBY-SPE. If so, the problem is the carrier A Duplication Interface circuit pack. Replace the carrier A Duplication Interface circuit pack as described in Chapter 6 and proceed with Steps 9, 10, and 11.</li><li>6. Issue the <b>display errors</b> command and check to see if an Error Type 82 is logged against STBY-SPE. If so, the problem is the carrier B Duplication Interface circuit pack. Replace the carrier B Duplication Interface circuit pack as described in Chapter 6 and proceed with Steps 9, 10, and 11.</li><li>7. Issue the <b>display errors</b> command and check to see if an Error Type 85 is logged against STBY-SPE. If so, the problem may be the Standby SPE Memory circuit pack. Replace the Memory circuit pack as described in Chapter 6 and proceed with Steps 9, 10, and 11.</li></ol> |

Table 10-388. TEST #318 Shadow Link Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | When the Shadow Link Test passes, the integrity of the Memory Shadowing Link has been verified and as long as memory shadowing is enabled, Standby SPE Memory is an up-to-date reflection of Active SPE Memory. This test also provides a positive indication of the functionality of Active SPE Memory, both sets of Common Shadow Circuit, and Standby SPE Memory. |

## SPE-SELEC (SPE Select Switch)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO   |
|------------------------|-------------|-------------------------------------|-------------------|
| SPE-SELEC              | MAJOR       | test duplication-interface 1C sh    | SPE Select Switch |
| SPE-SELEC              | WARNING     | test duplication-interface 1C sh    | SPE Select Switch |

- Where C is the carrier determined by the Port field in the error or alarm log.

The SPE Select Switch MO tracks the state of the SPE Select Switches in a High or Critical Reliability system. The switches are located on the Duplication Interface circuit pack and can be used to hard-select the active processor in a High or Critical Reliability system. Each switch has three positions: SPE-A (the left position), AUTO (the middle position), and SPE-B (the right position). To hard-select SPE-A, both switches must be in the SPE-A position. To hard-select SPE-B, both switches must be in the SPE-B position. Any other combination of SPE Select Switches leaves control of the active SPE to the software. Whenever a switch is out of the AUTO position, a Warning alarm is raised. If both switches are out of the AUTO position for six hours, a Major alarm is raised. Duplication Interface circuit pack B reports the state of the SPE-SELEC Switch B to Duplication Interface circuit pack A which, in turn, reports the state of SPE-SELEC Switch A directly to the system software.

**NOTE:**  
Each switch is a separate MO. If both switches are out of the AUTO position, then both switches are alarmed.

It is also possible to get an "init cause" of the SPE-SELEC Switch if SPE B is active and power to carrier B is lost. In this case, an SPE switch to SPE A occurs, and the "init cause" shows either "SPE-Select Switch" or "SPE-Down."

Error Log Entries and Test to Clear Values

Table 10-389. SPE Select Switch Error Log Entries

| Error Type     | Aux Data | Associated Test              | Alarm Level                 | On/Off Board | Test to Clear Value                  |
|----------------|----------|------------------------------|-----------------------------|--------------|--------------------------------------|
| 0 <sup>1</sup> | 0        | Any                          | Any                         | Any          | test duplication-interface 1C sh r 1 |
| 1              | Any      | SPE Select Query Test (#278) | WARNING/ MAJOR <sup>2</sup> | OFF          | test duplication-interface 1C sh r   |
| 257            | any      | SPE Select Query Test (#278) | WARNING/ MAJOR <sup>2</sup> | OFF          | test duplication-interface 1C sh r 2 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This error type initially raises a Warning alarm. If this error type persists and alarms are not downgraded on this MO due to the values of **set options**, then, after a period of time, a Major alarm is raised.

- Notes:
- a. The Warning alarm is upgraded to Major if the error is not resolved in six hours.
- b. Determine the carrier (a or b) by the Port field in the Error or Alarm Log. For SPE-SELEC, the Port field is 1A (**test duplication interface a**) or 1B (**test duplication interface b**).

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Duplication Interface Circuit Pack Status Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------------------|---------------------|--------------------|-------------------|
| Duplication Interface Circuit Pack Status Query Test (#315) (a)   | X                   | X                  | ND                |
| Duplication Interface Circuit Pack Sanity Circuit Test (#273) (a) |                     | X                  | D                 |

| Order of Investigation                                                   | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| Duplication Interface Circuit Pack Sanity Maze Test (#277) (a)           | X                   | X                  | ND                |
| Duplication Interface Circuit Pack SPE A Loop Back Test (#275) (a)       | X                   | X                  | ND                |
| Duplication Interface Circuit Pack SPE B Loop Back Test (#276) (a)       | X                   | X                  | ND                |
| Duplication Interface Circuit Pack Manager I Loop Back Test (#274) (a)   | X                   | X                  | ND                |
| Inter-Duplication Interface Circuit Pack Loop Back Test (#280)           | X                   | X                  | ND                |
| Duplication Interface Circuit Pack Background Test Query Test (#271) (a) | X                   | X                  | ND                |
| Duplication Interface Circuit Pack Invalid Message Query Test (#272) (a) | X                   | X                  | ND                |
| Common Shadow Circuit M-BUS Time-out Query Test (#285) (b)               |                     | X                  | ND                |
| Common Shadow Circuit Loop Back Test (#283) (b)                          | X                   | X                  | ND                |
| Common Shadow Circuit Address Decoder Test (#284) (b)                    | X                   | X                  | ND                |
| SPE Select Switch Query Test (#278)                                      | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to the DUPINT (Duplication Interface Circuit Pack) Maintenance documentation for description of this test.
- b. Refer to the SHDW-CIR (Common Shadow Circuit) Maintenance documentation for description of this test.

SPE Select Query Test (#278)

This test queries the Duplication Interface circuit pack for the state of SPE Select Switch. The test passes if the switch is in the AUTO position. The test fails if the switch is not in the AUTO position or if the Duplication Interface circuit pack is not present.

Table 10-390. TEST #278 SPE Select Query Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

|            | PASS        | The Duplication Interface circuit pack has reported that the SPE Select Switch is in the AUTO position.<br><br>1. If a visual inspection shows the SPE Select Switch is not in the AUTO position, then resolve all alarms logged against Duplication Interface circuit pack (DUPINT).<br>2. Repeat the test.<br><br>3. If Duplication Interface circuit pack B is being tested and a visual inspection shows that the switch is not in the normal position, Duplication Interface circuit pack A may be incorrectly reporting the state of SPE-Select Switch B. Replace Duplication Interface circuit pack A, and rerun the test. |

## STBY-SPE (Standby SPE)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| STBY-SPE               | WARNING     | status system 1        | Standby SPE     |
| STBY-SPE               | MAJOR       | test spe-standby       | Standby SPE     |

A high or critical reliability system contains two switch processing elements (SPEs). The first such element is known as the Active SPE. The Active SPE is currently responsible for all call processing, administration, and maintenance activities that are being performed by the system. The other SPE is known as the Standby SPE. The Standby SPE becomes the Active SPE whenever the current Active SPE fails. The Standby SPE does not perform call processing or administration activities. However, it does perform maintenance activities, but these activities are carried out completely under the direction of the Active SPE in order to monitor and maintain the health of the Standby SPE.

**⇒ NOTE:**  
Verify that the Standby SPE is functional (no duplication alarms exist and the SPE has returned to the Standby Mode) by running the **status system 1** command. If the standby SPE is in the maint/idle mode with no standby alarms, use the **standby refresh** command to put the standby SPE into the standby mode. Verify the results by using the **status system 1** command.

The Standby SPE is always in one of three modes: Standby, Maintenance, or Down. Usually, the Standby SPE is in Standby Mode. In this mode,

1. The Switch Control (SW-CTL) on the Standby SPE Network Control circuit pack is isolated from the TDM Bus so that it does not interfere with attempts by the Switch Control on the Active SPE Network Control circuit pack to control the TDM Bus
2. The Standby SPE (PKT-CTRL) Packet Control circuit pack is isolated from the Packet Bus to prevent interference with the activity on the Active SPE Packet Control circuit pack
3. The Standby SPE (PROCR) Processor is held in a reset state so that it does not run software
4. The 12 volt power supply on the Standby SPE Network Control circuit pack (TN777B) can not be turned on when the Standby SPE Processor is held in the reset state
5. Standby SPE Memory (MEMORY in a 386) is shadowed from Active SPE Memory. This means that Standby SPE Memory is updated to reflect every change in Active SPE Memory (for example, calls and administration changes).

In certain circumstances, the Standby SPE is put into Maintenance Mode by the Active SPE. In this mode, the SW-CTL and PKT-CTRL on the Standby SPE are still isolated from the TDM Bus and Packet Bus, memory shadowing is disabled, and its processor is no longer held in a reset state. Data Channels on the standby SPE Network Control circuit pack can access the TDM bus, and the maintenance testing can be executed in this maintenance mode. The 12 volt power supply on the standby SPE Network Control circuit pack can also be turned on for Memory Card maintenance testing. In Maintenance Mode, the Standby SPE accepts maintenance activity requests from the Active SPE to perform testing on Standby SPE components. For many of the requested activities, maintenance software on the Standby SPE is restarted in order to conduct the activity. Translation saves and announcement saves may be performed on the Standby SPE when it is in Maintenance Mode. While in Maintenance Mode, the Standby SPE is not as readily available to assume the role of the Active SPE, but it may do so depending upon the severity of the Active SPE fault(s).

Whenever the Standby SPE is returned to Standby Mode from Maintenance Mode, its DRAM Memory is refreshed. This means that the Active SPE DRAM Memory is shadowed over to Standby SPE DRAM Memory. The flash ROM memory in the Standby SPE is not refreshed, and the shadowing circuit cannot write data into the flash ROM memory. The refresh is necessary because, while in Maintenance Mode, memory shadowing to the Standby SPE is disabled and Standby SPE Memory is not updated to reflect changes in Active SPE Memory. After the refresh, Standby SPE Memory once again is an up-to-date reflection of Active SPE Memory.

The Standby SPE goes into Down Mode whenever certain error conditions are detected. These error conditions are described in detail in the "Hardware Error Log Entries and Test to Clear Values" section. Once the error condition(s) that cause(s) the Standby SPE to go into Down Mode are corrected, the Standby SPE is first put into Maintenance Mode to conduct testing on Standby SPE components. It is then returned to Standby Mode.

The current mode of the Standby SPE can be determined by issuing the **status system** command.

## **Components in Standby SPE Complex**

---

The Standby SPE maintenance object is actually a composite of all the circuit packs in the Standby SPE.

The TN778 Packet Control circuit pack, the TN765 Processor Interface circuit pack(s), and the TN772 Duplication Interface circuit pack are used.

### **WARNING:**

*Verify that there is an identical set of SPE complex circuit packs in each SPE. For example, there should be the same number of Memory circuit pack(s) in each SPE. If there are Processor Interface circuit pack(s) (one or*

*two) in the Active SPE, the same number of PI circuit packs must be present in the Standby SPE. If one SPE has a Packet Control Circuit Pack, the other SPE must also have one. If the set of circuit packs in each SPE is not identical, alarms could result against the STBY-SPE, DUPINT, SHDW-CIR, PI-BD, PKT-CTRL, PROCR, MEM-BD and MEMORY maintenance objects.*

The accessing and testing of the Standby SPE may be affected by the health of the circuit packs through which the Active SPE communicates with the Standby SPE. These circuit packs include the Active SPE Processor circuit pack, the Duplication Interface circuit pack in the A carrier, and the Standby SPE Processor circuit pack. Additionally, the Inter-Carrier Cable (ICC) and the backplane affect the ability of the Active SPE to communicate with the Standby SPE. The ability to shadow Active SPE memory into Standby SPE memory is affected by the Duplication Interface circuit pack in the A carrier, the Duplication Interface circuit pack in the B carrier, and the Memory circuit pack(s) in the Standby SPE. Additionally, the Active SPE Memory Bus, the ICC, backplane, and the Standby SPE Memory Bus affect the ability to correctly shadow Active SPE memory into Standby SPE memory.

These dependencies can be seen in [Figure 10-84](#) for the TN790. These figures depict the interconnection between the two SPEs of a high or critical reliability system. The following abbreviations are used in the figures:

- DUPINT for Duplication Interface circuit pack
- PROCR/MEM for TN786B or TN790 Processor Circuit Packs with Memory
- PROCR for Processor Circuit Pack
- MEMORY for Memory Circuit Pack(s)
- MTP for Maintenance Processor in Processor Circuit Pack
- NETCON for Network Control Circuit Pack
- MEM CARD for Memory Card Plugged in the Network Control Circuit Pack
- PI for Processor Interface Circuit Pack(s)
- PKT CTRL for Packet Control Circuit Pack
- TN CLK for Tone-Clock Circuit Pack
- TDM BUS for Time Division Multiplex Bus
- PACKET BUS for Packet Bus
- M-BUS for Memory Bus
- ICC for Inter-Carrier Cable
- SCC for Single-Carrier Cabinet

The dashed lines in the figure represent important logical connections between components.

Refer to the DUPINT, SHDW-CIR, MEM-BD, MEMORY, PROCR, PR-MAINT, TDM-BUS, PKT-BUS, TDM-CLK, PI-BD, PI-SCI, PKT-CTRL, SW-CTL, DATA-CHL, 12V-PWR, CARD-MEM and STBY-SPE for descriptions of the individual components.

Table 10-391. Standby SPE Error Log Entries — Continued

| Error Type | Aux Data | Associated Test                                      | Alarm Level | On/Off Board | Test to Clear Value |
|------------|----------|------------------------------------------------------|-------------|--------------|---------------------|
| 812 (y)    | any      | SPE interchanged forced with health-override option: | WARNIN G    | OFF          | See note (y).       |
| 822(z)     | any      | A non-hot interchange to the standby SPE occurred.   |             |              | See note (z).       |
| 826 (aa)   | any      | Standby software mismatch                            | MAJOR       | ON           | upgrade software    |

1. Run the short test sequence first. If all the tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

**NOTE:**

When more than one of the above error types exists at the same time, the alarm against the Standby SPE is cleared only when (1) any problems described by the Aux Data values for Error Types 1 and 257 are resolved **and** (2) all problems described in (b) through (o) are resolved.

**Notes:**

- a. Aux Data value 0 is equivalent to Aux Data value 2017. All Aux Data values listed for Error Type 1 are described in "System Technician-Demanded Tests: Test Result Error Codes". These values are shared between Standby SPE maintenance activity results and the test results for the System Technician commands on Standby SPE components because the values represent the common set of problems that can be encountered when attempting to conduct any form of maintenance activity on the Standby SPE.
- b. Error Type 58 is logged when the Duplication Interface circuit pack in the A carrier reports that the Standby SPE has gone into Down Mode. This implies an inability to communicate with the Standby SPE.

The ability to communicate with the Standby SPE should be checked by issuing the **test processor a | b short** command, where "a | b" indicates the carrier that contains the Standby SPE. If all of the tests execute such that no test returns an Aux Data value of 2014, 2015, 2016, 2017, 2022, 2024, or 2025, the Standby SPE was successfully put into Maintenance Mode. This indicates that the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the

functionality of the communication path, look for the presence of Error Types 80, 81, and 106 and use the recommended commands to clear these errors.

- c. Error Type 67 is logged when the Shadow Link Test (#318) fails. This implies that the shadowing mechanism is not functioning.

The functionality of the Memory Shadowing Link should be checked by issuing the **test shadow-link** command. If the test passes, the memory shadowing mechanism may be functional. However, to restore the memory shadowing, look for the presence of Error Types 82, 85, and 106 and use the recommended commands to clear these errors.

- d. Error Type 80 is logged when the Active SPE Maintenance/Tape Processor reports that the handshake that is maintained between the processor and the Duplication Interface circuit pack in the A carrier has been lost. This implies an inability to communicate with the Standby SPE.

The status of the handshakes should be checked by issuing the **test duplication-interface a** and the **test duplication-interface b** commands. These commands initiate background tests that verify whether the handshake between Dupint-A and Active-MTP is operational.

If the handshake between Dupint-A and Active-MTP is operational, the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the communication path, look for the presence of Error Types 58, 81, 82, 98, 99, and 106 and use the recommended commands to clear these errors.

- e. Error Type 81 is logged when the Duplication Interface circuit pack in the A carrier reports that the handshake that is maintained between the circuit pack and the Maintenance/Tape Processor on the Standby SPE has been lost. This implies an inability to communicate with the Standby SPE.

The status of the handshakes should be checked by issuing the **test duplication-interface a** and the **test duplication-interface b** commands. These commands initiate background tests that verify whether the handshake between Dupint-A and Standby-MTP is operational.

If the handshake between Dupint-A and Standby-MTP is operational, the communication path between the Active SPE and the Standby SPE may be functional. However, to restore the communication path, look for the presence of Error Types 58, 80, 82, 98, 99, and 106 and use the recommended commands to clear these errors.

- f. Error Type 82 is logged when the Duplication Interface circuit pack in the A carrier reports that the handshake that is maintained between the circuit pack and the Duplication Interface circuit pack in carrier B has been lost. This implies that the shadowing mechanism is not functioning.

The status of the handshakes should be checked by issuing the **test duplication-interface a** and the **test duplication-interface b** commands. These commands initiate background tests that verify whether the handshake between Dupint-A and Dupint-B is operational. If the handshake between Dupint-A and Dupint-B is operational, the memory

shadowing mechanism may be functional. However, to restore the memory shadowing, look for the presence of Error Types 67, 85, and 106 and use the recommended commands to clear these errors.

**⇒ NOTE:**

Because the handshake between Dupint-A and Dupint-B is tested in the background, the test results from executing the **test duplication-interface a** command do not indicate their current status. However, if the background testing determines that all three handshakes (that is, Dupint-A to Dupint-B, Dupint-A to Active-MTP, and Dupint-A to Standby-MTP) have become operational, and if there are no other current STBY-SPE errors, Error Types 80, 81, and 82 and the associated STBY-SPE alarm will be cleared in about 30 minutes.

- g. Error Type 85 is logged when the Duplication Interface circuit pack detects that writes made to the Standby SPE Memory are not being acknowledged. This implies that the shadowing mechanism is not functioning.

The presence of time-outs when shadowing to the Standby SPE Memory should be checked by issuing the **test duplication-interface a long** command. This command runs a test that forces memory writes to the Standby SPE Memory and detects time-outs waiting for acknowledgments. If time-outs are not detected, memory shadowing may be functional. However, to restore the functionality of memory shadowing, look for the presence of Error Types 67, 82, and 106 and use the recommended commands to clear these errors.

- h. Error Type 98 is logged when the Active SPEMTP Dual Port RAM Test (#104) fails. This implies an inability to communicate with the Active MTP.

The ability to communicate with the Active MTP should be checked by issuing the **test processor a | b short** command, where "a | b" indicates the carrier that contains the Active SPE.

- i. Error Type 99 is logged when the Active SPE detects that the handshake that is maintained between the Active SPE Processor and the Active SPE Maintenance/Tape Processor has been lost. This implies an inability to communicate with the Active MTP.

The ability to communicate with the Active MTP should be checked by issuing the **test processor a | b short** command, where "a | b" indicates the carrier that contains the Active SPE.

- j. Error Type 106 is logged when the Standby SPE Memory Functional Test (#332) fails. This implies an inability to communicate with the Standby SPE and also that the shadowing mechanism is not functioning.

The functionality of the Standby SPE Memory should be checked by issuing the **test memory a | b long** command, where "a | b" indicates the carrier that contains the Standby SPE. This command runs the Memory Functional Test. If the test passes, the communication path between the

Active SPE and the Standby SPE may be functional. However, to restore the functionality of the communication path, look for the presence of Error Types 58, 80, 81, 98, and 99 and use the recommended commands to resolve these errors.

Additionally, if the Memory Functional Test passes, the memory shadowing mechanism may be functional. However, to restore the functionality of memory shadowing, look for the presence of Error Types 67, 82, and 85 and use the recommended commands to resolve these errors.

- k. If Error Type 139 is present, this error type takes precedence over all other error types until it is resolved. This error type indicates an incompatibility between the two Processor circuit packs in a High or Critical Reliability system. For a High or Critical Reliability system to work, the two Processor circuit packs must function together so that the circuit packs can perform interchanges between themselves.

Use the following procedure to resolve this error:

1. Set the SPE-Select switches one at a time to select the Active SPE. This also forces the Tone-Clock in this SPE to become active.
2. If the active SPE is the B carrier, issue the **test duplication-interface a long** command.
3. Execute the **test spe-standby long** command.
4. Use the **display error** command with the "dup-spe" category to see if the Error Code 139 recurred. If the error did not recur, and if all STBY-SPE tests have passed, the system is functioning normally.
5. Restore the SPE-Select switches to normal.
6. If Error Code 139 still exists (and if the STBY-SPE tests have failed), one of the Processor circuit packs must be replaced. The system will function normally, but it will not be able to interchange properly to the Standby SPE without service disruption. Replacing the Standby processor is the best solution to this problem. However, the processor must be replaced with one of a vintage that is compatible with the current Active Processor.

However, if it is found that the Active processor must be replaced (for example, the Standby processor is of a newer vintage), the repair strategy is more complex. Use the following procedure to replace the Active Processor circuit pack:

 **NOTE:**

Replacing the Active Processor circuit pack will disrupt service. Schedule this procedure at the customer's convenience.

1. Set the SPE-Select switches one at a time to select the Standby SPE. An SPE-interchange with a reset level of 3 or 4 results.

2. Replace the new Standby (and former Active) SPE Processor circuit pack with a circuit pack of the appropriate vintage.
  3. Issue the **test spe-standby long** command. Use the **display error** command with the "dup-spe" category to verify that all tests pass and that Error Type 139 does not recur.
  4. Restore the SPE-Select switches to their normal position.
- l. Error Type 149 occurs when the Standby SPE goes into down mode during system technician demanded testing. Wait three minutes, then look for other STBY-SPE errors and follow the procedures described for these errors.
- m. Aux Data value 0 is equivalent to Aux Data value 2017. Aux Data values 2014, 2015, 2017, 2021, 2024, and 2051 for Error Type 257 are described in the "System Technician-Demanded Tests: Test Result Error Codes". The Aux Data values 2048, 2049, and 2050 for Error Type 257 are described in SHDW-LNK (Memory Shadowing Link) Maintenance documentation. These values are shared between Standby SPE maintenance activity results and the test results for System Technician commands on Standby SPE components because the values represent the common set of problems that can be encountered when attempting to conduct any form of maintenance activity on the Standby SPE.

Error Type 257 with an Aux Data value of 2051 and a Major alarm results when, in attempting to refresh the Standby SPE, it is determined that software cannot communicate with the Duplication Interface circuit pack in the A carrier. This implies that the shadowing mechanism is not functioning. This error type is accompanied by Error Type 80.

Error Type 257 with an Aux Data value of 2051 and no alarm results when, in attempting to refresh the Standby SPE, it is determined that software cannot communicate with the Duplication Interface circuit pack in the B carrier. This does not necessarily imply that the shadowing mechanism is not functioning, but it is possible that it is not functioning. This error type is accompanied by Error Type 82. However, Error Type 82 may not be logged until sometime later.

- n. After issuing the specified command(s) to clear this alarm, perform the following procedure to clear the STBY-SPE alarm:
1. If all the tests pass or abort, issue a **refresh spe-standby** command. If the refresh is successful, wait 1 minute and then check for alarms against STBY-SPE. If the refresh was not successful, or if there are still alarms against STBY-SPE, continue attempts to resolve other STBY-SPE error types. The **busyout spe-standby** and **release spe-standby** commands may also be used to clear out STBY-SPE alarms. After entering the **busyout spe-standby** command followed by the **release spe-standby** command, all STBY-SPE alarms are retired and, 1 minute later, the equivalent of scheduled maintenance is run on the standby SPE.

Note that the **busyout spe-standby** and **release spe-standby** commands do not affect alarms on other Maintenance Objects in the standby processor complex.

- 2. If some of the tests fail, refer to the appropriate MO section and follow the procedures described there.

The following table summarizes the error types that may affect the functionalities of the Communication Path to the Standby SPE and of Memory Shadowing. To restore the function, all error types that may affect the function must be investigated and resolved by following the recommended commands or procedures.

| Function Affected                 | Error Types                                                                                                    |
|-----------------------------------|----------------------------------------------------------------------------------------------------------------|
| Communication Path To Standby SPE | 58, 80, 81, 98, 99, 106, 1 with Aux Data values 2016, 2017, 2022, 2024, or 2025; 139 with Aux Data value 2015. |
| Memory Shadowing                  | 67, 82, 85, 106, 257 with Aux Data values 2014, 2015, 2021, 2024, 2048, 2049, 2050, or 2051.                   |

- o. Error Type 801 is logged when the **upgrade software** command failed due to the loss of communication with the Standby SPE during the upgrade. This implies that the software reprogramming of the Standby SPE never completed.

The **upgrade software** command should be re-executed. If it fails again, the Standby SPE Processor circuit pack should be replaced.

- p. Error Type 802 is logged when the **upgrade software** command failed due to the bad flash checksum on the Standby SPE after the completion of the upgrade. This implies that the on-board flash memory may not be functional. The Standby SPE is running the new software while the Active SPE is still running the old software. However, due to the bad flash checksum, the behavior of the Standby SPE may be unpredictable.

The **upgrade software** command should be re-executed. If the command fails again, the Standby SPE Processor circuit pack should be replaced.

- q. Error Type 803 is logged when the **upgrade software** command failed due to the failure to insert the translation card-mem into the Standby SPE in time during the reboot immediately following a successful upgrade. This implies that the Standby SPE is running the new software while the Active SPE is still running the old software.

The translation card-mem should be inserted into the Standby SPE at the appropriate time so as to allow the **upgrade software** command to be re-executed.

- r. Error Type 804 is logged when the **upgrade software** command failed due to a loss of communication with the Standby SPE during the reboot immediately following a successful software upgrade. This implies that the communication path between the Active SPE and the Standby SPE may not be functional.

Issue the **test duplication-interface a** and the **test duplication-interface b** commands. If the tests pass, re-execute the **upgrade software** command.

- s. Error Type 805 is logged when the **upgrade software** command failed due to the failure to insert the software card-mem in the Active SPE in time.

The software card-mem should be inserted into the Active SPE at the appropriate time so as to allow the **upgrade software** command to be re-executed.

- t. Error Type 806 is logged when the **upgrade software** command failed due to a bad flash checksum on the new Standby SPE after an upgrade of the old Standby SPE and SPE-Interchange. This implies that the on-board flash memory may not be functional. The behavior of the Standby SPE may unpredictable.

The **upgrade software** command should be re-executed. If the command fails again, the Standby SPE Processor circuit pack should be replaced.

- u. Error Type 807 is logged when the **upgrade software** command failed due to the failure to insert the translation card-mem into the new Standby SPE after an upgrade of the old standby SPE and SPE-Interchange.

The translation card-mem should be inserted into the Standby SPE.

- v. Error Type 808 is logged when the **upgrade software** command failed due to the loss of communication with the new Standby SPE during an upgrade following the upgrade of the old standby SPE and SPE-Interchange. This implies that the programming of the Standby SPE never completed.

Use the "Special Upgrade Procedure" to re-execute an upgrade on the Standby SPE only. If the upgrade fails again, the Standby SPE Processor circuit pack should be replaced.

- w. Error Type 809 is logged when the **upgrade software** command failed due to the failure to perform an SPE-Interchange immediately after the successful upgrade of the Standby SPE. This implies possible problems with the Dupint circuit packs.

Issue the **test duplication-interface a** and **test duplication-interface b** commands. If the tests pass, re-execute the **upgrade software** command.

- x. Error Type 810 is logged when the **upgrade software** command failed due to a bad checksum on the software card-mem during the upgrade of the new Standby SPE following the successful upgrade of the old Standby SPE and of SPE-Interchange.

The software card-mem should be replaced by one that has a good checksum. The **upgrade software** command should be re-executed.

- y. Whenever an SPE interchange is forced by using the **health-override** option as part of the **reset system interchange** command, a WARNING OFF circuit pack STBY-SPE alarm is raised, and the Fault Severity Level (FSL) of the new standby SPE is raised to its highest possible value to prevent an SPE interchange back to the original active SPE. This artificial FSL lasts one hour or until a **busyout spe-standby** command is executed, followed by a **release spe-standby** command. After this time, the FSL of the two SPEs are recomputed, and the healthiest SPE becomes or remains active.
- z. The system interchanged from the active SPE to the standby SPE with a restart that is more disruptive to service than the normal system hot start. The switches were not used to force this interchange. The level of restart can be observed by using the **display initcauses** command. Look for other alarms on the standby SPE that possibly caused this interchange. Also see "Reset System Interchange (High or Critical Reliability Systems Only)" in [Chapter 4, "Initialization and Recovery"](#).
- aa. The software vintage in the Standby SPE does not match the software vintage in the active SPE.

The **upgrade software** command should be executed for the standby SPE as described in [Chapter 5, "Routine Maintenance Procedures"](#).

---

## System Technician-Demanded Tests

---

The following commands can be used to test and manipulate part or all of the standby SPE:

- **busyout spe-standby**

The **busyout spe-standby** command is used to stop all standby maintenance activity, disable shadowing, and hold the standby processor reset. A warning off circuit pack alarm is also raised against STBY-SPE MO. This command is more powerful than the **refresh spe-standby** command because it preempts the standby and enters maintenance mode, where as the **refresh spe-standby** does not do this.

- **release spe-standby**

The **release spe-standby** command is used to remove the busyout condition, restore memory shadowing, and force a refresh. 1 minute after the command is executed, the equivalent of standby scheduled maintenance is run.

- **refresh spe-standby**

The **refresh spe-standby** command is used to put the Standby SPE immediately into Standby Mode. The command conducts the same activities regardless of whether the Standby SPE is already in Standby

Mode or whether it is in Maintenance Mode. Whenever this command is issued, any Standby SPE maintenance activity currently in progress (except for entering maintenance mode) is preempted, the Standby SPE Processor is held reset, and the Standby SPE's memory is refreshed. Recall that the refresh is necessary because, while the Standby SPE is in Maintenance Mode, memory shadowing is disabled. When the Standby SPE is returned to Standby Mode, its memory must be brought up-to-date with Active SPE memory.

Because they can preempt Standby SPE maintenance activities, the **refresh spe-standby** and **busyout spe-standby** commands should be used judiciously. If the Standby SPE is in Maintenance Mode when one of these commands is issued, the current maintenance activity being conducted by the Standby SPE is immediately terminated with the following potential side-effects:

- Testing of the Standby SPE components that are the target of the maintenance activity may not have completed. Depending on the maintenance activity and the point at which such activity is terminated, tests that detect faults and/or lack of faults on those Standby SPE components may not have had the opportunity to run. Accordingly, alarms will not be raised or retired on the components.
- If the maintenance activity is Scheduled Maintenance, and if the **refresh spe-standby** or **busyout spe-standby** command is issued before a scheduled translation save is performed, the translation save is not completed, and the translation data on both the Active SPE and Standby SPE and on the memory cards do not reflect the changes made since the last translation save.

In general, after a **refresh spe-standby** has been used, and after the user has finished working with the system, the **test spe-standby long** command should be issued in the event that the **refresh spe-standby** command preempted a Standby SPE maintenance activity. Testing the standby SPE allows standby maintenance to re-determine the health of the standby SPE and to compare this health to that of the active SPE. This testing could result in an SPE interchange to a healthier SPE.

If the **busyout spe-standby** command has been used, the **release spe-standby** command should also be used. The latter command fully tests the standby SPE 1 minute later.

Also, if the **refresh spe-standby** or **busyout spe-standby** command was used within the time frame that scheduled maintenance with a translation save was to have been conducted, the **save translation** command should be issued to ensure that the current translation data has been written to the Active SPE and Standby SPE tapes.

When using the **refresh spe-standby** to preempt Standby SPE maintenance activities, it may be necessary to issue the **refresh spe-standby** command multiple times in order to preempt all Standby SPE maintenance activity. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming

**10** Maintenance Object Repair Procedures  
STBY-SPE (Standby SPE)

Page 10-1270

labeled "standby" on the **status system** form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later". Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** command.

- **reset spe-standby <level>**

Normally, when the standby is brought into maintenance mode, it is done so with a Warm Restart. The **reset spe-standby** command can be used to bring the standby SPE from standby mode into maintenance mode with the requested restart level.

- **reset system-interchange <health-override>**

If the health-override option is NOT specified, and if the standby Fault Severity Level (FSL) is less than or equal to that of the active SPE, and if the standby SPE is in standby mode, the interchange is allowed. Actually, if the standby FSL is less than that of the active FSL, the system does its own interchange in due time. If the FSL of the standby SPE is higher than that of the active SPE, but the alarmed standby maintenance objects do not affect the ability of the standby SPE to be put into standby mode, the command is rejected. This indicates that the health-override option can be used. If there are problems that would prevent the standby SPE from running system software, the command is rejected outright.

If the health-override option is specified, and if the standby SPE is in standby mode, a Hot interchange is performed, regardless of the FSL level of the two SPEs. Once the interchange is performed, if the new active FSL is higher than the standby FSL, a STBY-SPE warning alarm is raised against the new standby SPE. This indicates that the system was forced to switch SPEs and is currently being held on the active SPE artificially. This prevents a SPE interchange back to the original active SPE. This STBY-SPE warning alarm lasts for one hour. After this time passes, system switches to the SPE with the lowest FSL.

The STBY-SPE alarm is also retired if there is some indication of system technician testing of the standby SPE before the one hour expires. The assumption here is that a system technician person is present because the health-override option was used. Therefore, if there is some indication that repair work is going on, the alarm generated by the health-override should be retired. The following are indications of system technician testing being done: the standby SPE is busied out and then released, the active SPE is hard selected via the switches, or a **test spe-standby long** command is performed.

- **test processor [1] a|b [short | long]**

Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the PROCR-BD and PR-MAINT sections for a complete list of the tests that are run.

- **test memory [1] a|b [short | long]**

For this command, there is one additional test for the Standby SPE Memory circuit pack: the Memory Functional Test #332. Refer to the MEM-BD section for a complete list of the tests that are run.

■ **test data-module <extension>**

Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the DATA-CHL section for a complete list of the tests that are run.

■ **test network-control [[0]1] a|b [short | long]**

Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the SW-CTL, DATA-BD, DATA-CHL, and CARD-MEM sections for a complete list of the tests that are run.

■ **test card-mem [[0]1] a|b [short | long]**

Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the CARD-MEM section for a complete list of the tests that are run.

■ **test packet-control [[0]1] a|b [short | long]**

For **test packet-control**, the most significant difference between testing the Active Packet Control versus the Standby Packet Control is that the Reset Test (#586) runs on the Standby SPE Packet Control circuit pack. Also, the short and long options cause the identical set of tests to run. Refer to the PKT-CTRL section for a complete list of the tests that are run.

■ **test interface [[0]1] a1 | a2 | b1 | b2 [short | long]**

For this command, there is a single test for the Standby SPE Processor Interface circuit pack(s) and a single test for each Processor Interface Port on a Processor Interface circuit pack. These tests are different from the tests that are run for the corresponding Active SPE Processor Interface circuit pack(s) and Processor Interface Port(s). Refer to the PI-PT section for a complete list of the tests that are run.

■ **test duplication-interface [0]1] a|b [short | long]**

Runs the same set of tests on the standby SPE as on the Active SPE. Refer to the DUPINT section for a complete list of the tests that are run.

■ **test spe-standby [short | long]**

The **test spe-standby [short | long]** command results in the execution of all tests that would be run if each of the previous commands in this list was executed individually. Because of the number of tests that it runs, **test spe-standby [short | long]** takes from 10 to 30 minutes to complete.

The Short and Long Test Sequences for **test spe-standby** are listed on the following pages. Refer to the appropriate maintenance section for a complete description of each of the tests.

Test Sequence of Test SPE-Standby Command

| Test Number | Name of Test and Associated MO                          | Short Test Sequence | Long Test Sequence |
|-------------|---------------------------------------------------------|---------------------|--------------------|
| 332         | Memory Functional Test                                  |                     | X                  |
| 318         | Shadow Link Test (SHDW-LNK)                             |                     | X                  |
| 285         | Common Shadow Circuit MBUS Time-out Query (SHDW-CIR)    |                     | X                  |
| 283         | Common Shadow Circuit Loop Back Test (SHDW-CIR)         | X                   | X                  |
| 284         | Common Shadow Circuit Address Decoder Test (SHDW-CIR)   | X                   | X                  |
| 278         | SPE Select Switch Query (SPE-SELEC)                     | X                   | X                  |
| 315         | Duplication Interface Status Query (DUPINT)             | X                   | X                  |
| 275         | Duplication Interface SPE A Loop Back Test (DUPINT)     | X                   | X                  |
| 276         | Duplication Interface SPE B Loop Back Test (DUPINT)     | X                   | X                  |
| 280         | Inter-Duplication Interface Loop Back Test (DUPINT)     | X                   | X                  |
| 271         | Duplication Interface Background Test Query (DUPINT)    | X                   | X                  |
| 277         | Duplication Interface Sanity Maze Test (DUPINT)         | X                   | X                  |
| 272         | Duplication Interface Invalid Message Query (DUPINT)    | X                   | X                  |
| 274         | Duplication Interface Manager I Loop Back Test (DUPINT) | X                   | X                  |
| 273         | Duplication Interface Sanity Circuit Test (DUPINT)      |                     | X                  |
| 85          | Read All Memory Test                                    |                     | X                  |
| 86          | RAM Checksum Test                                       |                     | X                  |
| 87          | Memory Parity Test                                      | X                   |                    |
| 52          | Control Channel Test (DATA-BD)                          | X                   | X                  |
| 50          | NPE Audit (DATA-BD)                                     |                     | X                  |

For each administered Network Control Data Channel in the Standby SPE, the following DATA-CHL tests are run:

|     |                                                           |   |   |
|-----|-----------------------------------------------------------|---|---|
| 107 | Data Channel Reset (DATA-CHL)                             |   | X |
| 108 | Data Channel DPR Test (DATA-CHL)                          |   | X |
| 109 | Data Channel Maintenance Loop Around Test (DATA-CHL)      | X | X |
| 110 | Data Channel Crosstalk Test (DATA-CHL)                    | X | X |
| 111 | Data Channel Loop Back Test (DATA-CHL)                    | X | X |
| 93  | Switch Control Reset Test (SW-CTL)                        |   | X |
| 325 | Destructive EPN Maintenance Board Interface Test (SW-CTL) |   | X |

Test Sequence of Test SPE-Standby Command

| Test Number | Name of Test and Associated MO                      | Short Test Sequence | Long Test Sequence |
|-------------|-----------------------------------------------------|---------------------|--------------------|
| 95          | Time-of-Day Clock Test (SW-CTL)                     | X                   | X                  |
| 92          | Control Channel Interface Test (SW-CTL)             | X                   | X                  |
| 94          | Control Channel Transmission Test (SW-CTL)          | X                   | X                  |
| 324         | EPN Maintenance Board Interface Test (SW-CTL)       | X                   | X                  |
| 77          | Processor Software Initiated Interrupt Test (PROCR) | X                   | X                  |
| 80          | Processor ROM Checksum Test (PROCR)                 | X                   | X                  |
| 82          | Processor Non-Maskable Interrupt Test (PROCR)       | X                   | X                  |
| 83          | Processor Sanity Timer Test (PROCR)                 |                     | X                  |
| 102         | MTP Outpulse Relay Test (PR-MAINT)                  | X                   | X                  |
| 103         | MTP Analog Loop Around Test (PR-MAINT)              | X                   | X                  |
| 106         | MTP Sanity Handshake Test (PR-MAINT)                | X                   | X                  |
| 228         | MTP Manager I Channel Loop Around Test (PR-MAINT)   | X                   | X                  |
| 229         | MTP Auxiliary Channel Loop Around Test (PR-MAINT)   | X                   | X                  |
| 101         | MTP Reset Test (PR-MAINT)                           |                     | X                  |
| 104         | MTP Dual Port RAM Test (PR-MAINT)                   |                     | X                  |

The following Memory Card and 12 Volt Power Supply tests are executed:

|     |                                                               |   |   |
|-----|---------------------------------------------------------------|---|---|
| 701 | 12 Volt Power Supply Test (12V-PWR)                           | X | X |
| 695 | Cartridge Insertion Test (CARD-MEM)                           | X | X |
| 696 | Cartridge Format and Read Test (CARD-MEM)                     | X | X |
| 697 | Cartridge Match Test (CARD-MEM)                               | X | X |
| 698 | Cartridge Write-Protected Test (CARD-MEM)                     | X | X |
| 699 | Cartridge Directory Sanity Check and Recovery Test (CARD-MEM) | X | X |
| 694 | Cartridge Translation Data Integrity Test (CARD-MEM)          |   | X |
| 693 | Cartridge Erase/Write/Read Test (CARD-MEM)                    |   | X |
| 703 | Flash Data Consistency Test (FL-DATA)                         |   | X |

For each Processor Interface circuit pack in the Standby SPE, the following PI-BD tests are run:

|     |                               |   |   |
|-----|-------------------------------|---|---|
| 52  | Control Channel Test (PI-BD)  | X | X |
| 50  | NPE Audit (PI-BD)             |   | X |
| 423 | Standby PI Board Test (PI-BD) | X | X |

For each administered Processor Interface Port, the following test is run:

|     |                              |   |   |
|-----|------------------------------|---|---|
| 404 | Standby PI Port Test (PI-PT) | X | X |
|-----|------------------------------|---|---|

Test Sequence of Test SPE-Standby Command

| Test Number                                                                                | Name of Test and Associated MO                              | Short Test Sequence | Long Test Sequence |
|--------------------------------------------------------------------------------------------|-------------------------------------------------------------|---------------------|--------------------|
| For a Packet Control circuit packet in the Standby SPE, the following three tests are run: |                                                             |                     |                    |
| 586                                                                                        | Packet Control System Technician Reset Test (PKT-CTRL)      | X                   | X                  |
| 583                                                                                        | Packet Control Read and Clear Error Counter Test (PKT-CTRL) | X                   | X                  |
| 585                                                                                        | Packet Control Loop Around Test (PKT-CTRL)                  | X                   | X                  |

Running Tests on the Standby SPE

Although this subsection is not about the individual test commands listed previously, several useful facts about executing these commands for Standby SPE components are mentioned here. These facts also apply to the **test spe-standby [short | long]** command.

1. If the Standby SPE is in Standby Mode, execution of the listed test commands results in the Active SPE putting the Standby SPE into Maintenance Mode. Up to a two minute delay may be observed before the first test in the sequence is run and its test results are displayed on the terminal. Each subsequent test in the sequence takes from 10 to 60 seconds to run, except for the CARD-MEM Erase/Write/Read test #693, which takes one to five minutes to run.
2. The **test memory [[0]1] a | b long** command is an exception to the first item. The first test in the sequence is the Memory Functional Test (#332) which takes from 30 seconds to two minutes. After the Memory Functional Test (#332) is run, the same delays described in Item 1 of this list are relevant.
3. The **test duplication-interface [[0]1] a | b long** command is also an exception to the first item. The first test in the sequence is the MBUS Time-out Query (#285) which takes from 30 seconds to 2 minutes to run. After the MBUS Time-out Query (#285) is run, the same delays described in Item 1 of this list are relevant.
4. The **test spe-standby long** command is also an exception to the first item. The first test in the sequence is, the Memory Functional Test (#332), takes from 30 seconds to two minutes to run. After the Memory Functional Test (#332) is run, the next test in the sequence, the Shadow Link Test (#318), takes from one to five minutes to run. After the Shadow Link Test (#318) is run, the next test in the sequence, the MBUS Time-out Query (#285), takes from 30 seconds to two minutes to run. After the MBUS Time-out Query (#285) is run, the same delays described in Item 1 of this list are relevant.
5. If one of listed test commands is executed so that the Active SPE puts the Standby SPE into Maintenance Mode, the Active SPE leaves the Standby SPE in Maintenance Mode for three minutes after the completion of the command. If an additional test command (with the exception of those

described in Items 6, 7, and 8) is executed within three minutes, the one to 20-minute delay prior to the first test will **not** be observed. Each test in the sequence, including the first test, takes from 10 to 60 seconds to run.

Furthermore, the Active SPE leaves the Standby SPE in Maintenance Mode for three minutes after the completion of the additional command. This is true for each additional test command issued on a Standby SPE component.

- 6. The **test memory [[0]1] a | b long** command is an exception to Item 5. Because of the nature of the Memory Functional Test (#332) the same delays as described in Item 2 are always observed for **test memory [[0]1] a | b long**.
- 7. The **test duplication-interface [[0]1] a | b long** command is also an exception to Item 5. Because of the nature of the MBUS Time-out Query (#285) the same delays as described in Item 3 are always observed for **test duplication-interface [[0]1] a | b long**.
- 8. The **test spe-standby long** command is also an exception to Item 5. Because of the nature of the Memory Functional Test (#285), the Shadow Link Test (#318), and the MBUS Time-out Query (#285) the same delays as described in Item 4 are always observed for **test spe-standby long**.
- 9. For test commands whose sequence spans multiple terminal screens (for example, **test spe-standby [short | long]**) the same 3-minute window that was described in Item 4 applies to pressing the "page" key to proceed to the next screen of test results. If the "page" key is not pressed within three minutes of the completion of the last test on the current screen, the one to 20 minute delay is observed before the first test on the next screen is run and its test results are displayed on the terminal. Each subsequent test on that screen takes from 10 to 60 seconds to run. If the "page" key is pressed within three minutes of the completion of the last test on the current screen, the one to 20 minute delay will **not** be observed.

Test Result Error Codes and Text Strings

The text string messages and error codes documented in the Error Codes tables at the end of this section may result from any of the system technician commands described earlier in this section.

In general, these error codes result from an inability of the Active SPE to successfully conduct a maintenance activity request on the Standby SPE and not from a problem detected by the test itself. In fact, all error codes except for 2015, 2021, 2047, 2048, 2049, and 2050 indicate that the test was not actually run.

If an error code returned from a test does not appear in the Error Code table, the Active SPE successfully conducted the maintenance activity request on the Standby SPE, and the test was actually run (in most cases). For details on this error code, refer to the documentation describing the specific object you now suspect as possibly being defective. In the Short and Long Test Sequences

listed earlier in this section, the name of the object tested appears directly after each test number and name.

Several of the conditions corresponding to the error codes documented here may be detected as soon as the **test <component> [[0]1 a | b [short | long]** command is issued. The net result is that none of the tests in the sequence for the component will be attempted and a message will appear on the terminal message line describing why the command was rejected.

The following is a list of these text strings.

- **Cannot interrupt Standby SPE while entering maintenance mode; please try later**

This message line error is displayed when a **refresh spe-standby** command is issued while maintenance software is in the process of putting the Standby SPE into Maintenance mode when any of the Error Types listed in "Hardware Error Log Entries and Test to Clear Value" have occurred and have not been resolved. It is also displayed when a system technician-demanded test has been issued and subsequently canceled because maintenance software is performing the Memory Functional Test, Shadow Link Test, or M-BUS Time-out Query. Another cause may be that maintenance software is in the process of putting the Standby SPE into Maintenance Mode to run any other system technician-demanded test that must be conducted on the Standby SPE in Maintenance Mode. Allow up to 10 minutes for the maintenance software to complete its attempt to put the Standby SPE into Maintenance Mode before issuing the **refresh spe-standby** command.

- **Cannot perform SPE interchange; for information use status system**

This message is displayed in response to the **reset system interchange** command and because there are outstanding STBY-SPE errors. Display the error log using the "dup-spe" category, and following the procedures for all STBY-SPE errors.

- **Cannot reset standby SPE at this time; use the 'status system' command**

This message is displayed when the standby SPE memory is not refreshed. Issue the **refresh spe-standby** command and try the reset again.

- **Could only hold Standby SPE reset because Active SPE is locked via SPE select switches**

This message is displayed when the **refresh spe-standby** command is issued when the active SPE is selected via the SPE select switches. Because the select switches disable shadowing, the refresh command can not refresh the memory on the standby SPE. The only effect the refresh command has is to hold the standby SPE reset.

- **Refresh not successful; use the 'display errors' and the 'dup-spe' category to check for standby SPE errors**

This message line error, which corresponds to Error Codes 2012, 2013, 2014, 2015, 2021, 2024, 2048, 2049, 2050, or 2051, is displayed when a **refresh spe-standby** command fails.

- **Standby SPE busy with another task; for information use status system**

This message line error, which corresponds to Error Code 2018, is displayed if a test command on a Standby SPE component is attempted while the Active SPE is performing some Maintenance Mode activity on the Standby SPE other than system technician-demanded maintenance.

1. Issue the **refresh spe-standby** command to put the Standby SPE into Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** and **release spe-standby** command to put the standby into standby mode.
2. Repeat the command.
3. Issue the **test spe-standby long** command.

- **Standby SPE failed to reset with requested restart level; check for STBY-SPE errors**

- **Standby SPE memory not refreshed; use the 'refresh spe-standby' command**

When a command that requires the standby SPE to be brought into maintenance mode is entered, but the standby SPE memory is not refreshed, this message is displayed. Issue the **refresh spe-standby** command and retry the command.

- **Standby SPE not available; for information use status system**

This message line error, which corresponds to Error Code 2020, is displayed if a test command on a Standby SPE component is attempted within the first five minutes of a restart of the Active SPE (that is, prior to the Active SPE holding the Standby SPE reset and refreshing it).

1. Issue the **refresh spe-standby** command to put the Standby SPE into Standby Mode. This command may have to be issued multiple times. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to

check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the **refresh spe-standby** command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the **busyout spe-standby** and **release spe-standby** command to put the standby into standby mode.

2. Repeat the command.
3. Issue the **test spe-standby long** command.

■ **Unable to interchange because the active SPE is locked active**

An SPE interchange cannot be performed when the active SPE is locked via the SPE select switches. Move the select switches back to the auto position and retry the **reset system interchange** command.

■ **Unable to interchange because the standby SPE is busied out**

An SPE interchange can not be performed when the standby SPE is busied out. Release the standby SPE by entering the **release spe-standby** command and retry the command.

■ **Unable to interchange due to alarms on the standby SPE; Use the 'health-override' option**

When components in the standby SPE complex are alarmed, and if these Standby alarms are more severe than the alarms in the active SPE complex, the **reset system-interchange** command returns this message. Using the **reset system-interchange health-override** command forces the interchange. See the **Reset System** command page for more details.

Table 10-392. Test Result Error Codes Associated with the Standby SPE

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4          | ABORT       | <p>The Active SPE was unable to disable or enable shadowing from Active SPE memory to Standby SPE memory. The communication path between the Active SPE and the carrier A Duplication Interface circuit pack may have failed, or the carrier A Duplication Interface circuit pack may have failed.</p> <ol style="list-style-type: none"><li>1. Check for Active SPE Maintenance/Tape Processor errors and alarms. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation and follow the prescribed procedures.</li><li>2. Check for carrier A Duplication Interface circuit pack errors and alarms. Refer to DUPINT (Duplication Interface Circuit Pack) Maintenance documentation and follow the prescribed procedures.</li><li>3. If the B carrier contains the Active SPE, check the Inter-Carrier Cable to see if it is loose or disconnected. If so, follow the repair procedures for connecting the Inter-Carrier Cable described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>.</li><li>4. If all problems found in Steps 1, 2, and 3 have now been repaired, proceed with Step 7. If no problems were found in Steps 1, 2, and 3, proceed with Step 5.</li><li>5. Issue the <b>display errors</b> command and check to see if an Error Type 80 is logged against STBY-SPE. If so, the problem is the carrier A Duplication Interface circuit pack. Replace the carrier A Duplication Interface circuit pack as described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a> and proceed with Steps 7, 8, and 9.</li></ol> |

Table 10-392. Test Result Error Codes Associated with the Standby SPE  
— Continued

| Error Code           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|----------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1030                 | ABORT       | <p>The component on which the test was to be run is on the Standby SPE. This test may only be run on this component when it resides on the Active SPE. If it is absolutely necessary to conduct this test on the Standby SPE component, implement the following steps to make it become an Active SPE component.</p> <ol style="list-style-type: none"><li>1. Issue the <b>refresh spe-standby</b> command to return the Standby SPE to Standby Mode. This command may have to be issued multiple times. If the <b>refresh spe-standby</b> command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the <b>refresh spe-standby</b> command once more.</li><li>2. Issue the <b>reset system interchange</b> command in order to cause an SPE switch. At this point, the component resides on the Active SPE.</li></ol> |
| 1030<br>(cont'd.)    | ABORT       | <ol style="list-style-type: none"><li>3. Move the SPE Select switches to make the SPE with the problem the current Active SPE. This action prevents software from switching to the other SPE since the current SPE has the error against it.</li><li>4. Repeat the test.</li><li>5. If the test passes and the alarm is resolved, return the SPE Select switches to the AUTO position.</li><li>6. If the test fails and the defective circuit pack is identified, the circuit pack needs to be replaced. However, the circuit pack now resides on the current Active SPE. Return the SPE Select switches to the AUTO position. Issue the <b>refresh spe-standby</b> command and then execute a <b>reset system interchange</b> command to cause an SPE switch.</li><li>7. The system is now on the healthy SPE. Replace the defective circuit pack on the Standby SPE as previously identified in Step 4. Refer to the "Replacing Defective SPE Circuit Packs" section in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>.</li><li>8. Repeat the procedure, beginning with Step 1.</li></ol>                                                           |
| 2011<br>2012<br>2013 | ABORT       | <p>Internal system error</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals a maximum of 5 times.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2015                 | ABORT       | <p>The Standby SPE Maintenance/Tape Processor did not reply to an Active SPE request to hold the Standby SPE Processor reset. The communication path between the Active SPE and the Standby SPE Maintenance/Tape Processor may have failed, or the Standby SPE Maintenance/Tape Processor may have failed. Follow the procedures described for Error Code 2024 in the STBY-SPE section.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|-------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2024<br>(cont'd.) | ABORT       | <div>11. Issue the <b>refresh spe-standby</b> command to put the Standby SPE into Standby Mode. This command may have to be issued multiple times. If the <b>refresh spe-standby</b> command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This does not include cases where the command completes with the terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later." Issue the <b>refresh spe-standby</b> command once more. If the Standby SPE is not labeled "standby" on the status system form after this attempt, use the <b>busyout spe-standby</b> and <b>release spe-standby</b> command to put the standby into standby mode.</div> <div>12. Repeat the command.</div> <div>13. Issue the <b>test spe-standby long</b> command.</div>                                                                                                                                                                                                                                                                                                                                                                             |
| 2025              | ABORT       | <div>The Standby SPE Maintenance/Tape Processor successfully released the Standby SPE processor, but the Standby SPE processor did not successfully carry out the requested function. Either there is a problem with one or more components that make up the Memory Shadowing Link such that Active SPE Memory was not accurately shadowed to Standby SPE Memory <b>OR</b> there is a problem with the Standby SPE Processor circuit pack or the Standby SPE Memory circuit pack.</div> <div>1. Check for both Active SPE and Standby SPE Common Shadow Circuit errors and alarms. Refer to SHDW-CIR (Common Shadow Circuit) and follow the procedures.</div> <div>2. Check for Standby SPE Memory errors and alarms. Refer to MEM-BD (Memory circuit pack) and follow the procedures.</div> <div>3. Check for Standby SPE Processor errors and alarms. Refer to PROCR and follow the procedures.</div> <div>4. Check the Inter-Carrier Cable to see if the cable is loose or disconnected. If so, follow the repair procedures for reconnecting the Inter-Carrier Cable described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>.</div> <div>5. If all problems found in Steps 1, 2, 3, and 4 have now been repaired, proceed with Step 10. If no problems were found in Steps 1, 2, 3, and 4, proceed with Step 6.</div> |

Table 10-392. Test Result Error Codes Associated with the Standby SPE  
— Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                        |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2054       | ABORT       | This indicates an incompatibility between the two Processor circuit packs in a Duplication Option system. Follow the repair steps for STBY-SPE error 139 note (k).                                                                                 |
| 2068       | ABORT       | When attempting to refresh Standby SPE memory from Active SPE memory, a problem was encountered when refreshing Packet Control circuit pack memory.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                        |
| other      | ABORT       | Any ABORT with an error code other than the ones listed previously indicates a problem that prevented the test from running. See Test Result of each maintenance object under test for details.                                                    |
| other      | FAIL        | Any FAIL indicates that the test was actually run on the associated Standby SPE component. However, the test did not succeed and returned FAIL with the reason for the failure. See Test Result of each maintenance object under test for details. |
|            | PASS        | The test was actually successfully run on the associated Standby SPE component and returned PASS. See Test Result of each maintenance object under test for details.                                                                               |

## STRAT-3 (Stratum 3 Clock)]

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO |
|------------------------------------|-------------|------------------------------------------|-----------------|
| STRAT-3                            | MAJOR       | test synchronization                     | Stratum 3 Clock |
| STRAT-3                            | MINOR       | test synchronization                     | Stratum 3 Clock |
| STRAT-3                            | WARNING     | test synchronization                     | Stratum 3 Clock |

The *Digital Synchronization Network Plan (PUB 60110)* specifies a hierarchy of synchronization nodes consisting of strata 1 to 4, where the sole Stratum 1 clock in the network is the most accurate. DEFINITY supports both Stratum 3 and Stratum 4 operations. Refer to SYNC (Synchronization) Maintenance documentation for details on Stratum 4 operation.

A Stratum 3 clock derives its timing from two DS1 references that are connected to a Stratum 3 or better (that is, lower stratum) source. The Stratum 3 clock provides a holdover of at least 24 hours should both DS1 references fail. (After 24 hours, the Stratum 3 clock still provides service but its accuracy may be degraded). The *Digital Synchronization Network Plan (PUB 60110)* requires that the Stratum 3 clock have duplicated components.

The recognition of the Stratum 3 clock itself as well as its alarm signals, is supported only by the TN780 Tone-Clock circuit pack. The TN780 Tone-Clock circuit pack is also backwards-compatible with the TN768 Tone-Clock circuit pack.

The Stratum 3 clock may be connected to either the PPN or an EPN if the TN780 Tone-Clock circuit pack(s) is present in that port network. However, for reliability, it is recommended that the clock be connected to the PPN. Refer to *DEFINITY Communications System Generic 3 Implementation*, 555-230-653 for details on how to move the Stratum 3 clock between port networks.

The only operation that software can perform is a query of the alarm leads. The only recovery action that can be performed on a catastrophic failure of the Stratum 3 clock is the utilization of the local oscillator on the Active TN780 Tone-Clock circuit pack. Neither software nor the TN780 Tone-Clock circuit pack can request additional information about the health of the Stratum 3 clock other than the information provided by the alarm leads. Furthermore, neither the software nor the TN780 Tone-Clock circuit pack can request that the external clock switch references, change configuration, disable/enable, initialize, etc.

In G3iV1.1-286 and G3iV2-386, the Stratum 3 clock has been implemented as an external that follows the specification in PUB 60110 for Stratum 3. [Figure 10-85](#) shows how the Stratum 3 hardware configuration provides clock and alarm signals to the TN780 Tone-Clock circuit pack(s). The reference DS1 facilities are

connected directly to the Stratum 3 clock for timing purposes, but the DS1 data may be routed into the switch by using a Y connector.

**Figure 10-85. Stratum 3 Clock Hardware Configuration**

**NOTE:**

When looking in the Stratum 3 cabinet, "A" card is on the left and "B" card is on the right.

## **Stratum 3 Clock LED Strategy**

---

Red and green LEDs are provided on the components of the Stratum 3 clock for status and alarm indications.

**WARNING:**

*The normal LED scheme is not followed for this device. Green LEDs do not indicate maintenance activity. There are no yellow LEDs, and there are more than three LEDs per circuit pack.*

The Stratum 3 clock has the following components:

- 2 Clock Input cards (CI)  
Provides the logic to select the better DS1 reference or Clock Input card. The red FAIL LED on this card indicates a failure with the card or the DS1 reference connected to it.
- 2 Stratum 3 Cards (ST3)  
Provides 24-hour holdover. The red FAIL LED on this card indicates a failure with the card. Replace the card.
- 2 Timing Output Cards (TOC)  
Provides cable length compensation, multiple output ports, selection of the ST3, and CI outputs. This type of card has two red failure LEDs: one indicates a failure of the card; the other indicates a failure in one or more output ports. In either case, replace the card.
- 1 PBX Alarm Interface (PAI)  
Filters power supplied to the clock, provides fuse protection, and provides alarm indications based on inputs supplied by other cards. The six LEDs on this card provide indications for the six alarm or status conditions as follows:
  - 1.Loss of DS1 reference A.
  - 2.Loss of DS1 reference B.
  - 3.Loss of one clock unit.
  - 4.Loss of both clock units.
  - 5.Loss of one power supply.
  - 6.Loss of both power supplies.

**⇒ NOTE:**  
Removal of a card in the Stratum 3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum 3 clock to full service.

The output of the CI and PAI cards go directly to the TN780 Tone-Clock circuit pack via two 25-pair amp-terminated cables. All of the cards have red and/or green LEDs for providing status or alarm indications. The following table shows the Stratum 3 Clock LED indications.

**⇒ NOTE:**  
The abbreviations used in the table were defined previously with the exception of SRC (source) and PLL (Phase Locked Loop).

**Table 10-393. Stratum 3 Clock LED Indications**

| Card | Name       | Color | Indication                                    |
|------|------------|-------|-----------------------------------------------|
| PAI  | REF A      | Red   | Loss of input reference A or CI A failed      |
|      | REF B      | Red   | Loss of input reference B or CI A failed      |
|      | ST A       | Red   | Failed Stratum 3 clock A                      |
|      | ST B       | Red   | Failed Stratum 3 clock B                      |
|      | PWR A      | Green | -48VDC A present                              |
|      | PWR B      | Green | -48VDC B present                              |
| CI   | FAIL       | Red   | Card failure                                  |
|      | DS1        | Green | DS1 source present                            |
|      | CC         | Green | Composite clock source <sup>1</sup> present   |
|      | SRC ACTIVE | Green | Card is currently on-line                     |
| ST3  | FAIL       | Red   | Card failure                                  |
|      | LOCK       | Red   | PLL lost sync with reference or holdover mode |
|      | REF A      | Red   | Timing Reference from CI A                    |
|      | REF B      | Red   | Timing Reference from CI B                    |
| TOC  | FAIL       | Red   | Card failure                                  |
|      | PORT ALM   | Red   | Output port alarm (one or more)               |
|      | ST         | Green | Reference present from ST clock               |
|      | INPUT      | Green | Reference present from CI                     |
|      | 500'       | Green | 500 feet phase advance                        |
|      | 1000'      | Green | 1000 feet phase advance                       |

- 
1. Composite Clock source refers to the protocol used to electrically transfer timing from the Stratum 3 clock to the PBX switch. The Composite Clock source is not relevant to Definity Generic 1.1.

 **NOTE:**

When looking in the Stratum 3 cabinet, "A" card is on the left and "B" card is on the right.

Hardware Error Log Entries and Test to Clear Values

| Stratum 3 Clock Error Log Entries |          |                                    |                 |              |                          |
|-----------------------------------|----------|------------------------------------|-----------------|--------------|--------------------------|
| Error Type                        | Aux Data | Associated Test                    | Alarm Level     | On/Off Board | Test to Clear Value      |
| 0 <sup>1</sup>                    | 0        | Any                                | Any             | Any          | test synchronization r 4 |
| 1 (d)                             | Any      | Stratum 3 Clock Alarm Query (#649) | MINOR           | OFF          | test synchronization r 4 |
| 257 (e)                           | Any      | Stratum 3 Clock Alarm Query (#649) | MINOR           | OFF          | test synchronization r 4 |
| 257 (c)                           |          | None                               | WARNING         | ON           |                          |
| 513 (f)                           | Any      | Stratum 3 Clock Alarm Query (#649) | MINOR           | ON           | test synchronization r 4 |
| 769 (g)                           | Any      | Stratum 3 Clock Alarm Query (#649) | MINOR           | ON           | test synchronization r 4 |
| 1025 (h)                          | Any      | Stratum 3 Clock Alarm Query (#649) | MINOR/ MAJOR(a) | ON           | test synchronization r 4 |
| 1281 (i)                          | Any      | Stratum 3 Clock Alarm Query (#649) | MINOR/ MAJOR(a) | ON           | test synchronization r 4 |
| 1537 (b)                          |          | none                               | MINOR/ MAJOR(a) | ON           |                          |

- 
1. Run the Short Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- 
- a. In the context of the Stratum 3 clock, an OFF-BOARD alarm occurs when there is a DS1 facility problem; otherwise, the alarm is ON-BOARD indicating that there is a fault in the Stratum 3 clock or in the connection between the Stratum 3 clock and the PBX (Private Branch Exchange) switch. If the Stratum 3 clock cannot be referenced, and therefore the

local oscillator on the TN780 Tone-Clock circuit pack must serve as the reference instead, a Major alarm is raised. Otherwise, a Minor alarm is raised.

- b. This error can be caused by one of the following conditions:
  - 1. One or both TOCs (Timing Output Cards) may have failed,
  - 2. the connection between the Stratum 3 clock and the TN780 Tone-Clock circuit pack may be faulty, or
  - 3. the TN780 Tone-Clock circuit pack may be defective.

A Minor alarm results if the Stratum 3 clock can still provide timing to the PBX; otherwise, a Major alarm is raised because the Stratum 3 clock is not providing timing and the PBX is referencing the local oscillator on the TN780 Tone-Clock circuit pack. If only the Active TN780 Tone-Clock circuit pack were faulty, the Standby TN780 Tone-Clock circuit pack would become active and still synchronize to the Stratum 3 clock. When the system switches to the Standby Tone-Clock circuit pack, the alarm is resolved, and it raises a TDM-CLK (TDM Bus Clock) alarm to indicate that the TN780 Tone-Clock circuit pack may be defective.

If the alarm is minor:

Look for a red LED on either or both TOC cards. If there is a red LED, then replace the card. If there is no red LED, then, using the *Stratum 3 Wiring Guide*, check that the wiring installation is correct. After replacing the card or correctly rewiring the installation, clear the alarm by first issuing the **disable synchronization-switch** command followed by the **enable synchronization-switch** command. Wait two minutes and then execute the **status synchronization** command. If Maintenance Name on the status screen shows "STRAT-3," then the problem is resolved. If not, then escalate the problem.

If the alarm is major:

Check connections between the Stratum 3 clock and the PBX. If there are no loose connections, using the *Stratum 3 Wiring Guide*, check that the wiring installation is correct. After reconnecting the loose connection or correctly rewiring it, clear the alarm by first issuing the **disable synchronization-switch** command followed by the **enable synchronization-switch** command. Wait one minute, and then execute the **status synchronization** command. If Maintenance Name on the status screen shows "STRAT-3," then the problem is resolved. If not, then escalate the problem.

If the Standby Tone-Clock circuit pack become active:

Check connection between the Stratum 3 clock and the TN780 Tone-Clock circuit pack from which the system has just switched. If there are no loose connections, then, replace the TN780 Tone-Clock circuit pack. Refer to the "How to Replace a Tone-Clock Circuit Pack" section in the TDM-CLK (TDM Bus Clock)

Maintenance documentation. Before switching back to the new TN780 Tone-Clock circuit pack, use the **test tone-clock PC long** command to check that the Tone-Clock is receiving a signal from the Stratum 3 clock. The notation "PC" denotes a port network number and carrier. If all tests pass, switch to the new Tone-Clock circuit pack via the **set tone-clock PC override** command. If Test #651 fails, then the original TN780 Tone-Clock should be reinserted, and the cable between the Stratum 3 clock and the TN780 Tone-Clock circuit pack should be replaced. If Test #651 continues to fail, then escalate the problem.

- c. This error indicates that the Tone/Clock circuit pack in the master port network is not a TN780 Tone/Clock circuit pack when a Stratum 3 clock is administered. Verify that the Tone/Clock in the master port network is TN780.
  - d. This error indicates that the Stratum 3 clock has either reference A or CI card A failed. Please refer to the error code 1 in the test description of the Test #649 for the repair procedure.
  - e. This error indicates that the Stratum 3 clock has one power supply failed. Please refer to the error code 2 in the test description of the Test #649 for the repair procedure.
  - f. This error indicates that the Stratum 3 clock has one clock unit failed. Please refer to the error code 4 in the test description of the Test #649 for the repair procedure.
  - g. This error indicates that the Stratum 3 clock has either reference B or CI card B failed. Please refer to the error code 8 in the test description of the Test #649 for the repair procedure.
  - h. This error indicates that the Stratum 3 clock has all power supplies failed. Please refer to the error code 16 in the test description of the Test #649 for the repair procedure.
  - i. This error indicates that the Stratum 3 clock has all clock units failed. Please refer to the error code 32 in the test description of the Test #649 for the repair procedure.
-

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Stratum 3 Clock Alarm Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation             | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------|---------------------|--------------------|-------------------|
| Stratum 3 Clock Alarm Query (#649) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Stratum 3 Clock Alarm Query (#649)

The Stratum 3 clock provides the system with the following six alarm indications via the TN780 Tone-Clock circuit pack:

- 1. Reference A failed or CI card A failed.
- 2. Reference B failed or CI card B failed.
- 3. One power supply failed.
- 4. All power supplies failed.
- 5. One clock unit failed.
- 6. All clock unit(s) failed.

This test queries the Stratum 3 clock for its alarm status (through the TN780 Tone-Clock circuit pack) and reports the results of the query.

**WARNING:**  
*The removal of a card in the Stratum 3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum 3 clock to full service.*

**Table 10-394. TEST #649 Stratum 3 Clock Alarm Query**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                           |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1001       | ABORT       | <p>The system could not allocate the necessary resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol> |
| 1005       | ABORT       | <p>This test aborts when it is run on a Stratum 4 system. Do not change synchronization to Stratum 3 without consulting the synchronization plan administrator for this switch.</p>                                                                                   |

| 16             | FAIL        | <div>All power supplies failed.</div> <div>1. Replace the failed power supplies.</div> <div>2. If battery backup for the Stratum 3 clock is not supplied or if the battery backup holdover time has been exceeded, the system references the local oscillator on the Active TN780 Tone-Clock circuit pack until software detects one or both power supplies has(have) been restored (approximately 40 minutes). To speed up this restoration, issue the <b>test synchronization r 4</b> command. All tests should pass. If any repetitions should fail, follow the procedures for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures.</div>                                                                                                                                                                                                |

Table 10-394. TEST #649 Stratum 3 Clock Alarm Query — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 32         | FAIL        | All clock unit(s) failed.<br><br>1. Look at the Stratum 3 cabinet for red LEDs on circuit cards marked "ST3." Replace the card(s).<br><br>2. Determine if the alarm still exists by issuing the <b>test synchronization r 4</b> command to clear the alarm. If any test repetitions fail, follow the procedure for those failures. If the problem persists after you have performed this procedure three times, follow normal escalation procedures. |
| 2101       | FAIL        | The TN780 Tone-Clock circuit pack detects loss of signal. Refer to Note (b) of the STRAT-3 Hardware Error Log Entries table in the STRAT-3 (Stratum 3 Clock) Maintenance documentation for replacement procedures.                                                                                                                                                                                                                                   |
|            | PASS        | The Stratum 3 clock has reported that it has no alarm conditions. If synchronization problems have been reported, look for SYNC errors and refer to SYNC (Synchronization) Maintenance documentation for recommended strategy for those errors.                                                                                                                                                                                                      |

## SVC-SLOT (Service Slot)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO |
|------------------------------------|-------------|------------------------------------------|-----------------|
| SVC-SLOT                           | MINOR       | none                                     | Service Slot    |

The Service Slot maintenance object is used to detect when an invalid circuit pack is inserted into a SERVICE slot. The SERVICE slot is the leftmost slot in the J58890BB Port Carrier. It is identified as circuit pack slot location "00" in all commands, field entries, and displays used by the system administrator and the service technician.

This slot does not provide tip and ring connectivity to the wall field. Therefore, only the following circuit pack types are allowed in the slot:

- Call Classifier (TN744)
- Integrated Announcement (TN750)
- Maintenance/Test (TN771C)
- Speech Synthesizer (TN725B)
- Tone Detector (TN748C)

A MINOR alarm is generated against the Service Slot maintenance object when a circuit pack of a type other than that included in the previous list is inserted into a SERVICE slot.

The Service Slot maintenance object name is used instead of the maintenance object name for the illegal circuit pack to prevent any attempt to assign a port to an illegal circuit pack that is physically inserted into the SERVICE slot.

### Hardware Error Log Entries and Test to Clear Values

| Service Slot Error Log Entries |          |                 |             |              |                     |
|--------------------------------|----------|-----------------|-------------|--------------|---------------------|
| Error Type                     | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
| 600 (a)                        |          | None            | MINOR       | ON           |                     |

Notes:

- This error type indicates that a circuit pack type other than one of the following types was inserted into slot 00 (SERVICE slot) of the J58890BB port carrier.

- Call Classifier (TN744)
- Integrated Announcement (TN750)
- Maintenance/Test (TN771C)
- Speech Synthesizer (TN725B)
- Tone Detector (TN748C)

The code of the invalid circuit pack can be displayed by using the **list configuration board UUCSS** command, where "UU" is the universal cabinet number, "C" is the carrier number, and "SS" is the slot number (always 00) of the alarmed circuit pack.

Remove the invalid circuit pack to retire the alarm.

## SW-CTL (Switch Control)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run      | Full Name of MO |
|------------------------|-------------|-----------------------------|-----------------|
| SW-CTL                 | MINOR       | test network-control a/b sh | Switch Control  |
| SW-CTL                 | MAJOR       | test network-control a/b sh | Switch Control  |

The Switch Control resides on the TN777 Network Control (Netcon) circuit pack. The data channels (DATA-BD and DATA-CHL) also reside on the Netcon circuit pack. Standard systems have a single Netcon circuit pack and High and Critical Reliability systems have a Netcon circuit pack in each SPE complex. The Netcon in a standard system cannot be replaced without bringing the system down. The Netcon in the standby SPE of a High or Critical Reliability system can be changed without affecting normal system operation.

The Switch Control is used to send control information between port circuit packs and the processor (see [Figure 10-86](#)). This control information is sent via the PPN cabinet's Time Division Multiplex (TDM) Bus. The portion of the TDM Bus used to transmit control messages is called the control channel. The control channel can be on either TDM Bus A or TDM Bus B, but only one bus is used for the control channel at any given time.

The Switch Control is critical in the setup and take down of all calls but is not involved in the voice or data transmission that takes place during established calls. It is the Switch Control that detects when port circuit packs are plugged into or removed from the PPN cabinet. This information is then sent to the processor. The Switch Control monitors the health of the control channel on the PPN cabinet TDM Bus and informs the processor when errors occur.

The Switch Control contains the hardware Time of Day (TIME-DAY) clock that the system uses for all its date and time information. In addition, the Switch Control also contains hardware to monitor critical system timing signals and informs the processor when these signals fail. For example, if the timing signals from a Tone-Clock circuit pack in the PPN cabinet fail, the Switch Control informs the processor, and the processor can switch in a spare Tone-Clock circuit pack, if one is available (High or Critical Reliability system).

**Figure 10-86. Switch Control Connectivity**

Error Log Entries and Test to Clear Values

Table 10-395. Switch Control Error Log Entries

| Error Type     | Aux Data | Associated Test                       | Alarm Level | On/Off Board | Test to Clear Value             |
|----------------|----------|---------------------------------------|-------------|--------------|---------------------------------|
| 0 <sup>1</sup> | 0        | Any                                   | Any         | Any          | test network-control a/b sh r 1 |
| 1              | Any      | Control Channel Test (#94)            | MAJOR       | ON           | test network-control a/b r 3    |
| 2 (a)          |          | Control Channel Test (#94)            | MAJOR       | ON           | test network control a/b r 3    |
| 257 (b)        | 0 or 1   | None                                  |             |              |                                 |
| 513            | (c)      | Time of Day Clock Test (#95)          | MINOR       | ON           | test network-control a/b l r 3  |
| 769 (d)        | Any      | None                                  |             |              |                                 |
| 1025           |          | Switch Control Loop Around Test (#92) | MAJOR       | ON           | test network-control a/b r 3    |
| 1281 (e)       | Any      | None                                  |             |              |                                 |
| 1537           |          | Switch Control Reset Test #93         | MAJOR       | ON           | test network-control a/b l r 2  |
| 1793 (f)       | Any      | None                                  |             |              |                                 |
| 2817           |          | MCD Loop Around Test (#324)           | MAJOR       | ON           | test network-control a/b r 2    |
| 3073           |          | MCD Memory Test (#325)                | MAJOR       | ON           | test network-control a/b r 3    |
| 3329 (g)       |          | None                                  | MAJOR       | ON           | (g)                             |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error may not cause a Switch Control alarm if Error Type 769 is also present since this error may actually be caused by the loss of clock signals and not by a Switch Control failure.
- b. The 257 errors are reported to the processor by the Switch Control and indicate possible hardware problems on the Network Control circuit pack. The receipt of these errors causes Switch Control maintenance to run specific Switch Control tests. If there really is a problem, the Switch Control tests usually causes other errors to be logged. In the rare case where no other errors are logged but 257 errors are occurring at a high rate (more than 10 in the last hour), the Network Control circuit pack should be replaced at the customer's convenience.

- c. If the Aux Data is less than 100, the test may have been interrupted by LMM operations. Wait 1 minute, then test again. Retry the test a maximum of three times. If the Aux Data is more than 100 or fails two out of three times with Aux Data less than 100, the Netcon circuit pack needs to be replaced.
- d. A 769 error occurs when the Switch Control reports a loss of timing signals to the processor. When this error is present, the Switch Control is usually not alarmed since any Switch Control test failures are really the result of faulty signals from the PPN cabinet Tone-Clock circuit pack. See TDM-CLK (TDM Bus Clock) Maintenance documentation for the procedures needed to diagnose Tone-Clock circuit pack troubles.
- e. This error indicates a loss of handshake between SW-CTL and the system software. Look for and resolve all other SW-CTL errors. In the rare case where no other errors are logged, but Error Type 1281 is occurring at a high rate (more than 10 in the previous hour), escalate the problem.

For G3s, a loss of handshake between Switch Control in Network Control circuit pack (TN777B) and Processor circuit pack (TN786B or TN790) can be caused by the following components: Network Control circuit pack (TN777B), Processor circuit pack (TN786), Processor Interface circuit pack (TN765), Packet Control circuit pack (TN778), and M-BUS.

Follow these repair steps:

1. Look for and resolve all other SW-CTL errors.
2. Look for and resolve all other PI-SCI, PI-BD, and PKT-CTRL errors.
3. If the error indicates a failure in the Network Control circuit pack, [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions to replace the Network Control circuit pack. Boot the system up after the Network Control circuit pack has been inserted successfully into the control carrier.
4. If the error of loss of handshake persists after the replacement of the Network Control circuit pack, then refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions to replace the Processor circuit pack.

Refer to the "Software Upgrade" section in [Chapter 5, "Routine Maintenance Procedures"](#), to load the system software from the Memory Card (J58890TG-1 List 3) with the correct software release into the Processor circuit pack. Boot the system up after the system software is successfully loaded into the Processor circuit pack.

5. If the error of loss of handshake persists after the replacement of the Processor circuit pack, consider the replacement of the control carrier. It's possible that the M-bus on the backplane of the control carrier may be defective.

**Recommended Repair Kits:** Network Control circuit pack (TN777B), Processor circuit pack (TN786B or TN790), and Memory Card (J58890TG-1 List 3) with correct software release.

- f. The Aux Data for this error is not meaningful. The 1793 errors are in-line errors that indicate a possible problem with the interface between the Switch Control and the processor. The receipt of these errors causes Switch Control maintenance to run specific Switch Control tests. If there really is a problem, the Switch Control tests usually causes other errors to be logged. In the rare case where no other errors are logged but 1793 errors are occurring at a high rate (more than 10 in the last hour), the Network Control circuit pack should be replaced at the customer's convenience.
- g. This error indicates bad clock detection circuitry on the Netcon circuit pack. Replace the Netcon circuit pack according to the control carrier circuit pack replacement procedures.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Switch Control Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------------|---------------------|--------------------|-------------------|
| Switch Control Reset Test (#93)                         |                     | X                  | D                 |
| Control Channel Interface Test (#92)                    | X                   | X                  | ND                |
| Control Channel Transmission Test (#94)                 | X                   | X                  | ND                |
| Destructive EPN Maintenance Board Interface Test (#325) |                     | X                  | D                 |
| EPN Maintenance Board Interface Test (#324)             | X                   | X                  | ND                |
| Time of Day Clock Test (#95)                            | X                   | X                  | ND                |
| Control Channel Loop Around Test (DATA-BD) (#52) (a)    | X                   | X                  | ND                |
| NPE Audit Test (DATA-BD) (#50) (a)                      |                     | X                  | ND                |
| Data Channel Reset Test (DATA-CHL) (#107) (b)           |                     | X                  | D                 |
| Data Channel Interface Test (DATA-CHL) (#108) (b)       |                     | X                  | D                 |
| Maintenance Loop Around Test (DATA-CHL) (#109) (b)      | X                   | X                  | ND                |
| Data Channel Crosstalk Test (DATA-CHL) (#110) (b)       | X                   | X                  | ND                |
| Data Channel Local Loop Back Test (DATA-CHL) (#111) (b) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

- Notes:
- a. Refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation for a description of these tests.
  - b. Refer to DATA-CHL (Network Control Channel) Maintenance documentation for a description of these tests.

Control Channel Interface Test (#92)

Loop back messages are sent to the Switch Control via the interface used for control channel messages. The messages are returned to the SPE for verification via the same interface.

Table 10-396. TEST #92 Control Channel Interface Test

| Error Code | Test Result | Description/ Recommendation                                         |
|------------|-------------|---------------------------------------------------------------------|
| 2012       | ABORT       | Internal system error                                               |
| 2013       | ABORT       | Could not allocate the necessary system resources to run this test. |
| 2100       |             | 1. Retry the command at 1-minute intervals a maximum of 5 times.    |
| none       |             |                                                                     |
| 1029       | ABORT       | Refer to STBY-SPE for a description of these error codes.           |
| 2014       |             |                                                                     |
| 2015       |             |                                                                     |
| 2016       |             |                                                                     |
| 2017       |             |                                                                     |
| 2018       |             |                                                                     |
| 2020       |             |                                                                     |
| 2022       |             |                                                                     |
| 2024       |             |                                                                     |
| 2025       |             |                                                                     |
| 2051       |             |                                                                     |

Table 10-396. TEST #92 Control Channel Interface Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| other      | FAIL        | <p>Messages could not be looped back through the control channel interface. If this is a standard system, the customer probably cannot make or receive calls.</p> <ol style="list-style-type: none"><li>1. This failure could be due to either a Netcon circuit pack failure or the loss of system timing signals. If the Switch Control is alarmed, then suspect a Netcon circuit pack failure. If the Switch Control is not alarmed, investigate the possible loss of system timing signals before replacing the Netcon circuit pack. Test #94 also fails if the system timing signals are lost. If Test #94 passes, do not suspect the loss of timing signals.</li><li>2. Run the Short Test Sequence several times to make sure that this failure is occurring consistently, run the Long Test Sequence to reset the Switch Control. Sometimes running the Long Test Sequence may clear the problem. If the test is still failing, proceed to Step 3 or 4.</li><li>3. If the system can process calls, replace the Netcon board.</li><li>4. If calls cannot be made, replace the Netcon board immediately.</li><li>5. The procedure for replacing the Network Control circuit pack (DATA-BD) in a High or Critical Reliability system is described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>. The procedure for doing the same in systems without High or Critical Reliability is described in <a href="#">Chapter 5, "Routine Maintenance Procedures"</a>.</li></ol> |
|            | PASS        | <p>The control channel interface between the processor and the Switch Control is working correctly.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Switch Control Reset Test (#93)

This test is destructive.

This test resets the Switch Control and determines if it can successfully go through its initialization sequence. The test is destructive since there is the possibility of losing some control messages to or from port circuit packs.

If this is a standard system, the customer probably cannot make or receive calls.</p> <ol style="list-style-type: none"><li>1. This failure could be due to either a Network Control circuit pack failure or the loss of system timing signals. If the Switch Control is alarmed, then suspect a Network Control circuit pack failure. If the Switch Control is not alarmed, investigate the possible loss of system timing signals. See "TDM Bus Clock". If many port circuit pack LEDs are lit, suspect a TDM Bus Clock problem. If only the Network Control circuit pack LED is lit, suspect the Network Control circuit pack. If the Network Control circuit pack is determined to be at fault, proceed to Step 2.</li><li>2. If the system can process calls, replace the Netcon board.</li><li>3. If calls cannot be made, replace the Netcon board.</li><li>4. The procedure for replacing the Netcon circuit pack in a High or Critical Reliability system is described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>. The procedure for doing the same in systems without High or Critical Reliability is described in <a href="#">Chapter 5, "Routine Maintenance Procedures"</a>.</li></ol> |
|                                                                                      | PASS        | The Switch Control has initialized correctly. Look at results of the other tests to see if it is operating correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Control Channel Transmission Test (#94)

Control channel messages are sent from the SPE to selected port circuit packs and the response from the port circuit packs is checked. This tests the ability of the Switch Control to send and receive messages on the control channel of the TDM Bus.

This test cannot run on the Standby SPE Switch Control. Therefore, it is possible to have defective hardware on the Standby Network Control circuit pack that is not detectable.

| 0          | FAIL        | <p>The Switch Control cannot communicate on the TDM Bus control channel. The customer probably cannot make or receive calls.</p> <ol style="list-style-type: none"><li>1. Run the Short Test Sequence several times to make sure this failure is occurring consistently, run the Long Test Sequence to reset the Switch Control. Sometimes, running the Long Test Sequence may clear the problem. Remember that the Long Test Sequence is <b>destructive</b>. Placing and receiving calls is affected for several seconds.</li><li>2. If there are no TDM Bus alarms against the Standby TDM Bus, switch the control channel from its current bus to the Standby bus. If this test passes on the new bus, investigate the possibility of TDM Bus failures. If the test fails even after the control channel is switched to the standby TDM Bus, proceed to Step 3 or 4.</li><li>3. If the system is still able to process calls, replace the Netcon circuit pack at the customer's convenience (Standard system) or right away (High or Critical Reliability system).</li><li>4. If calls cannot be made, replace the Netcon circuit pack immediately.</li><li>5. The procedure for replacing the Netcon circuit pack in a High or Critical Reliability system is described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>. The procedure for doing the same in systems without High or Critical Reliability is described in <a href="#">Chapter 5, "Routine Maintenance Procedures"</a>.</li></ol> |
|            | PASS        | <p>The Switch Control can communicate with the port circuit packs over the TDM Bus.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Time of Day Clock Test (#95)

The short term accuracy of the Time of Day (TIME-DAY) clock is tested. The test reads the clock once, waits a short time, and reads the clock again. The second reading of the clock must be within certain limits relative to the first reading for the test to pass. The **display time** command can be used to display the current setting of the TIME-DAY clock.

Table 10-399. TEST #95 Time of Day Clock Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

The procedure for replacing the Network Control (DATA-BD) circuit pack is described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a> . The procedure for doing the same in systems without High or Critical Reliability is described in <a href="#">Chapter 5, "Routine Maintenance Procedures"</a> . |
|                                                                                      | PASS        | The Time of Day clock on the Switch Control circuit pack is operating correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Switch Control EPN Maintenance Board Interface  
Test (#324)

Loop back messages are sent to the Switch Control via the interface used for EPN maintenance circuit pack messages. The messages are returned to the SPE for verification via the same interface.

Table 10-400. TEST #324 Switch Control EPN Maintenance Board Interface Test

| Error Code                                                                           | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                 |

| any        | FAIL        | <p>This failure indicates that communications with the Maintenance circuit pack in the EPN is probably not possible. The EPN Manager I may not be usable.</p> <ol style="list-style-type: none"><li>1. Run the Short Test Sequence several times to make sure the error is occurring consistently, run the Long Test Sequence to reset the Switch Control. Sometimes running the Long Test Sequence may clear the problem. Remember the Long Test Sequence is <b>destructive</b>. Placing and receiving calls is affected for several seconds.</li><li>2. Replace the Netcon circuit pack whenever it is convenient for the customer (unduplicated system) or right away (High or Critical Reliability system).</li><li>3. The procedure for replacing the Netcon circuit pack is described in <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a>. The procedure for doing the same in systems without High or Critical Reliability is described in <a href="#">Chapter 5, "Routine Maintenance Procedures"</a>.</li></ol> |
|            | PASS        | <p>The EPN Maintenance circuit pack interface between the processor and the Switch Control is working correctly. Test #325 is a more thorough test of this interface but it is <b>destructive</b>.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Switch Control Destructive EPN Maintenance Board Interface Test (#325)

This test is destructive.

This test writes test patterns into the EPN Maintenance circuit pack interface and verifies that it can read back these test patterns successfully. Messages to or from the EPN Maintenance circuit pack can be lost when this test is run.

Table 10-401. TEST #325 Switch Control Destructive EPN Maintenance Board Interface Test

| Error Code | Test Result | Description/ Recommendation                                      |
|------------|-------------|------------------------------------------------------------------|
| 1005       | ABORT       | The system does not contain an EPN so this test is not executed. |
| 32500      | ABORT       | Test disabled via software patch.                                |

Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1029<br>2014<br>2015<br>2016<br>2017<br>2018<br>2020<br>2022<br>2024<br>2025<br>2051 | ABORT       | Refer to “Standby SPE” for a description of these error codes.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 32515                                                                                | FAIL        | This failure indicates that communications with the Maintenance circuit pack in the EPN is probably not possible. The EPN management terminal may not be usable.<br><br>1. Run the Long Test Sequence several times to make sure the error is occurring consistently. Remember the Long Test Sequence is <b>destructive</b> . Placing and receiving calls is affected for several seconds.<br><br>2. Replace the Netcon circuit pack.<br><br>3. The procedure for replacing the Netcon circuit pack is described in <a href="#">Chapter 6, “Reliability Systems: A Maintenance Aid”</a> . The procedure for doing the same in systems without High or Critical Reliability is described in <a href="#">Chapter 5, “Routine Maintenance Procedures”</a> . |
|                                                                                      | PASS        | The EPN Maintenance circuit pack interface between the processor and the Switch Control is working correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## SYNC (Synchronization)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO             |
|------------------------|-------------|------------------------|-----------------------------|
| SYNC                   | MAJOR       | display errors         | Synchronization Maintenance |
| SYNC                   | MINOR       | display errors         | Synchronization Maintenance |
| SYNC                   | WARNING     | test synchronization   | Synchronization Maintenance |

The Synchronization Maintenance is composed of both hardware and software components and its purpose is to provide a common reference frequency for reliable digital communication between systems and other PBXs, COs or CPE. Synchronization is achieved via the use of several system components which include the Tone-Clock, the DS1 Interface, and the Expansion Interface circuit packs. Synchronization is achieved between the PPN and the EPNs via the Expansion Interface Link (EXP-LINK) between the networks.

Depending on the network synchronization plan and the status of synchronization sources, the system timing reference may be a Tone-Clock circuit pack, DS1 interface circuit packs or an external Stratum 3 clock. Stratum 4 synchronization extracts timing information directly from a DS1 reference or from a Tone-Clock. Stratum 3 synchronization requires the use of a Stratum 3 clock which provides a timing signal, derived from DS1 references, to the TN780 Tone-Clock circuit pack. The external Stratum 3 clock is a more stable timing source than the Stratum 4 clock and provides 24-hour holdover in case of reference failures. The Stratum 3 clock has redundant components.

### Stratum 4 Synchronization

The system can be configured with primary and secondary synchronization references (DS1 interface circuit packs) when using Stratum 4 synchronization. Both references are optional (since the local oscillator can be used), and the secondary reference is optional if a primary is provided. If this system is the master for the network, then its local oscillator would be used and no DS1s would be used as references.

If the primary synchronization reference is not providing a valid timing signal, the system automatically switches to the secondary synchronization reference. If the secondary reference does not provide a valid timing signal or is not administered as a synchronization reference, a Tone-Clock circuit pack provides the system timing source. The system does not revert to the primary if the current reference is the secondary and is failing; however the system switches from the local oscillator to another reference when the new reference becomes available. The following diagram should assist in understanding Stratum 4 Synchronization Maintenance components within the system. This diagram depicts a possible Generic 1.2 configuration; DEFINITY Generic 1 does not support two EPNs, but

the operation and maintenance described below is the same except for the references to multiple EPNs.

**Figure 10-87. Typical Stratum 4 Synchronization Configuration**

If the primary synchronization reference in the previous diagram is providing a valid timing signal, then the flow of system synchronization would travel from the DS1 interface circuit pack in the PPN across the active Expansion Interface fiber link to the two EPNs. The PPND S1 interface circuit pack provides a timing signal for the PPN Tone-Clock circuit pack and the PPN Tone-Clock circuit pack provides timing for all circuit packs in the PPN. The PPN Expansion Interface circuit pack uses the timing generated by the Tone-Clock circuit pack to generate a data stream which is sent across the Expansion Interface link to the Expansion Interface circuit packs in the two EPNs. The EPN Expansion Interface circuit pack uses the received data stream to generate a timing signal. The Tone-Clock circuit pack in the EPNs uses this signal to generate timing for all the circuit packs in their respective EPNs. The PPN, in the above mentioned

scenario, is designated the *master* port network and the EPNs are called *slave* port networks. The *master* port network is defined as the port network that contains the system synchronization source. If the primary synchronization reference does not provide a valid timing signal, Synchronization Maintenance switches to the secondary reference. **Both the primary and secondary references must reside in the same port network, but there is no restriction as to in which port network both must reside (that is, both references may be in an EPN). The recommended placement of the references is in the PPN.**

There are two kinds of Stratum 4 synchronization that are supported: Type I and Type II. Stratum 4 type I is more stable than Type II and provides some switching capability at the hardware level. Stratum 4 Type II operation is the only synchronization strata provided by Generic 1. It is important to note that Stratum 4 Type I operation is not possible when one or both of the DS1 interface circuit packs providing the reference sources is a TN722. Both must be the TN767 or TN464 (suffix C or higher).

## **Stratum 3 Synchronization**

---

The following diagram may help you to understand the synchronization components needed for Stratum 3 synchronization.

**NOTE:**

This is only one possible configuration.

**Figure 10-88. Example Stratum 3 Synchronization Configuration**

For Stratum 3 synchronization, an external clock provides a timing signal to a TN780 Tone-Clock circuit pack, and the TN780 provides timing to all circuit packs in the port network in which the TN780 resides (that is, the PPN in the previous diagram). The PPN Expansion Interface circuit pack uses the timing generated by the TN780 to generate a data stream which is sent across the two Expansion Interface Links to the two EPNs to the EPN Expansion Interface circuit packs. The EPN Expansion Interface circuit packs use the received data stream to generate a timing signal which is used by the Tone-Clock circuit packs in the EPNs to provide timing for all circuit packs in both EPNs. (The Tone-Clock circuit pack is not necessarily a TN780; only the Tone-Clock circuit pack connected to the external Stratum 3 clock must be a TN780.) The PPN, in the above mentioned scenario, is designated the *master* port network and the EPNs are called *slave*

port networks. The *master* port network is defined as the port network whose Tone-Clock is connected to the Stratum 3 clock.

⇒ **NOTE:**

The Stratum 4 equipment (usually a PBX) should never provide timing to a Stratum 3 PBX.

⇒ **NOTE:**

The external Stratum 3 clock may be connected to the TN780 Tone-Clock in any port network. However, it is recommended that it be connected to the PPN.

## Synchronization Troubleshooting

---

For both Stratum 3 and 4 operation, major and minor alarms indicate that there is a problem with the system synchronization references. These alarms are resolved when the alarmed synchronization reference is restored.

The **status synchronization** and **display synchronization** commands are used to determine the current system synchronization reference and the primary and secondary references that are administered respectively.

Other commands associated with Synchronization Maintenance are **disable synchronization-switch** and **enable synchronization-switch**. These commands are used to disable the ability of Synchronization Maintenance to switch between synchronization references and to enable this switching ability, respectively. The **set synchronization** command is executed only after synchronization has been disabled and is used to manually switch to a specific synchronization reference. This command is useful to diagnose synchronization problems by forcing a specific reference (DS1 or Tone-Clock) to be the system synchronization reference to determine if a specific reference is providing a valid timing signal. For Stratum 3 operation, only a TN780 Tone-Clock circuit pack may be specified. To switch synchronization to the Stratum 3 clock, use the **enable synchronization-switch** command after verifying that the Stratum 3 clock is wired correctly.

The system synchronization planner must avoid creating a *timing loop* when administering the primary and secondary synchronization references in a system. A timing loop exists whenever a system receives timing from another system whose timing reference is directly or indirectly derived from itself. Timing loops can lead to loss of digital data between systems that are exchanging data with any system within the loop. An invalid timing signal is also generated by any system within the loop, thus propagating the invalid timing signal to any system(s) using a system within the loop as a synchronization reference. [Figure 10-89](#) shows a timing loop and a correct distribution of timing between the systems.

**Figure 10-89. Synchronization Timing Loop**

A correctly designed network has no loops and each piece of equipment in the network is supplied by a clock of equal or lower stratum (that is, the inputs to a Stratum 3 clock should NEVER be from a Stratum 4 device). **It is strongly recommended that the network administrator be consulted before administering any synchronization changes.**

The yellow LEDs of the TN768 and 780 Tone-Clock circuit packs flash in a specific pattern to indicate the status of the circuit pack. These flashing LED patterns are used to indicate if a Tone-Clock circuit pack is deriving timing from an external source or whether the Tone-Clock circuit pack is providing the timing signal for the port network. The yellow LED patterns for the TN768 and 780 Tone-Clock circuit packs are as follows:

1. Yellow LED is on 2.7 seconds and off 0.3 seconds—This light pattern indicates that an external timing source is being used as a synchronization reference and the circuit pack is in Active mode.
2. Yellow LED is on 0.3 seconds and off 2.7 seconds—This light pattern indicates that the local oscillator on the Tone-Clock circuit pack is being used as a synchronization reference and the circuit pack is in Active mode.
3. Yellow LED stays on—This light pattern indicates that the circuit pack has been reset but no translation has been downloaded. This pattern indicates the circuit pack is providing clocks and is in Active mode.
4. Yellow LED off is an indication that the Tone-Clock circuit pack is in Standby mode (neither generating tones nor supplying clocks).

5. The following two patterns may occur when the circuit pack is either in Active or Standby mode. The best approach to determine the mode of the circuit pack is to use the **status system** system technician command.
  - Maintenance running on the Standby circuit pack is indicated by the following pattern (yellow and green LEDs flashing): LED on 0.1 seconds, off for 0.2 seconds, on for 0.1 seconds, off for 0.4 seconds, on for 0.4 seconds, off for 0.4 seconds.
  - Green flashing and yellow flashing in a pattern different than the previously mentioned pattern indicates that maintenance is running on the Active circuit pack.

Error Log Entries and Test to Clear Values

Table 10-402. Synchronization Error Log Entries

| Error Type                   | Aux Data | Associated Test | Alarm Level                       | On/Off Board | Test to Clear Value  |
|------------------------------|----------|-----------------|-----------------------------------|--------------|----------------------|
| 0 <sup>1</sup>               | 0        | Any             | Any                               | Any          | test synchronization |
| 1 (a) <sup>1</sup>           | Any      | None            | WARNING/<br>MINOR(j) <sup>2</sup> | OFF          | None                 |
| 18 (b)                       | 0        | disable sync    | WARNING                           | OFF          | enable sync          |
| 257 (c) <sup>1</sup>         | Any      | None            | WARNING/<br>MINOR(j) <sup>2</sup> | OFF          | None                 |
| 513 (d) <sup>1</sup>         | Any      | None            | WARNING/<br>MAJOR(j) <sup>2</sup> | OFF          | None                 |
| 769 (e)                      |          | None            | MAJOR/<br>WARNING <sup>3</sup>    | OFF          | None                 |
| 1793 (f) <sup>4</sup>        | 0-50     | None            | MAJOR/<br>WARNING                 | OFF          | enable sync          |
| 2049 (g)<br>(i) <sup>4</sup> | 0        | None            | WARNING                           | OFF          | None                 |
| 2305 (h)<br>(i) <sup>4</sup> | 0        | None            | WARNING                           | OFF          | None                 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This error type initially raises a Warning alarm. If this error type persists and alarms are not downgraded on this MO due to the value of **set options**, then, after a period of time, a Minor or Major alarm is raised.
3. Major alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.
4. It may take up to one hour for these SYNC alarms to clear due to "leaky bucket" strategy.

Notes:

- a. This error indicates a problem with the primary DS1 reference. It is cleared when the primary reference is restored. The following steps should give an indication of the source of the problem:
  - 1.Check if the primary DS1 interface circuit pack is inserted in the carrier via the **list configuration board PCSS** command.
  - 2.Check the connection of the cable supplying the external timing source to the primary DS1 interface circuit pack.
  - 3.Test the primary DS1 interface circuit pack via the **test board PCSS long** command. Check the Error Log for DS1-BD errors and refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance

documentation to resolve any errors associated with the primary DS1 interface circuit pack. If no errors are listed in the Error Log for the primary DS1 interface circuit pack, continue with the following steps.

4. Test the active Tone-Clock circuit pack in the master port network via the **test tone/clock PC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to "TDM-CLK" to resolve the problem. If not, continue with the following steps.
5. Execute the **disable synchronization-switch** and the **enable synchronization-switch** commands. These two commands (when executed together) switch the system synchronization reference to the primary DS1 interface circuit pack. Check the Error Log and execute the **status synchronization** command to verify that the primary DS1 interface circuit pack is still the system synchronization reference. If the primary DS1 interface circuit pack is not the system synchronization reference, and this is not a High or Critical Reliability system, continue with the following step.

#### 6. High or Critical Reliability system:

Switch Tone-Clock circuit packs on the master port network via the **set tone/clock PC** command, and repeat the disable/enable commands described in the previous step.

- b. This error indicates that Synchronization Maintenance has been disabled via the **disable synchronization-switch** command. Execute the **enable synchronization-switch** command to enable Synchronization Maintenance reference switching and to resolve this alarm.
- c. This error indicates a problem with the secondary DS1 reference. It is cleared when the secondary reference is restored. Refer to note (a) to resolve this error substituting **secondary** for **primary** in the preceding resolution steps.
- d. This error indicates that the Tone-Clock circuit pack is providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.
- e. This error indicates that the external Stratum 3 Clock fails to provide the system timing reference. Refer to Stratum 3 Clock Maintenance document to resolve the defective synchronization reference.

This error indicates excessive switching of system synchronization references has occurred. When this error occurs, synchronization is disabled and the Tone-Clock circuit pack (in the master port network) becomes the synchronization reference for the system. Execute the following steps to resolve this error:

1. Check for timing loops and resolve any loops that exist.

2. Test the active Tone-Clock circuit pack in the master port network via the **test tone/clock PC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to the TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem. If not, continue with the following steps.

3. **High or Critical Reliability system:** Switch Tone-Clock circuit packs on the master port network via the **set tone/clock PC** command.

**Standard system:** Replace the primary and secondary (if administered) DS1 Interface circuit packs.

4. Check for an error logged against the primary or secondary DS1 board. If there is an error, follow the DS1 section to resolve the errors. If there is not, enter **enable sync**, and wait for two to five minutes for the primary sync source to come on-line.

**In Release 5si + memory:** This error indicates that some reference switches have occurred. If there is not a major SYNC alarm, then investigate other SYNC errors. If there is an active major SYNC alarm, and if this is not a Stratum 3 system, then follow the steps above.

- f. This error indicates that the Expansion Interface Link is experiencing timing slips. The two port networks are not synchronized. This error increases the bit error rates for data transmission between port networks. Verify that all the TDM/LAN Bus cables on the backplane are AT&T Parts number AT&T SK00199-001 rather than flat ribbon cables. Also, check that the bus terminators are the ZAHF V1 TDM/LAN Bus Terminator type. Refer to note (i) for error resolution steps.

This error is cleared by a leaky bucket strategy and takes one hour to clear (leak away) the error counter once it is alarmed. Therefore, it may take up to one hour to clear the alarm after the problem is cleared.

- g. This error indicates that the slave Tone-Clock circuit pack is experiencing loss of signal. Refer to note (i) for error resolution steps.
- h. The following steps should be executed to resolve error 2049 and 2305:
1. Check for timing loops, and resolve any loops that exist.
  2. Check the Error Log for any active as well as resolved Expansion Interface circuit pack errors and refer to EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation to resolve any errors found.

3. **High or Critical Reliability system:**

- Switch Tone-Clock circuit packs in the slave port network via the **set tone/clock PC** system technician command. The error count for this particular error should start decrementing once the problem is solved—if the count does not decrease in 15 minutes the problem still persists.

- If the problem still persists, switch the Tone-Clock in the slave port network back to the previous configuration. Then, switch Expansion Interface Links via the **set expansion-link PCSS** command.
- If the problem still persists, switch the Expansion Interface Links back to the previous configuration via the **set expansion-link PCSS**. Then, switch the Tone-Clock circuit packs in the master port network.
- If the problem still persists, switch the Tone-Clock circuit packs in the master port network back to the previous configuration. If the system synchronization reference is a Tone-Clock circuit pack, follow normal escalation procedures. If the system synchronization reference is a DS1 interface circuit pack, administer a different DS1 interface circuit pack as the primary synchronization reference.

#### 4. Standard system:—Error 2049:

- Test the Tone-Clock circuit packs in the master and slave port networks via the **test tone/clock PC long** command. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to “TDM-CLK” to resolve the problem. If not, continue with the following steps.
- If the master and slave Tone-Clock circuit packs **do not** fail TDM Bus Clock Test #150 (PPM Inquiry), replace the Expansion Interface circuit packs in the system.
- If the system synchronization reference is a Tone-Clock circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, follow the steps listed in “TDM-CLK” to replace the master Tone-Clock circuit pack.
- If the system synchronization reference is a DS1 interface circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, the primary or secondary (if administered) synchronization references are not providing valid timing signals for the system. Check the system synchronization references administered, and follow the steps outlined in note (a) if the primary synchronization reference is providing timing for the system or note (c) if the secondary synchronization reference is providing timing for the system.
- If the slave Tone-Clock circuit pack fails the TDM Bus Clock Test #150 but the master Tone-Clock **does not** fail this test, the master Tone-Clock circuit pack must be replaced. Follow the Tone-Clock replacement steps listed in the “TDM-CLK”.

If SLIP errors remain follow SLIP ANALYSIS.

5. **Standard system:**—Error 2305:

- Replace the Expansion Interface circuit pack in this port network and the Expansion Interface circuit pack in the PPN that is connected to this port network.
  - If the problem persists, replace the Tone-Clock circuit pack in the slave port network. Follow the steps listed in “TDM-CLK” to replace the Tone-Clock circuit pack.
- i. Noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a synchronization problem occurs causing error types 1, 257, or 513, a WARNING alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MAJOR or MINOR alarm.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Test Synchronization Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------|---------------------|--------------------|-------------------|
| Test Synchronization Test (#417) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

**Test Synchronization Test (#417)**

This test updates all the Synchronization Maintenance component circuit packs with the correct information regarding their role in providing synchronization for the system. All the Tone-Clock, Expansion Interface, and DS1 Interface circuit packs in the system are updated via this test. This test will either pass or abort.

**Table 10-403. TEST #417 Test Synchronization Test**

| Error Code | Test Result | Description/ Recommendation                                                                   |
|------------|-------------|-----------------------------------------------------------------------------------------------|
|            | ABORT       | Internal system error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times. |

Table 10-403. TEST #417 Test Synchronization Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                             |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | The Synchronization Maintenance component circuit pack parameters have been successfully updated. The system should be synchronized after successful execution of this test. If synchronization problems still exist, refer to the Error Log to obtain information regarding the source of the problem. |

## SYS-PRNT (System Printer)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| SYS-PRNT               | MINOR       | test sp-link l         | System Printer  |
| SYS-PRNT               | WARNING     | release sp-link        | System Printer  |

The Report Scheduler feature provides the capability to schedule selected administration commands to be printed by an asynchronous System Printer (SYS-PRNT) or sent to a Personal Computer (PC). The System Printer Link to this external device can be administered either as a data extension or to the EIA port on the switch Processor (PROCR) circuit pack which provides a standard EIA 232C interface.

System Printer Link Maintenance provides a strategy for maintaining the link between the system and an external SYS-PRNT output device. The strategy includes a set of tests for detection of errors during normal operation, troubleshooting actions, and alarms for serious problems. System Printer Link Maintenance uses a try-and-wait mechanism for maintaining the SYS-PRNT link. If the link set-up fails, a minor alarm is raised for service attention. A warning alarm is raised when the SPE has been busied out. A maximum of two link retry attempts is made. After the second attempt, set-up attempts are only made by the application software (that is, the 15-minute timer fires and jobs are printed unless an immediate job was entered.) After two unsuccessful attempts to establish the link, a MINOR alarm is raised for service attention. If the System Printer Link is torn down due to an error, System Printer Link Maintenance raises a MINOR alarm but does not attempt to bring up the System Printer Link.

In DEFINITY Generic 1, the following physical configurations are supported for the System Printer Link:

- a. from the EIA port on the Processor circuit pack to a SYS-PRNT output device via the standard EIA 232C interface
- b. from a data channel (DATA-CHL) on the Network Control circuit pack (DATA-BD) to a data extension where the SYS-PRNT output device connects via the standard EIA 232C interface

The data extension can be a(n) PDM, MPDM, DTDM, or ADU. The PDM, MPDM, or DTDM connects to a Digital Line (DIG-LINE) on the TN754 or TN754B Digital Line circuit pack (DIG-BD); the ADU connects to a Data Line (DAT-LINE) of the TN726 Data Line circuit pack (DT-LN-BD).

System Printer Link Maintenance does not cover the elements comprising the SYS-PRNT physical link; that is, the external SYS-PRNT output device, the EIA port on the Processor circuit pack, the Data Module (PDM/MPDM/DTDM) and the Digital Line of TN754 or TN754B Digital Line circuit pack, the ADU and the Data Line of TN726 Data Line circuit pack, and the data channels on the TN777

Network Control circuit pack. If System Printer Link Maintenance cannot restore the System Printer Link, the maintenance tests of these individual components of the System Printer Link must be executed to diagnose faults.

## Procedures for Restoring the System Printer Link

The following procedures should be followed to restore the System Printer Link:

1. Determine the status of the System Printer Link via the **status sp-link** command. Verify that the System Printer Link is not busied out for maintenance. On the System Printer Link Status Form, this is indicated by a "no" in the "Maintenance Busy?" field. If the System Printer Link has been busied out, issue the **release sp-link** command. If the link is "down," proceed to Step 2.
2. Issue the **display system feature** command to determine the destination of the System Printer Link.

If the destination is an *extension number*, enter the **status data-module <extension>** command and verify that the data extension is in-service/idle. If the data extension is NOT available, refer to the "Port/Channel Number" field on the "Data-Module Status" Form. Look for errors and/or alarms on the circuit pack with which this extension is associated. Refer to the appropriate MO documentation for recommended repair strategy. Continue with Step 3.

If the destination is *eia*, look for PR-MAINT errors in the Hardware Error Log. If errors are present, refer to Maintenance/Tape Processor Maintenance documentation, and continue with Step 5.

3. Determine if a data channel on the Network Control circuit pack is in-service/idle as follows:
  - a. Use the **list data-module** command to find out the extension numbers of the data channels on the Network Control circuit pack. (There is a maximum of 4. They are listed as "netcon" on the Active SPE. Ignore the Standby data channels.)
  - b. Enter the **status data-module <extension>** command to verify that at least one Active data channel is in-service/idle.
4. If four data channels are administered and none are available, then look for DATA-CHL/DATA-CON/DATA-BD errors in the Hardware Error Log. If errors are present, refer to these MO sections for recommended maintenance strategy. When problems (if any) with DATA-CHL/DATA-CON/DATA-BD have been resolved, continue with Step 5.

If fewer than four data channels are administered, then use the **add data-module** command to add a network control data module to the system.

5. Verify the availability of the external SYS-PRNT output device as follows:

Make sure that the SYS-PRNT output device is *on-line* and ready-for-service. Check the physical connectivity between the Data Module and the SYS-PRNT output device or between the EIA port on the backplane of the switch and the SYS-PRNT output device.

- 6. Verify that there are less than three active logins to the system. If this condition exists, a login session must be terminated before the System Printer Link can be established.

 **NOTE:**  
It is recommended that the System Printer Link be busied out before executing maintenance tests over objects which compose the System Printer Link. If the System Printer Link is busied out, then all System Printer Link maintenance actions are deactivated.

Error Log Entries and Test to Clear Values

Table 10-404. SYS-PRNT Maintenance Error Log Entries

| Error Type     | Aux Data | Associated Test        | Alarm Level                    | On/Off Board | Test to Clear Value |
|----------------|----------|------------------------|--------------------------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any                    | Any                            | Any          | test sp-link        |
| 18 (a)         | 0        | busyout sp-link        | WARNING                        | OFF          | release sp-link     |
| 257 (b)        | 1 to 6   | Link Retry Test (#215) | MINOR/<br>WARNING <sup>2</sup> | OFF          | test sp-link l      |
| 513 (c)        | 0        | None                   | MINOR                          | OFF          | test sp-link        |

- 1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- 2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. System Technician has busied out the System Printer Link.
- b. A failure was encountered while attempting to set up the System Printer Link. This attempt could have been initiated by either the Report Scheduler software or link maintenance [automatic link retry or the as the result of a Link Retry Test (#215) request]. The Aux Data field contains the following diagnostic information to aid in the correction of the failure:
  - 1.unavailability of system resources (too many active logins to the system).
  - 2.no data channels (DATA-CHLs) available on the Network Control circuit pack (DATA-BD).

- 3.4- time-out during setup attempt. Most likely due to problem with physical link or printer status.
- 4.internal system error. Most likely temporary/sporadic failure.
- 5.the data module the printer is trying to use is busy with another call. Use the **Status data module** command to determine when the port is available for testing.

Refer to the [“Procedures for Restoring the System Printer Link”](#) section for recommended maintenance strategy.

- c. The SYS-PRNT was interrupted because of one of the following reasons:
  - 1.the cable to the SYS-PRNT output device is disconnected;
  - 2.the SYS-PRNT output device is powered off;
  - 3.the data extension to which the SYS-PRNT output device connects has been busied out;
  - 4.internal software error.

Check the connectivity of the wires and cables among the wall jacket, data module, and SYS-PRNT output device. Follow the instructions provided in the [“Procedures for Restoring the System Printer Link”](#) section.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

When inspecting errors in the system and deciding which ones to address, always investigate errors in the order they are presented in the table below. By clearing error codes associated with the *Link Retry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------|---------------------|--------------------|-------------------|
| Link Tear Down Test (#213) |                     | X                  | D                 |
| Link Retry Test (#215)     | X                   | X                  | ND                |
| Link Tear Down Test (#213) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

**Link Tear Down Test (#213)**

**This test is destructive.**

The Link Tear Down Test disconnects the existing link between DEFINITY Generic 1 and the external SYS-PRNT output device. If the link has been

disconnected already, this test just returns PASS. All resources allocated for a System Printer Link are released after this test.

Table 10-405. TEST #213 Link Tear Down Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                    |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 40, 50     | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 2 times.                                                                                                                                      |
| 1010       | ABORT       | The System Printer Link has been busied out.<br>1. Enter the <b>release sp-link</b> command to release the System Printer Link from the busyout state.<br>2. Reissue the <b>test sp-link long</b> command to execute the test. |
|            | FAIL        | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 2 times.                                                                                                                                      |
|            | PASS        | The System Printer Link is torn down or a Short Test Sequence was executed and the link was not torn down.                                                                                                                     |

Link Retry Test (#215)

The Link Retry Test sends a message to the SYS-PRNT software process either (1) to make a data call to the extension to which the SYS-PRNT output device connects OR (2) to open the EIA port to the SYS-PRNT output device. If the System Printer Link is already up, this test passes without making a data call or opening the EIA port.

Table 10-406. TEST #215 Link Retry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                               |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10, 20     | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 2 times.                                                                 |
| 30         | ABORT       | Internal system error<br>1. Refer to the <a href="#">“Procedures for Restoring the System Printer Link”</a> section for recommended maintenance strategy. |

Table 10-406. TEST #215 Link Retry Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                            |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1010       | ABORT       | The System Printer Link has been busied out.<br><br>1. Enter the <b>release sp-link</b> command to release the System Printer Link from the busyout state.<br><br>2. Reissue the <b>test sp-link long</b> command to execute the test. |
|            | FAIL        | The System Printer Link CANNOT be established.<br><br>1. Refer to the <a href="#">"Procedures for Restoring the System Printer Link"</a> section for recommended maintenance strategy.                                                 |
|            | PASS        | The System Printer Link is up.                                                                                                                                                                                                         |

## SYSTEM (System)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO |
|------------------------|-------------|-------------------------------------|-----------------|
| SYSTEM                 | None        | None                                | SYSTEM          |

1. SYSTEM only has errors associated with it and thus only appears in the Error Log and not in the Alarm Log. There are no tests that can be run with SYSTEM.

SYSTEM is generally used when software encounters a problem with either hardware or itself and requests a restart to clear the problem. For example, if there is a loss of clock in a system with high or critical reliability, the system asks for a Reset 2 to switch to the other clock. SYSTEM also logs errors that cannot be associated with any single process. This is not a problem. The initcauses log should also confirm that a software-requested restart was performed.

### Error Log Entries and Test to Clear Values

The Aux Data field may be 0 or the return code from a bad software call, and the following examples in no way exhaust the possibilities. Often, two errors are logged at the same time for each problem.

Table 10-407. System Error Log Entries

| Error Type     | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-----------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any             | Any         | Any          | None                |
| 8 (a)          | 0        | None            |             |              |                     |
| 9 (b)          | Any      | None            |             |              |                     |
| 10 (c)         | Any      | None            |             |              |                     |
| 21 (d)         |          | None            |             |              |                     |
| 355 (e)        | Any      | None            |             |              |                     |
| 356 (f)        | Any      | None            |             |              |                     |
| 601 (g)        |          | None            |             |              |                     |
| 602 (h)        |          | None            |             |              |                     |
| 603 (i)        |          | None            |             |              |                     |
| 9012 (j)       | Any      | None            |             |              |                     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. A System Restart Level 3 was requested.
  - b. A System Restart Level 2 was requested. This can happen due to a loss of tones (due to a faulty Tone-Clock circuit pack).
  - c. A System Restart Level 1 was requested.
  - d. A process trapped.
  - e. A Restart Level 2 occurred due to a power loss.
  - f. A Restart Level 2 occurred due to a tone clock loss.
  - g. An error occurred during initialization.
  - h. An error occurred while loading translations and the system requested a Restart Level 3.
  - i. A process was reset.
  - j. In a Generic 1 system configured with High or Critical Reliability, a scheduled SPE-interchange was blocked because a tape operation was in progress.
-

TAPE (Tape Unit) [G3iV1.1-286]

| MO Name As It<br>Appears in<br>Alarm Log | Alarm<br>Level | Initial System<br>Technician<br>Command to Run | Full Name of MO |
|------------------------------------------|----------------|------------------------------------------------|-----------------|
| TAPE                                     | MAJOR          | test tape long <sup>1</sup>                    | Tape Unit       |
| TAPE                                     | MINOR          | test tape long                                 | Tape Unit       |
| TAPE                                     | WARNING        | test tape long                                 | Tape Unit       |

1. This alarm occurs only at power-up time or on a Reset System 3, 4, or 5 when the system cannot load **all** translations from tape. Refer to the footnote associated with Error Type 3329 in the "Hardware Error Log Entries and "Test to Clear Values" section.

**NOTE:**  
Alarms on the TAPE, PROCR, and PR-MAINT MOs are indicated by the red LED on the Processor circuit pack.

The Tape Unit consists of a Wangtek FAD3500 series tape drive mounted on the TN774 Tape Drive circuit pack, which is controlled by the TN773 Processor circuit pack. For tape controller functions, the processor uses memory on the TN770 Memory circuit pack.

The Tape Unit is used to:

- Boot the system
- Save or load translations and announcements
- Save the Error Logs
- Save core dumps

There are two versions of the **test tape** system technician command that can be used to initiate maintenance tests on the Tape Unit: one for Standard systems and one for High and Critical Reliability systems. In a Standard system, the command line entry to test the TAPE (Tape) MO is **test tape [short/long] [repeat n/clear]**. In a High or Critical Reliability Option system, the command line entry to test the TAPE (Tape) MO is **test tape [short/long] [a/b] [repeat n/clear]**.

In a High or Critical Reliability system, if an alarm is raised against the Tape Unit, the alarm also indicates the carrier (either 1A or 1B), depending on which SPE has the problem.

**NOTE:**  
CLEANING THE TAPE DRIVE HEAD IS VERY IMPORTANT because a tape drive head with abrasive particles can permanently damage a new tape. In

addition, a worn tape may leave abrasive particles in the tape drive head. Before implementing any of the following repair procedures, the tape head of all the tape drive units in the system should be cleaned. Follow the directions given in the ["Tape Drive Head Cleaning Procedure"](#) section.

Hardware Error Log Entries and Test to Clear Values

Tape Unit Error Log Entries

| Error Type | Aux Data | Associated Test            | Alarm Level | On/Off Board | Test to Clear Value |
|------------|----------|----------------------------|-------------|--------------|---------------------|
| 0 (a)      | 0        | Any                        | Any         | Any          | test tape           |
| 1 (b)      | Any      | Tape Status Test (#69)     | MINOR       | OFF          | test tape r 2       |
| 257 (c)    | Any      | Tape Status Test (#69)     | WARNING     | OFF          | test tape r 2       |
| 513        | Any      | Tape Reset Test (#67)      | MINOR       | OFF          | test tape l r 2     |
| 1025       | Any      | Tape Diagnostic Test (#66) | MINOR       | OFF          | test tape r 2       |
| 1281       | Any      | Tape Diagnostic Test (#66) | MINOR       | OFF          | test tape r 3       |
| 1537       | Any      | Tape Diagnostic Test (#66) | MINOR       | OFF          | test tape r 3       |
| 1793 (d)   | Any      | None                       | MINOR       | OFF          | see (d)             |
| 1828 (e)   | Any      | None                       | MINOR       | OFF          | see (e)             |

| 2051 (o)   | Any      | Tape Read/Write Test (#65) | WARNING     | OFF          | see (o)             |
| 2084 (g)   | Any      | None                       | WARNING     | OFF          | see (g)             |
| 2561       | Any      | Tape DMA Latch Test (#230) | MINOR       | ON           | test tape r 3       |
| 2817 (h)   | Any      | Tape Read/Write Test (#65) | MINOR       | OFF          | test tape l r 2     |
| 3329 (i)   | Any      | Save the Translations      | MINOR       | OFF          | see (i)             |
| 3841 (j)   | Any      | Save the Translations      | MINOR       | OFF          | save translation    |

Tape Unit Error Log Entries

| Error Type | Aux Data | Associated Test       | Alarm Level | On/Off Board | Test to Clear Value |
|------------|----------|-----------------------|-------------|--------------|---------------------|
| 3842 (k)   | Any      | Save the Translations | MINOR       | OFF          | save translation    |
| 3843 (l)   | Any      | Save the Translations | MINOR       | OFF          | save translation    |
| 3984(m)    | Any      | Save Translations     | MINOR       | OFF          | save translation    |
| 10498 (n)  | 0        | Save the Translations |             |              |                     |
| 10508 (o)  | 0        | Save the Translations |             |              |                     |

Notes:

- a. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. Error 1 indicates that the tape unit does not recognize that a cartridge is inserted into the tape drive. If, in fact, there is no cartridge in the drive, the problem can be corrected by simply inserting a cartridge. Follow the directions given in "Error Type #1 - Repair Procedure."

If there is a tape cartridge inserted into the tape drive, the problem is that certain tape or tape drive failures may cause the tape drive to erroneously report "missing tape" errors (tape Error Type #1 OR Aux Data value 9024). Since this error may be the result of a problem with either the tape or the tape drive unit, the tape cartridge should be replaced first. If the problem persists, the tape unit should be replaced. When this error is first detected, follow "Error Type #1 - Repair Procedure."

Error Type #1 - Repair Procedure:

- 1.Replace the tape cartridge (if one exists) in the tape unit associated with this error with a new tape cartridge.
- 2.Issue the **test tape [a/b] repeat 2** command for the tape drive unit that has the error.
- 3.If all the tests pass, assume that the problem has been resolved.  
  
If some of the tests fail, resolve the corresponding errors, and repeat step #2.
- 4.If translations have not already been saved onto the new tape, issue the **save translations** command.
- 5.If the system contains recorded announcements, issue the **save announcements** command.

If Error Type #1 reappears and becomes a chronic problem, the fault may be with the tape drive unit, and it could be intermittent in nature. In this case, replace the tape drive unit with a new tape drive unit and repeat "Error 1 - Repair Procedure." Refer to Step 5 of the "[Tape Maintenance and Repair Procedures](#)" section for directions on how to replace the tape drive unit.

- c. Error Type #257 indicates that the tape cartridge is write-protected. To disable the tape write-protect feature, move the sliding write-protect switch (which is labeled RECORD) on the tape cartridge away from the RECORD position. The RECORD position is indicated by an arrow pointing to the left. Error Type #257 can then be cleared by issuing the **test tape [a/b] repeat 2** command for the tape drive unit that has the error.
- d. Error Type #1793 is reported whenever the system software detects an uncorrectable tape block error during a read or write operation on the tape.

An **uncorrectable tape error** is one in which a block error persists during a read or write operation to the tape. Errors of this type were unable to be corrected by several attempts at rereading or rewriting the block on the tape. This type of error is most likely the result of one or more hard errors on the tape (for example, a scratch or a hole in the tape that spans multiple sectors).

The auxiliary data field indicates the file on the tape in which the error was detected. Refer to Table C for a list of possible auxiliary data field values and the corresponding tape file.

Since this error may be the result of a problem with either the tape or the tape drive unit, the tape cartridge should be changed first. If the problem persists, the tape unit should be changed. When this error is first detected, follow "Error Type #1793 - Repair Procedure."

Error Type #1793 - Repair Procedure:

1. Replace the tape cartridge in the tape unit on which the error occurred with a new tape cartridge.
2. [G1.2, G3iV1.1-286] Issue the **test tape [a/b] long clear** command for the associated tape drive unit.  
  
[G1.1] Issue the **test tape [a/b] long repeat 3** command for the associated tape drive unit. If the system release is earlier than G1.1, refer to Note (o) also.
3. If all tests pass, assume that the problem has been resolved.  
  
If some tests fail, resolve those errors and repeat Step #2.
4. If translations have not already been saved onto the new tape, issue the **save translations** command.
5. If the system contains recorded announcements, issue the **save announcements** command.

If this error reappears and becomes a chronic problem, the fault may be with the tape drive unit, and it could be intermittent in nature. In this case, replace the tape drive unit with a new tape drive unit and repeat "Error Type #1793 - Repair Procedure." Refer to Step 5 of the "[Tape Maintenance and Repair Procedures](#)" section for directions on how to replace the tape drive unit.

- e. Error Type #1828 is reported under the following conditions;
- [G3iV1, EDI 7.0 and earlier] This error is never reported.
  - [G3iV1, EDI 6.0 and earlier] Whenever Test #692 (Tape Block Error Test) fails due to an uncorrectable tape block error.
  - [G1.1] Whenever any maintenance test fails due to an uncorrectable tape block error.

To clear Error Type #1828, follow the procedures given in the footnotes for Error Type #1793.

- f. Error Type #2049 is reported under the following conditions;
- [G3iV1 EDI 7.0 and later] This error is never reported.
  - [G1.1, G3iV1 EDI 6.0 and earlier] Error Type #2049 is reported whenever the software detects a correctable tape block error during a read or write operation on the tape.

A **correctable tape error** is one in which a block error is detected but corrected during a read or write to the tape. This type of error may be caused by either a soft tape error (for example, the tape head is jiggled while reading or writing data), or by a hard tape error (for example, a scratch or a hole in the tape that affects only a single sector of the tape).

The auxiliary data field indicates the file on the tape in which the error was detected. Refer to Table C for a list of possible auxiliary data field values and the corresponding tape file.

With this error, the tape is fully functional but is in danger of developing an uncorrectable tape error. The tape cartridge should be changed when it is convenient to do so.

To clear Error Type #2049, follow the procedures given in the footnotes for Error Type #1793.

- g. Error Type #2084 is reported under the following conditions;
- [G3iV1 EDI 7.0 and later] This error is never reported.
  - [G3iV1 EDI 6.0 and earlier] Whenever Test #692 (Tape Block Error Test) fails due to a correctable tape block error.
  - [G1.1] Whenever any maintenance test fails due to an correctable tape block error.

To clear Error Type #2084, follow the procedures given in the footnotes for Error Type #1793.

- h. [G1.1, G3iV1 EDI 6.0 and earlier] Error Type #2817 is reported whenever the tape read/write test fails. The auxiliary data field indicates the cause of the test failure as follows:

|        |                                                                                |
|--------|--------------------------------------------------------------------------------|
| 9032 – | Significant portion of the scratch area on the tape cannot be read.            |
| 9033 – | Significant portion of the scratch area on tape cannot be written.             |
| 9034 – | Significant portion of the scratch area on the tape cannot be read or written. |

- i. Error Type #3329 indicates that an error occurred while loading translations. This error and the corresponding alarm occurs at power-up or on a Reset System 3, 4, or 5 if the system cannot load translations. This error results in a MAJOR alarm if translations are not already loaded and in a MINOR alarm otherwise. If the system does not contain valid translations, this alarm will invoke Emergency Transfer.

Standard System

 **NOTE:**  
The following repair procedure assumes that no major alarms exist on the PROCR (Processor) or MEM-BD (Memory) circuit packs. If any of these alarms exists, resolve them before trying to resolve this alarm.

Error Type #3329—Repair Procedure (Standard System):

- 1.Look in the Hardware Error Log for Error Type #1793. If this error exists, replace the tape cartridge with a backup cartridge that has valid system translations.
- 2.[G1.2, G3iV1.1-286] Issue the **test tape long clear** command.
- 3.[G1.1] Issue the **test tape long repeat 3** command.
- 4.If all tests except for Test #505 pass, assume that the problem has been resolved. Test #505 will fail if a successful load translations has not occurred.  
  
If some other tests besides Test #505 fail, resolve those errors, and repeat Step #2.
- 5.Issue the **reset system 3** command.
- 6.Issue the **list configuration software** command.
- 7.If the tape resident translations date is "none," insert a backup tape cartridge and go back to Step #2 (try up to 2 backup tapes).
- 8.If the problem is *not* resolved, follow normal escalation procedures.

High and Critical Reliability Systems

 **NOTE:**

In a High or Critical Reliability system, the following repair procedure assumes that no major alarms exist on the PROCR (Processor), MEM-BD (Memory), or DUPINT (Duplication Interface) circuit packs or on the STBY-SPE (Standby SPE) MO. If any of these alarms exists, resolve them before trying to resolve this alarm.

Both Active and Standby SPE Tapes alarmed

This situation arises whenever translations cannot be loaded on either SPE. If the system was powered up, both tapes were alarmed at almost the same time as a result of this error. It is very possible that no SPE-Interchange occurred. However, if the system was restarted as a result of a **reset system [3 | 4 | 5]** command, and when an alarm was raised against the Active SPE as a result of Error Type #3329, a Level 3 SPE-Interchange automatically occurred, and the "new" Active SPE attempted to load translations. When this SPE failed to load translations, its tape was alarmed as well.

Error Type #3329 - Repair Procedure #1 (High or Critical Reliability System):

1. Issue the **status system** command to determine which SPE (A or B), is the Active SPE. It is labeled as "active."
2. Use "Error Type #3329—Repair Procedure (Standard System)" to ensure that the tape and tape unit in the Active SPE are functioning properly and to read in translations.
3. Log into the Manager I terminal again and issue the **display alarms** command to see if any alarms were raised against the Active SPE tape.
  - a. If a major alarm against the Active SPE tape now exists, escalate the problem.
  - b. If minor alarms against the Active SPE tape now exist, resolve those alarms before continuing with Step #5.
  - c. If no alarm exists against the Active SPE tape, continue with Step #4.
4. Replace the tape in the Standby SPE. If a new tape is used, translations must have been successfully saved in order to clear Error Type #3329.
5. Issue the **refresh spe-standby** command. It may be necessary to issue this command multiple times. However, if you have issued the **refresh spe-standby** command five times, and if the Standby SPE is still not labeled "Standby" on the Status System Form, escalate the problem.

6. The Standby SPE must be in Standby Mode before issuing the **test tape [a/b] long** command. If the Standby SPE is not in Standby Mode, the additional tests needed to clear Error Type #3329 are not run. These additional tests also cause the **test tape [a/b] long** command to take longer to execute.

7. Test the Standby tape by issuing the **test tape [a/b] long** command. Issuing this command whenever the SPE contains an active Error Type #3329 causes the SPE to undergo a COLD 1 restart. This restart attempts to load translations and, if successful, it clears the error.

8. If the problem is not resolved, follow normal escalation procedures.

Only one SPE Tape alarmed

A typical scenario that results in a single minor TAPE alarm follows: The system boots up on an SPE and cannot read in translations. As a result, a major alarm against TAPE is raised. The system performs a Level 3 SPE-interchange and then reads in translations from the tape on the "new" Active SPE. At this point, the major TAPE alarm is downgraded to a minor TAPE alarm.

Error Type #3329 - Repair Procedure #2 (High or Critical Reliability System):

1. The tape against which Error Type #3329 has been logged should reside in the Standby SPE. Issue the **status system** command to determine which SPE is active.

If Error Type #3329 is logged against the Active SPE, follow Steps 1 through 3 of "Error Type #3329—Repair Procedure #1 (High and Critical Reliability Systems)."

If Error Type #3329 is logged against the Standby SPE, follow Steps 4 through 7 of "Error Type 3329 - Repair Procedure #1 (High and Critical Reliability Systems)."

2. Error while saving translations. Resolve other tape errors, and reissue the **save translations** command.

j. Error Type #3841 indicates that a save translations operation failed because the tape was in use. Wait two minutes, then issue the **save translations** command. Try this a maximum of five times.

k. Error Type #3842 indicates a save translation failure due to a tape-related problem. The following procedure is recommended to clear this error.

Error Type 3842 - Repair Procedure:

1. Look in the Hardware Error Log for Error Type #1793. If this error exists, replace the tape cartridge in the tape unit on which the error occurred with a new cartridge.

2. [G1.2 and later] Issue the **test tape [a/b] long clear** command for the associated tape drive unit.

[G1.1 and earlier] Issue the **test tape [a/b] long repeat 3** command for the associated tape drive unit.

3. If all tests up to Test #505 pass, assume that the problem has been resolved. Test #505 will fail if a successful save translations has not occurred since the original failure.

If any tests other than Test #505 fail, resolve those errors and repeat Step #3.

4. Issue the **save translations** command.

5. If the system contains recorded announcements, issue the **save announcements** command.

- l. Error Type #3843 indicates that during daily scheduled maintenance, the automatic save translation failed. The failure occurred most likely as a result of a hardware problem rather than a tape problem.

To clear Error Type #3843, follow the procedures given in the footnotes for Error Type #3842.

- m. [G1.1 and earlier] Translations were not saved on the tape(s) corresponding to the port field(s) indicated. In this case, the port field points to the Standby SPE at the time the error occurred. Resolve other tape errors, and then issue the **test tape long** and **save translations** commands, respectively.
    - n. [G1.1 and earlier] If these errors occur in conjunction with Error Type #3329, a major alarm is logged against the error type. To resolve this alarm, follow the instructions for Error Type #3329.
    - o. [G1.1 and earlier] "Leaky Bucket" strategy for Error Types #1793, #1828, #2049, #2051, and #2084 on the Active SPE. Whenever any of these errors appear in the Error Log, they will be automatically resolved within 48 hours if the errors do not recur within that period. In G1.0, this is the only way these errors can be cleared (without resetting the system).
-

System Technician Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Tape DMA Latch Test* for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                    | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------|---------------------|--------------------|-------------------|
| Tape Reset Test (#67)                     |                     | X                  | ND                |
| Tape DMA Latch Test (#230)                | X                   | X                  | ND                |
| Tape Diagnostic Test (#66)                | X                   | X                  | ND                |
| Tape Read/Write Test (#65) (a)            |                     | X                  | ND                |
| Tape Block Error Test (#692) (b)          |                     | X                  | ND                |
| Tape Status Test (#69)                    | X                   | X                  | ND                |
| Tape Translation Status Test (#505)       |                     | X                  | ND                |
| TAPE-DAT Tape Consistency Test (#421) (c) |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. The Tape Read/Write Test only runs in the following software releases;
  - G1
  - G3iV1, EDI 6.0 and earlier.
- b. The Tape Block Error Test runs only in software release G3iV1, EDI 15.0 and earlier.
- c. Refer to TAPE-DAT (Tape Consistency) Maintenance documentation for the description of this test.

Tape Read/Write Test (#65)

The purpose of this test is to exercise the hardware read/write circuitry and the basic functionality of the tape cartridge. This test is done by reading 22 blocks of data and by then writing 22 blocks of data into reserved space on the tape cartridge.

**NOTE:**  
This test does not check for tape cartridge data consistency, nor does it check the integrity of every block on tape.

**Table 10-408. TEST #65 Tape Read/Write Test**

| Error Code                    | Test Result   | Description/ Recommendation                                                                                                                                    |
|-------------------------------|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1029 to 1030 and 2011 to 2051 | ABORT         | Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.                                                          |
| 9000's                        | ABORT or FAIL | Refer to Table A in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data.                  |
| Any Others                    | ABORT or FAIL | Refer to Table B in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data.                  |
|                               | PASS          | All tape hardware is in good working order. Passing this test does not guarantee that every single data block on the tape cartridge can be read or written to. |

**Tape Diagnostic Test (#66)**

This test activates the diagnostic tests built into the Maintenance/Tape Processor (MTP) firmware on the TN773 Processor circuit pack. The test verifies the basic read/write capability of the tape drive and tape cartridge. Also, the test performs controller/MTP hardware diagnostics.

The test reads from the tape and performs write verification testing by writing data into a maintenance block and reading it back. It also performs a tape drive head step check by advancing the tape drive head through all even streams on the tape (streams 0 through 18) to make sure the head is operational.

The test does not test every data block on the tape.

Table 10-409. TEST #66 Tape Diagnostic Test

| Error Code   | Test Result   | Description/ Recommendation                                                                                                                   |
|--------------|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 1029 to 2051 | ABORT         | Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.                                         |
| 9000's       | ABORT or FAIL | Refer to Table A in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data. |
| Any Others   | ABORT or FAIL | Refer to Table B in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data. |
|              | PASS          | This is a comprehensive test of the Tape Unit. The test verifies that the tape drive is in good working order.                                |

Tape Reset Test (#67)

This test resets the tape portion of the Processor on the Maintenance/Tape Processor (PR-MAINT), and it resets the shared RAM on the Processor circuit pack (TN770). The test can pass when no drive is present because it never accesses the tape drive.

Table 10-410. TEST #67 Tape Reset Test

| Error Code   | Test Result | Description/ Recommendation                                                                                                                   |
|--------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 1029 to 2051 | ABORT       | Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.                                         |
| 9000's       | FAIL        | Refer to Table A in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data. |
| Any Others   | FAIL        | Refer to Table B in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data. |
|              | PASS        | Communication with the tape processor is possible at a very basic level.                                                                      |

Status Request Test (#69)

This test requests the Maintenance/Tape Processor (MTP) firmware on the TN773 Processor circuit pack for the current Tape Unit status and displays the results.

Table 10-411. TEST #69 Status Request Test

| Error Code   | Test Result | Description/ Recommendation                                                                                                                   |
|--------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| 1029 to 2051 | ABORT       | Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.                                         |
| 9000's       | ABORT       | Refer to Table A in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data. |
| Any Others   | FAIL        | Refer to Table B in <a href="#">"Tape Unit Aux Data/Error Codes Tables"</a> and follow the recommended repair strategy for specific Aux Data. |
|              | PASS        | This test verifies the basic communication between the Processor and the Tape Drive circuit pack.                                             |

Tape DMA Latch Test (#230)

Also known as the *Tape Interface Test*, this test checks the shared RAM on the TN770 Memory circuit pack. The test also checks the communication paths on the TN773 Processor circuit pack.

Table 10-412. TEST #230 DMA Latch Test

| Error Code   | Test Result | Description/ Recommendation                                                                                                                                                                                      |
|--------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1029 to 2051 | ABORT       | Refer to the STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.                                                                                                            |
| 23001        | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem. |

|            | FAIL        | The tape is currently alarmed because a save translation or a load translation attempt failed on this tape. Look for Errors Types #3329, #3841, #3842, and #3843 in the Hardware Error Log and resolve these errors by following the procedures provided in the "Hardware Error Log Entries and Test to Clear Values" section.                                                                                                                                                                                                                                                                                                                        |
|            | PASS        | The last load translation and (if any) save translation attempts were successful on this tape.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Tape Block Error Test (#692)

This test is performed by rereading the list of tape blocks that have been reported by the software to contain correctable (Error Type #2049) or uncorrectable (Error Type #1793) block errors.

A **correctable tape error** is one in which a block error is detected but corrected during a read or write to the tape. This type of error may be caused by either a soft tape error (for example, the tape head is jiggled while reading or writing data) or by a hard tape error (for example, a scratch or a hole in the tape that affects only a single sector of the tape).

An **uncorrectable tape error** is one in which a block error persists during a read or write operation to the tape. Errors of this type are unable to be corrected by several attempts at rereading or rewriting the block on the tape. This type of error is most likely the result of one or more hard errors on the tape (for example, a scratch or a hole in the tape that spans multiple sectors).

This test passes only if no block errors of any type are detected after the test completes. Otherwise, the test fails and returns an error code of the form "x0y," where:

- x** indicates the number of uncorrectable block errors detected by the test [0-5]
- y** indicates the number of correctable block errors detected by the test [0-5]

The software stores the block location for at most five errors of each type.

**Table 10-414. TEST #692 Tape Block Error Test**

| Error Code   | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

How to Use Table B to Determine Aux Data Values

In this table, the numbers can have one to five digits. If the first or leftmost digit is "1," the number has five digits. If the first digit or leftmost digit is "2," the number has four digits. If the first or leftmost digit is "3," the number has three digits. If the first or leftmost digit is "4," the number has two digits. If the first or leftmost digit is

"5," the number has one digit. For example, if the number is "2300," "2" indicates that the tape cartridge should be replaced soon. "3" indicates that the Tape Drive could not read or write at least one block of data from the tape.

| 0     | 0                           | Exact cause of error is not determined.                                   | <div>1. Follow the instructions provided in the <a href="#">"Tape Maintenance and Repair Procedures"</a> section.</div> <div>2. If the tape alarm still exists, escalate the problem. If this is the only error and there is no alarm, ignore this error.</div> |
| 1     | 1xxxx                       | If the aux data is "10000," the error is non-fatal.                       | Ignore the "10000" case.                                                                                                                                                                                                                                        |
|       |                             | Each of the last four digits of the Aux Data "1xxxx" is a non-zero value. | Follow the steps in the appropriate aux data section.                                                                                                                                                                                                           |
| 2     | 2xxx                        | The tape cartridge should be replaced soon.                               | <div>1. Follow the instructions provided in the <a href="#">"Tape Maintenance and Repair Procedures"</a> section.</div> <div>2. If the problem still exists, escalate the problem.</div>                                                                        |
| 3     | 3xx                         | Cannot read or write at least one block of data from the tape.            |                                                                                                                                                                                                                                                                 |
| 4     | 4x                          | A problem was found reading the Shared Memory.                            |                                                                                                                                                                                                                                                                 |
| 5     | 5                           | Tape drive self-test failed.                                              |                                                                                                                                                                                                                                                                 |

Aux Data Values Indicating the Tape File Type

This table translates Aux Data values to the corresponding tape file type.

Table 10-417. Table C. Tape File Types

| Aux Data Value | File Type                                   |
|----------------|---------------------------------------------|
| 0              | Primary Translation File                    |
| 1              | Backup Translation File                     |
| 2              | Core Dump File                              |
| 3              | Program Update File                         |
| 4              | Boot Image File                             |
| 6              | Error Log File (not including scratch area) |
| 12             | Stored Announcement File                    |
| 16             | Processor Interface Firmware File           |
| 17             | Header Block                                |
| 19             | Packet Control Firmware File                |
| 20             | NIPM File                                   |
| 21             | X25 File                                    |
| 22             | Primary Directory File                      |
| 23             | Backup Directory File                       |

Tape Drive Head Cleaning Procedure

The tape drive head (also called the tape head) should be cleaned at least once a year. **However, as part of the preventive maintenance strategy, it is recommended that you inspect the tape head during each maintenance visit and that you clean the tape head several times a year.** In addition, a dated label should be placed on the tape drive unit after the tape head is cleaned. You should also complete the "AT&T Preventive Maintenance Log" sheet. (Refer to [Chapter 5, "Routine Maintenance Procedures"](#).)

New tapes leave more abrasive particles on the tape head. Therefore, if a new tape is used, issue the **test tape long repeat 3** command, and then clean the tape head.

The tape head can be accessed for cleaning from the front of the drive by opening the tape access door with your finger. See [Figure 10-90](#).

**Figure 10-90. Front View of the Tape Drive**

To position the tape drive head properly for cleaning, do the following:

1. Install a tape cartridge into the drive with the power on.
2. Wait 10 seconds or until the spinning of the tape stops.
3. Remove the tape cartridge.

**CAUTION:**

*The tape drive head should be cleaned by using only Freon TF and polyurethane swabs. These products are usually available in VCR head cleaning kits sold in video stores.*

4. Wet the swab with the Freon TF solution.
5. Using a "side-to-side" motion, wipe the tape drive head.

**WARNING:**

*DO NOT GET TAPE HEAD CLEANING SOLUTION ON THE CAPSTAN.*

6. With a dry swab, wipe away any remaining residue from the tape head.

## **Tape Maintenance and Repair Procedures**

This section contains commonly used procedures to resolve tape alarms. The following equipment may be needed to complete these procedures:

- Tape Cartridges (3)
- TN774 Tape Drive Circuit Pack (1)
- TN773 Processor Circuit Pack (1)
- TN770 Memory Circuit Pack (1)

**NOTE:**

In the following repair procedures, the term "main tape(s)" is used to refer to the tape(s) that were physically present in the tape drive(s) at the time the problem occurred. The "main tape(s)" should not be confused with the term "backup tape(s)". Backup tapes are physically stored outside of the tape drive(s). The term "new tape(s)" refers to the three new tapes that you should bring with you to the customer's site; these tapes may be needed to complete the tape maintenance procedures. The new tapes should not have been used previously in the customer's system. **It is very important to keep track of these tapes.**

1. Check the Error Log for power-related problems and refer to the POWER, DC-POWER, and CARR-POW Maintenance documentation sections. If no power errors exist, check the tape drive for power as follows:
  - If there is a problem with the 12V supplied to the tape drive, its yellow LED will be in a blinking mode. The 12V is supplied by the 631DB or 676B power unit in a multicarrier cabinet system and by a WP91153 in the single-carrier cabinet system. This problem can also be caused by a failure in the 984D DC power converter on TN774 Tape Drive circuit pack.
  - If there is a problem with the five volts supplied to the tape drive, there is no visible way to determine this except by using the TN2036 Voltage Range circuit pack (see the "Troubleshooting Backplane Voltage Problems" section in [Chapter 5, "Routine Maintenance Procedures"](#) or by using the following procedure:

Insert a tape cartridge into the tape drive. There should be a spinning noise indicating that the tape drive is doing a short retention pass. If there is no noise, the power may be disconnected.

2. Check for a dirty tape drive head.

- Clean the tape drive head (refer to the [“Tape Drive Head Cleaning Procedure”](#) section, which immediately precedes this section).
- Reinsert the main tape cartridge (for example, the tape that was in the tape drive). Make sure the tape is not write-protected.
- Issue the **test tape long repeat 3** or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

If all tests pass:

The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was a dirty tape drive head.

If any of the tests failed, proceed to Step 3.

3. Check the health of the main tape cartridge.

- Clean the tape drive head again since the main tape may have left abrasive particles on the tape drive head during the execution of the **test tape** commands.
- Insert the backup tape cartridge. **Make sure it is not write-protected.**
- Issue the **test tape long repeat 3** command or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

If all tests pass:

The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was a defective main tape. Mark the defective tape and follow the standard disposal procedures.

If any of the tests failed, proceed to Step 4.

4. Check for the health of the backup tape.

- Clean the tape drive head again since the backup tape may have left abrasive particles on the tape drive head during the execution of the **test tape** commands.
- Insert a new tape cartridge.

**CAUTION:**

*Make sure that the tape is not write-protected and that the new tape contains the same or newer vintage of software compared to the vintage currently in the system.*

- Issue the **test tape long repeat 3** command or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

If all tests pass:

The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was that both the main tape and backup tape became defective. Mark the defective tape and follow the standard disposal procedures.

Use the following procedure to save translations and announcements on the new tape:

- On a High or Critical Reliability system, issue the **refresh spe-standby** command. It may be necessary to issue this command multiple times. However, if you have issued the **refresh spe-standby** command five times and the Standby SPE is still not labeled "Standby" on the Status System Form, escalate the problem.
- Issue the **save translations** command. If there is a TN750 Announcement circuit pack in the system, issue the **save announcements** command. Saving announcements may take longer than 30 minutes to complete.
- If this is a High or Critical Reliability system, run the Tape Consistency Test (#421) by issuing the **test tape [a|b] long** command. Refer to the TAPE-DAT Maintenance documentation to resolve any errors.
- Clean the tape head since new tapes leave more abrasive particles on the tape head (refer to the ["Tape Drive Head Cleaning Procedure"](#) section).

If any of the tests fail, proceed to Step 5.

5. Check the health of the tape drive.

**WARNING:**

*Vintage 6 and Vintage 8 of the TN773 Processor circuit pack in a Medium Cabinet use 12V DC power supplied from the Tape Drive circuit pack and thus may cause severe service disruption when the Tape Drive circuit pack is unseated from its slot. Therefore, when repairing a High or Critical Reliability system with this configuration, make the carrier with tape errors/alarms the Standby carrier before proceeding. For a Standard system with this configuration, arrange to do the work in off-hours before proceeding.*

- Replace the tape drive. **DO NOT TURN OFF THE POWER.**
- Clean the tape drive head of the new tape drive.
- Insert the main tape cartridge.
- Issue the **test tape long repeat 3** command, or, for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

If all tests pass:

The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was that the original tape drive was defective. (To see the hardware errors against the TAPE MO, issue the **display errors** command. Enter "a" in the Interval field and "tape" in the Category field.)

If any of the tests fail, proceed to Step 6.

6. Determine if the defective tape drive has damaged the tapes.

- Clean the tape drive head again since the main tape may have left abrasive particles on the tape drive head during the execution of the **test tape** commands.
- Insert a new tape (not the one used in Step 4).

**CAUTION:**

*Make sure that the tape is not write-protected and that the new tape contains the same or newer vintage of software compared to the vintage currently in the system.*

- Issue the **test tape long repeat 3** command, or for a High or Critical Reliability system, the **test tape [a|b] long repeat 3** command.

If all tests pass:

The alarm should be cleared ([G1 Only] unless Error Type #1793, #1828, #2049, or #2084 is present, in which case 48 hours must elapse). The problem was that the original drive is defective and that it damages any tape you put in it. (To see the hardware errors against the TAPE MO, issue the **display errors** command. Enter "a" in the Interval field and "tape" in the Category field.)

If the alarm persists, the cause of the problem is either the Maintenance/Tape Processor (MTP) residing on the TN773 Processor circuit pack or the Shared Memory (SRAM) on the TN770 Memory circuit pack. **Replacement of either of these two circuit packs in a Standard system requires powering down of the control carrier.** Therefore, use the following procedures to determine that there is a good (bootable) tape with the customer's translations (since the main and backup tapes may have been corrupted and, as a result, would then prevent the successful reading in of translations during power-up).

**NOTE:**

Follow Steps 7 through 10 for Standard systems and Steps 11 through 13 for High or Critical Reliability systems.

**For Standard Systems**

 **NOTE:**

Before performing the following repair procedures, refer to the "Handling Control Circuit Packs" section in [Chapter 5, "Routine Maintenance Procedures"](#) for instructions on how to replace a circuit pack in a Standard system.

7. **Make sure that there is a good tape drive and a good tape with the customer's translations before powering down the system.**

- Insert a new tape cartridge. **Recall that a "new tape" is a tape that has not been used previously in the customer's system.**

**CAUTION:**

*Make sure that the tape is not write-protected and that the new tape contains the same or newer vintage of software compared to the vintage currently in the system.*

- Try to make a tape with the customer's translations by issuing the **save translations** command. If successful, proceed to Step 8. If the translations were not saved successfully, request that the TSC remotely make a copy of the customer's tape by saving the translations and announcements. When you receive this tape from the TSC, continue with Step 8.
8. With the tape that has the customer's translations set aside, replace the TN770 Memory circuit pack.

**CAUTION:**

*Make sure that you are using the customer's existing tape drive and tape and not the tape made in Step 7.*

- Power down the system.
- Replace the TN770 Memory circuit pack.
- Power up the system.
- If the existing tape cannot bring up the system with the customer's translations, replace the tape drive and tape with a new tape drive and the tape made in Step 7. Reboot the system again.
- If the tape made in Step 7 cannot bring up the system with the customer's translations, proceed to Step 9.
- If the system comes up with the customer's translations, enter the **test tape long repeat 3** command.

If all tests pass:

The problem was a defective Memory circuit pack. If the tape was replaced, the Memory circuit pack and the tape may be defective.

If any test failed, proceed to Step 9.

9. Replace the TN773 Processor circuit pack.

- Power down the system.
- Reinsert the original TN770 Memory circuit pack.
- Replace the TN773 Processor circuit pack.
- Power up the system.
- If the system boots up with the customer's translations, enter the **test tape long repeat 3** command.

If all tests pass:

The problem was a defective TN773 Processor circuit pack. The TN770 Memory circuit pack is working fine.

If any test failed or if the system cannot be brought back into service successfully, proceed to Step 10.

10. Replace the TN770 Memory circuit pack. Use both the new Memory circuit pack and the new Processor circuit pack.

- Power down the system.
- Replace the TN770 Memory circuit pack.
- Power up the system.
- If the system comes up with the customer's translations, issue the **test tape long repeat 3** command.

If all tests pass:

The problem was a defective Memory circuit pack and a defective Processor circuit pack.

If any test still fails, escalate the problem.

## For High or Critical Reliability Systems

### NOTE:

Before performing the following repair procedures, refer to the ["Circuit Pack Replacement Procedure"](#) section in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions on how to replace a circuit pack in a High or Critical Reliability System.

**Make sure that the SPE that has the alarmed tape/tape drive is the Standby SPE before replacing the Processor circuit pack or the Memory circuit pack.**

11. Replace the TN770 Memory circuit pack on the STANDBY control carrier.

- Replace the TN770 Memory circuit pack (see the previous Note).
- Test the tape in the Standby control carrier by issuing the **test tape [a|b] long repeat 3** command, where "[a|b]" is the Standby control carrier.

If all tests pass:

The problem was a defective Memory circuit pack.

If any test failed, proceed to Step 12.

12. Replace the TN773 Processor circuit pack on the STANDBY control carrier.
  - Reinsert the original TN770 Memory circuit pack.
  - Replace the TN773 Processor circuit pack (see the previous Note).
  - Test the tape in the Standby Control Carrier by issuing the **test tape [a|b] long repeat 3** command, where "[a|b]" is the Standby control carrier.

If all tests pass:

The problem was with the TN773 Processor circuit pack.

If any test failed, proceed to Step 13.

13. Replace the TN770 Memory circuit pack on the STANDBY control carrier. Use both the new Memory circuit pack and the new Processor circuit pack.
  - Replace the Memory circuit pack (see the previous Note).
  - Test the tape in the Standby Control Carrier by issuing the **test tape [a|b] long repeat 3** command, where "[a|b]" is the Standby control carrier.

If all tests pass:

The problem was a defective Memory circuit pack and a defective Processor circuit pack.

If any test still fails, the problem could be with other control carrier circuit packs. Replace each circuit pack, one at a time, until all the tape tests pass. If the problem persists, escalate the problem.

## TAPE-DAT (Tape Consistency)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO  |
|------------------------|-------------|------------------------|------------------|
| TAPE-DAT               | MINOR       | test tape a/b l        | Tape Consistency |

In High and Critical Reliability systems, the system software translations, as well as other information, can be stored on two tapes: one in the Active SPE and one in the Standby SPE. In order to flag a problem when these tapes become mismatched, Tape Consistency monitors the translations, announcements, update files, and software vintage number on both tapes in a High or Critical Reliability PPN system. If the translation time stamp, announcement time stamp, and update file time stamp and identifiers on the two tapes are not the same and/or if the software vintage numbers do not match, an alarm is raised. The software vintage can be displayed via the **list configuration software-vintage** command. The Tape Consistency Test is run on system technician command and once a week as part of daily Standby SPE maintenance. Tape Consistency does not apply and does not exist in Standard systems.

### Error Log Entries and Test to Clear Values

Table 10-418. Tape Consistency Error Log Entries

| Error Type             | Aux Data | Associated Test              | Alarm Level | On/Off Board | Test to Clear Value |
|------------------------|----------|------------------------------|-------------|--------------|---------------------|
| 0 <sup>1</sup>         | 0        | Any                          | Any         | Any          | test tape a/b l     |
| 8 or 16                | 8 or 16  | Tape Consistency Test (#421) | WARNING     | OFF          | test tape a/b l     |
| 1-7,<br>9-15,<br>17-86 | 8 or 16  | Tape Consistency Test (#421) | MINOR       | OFF          | test tape a/b l     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. An "8" in the log refers to carrier A and a "16" refers to carrier B. The Aux Data field records which SPE was active at the time the Tape Consistency Test failed.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Tape Diagnostic Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                    | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------|---------------------|--------------------|-------------------|
| Tape Reset Test (#67) (a)                 |                     | X                  | ND                |
| Tape DMA Latch Test (#230) (a)            | X                   | X                  | ND                |
| Tape Diagnostic Test (#66) (a)            | X                   | X                  | ND                |
| Tape Read/Write Test (#65) (a) (b)        |                     | X                  | ND                |
| Tape Block Error Test (#692) (a) (b)      |                     | X                  | ND                |
| Tape Status Test (#69) (a)                | X                   | X                  | ND                |
| Tape Translation Status Test (#505) (a)   |                     | X                  | ND                |
| TAPE-DAT Tape Consistency Test (#421) (c) |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. See TAPE (Tape Unit) Maintenance documentation for this test description.
- b. This test does not run in release G3iV1 EDI 7.0 or later.
- c. The Tape Consistency Test does not run in a Standard system.

Tape Data Consistency Check Test (#421)

The software vintage number, translation time stamps, announcement time stamps, and update file time stamps and identifiers are read off both tapes and compared. If the comparison shows any discrepancy, TAPE-DAT is alarmed. This test is run in a High or Critical Reliability Option system. The test is run as part of the **test tape long** and as part of weekly TAPE maintenance.

Table 10-419. TEST #421 Tape Data Consistency Check Test

| Error Code                                                                                                                                   | Test Result    | Description/ Recommendation                                                                                                                                                                                                                                                                                                                |

Table 419. TEST #421 Tape Data Consistency Check Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 44         | FAIL        | The update files, load vintages, and announcements are different in both SPEs. The Active SPE has the most current update file and announcements.                                                                                                                                                                                                                                                                                                                                               |
| 45         | FAIL        | The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, translations, and announcements.                                                                                                                                                                                                                                                                                                                  |
| 46         | FAIL        | <p>The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and announcements, and the Standby SPE has the most current translations.</p> <p>1. Follow the procedures for Error Code 4 to get the correct load vintage. Be sure to save announcements. After running the <b>test tape long</b> command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.</p> |
| 48         | FAIL        | <p>The update files and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current announcements.</p> <p>1. Follow the procedures for Error Code 40.</p>                                                                                                                                                                                                                                                               |
| 49         | FAIL        | The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and translations, and the Standby SPE has the most current announcements.                                                                                                                                                                                                                                                                                         |
| 50         | FAIL        | <p>The update files, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current translations and announcements.</p> <p>1. Follow the procedures for Error Code #41.</p>                                                                                                                                                                                                                              |
| 52         | FAIL        | The update files, load vintages, and announcements are different in both SPEs. The Active SPE has the most current update file, and the Standby SPE has the most current announcements.                                                                                                                                                                                                                                                                                                         |
| 53         | FAIL        | The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file, and translations, and the Standby SPE has the most current announcements.                                                                                                                                                                                                                                                                         |
| 54         | FAIL        | <p>The update files, load vintages, translations, and announcements are different in both SPEs. The Active SPE has the most current update file and the Standby SPE has the most current translations and announcements.</p> <p>1. Follow the procedures for Error Code 4 to get the correct load vintage. After running the <b>test tape long</b> command, check for Error Code #32 or #64. Follow the recovery procedure under the applicable error code.</p>                                 |

## TDMODULE (Trunk Data Module)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO   |
|------------------------|-------------|------------------------|-------------------|
| TDMODULE <sup>1</sup>  | MINOR       | test port PCSSpp I     | Trunk Data Module |
| TDMODULE (a)           | WARNING     | test port PCSSpp I     | Trunk Data Module |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...,etc.); and pp is the 2-digit port number (for example, 01).

The TDMODULE (Trunk Data Module) Maintenance documentation is covered in the PDMODULE (Processor Data Module) Maintenance documentation.

## TDM-BUS (TDM Bus)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| TDM-BUS                | MAJOR       | test tdm P             | TDM Bus         |
| TDM-BUS                | MINOR       | test tdm P             | TDM Bus         |
| TDM-BUS                | WARNING     | test tdm P             | TDM Bus         |

The TDM Bus consists of a duplicated TDM Bus on each port network (PPN and EPN): TDM Bus A and TDM Bus B. Each TDM Bus consists of 256 time slots. The first five time slots on each bus are called the Control Channel. The Control Channel is active on only one bus at a time in each Port Network. The next 17 time slots are reserved for dedicated tones (that is, dial tone). These time slots are called the dedicated tone time slots and only one bus at a time carries the dedicated tones. The rest of the time slots on each bus are for general system use (that is, phone call).

On system initialization, the Control Channel is on TDM Bus A and the dedicated tones on TDM Bus B in each Port Network.

Systems with High or Critical Reliability have the ability to set the Control Channel and Tone Bus to a specific TDM Bus via the **set tdm PC** command, where **P** stands for the Port Network Number and **C** stands for the TDM Bus A or B (A for TDM Bus A or B for TDM Bus B). Throughout this document, PC is used to refer to a TDM Bus.

Terminology:

- Control Channel Bus - The TDM Bus control channel is on.
- Non-Control Channel Bus - The TDM Bus control channel is NOT on.
- Tone Bus - The TDM Bus dedicated tone time slots are on.
- Non-Tone Bus - The TDM Bus dedicated tone time slots are NOT on.

### TDM Bus Fault Detection and Isolation Procedure

TDM Bus faults are most likely caused by a defective circuit pack connected to the backplane or bent pins on the backplane. It is possible that a circuit pack can cause a TDM Bus fault but still exhibit trouble-free operation. For example, the insertion of an MBUS (Memory Bus) only circuit pack can bend the TDM Bus pins on the backplane and short two leads together. The four circuit packs that may cause this problem are the TN770 Memory circuit pack, the TN777 80286 Processor circuit pack, the TN772 Duplication Interface circuit pack, and the TN777 Network Control circuit pack. The latter exists only on High and Critical Reliability systems. Since the TDM Bus is a shared resource, automatic

identification of the cause of a TDM Bus fault is difficult. If a TDM Bus problem is suspected, the system technician should run the **test tdm P** system technician command. If any of the resulting tests fail, then the system technician must manually perform a TDM Bus isolation procedure to identify the cause of the problem.

**WARNING:**

*Since the TDM Bus fault isolation procedure involves removing circuit packs and possibly disconnecting entire carriers, the procedure is extremely destructive to the port network that contains the TDM Bus being tested. If possible, this procedure should be used after hours or during hours with minimum system use.*

As circuit packs are removed or entire carriers are disconnected, any active calls terminating on those circuit packs or carriers are dropped. If the system technician has any hints about a particular circuit pack that may be causing the TDM Bus problem (for example, a new circuit pack was inserted into the Port Network just before the TDM Bus problem appeared), then those hints should be investigated before performing this procedure.

For this procedure, make sure at least one Tone Detector circuit pack is in the same Port Network in which the TDM Bus fault is being isolated. The Tone Detector circuit pack is needed by maintenance to test the TDM Bus.

Procedure 1

This procedure is an attempt to isolate the TDM Bus fault to circuit packs that are essential to the system operation. For each of the following circuit packs, perform Procedure 1.

| Circuit Pack                                                             | Error Log Names               |
|--------------------------------------------------------------------------|-------------------------------|
| Tone-Clock                                                               | TONE-BD, TONE-PT, and TDM-CLK |
| Network Control                                                          | SW-CTL                        |
| Tone Detector                                                            | DETR-BD, GPTD-PT, and DTMR-PT |
| Processor Interface                                                      | PI-BD and PI-PT               |
| Duplication Interface—only for systems with High or Critical Reliability | DUPINT                        |
| Expansion Interface                                                      | EXP-INTF                      |

1. Display the Hardware Error and Alarm Logs for the circuit pack via the **display errors** and **display alarms** commands.
2. If there are errors for the circuit pack, refer to its Maintenance documentation and try to resolve the errors.

3. Whether or not all the errors can be cleared, test the TDM Bus again via the **test tdm P** command.
4. If some TDM Bus tests fail, continue with the next circuit pack.
5. If there are no more circuit packs in the list, go to Procedure 2.
6. If all the TDM Bus tests pass, the problem has been fixed.

## Procedure 2

This procedure removes and re-inserts port circuit packs (purple slot); one or several at a time.

If all of the TDM Bus tests pass when the circuit pack is removed, but some of the tests fail when the circuit pack is inserted, the circuit pack is the cause of the problem and should be replaced. If some of the tests fail regardless of whether the circuit pack is inserted or removed, the circuit pack is not the cause of the problem (see Note). Repeat this procedure for each purple slot circuit pack in the Port Network.

### NOTE:

Of course, in a multiple failure situation, the circuit pack may be one cause of the TDM Bus problem and there may be other failures that are causing TDM Bus faults. Also, the circuit pack itself may not be the cause of the problem, but the backplane pins may have been bent when the circuit pack was inserted.

1. Remove port circuit packs which have failed the NPE Crosstalk Test (#6) first. To find which circuit packs failed this test, display the Hardware Error Log via the **display errors** command. Refer to the Maintenance documentation of each port circuit pack that has port errors to check if any error indicates the failure of the NPE Crosstalk Test.
2. If no circuit pack failed the NPE Crosstalk Test (#6), remove one or several purple slot circuit packs.
3. Run the **test tdm P** command.
4. If any of the TDM Bus tests fail:
  - Check if the backplane pins in the removed circuit pack's slot appear to be bent.
  - If the backplane pins are bent, straighten or replace the pins, re-insert the circuit pack, and do this procedure again for the same circuit pack.
  - If the backplane pins are not bent, re-insert the circuit pack and do this procedure for the next set of circuit packs.
5. If none of the TDM Bus tests fail:
  - Re-insert the circuit pack.
  - Run the **test tdm** system technician command.

- If any of the TDM Bus tests fail, the re-inserted circuit pack is faulty. Replace the circuit pack and do this procedure again for the new circuit pack.
- If none of the TDM Bus tests fail, then the problem has been fixed.

### Procedure 3

This procedure removes and re-inserts control carrier circuit packs one at a time. The Network Control circuit pack and the Processor Interface circuit pack are the only processor complex circuit packs that communicate on the TDM Bus, and thus are the only processor complex circuit packs likely to cause a TDM Bus problem in a stable system. This procedure should be performed for the Processor Interface circuit pack before it is attempted for any other processor complex circuit packs.

#### In a System Without High or Critical Reliability

To perform this procedure for the Network Control circuit pack, this circuit pack must be replaced. The system cannot operate without the Network Control circuit pack.

1. Power down the control carrier.
2. Remove the suspected circuit pack.
3. Check if the backplane pins in the removed circuit pack's slot appear to be bent.
4. If the backplane pins are bent:
  - Straighten or replace the pins.
  - Insert the same circuit pack.
  - Repeat from Step 2 with the same circuit pack.
5. If the backplane pins are not bent, insert or replace the circuit pack.
6. Turn the power back on to reboot the system.
7. Run the **test tdm P** command.
8. If any of the TDM Bus tests fail:
  - If the circuit pack in Step 5 was inserted, do this step again replacing the circuit pack.
  - If the circuit pack in Step 5 was replaced, do this step again with the next circuit pack.
9. If none of the TDM Bus tests fail, the problem has been fixed.
10. If this step fails to identify the cause of the problem, go to Procedure 4.

## In a High or Critical Reliability System

A less destructive procedure for processor complex circuit packs can be used rather than the one described for standard systems. Perform the procedure on the Processor Interface circuit pack and Network Control circuit pack before it is attempted for any other processor complex circuit packs.

Pulling out processor complex circuit packs from the Standby SPE does not require powering down the carrier and does not require starting the system again. See [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for more details.

1. Perform Procedure 2 for the suspected processor complex circuit pack in the Standby SPE to determine if it is causing the TDM Bus problem. The **status system** command indicates which SPE is in standby mode. If the suspected circuit pack is the Tone-Clock circuit pack, make sure it is in standby mode via the **status system** command or its LED state. The SYSTEM CLOCKS and SYSTEM TONES fields of the status system form should read "standby" or the yellow LED on the circuit pack is off.

### ⇒ NOTE:

When doing Procedure 2 as a request of Procedure 3, pull out processor circuit packs instead of purple slot port circuit packs.

2. If it fails to identify the processor complex circuit pack as the cause of the problem, perform an SPE switch via the **reset system i** command (see Note).

### ⇒ NOTE:

Make sure that the current Standby SPE is in the standby mode via the **status system** command before performing the SPE switch.

3. Perform Procedure 2 for the suspected processor complex circuit pack in the new Standby SPE to determine if it is causing the TDM Bus problem.
4. If it fails again to identify the processor complex circuit pack as the cause of the problem, perform Procedure 2 for the remaining processor complex circuit packs.
5. If this procedure fails to identify the cause of the problem, go to Procedure 4.

## Procedure 4

Procedure 4 attempts to isolate the failure to a particular set of carriers, and then checks only the circuit packs in those carriers. This procedure involves terminating the TDM Bus so that certain carriers are disconnected from the TDM Bus. This is done by moving the TDM Bus terminators (AHF1) on the carrier backplane. To terminate a TDM Bus at the end of a particular carrier, the TDM Bus cable that connects the carrier to the next carrier should be unplugged and replaced with the TDM Bus terminator. The TDM Bus terminators can be taken from one carrier to the other. To get to the TDM Bus cables, remove the back

cover of the cabinet. When the length of the TDM Bus is modified via this procedure, the circuit packs that are essential to system operation and TDM Bus maintenance (for example, Network Control circuit pack, Tone-Clock circuit pack, Tone Detector circuit pack) must still be connected to the new *shortened* TDM Bus.

### For the Processor Port Network (PPN)

1. Terminate the TDM Bus so that it extends within the active control carrier.
2. Run the **test tdm** system technician command. If any of the TDM Bus tests fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in those carriers connected to the *shortened* TDM Bus. Procedure 2 is performed for port circuit packs (purple slots) and Procedure 3 for control carrier circuit packs.
3. If none of the TDM Bus tests fail, extend the TDM Bus to another carrier and repeat this procedure. When a carrier is added that causes some of the TDM Bus tests to fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.

### For the Expansion Port Network (EPN)

1. Terminate the TDM Bus so that it only extends within the carrier containing the active Expansion Interface (EXP-INTF) circuit pack.
2. Run the **test tdm** system technician command. If any of the TDM Bus tests fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in those carriers connected to the shortened TDM Bus.
3. If none of the TDM Bus tests fail, extend the TDM Bus to another carrier and repeat this procedure. When a carrier is added that causes some of the TDM Bus tests to fail, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.

If the above steps fail to identify a particular circuit pack or slot, the problem may be caused by a TDM Bus common component such as the termination resistors on the ends of the bus.

### Restarting Nonfunctioning Port Circuit Packs

A defective TDM Bus Control Channel or system timing reference on one of the networks can result in port circuit packs (that is non-control carrier circuit packs) on this defective network entering the reset state. When this situation occurs, the circuit pack stops functioning and its red LED lights. The system does not detect the presence of a circuit pack when the circuit pack is in the reset state. Hence, executing the **list config board PCSS** command indicates that the circuit pack is not present.

If a circuit pack enters the reset state when the control channel is on TDM Bus PT (where network P contains the circuit pack), this circuit pack stops functioning

until it receives a restart message when the control channel is on the same TDM Bus PT or when this circuit pack is powered up again.

To force the system to send a restart message to all circuit packs on a network, try one of the following methods depending on the circumstances:

**NOTE:**

A circuit pack functioning normally (that is, not in the reset state) ignores the restart message.

### Procedure 1 (Nondestructive)

Execute the Idle Time Slot Test (#294) by issuing the command **test tdm P** when the control channel is on the same TDM Bus as it was when the circuit pack entered the reset state. If using this method is not feasible, try the other procedures in this section.

### Procedure 2 (Non-Destructive)

**if you are at the site:** Reseat the circuit pack. This action causes the circuit pack that was in the reset state to begin functioning on the *current* Control Channel bus.

### Procedure 2 (Nondestructive)

Execute the Idle Time Slot Test (#294) by issuing the command **test tdm P** when the control channel is on the same TDM Bus as it was when the circuit pack entered the reset state. If using this method is not feasible, try the other procedures in the section.

### Procedure 3 (Destructive)

Reset the port network that contains the circuit pack that is in the reset state. When a network is reset, two restart messages, one on the control channel of each TDM Bus, are sent to each circuit pack on the network. Executing the **reset system L** command (where L=2, 3, 4, or 5) resets all networks in the system. *To reset an EPN only*, busyout all links to the EPN via the **busyout board PCSS** command and then release them via the **release board PCSS** command.

**WARNING:**

*The **reset system** command disrupts all calls in the system. Resetting the EPN only disrupts all calls going to and originating from the EPN.*

### Procedure 4 (Destructive)

Execute the **recycle carrier PC** command where P is the Port Network Number of the network containing the circuit pack and C is the designation of the carrier containing the circuit pack.

 **WARNING:**

*This command removes power and returns power to the designated Medium cabinet port carrier. Thus, any other circuit packs on this carrier is also temporarily taken out-of-service.*

Error Log Entries and Test to Clear Values

Table 10-420. TDM Bus Error Log Entries

| Error Type     | Aux Data | Associated Test             | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-----------------------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any                         | Any         | Any          | test tdm            |
| 1              | 0        | Control Channel Test (#296) | MINOR       | ON           | test tdm P r 3      |
| 18 (a)         | 0        | busyout tdm PC              | WARNING     | ON           | release tdm PC      |
| 35 (b)         | 0-1      | TDM Bus Corruption          | MINOR       | ON           | set tdm PC          |
| 257 (c)        | 0        | none                        | MAJOR       | ON           |                     |
| 513 (d)        | Any      | Idle Time Slot Test (#294)  | MINOR       | ON           | test tdm P r 3      |
| 769 (e)        | Any      | Idle Time Slot Test (#294)  | WARNING     | ON           | test tdm P r 3      |
| 769 (f)        | Any      | Idle Time Slot Test (#294)  |             |              | (see Notes)         |
| 1025           | Any      |                             |             |              |                     |
| 3872 (g)       | Any      | none                        |             |              |                     |
| 3873 (g)       | Any      | none                        |             |              |                     |
| 3874 (g)       | Any      | none                        |             |              |                     |
| 3877 (g)       | Any      | none                        |             |              |                     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

 **NOTE:**

For TDM-BUS, an ON-BOARD alarm refers to a problem with the TDM-BUS itself.

Notes:

- a. The TDM Bus has been busied out by the technician. The error retires when the technician releases the TDM Bus.

- b. This error indicates the TDM Bus is corrupted. If the corruption was on the Control Channel bus and this system has High or Critical Reliability, TDM Bus maintenance automatically switches the control channel and/or tones to the other bus. The same strategy applies if the corruption was on the bus carrying the tones.

An aux data value of 0 indicates the last reported TDM Bus corruption was on the Control channel bus.

An aux data value of 1 indicates the last reported TDM Bus corruption was on the Non-Control channel bus.

If this error is logged on both TDM Buses (A and B) on the PPN within two or three minutes, the red LED of several circuit packs may or may not be lit and there could be Switch Control errors. Under these circumstances do the following:

- Display the Hardware Error Log via the **display errors** command and look for SW-CTL (Switch Control) errors.
  - If there are any errors logged against the Switch Control, try to resolve them.
  - Test the TDM Bus via the **test tdm P** command.
  - If all the TDM Bus tests pass, the problem has been fixed.
  - If some of the TDM Bus tests fail, replace the Duplication Interface circuit pack in the A carrier (see [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for details). None of the Duplication Interface circuit pack tests detect this particular type of failure. Therefore, all its tests may still pass.
  - Test the TDM Bus via the **test tdm P** command.
  - If all the TDM Bus tests pass, the problem has been fixed.
- c. This error indicates the TDM Bus was switched to the other bus due to TDM Bus corruption. The aux data value is not meaningful and no action is required.
- d. This error indicates that some time slots are corrupted in the specified TDM Bus. The Minor alarm is raised when there are more than 50 bad time slots in the bus. The aux data indicates the number of bad time slots found by the test.
- e. This error indicates that some time slots are corrupted in the specified TDM Bus. The Warning alarm is raised when there are more than 10 bad time slots but less than or up to 50 bad ones in the bus. The aux data value indicates the number of bad time slots found by the test.
- f. This error indicates the idle time slot test found less than 10 bad time slots in the TDM Bus. The aux data value indicates the number of bad time slots found by the test. There is no alarm associated with this error.

- g. These errors indicate communication problems. On a High or Critical Reliability system, TDM Bus maintenance may switch the Control Channel bus and/or Tone bus to the other bus. Test the TDM Bus via the **test tdm P** command and follow the procedures according to the error codes reported from the test.
- The aux data value shows the Angel ID number for which a downlink message was lost.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Control Channel Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------------|---------------------|--------------------|-------------------|
| Control Channel Test on the Control     |                     |                    |                   |
| Channel Bus (#296)                      | X                   | X                  | ND                |
| Digit Detection Test on the Non-Control |                     |                    |                   |
| Channel Bus (#297)                      | X                   | X                  | ND                |
| Idle Time Slot Test on TDM Bus A (#294) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Idle Time Slot Test on TDM Bus A or B (#294)

The Idle Time Slot Test detects noisy time slots on the bus and takes them out-of-service. The Tone Detector circuit pack is told to listen to idle time slots and if it detects any noise on a time slot, it returns a failure. At the end of the test, any out-of-service time slots are retested to see if they are still noisy and restored to service if they are idle. After all the time slots have been tested, maintenance counts the number of bad time slots and reports the number to the technician in the error code field. No more than 220 time slots are taken out-of-service on one bus, and no more than 300 are taken out-of-service on both buses at one time.

Table 10-421. TEST #294 or #295 Idle Time Slot Test on TDM Bus A or TDM Bus B

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none       | ABORT       | Could not allocate the necessary system resources to run this test. For example, maintenance could be running on the Tone Detector circuit pack and it is using the CPTRs.                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 1115       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| number     | FAIL        | The error code indicates the number of bad time slots that were detected. The cause of this failure is most likely due to a bad port circuit pack and not the TDM Bus itself.<br><br>1. Execute the command again.<br><br>2. If the error persists, check the Error and Alarm Logs for alarms on port circuit packs from the NPE Crosstalk Test.<br><br>3. Refer to the appropriate circuit pack's documentation to clear the circuit pack's problem.<br><br>4. Test the TDM Bus again. If the error continues, refer to the <a href="#">"TDM Bus Fault Detection and Isolation Procedure"</a> described earlier. |
|            | PASS        | The success of this test indicates all the idle time slots that are supposed to be idle are indeed idle. There is no noise on any of the idle time slots.                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

Control Channel Test (#296)

This test tests the integrity of the Control Channel bus. It ensures that communication through the TDM Bus is operational.

Table 10-422. TEST #296 Control Channel Test

| Error Code               | Test Result | Description/ Recommendation                                                                                                                                                                                                           |
|--------------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| any code other than 1005 | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                             |
| 1005                     | ABORT       | Since this test is valid only on the control channel bus, it aborts execution when run on the non-control channel bus. This is a valid response. Use the <b>status system</b> command to verify which bus is the control channel bus. |

Table 10-422. TEST #296 Control Channel Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

|            | PASS        | <p>Communication through the TDM Bus is operational.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

Digit Detection Test (#297)

This test is executed on the Non-Control Channel bus. The Tone-Clock circuit pack is told to put a tone on the Non-Control Channel bus and the Tone Detector circuit pack is told to listen to it. The test passes if the tone is successfully transmitted on the Non-Control Channel bus.

Table 10-423. TEST #297 Digit Detection Test

| Error Code            | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|-----------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none,<br>1001<br>2100 | ABORT       | Could not allocate the necessary system resources to run this test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 1005                  | ABORT       | Since this test is valid only on the non-control channel bus, it aborts execution when run on the control channel bus. This is a valid response. Use the <b>status system</b> command to verify which bus is the control channel bus.                                                                                                                                                                                                                                                                                                                                                                    |

Execute the command again.<br><br>4. If the problems persists, refer to the <a href="#">“TDM Bus Fault Detection and Isolation Procedure”</a> described earlier. |
|                       | PASS        | The non-control channel bus is operational.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

System Technician-Demanded Tests:  
Descriptions and Error Codes

Use the **list configuration control** command to find the Tone-Clock circuit pack code of the system, and then proceed to look for the Short and Long Test Sequences according to the Tone-Clock circuit pack code.

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *SAKI Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For a system with a TN756 Tone-Clock Circuit Pack:

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| SAKI Reset Test (#53) (a)                  |                     | X                  | D                 |
| Clock Health Test (#46) (b)                | X                   | X                  | ND                |
| Control Channel Loop Around Test (#52) (a) | X                   | X                  | ND                |
| Tone Detection Verification Test (#42) (c) | X                   | X                  | ND                |
| Tone Detector Audit/Update Test (#43) (c)  | X                   | X                  | ND                |
| Tone Generator Crosstalk Test (#90) (d)    |                     | X                  | ND                |
| Tone Generator Transmission Test (#40) (d) | X                   | X                  | ND                |
| Tone Generator Audit/Update Test (#41) (d) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.
- b. Refer to TONE-BD (Tone-Clock Circuit Pack) documentation for a description of this test.
- c. Refer to Dual Tone Multifrequency Receiver Port (TTR) (DTMR-PT) or General Purpose Tone Detector Port (CPTR) (GPTD-PT) Maintenance documentation for descriptions of this test.
- d. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.

For a system with a TN768,TN780 or TN2182 Tone-Clock Circuit Pack:

Table 10-424. System Technician-Demanded Tests: TDM-BUS

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| SAKI Reset Test (#53) (a)                  |                     | X                  | D                 |
| Clock Health Test (#46) (b)                | X                   | X                  | ND                |
| Control Channel Loop Around Test (#52) (a) | X                   | X                  | ND                |
| Tone Generator Crosstalk Test (#90) (c)    |                     | X                  | ND                |

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| Tone Generator Transmission Test (#40) (c)       | X                   | X                  | ND                |
| Tone Generator Audit/Update Test (#41) (c)       | X                   | X                  | ND                |
| TDM Bus Clock Circuit Status Inquiry Test (#148) | X                   | X                  | ND                |
| TDM Bus Clock Slip Inquiry Test (#149) (e)       | X                   | X                  | ND                |
| TDM Bus Clock PPM Inquiry Test (#150)            | X                   | X                  | ND                |
| TDM Clock Board Type (#574)                      |                     | X                  | ND                |
| TDM Bus Clock Parameter Update Test (#151)       | X                   | X                  | ND                |
| Standby Reference Health Check Test (#651) (d)   |                     | X                  | ND                |

1. D = Destructive, ND = Non-destructive

- Notes:
- a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.
  - b. Refer to TONE-BD (Tone-Clock Circuit Pack) documentation for a description of this test.
  - c. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.
  - d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above or be a TN2182.
  - e. Test #149 is not run on a TN2182.

**TDM Bus Clock Slip Inquiry Test (#149)**

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack. This test does not apply to the TN2182.

Table 10-425. TEST #149 TDM Bus Clock Slip Inquiry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| ANY        | FAIL        | This error represents the number of timing slips detected on the incoming synchronization source since the last slip inquiry was sent to the Tone-Clock circuit pack. The incoming synchronization source can be from one of three sources: (1) a DS1 Interface circuit pack, (2) an EXP-INTF circuit pack if the port network on which the test was executed does not contain the current system synchronization reference; (3) a local oscillator on an Active Tone-Clock circuit pack. The error code is a variable amount ranging from 1 to 255.<br><br>1. If there are errors against synchronization (SYNC), refer to the Synchronization Maintenance documentation to change the system synchronization reference.<br><br>2. If there are errors against DS1 Interface circuit pack (DS1-BD), refer to the DS1 Interface circuit pack Maintenance documentation to resolve the errors. |

| Error Code       | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ANY<br>(cont'd.) | FAIL        | <div>3. If there are no SYNC or DS1-BD errors and<ol style="list-style-type: none"><li>this error was logged against the Tone-Clock circuit pack that was the current system synchronization reference at the time (use the command <b>status synchronization</b> to determine this), replace this Tone-Clock circuit pack.</li></ol><div> <b>NOTE:</b><br/>Disruption may occur when executing the following procedures.</div><ol style="list-style-type: none"><li>the Tone-Clock circuit pack you are testing is in Active mode but does not contain the current system synchronization reference, switch the synchronization reference to the Tone-Clock circuit pack under test via the <b>set synchronization PC</b> command. Retry the command. If the error is still present, replace this Tone-Clock circuit pack.</li><li>the Tone-Clock circuit pack under test is in Standby mode, make it active via the <b>set tone-clock PC</b> command and switch the synchronization reference to it. Reissue the command. If the error is still present, replace this Tone-Clock circuit pack.</li></ol></div> |
|                  | PASS        | The Tone-Clock circuit pack does not detect any timing slips. This indicates that the external synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The <b>status synchronization</b> command should be used to verify that the desired synchronization reference is providing timing for the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

TDM Bus Clock PPM Inquiry Test (#150)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack.

Table 10-426. TEST #150 TDM Bus Clock PPM Inquiry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|------------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ANY<br>(cont'd.) | FAIL        | <div>4. If there are no other errors besides Error Type 1537 against TDM-CLK and if this error was logged against the Tone-Clock circuit pack that provided the current system synchronization reference (use the <b>status synchronization</b> command to determine this), replace the defective Tone-Clock circuit pack.</div> <div> <b>WARNING:</b><br/><i>Since service may be disrupted when the following procedures are carried out, try to perform the following steps when it is convenient for the customer.</i></div> <div>5. If the Tone-Clock circuit pack under test is in the Active mode but is not providing the current system synchronization reference, switch the synchronization reference to the Tone-Clock circuit pack under test using the <b>set synchronization PC</b> command. Rerun the test. If the test still fails, replace the defective Tone-Clock circuit pack.</div> <div>6. If the Tone-Clock circuit pack under test is in the Standby mode place it in the Active mode via the command <b>set tone-clock PC</b>. Switch the synchronization reference to the Tone-Clock circuit pack under test using the <b>set synchronization PC</b> command. Rerun the test. If the test still fails, replace the defective Tone-Clock circuit pack.</div> |
|                  | PASS        | The Tone-Clock circuit pack does not detect timing any PPM errors. This indicates that the external synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The <b>status synchronization</b> command should be used to verify that the desired synchronization reference is providing timing for the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

TDM Bus Clock Parameter Update Test (#151)

This action updates the Tone-Clock internal circuit pack parameters. Tone-Clock circuit pack:

- Disable in-line duplication status messages.
- Disable in-line subrate frame maintenance messages (TN768, TN780 only).
- Set the PPM threshold at 60 PPM for TN768 and TN780. Set the PPM threshold at 85 PPM for TN2182.
- Enable PPM threshold switching

- Set the number of slips to trigger *loss of signal* - currently 30 per 5 millisecond period
- Enable the on-board synchronization switching algorithm (see above)
- Enable holdover operation (TN2182 only).

This is not a test and will always pass without identifying or reporting any Tone-Clock circuit pack errors.

TDM-Clock Circuit Pack Type Test (#574)

The purpose of this query is to check if the required type of Tone-Clock circuit pack (TN780) is present when the Stratum 3 clock is administered.

Table 10-428. TEST #574 TDM Clock Circuit Pack Type Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                            |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | The system could not allocate the necessary resources for the test.<br><br>1. Wait 1 minute and retry the test.                                                                                                                                        |
|            | FAIL        | The Tone-Clock circuit pack in the system is not a TN780. The Stratum 3 clock requires a TN780 Tone-Clock circuit pack.<br><br>1. Replace the Tone-Clock circuit pack with a TN780. The old circuit pack may still be good, and need not be discarded. |
|            | PASS        | The required TN780 circuit pack is present.                                                                                                                                                                                                            |

Standby Reference Health Check Test (#651)

This test evaluates the quality of the external synchronization timing source for the Standby Tone-Clock circuit pack.

Table 10-429. TEST #651 Standby Reference Health Check Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | This test may already be running due to a tone-clock installation, scheduled maintenance, alarm activity, or a technician-demand test from another terminal. This abort can also occur due to an internal system error.<br><br>1. Try the command again at 1-minute intervals up to five times.                                                                                                                                                                                                                 |
| 1184       | ABORT       | This test requires an external synchronization source to be administered (DS1 primary, DS1 primary and secondary, or Stratum 3 Clock).<br><br>1. Administer the external synchronization source and retry the test.                                                                                                                                                                                                                                                                                             |
| 2500       | ABORT       | Internal system error<br><br>1. Try the command again at 1-minute intervals up to 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0          | FAIL        | <b>If the Tone-Clock circuit pack is in the PPN</b> , the external synchronization timing source for side A of the Stratum 3 clock, or for the Primary DS1 reference is either absent or invalid. <b>If the Tone-Clock circuit pack is in an EPN</b> , the synchronization reference from the active EI circuit pack is either absent or invalid.                                                                                                                                                               |
| 1          | FAIL        | <b>If the Tone-Clock circuit pack is in the PPN</b> , both external synchronization timing sources are either absent or invalid. <b>If the Tone-Clock circuit pack is in an EPN</b> , the synchronization references from both EI circuit packs are either absent or invalid.<br><br>1. Correct the synchronization source problem. Refer to the Synchronization (SYNC) maintenance section of this manual.<br><br>2. If the error still exists, replace the Tone-Clock circuit pack reported in the error log. |
|            | PASS        | The external synchronization timing source is valid.                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## TDM-CLK (TDM Bus Clock)

| MO Name (in Alarm Log) | Alarm Level | Initial Command To Run <sup>1</sup> | Full Name of MO |
|------------------------|-------------|-------------------------------------|-----------------|
| TDM-CLK                | MAJOR       | test tone-clock UUC short           | TDM Bus Clock   |
| TDM-CLK                | MINOR       | test tone-clock UUC short           | TDM Bus Clock   |
| TDM-CLK                | WARNING     | release tone-clock UUC              | TDM Bus Clock   |

1. UU is the universal cabinet number (1 for PPN, 2 -44 for EPNs). C is the carrier designation (A, B, C, D, or E).

**⇒ NOTE:**  
Replacing the tone/clock circuit pack requires a special procedure described in the documentation for TONE-BD. That section also describes the LED displays for this board.

The Time Division Multiplex (TDM) Bus Clock resides on the Tone-Clock circuit pack, providing clocking signals both for the TDM Bus and the LAN Bus. The Tone-Clock circuit pack is a critical component in the system and is necessary to ensure the operation of all port circuit packs in the system. The TDM buses of the PPN and any EPNs are synchronized together. The system timing reference can be derived internally from the Tone-Clock circuit pack in any PN, or from an external (off-board) timing reference. Currently, the TDM Bus Clock supports synchronizing the TDM Bus with interface rates from Digital Signal 1 (DS1) facilities as primary or primary and secondary references, and from Stratum 3 Clock (STRAT-3) facilities. Only the TN780 tone-clock supports a Stratum 3 clock.

Moreover, the Tone-Clock circuit pack aids in monitoring and selecting synchronization references. The Tone-Clock circuit pack, after detecting that the external source of timing is not valid, will automatically begin its escalation procedure, according to the facilities administered.

**⇒ NOTE:**  
Switching back to a DS1 source is handled by synchronization maintenance, once any problems with it have been corrected and tested. However, once synchronization has been switched to the internal timing source of the master Tone-Clock circuit pack, *switching back to a Stratum 3 Clock must be initiated by a technician* after the external reference has been repaired.

| Tone-Clock Role | Synchronization Facilities | Initial External Synchronization Source | Backup External Synchronization Source | Internal Source  |
|-----------------|----------------------------|-----------------------------------------|----------------------------------------|------------------|
| MASTER          | Stratum 3 Clock            | Source "A"                              | Source "B"                             | Local oscillator |
|                 | DS1 Primary and Secondary  | DS1 Primary                             | DS1 Secondary                          |                  |
|                 | DS1 Primary Only           | DS1 Primary                             | None                                   |                  |
|                 | No External Source         | None                                    | None                                   |                  |
| SLAVE           | PNC Duplication            | Active EI                               | Standby EI                             |                  |
|                 | No PNC Duplication         | Active EI                               | None                                   |                  |

See [“SYNC \(Synchronization\)”](#) for more details of the escalation plan. *There exists a strong interdependency among the DS1 Interface circuit pack Maintenance, Synchronization Maintenance, and TDM Bus Clock Maintenance MOs.*

See the section on “TONE-BD” for a discussion of the relationship of Tone-Clock circuit packs with the various Reliability Options.

Error Log Entries and Test to Clear Values

Table 10-430. TDM Bus Clock Error Log Entries

| Error Type     | Aux Data | Associated Test                     | Alarm Level        | On/Off Board <sup>1</sup> | Test to Clear Value         |

- 
- As a general rule, any *on board* errors against the TDM Bus Clock should be resolved before pursuing any other errors against SPE or PNC components. *Off board* clock errors may be caused by other board errors, and should usually be addressed once any on board errors have been resolved.
  - Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
  - Major or Minor alarms on this MO may have been downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. The Tone-Clock circuit pack may have a clock at the edge of its specified frequency. This can cause Expansion Interface circuit packs and SNI circuit packs to go out-of-frame or report no-neighbor conditions. This can in turn cause EPNs, Expansion Archangel Links (EALs), Remote Neighbor Links (RNLs), and/or Local Neighbor Links LNLs) to go down. When this error is alarmed, Clock Health Inquiry Test (#46) will fail with an error code of 1.  

1.Replace the Tone-Clock circuit pack identified in the error log. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.
- b. The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock UUC** command. It only applies to systems which have the High or Critical Reliability Option administered, because only a standby Tone-Clock circuit pack may be made busy by that command. To resolve this error, execute the **release tone-clock UUC** command for the alarmed circuit pack.
- c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

- d. The Tone-Clock circuit pack in the PPN is not a TN780 while a Stratum 3 synchronization is administered. Replace the Tone-Clock in the PPN with a TN780, or change synchronization administration to Stratum 4 if a Stratum 3 clock is not being used.
- e. The tone-clock has reported an out-of-lock condition. A aux value of 1 indicates this error is an out-of-lock with the primary reference. A aux value of 2 indicates this error is an out-of-lock with the secondary reference. It could not lock onto the frequency of that synchronization reference. This will lead to a change in the synchronization reference if the condition continues.
- f. The Tone-Clock circuit pack may be defective.

1. If this error was logged against an Active Tone-Clock circuit pack, then test that circuit pack via the **test tone-clock UUC**. If there are error codes from any tests, follow the recommended maintenance procedures for the error code(s) to resolve the problem(s). If all tests pass, consider the 769 error type to have been a transient problem, and clear the error log entry with **test tone-clock UUC long clear**.

2. If this error was logged against the Standby Tone-Clock circuit pack, and if the Aux Data value was 18369, Synchronization maintenance acts on this error. No corrective action is required. For all the other Aux Data values, replace the Standby Tone-Clock circuit pack. Refer to the TONE-BD section on "How to Replace the Tone-Clock Circuit Pack".

- g. Tone-Clock circuit pack on-board maintenance has detected one or more *clock slips*, timing differences between its internal reference source and the synchronization signal provided by the master Tone-Clock. Although no clock slip errors are expected during normal operation, both manual and automatic interchanges of Tone-Clock circuit packs, synchronization references, and PNCs, may result in clock slip counts.

If error 1281 also is logged for the same Tone-Clock circuit pack, it is related to this problem, and should be corrected first. Otherwise, continue with the procedure below.

1. Use **test tone-clock UUC**, and examine the results of test #149 to see if slip errors are still occurring. If no new slip errors are reported, and if these errors are not causing a TDM-CLK alarm, they may be ignored. Use **test tone-clock UUC long clear** to clear the errors.

2. Otherwise, enter the **display errors** command, and follow corrective procedures for any other TDM-CLK, TONE-BD, SYNC, DS1C-BD, EXP-INTF, SNC-BD, and SNI-BD errors logged, except for those in the following table.

| Error Log Entries for Slip Errors |                |                           |
|-----------------------------------|----------------|---------------------------|
| Circuit Pack Name                 | Error Log Name | Error Log Entry for Slips |
| DS1 Interface                     | DS1-BD         | 3073 to 3160              |
| Expansion Interface               | EXP-INTF       | 2305                      |
| Switch Node Interface             | SNI-BD         | 1537                      |
| Tone-Clock                        | TDM-CLK        | 1025                      |
| UDS1 Interface                    | UDS1-BD        | 3073 to 3160              |
| DS1C Circuit Pack                 | DS1C-BD        | 3329                      |

3.If 1025 errors persist, refer to SYNC Maintenance in this manual and follow the procedures in the "Approach to Troubleshooting" section.

- h. Error Type 1281—This error is an indication that the Tone-Clock circuit pack has detected a loss of timing signal from the system synchronization reference. The Tone-Clock circuit pack has switched synchronization references.

- 1.Resolve any errors logged against the SYNC or STRAT-13 maintenance objects.
- 2.Refer to SYNC maintenance, in the “Approach to Troubleshooting” section, if the error is not resolved by step 1

Error Type 1282—Indicates that the TN2182 tone-clock was synchronized to a DS1 facility and that the reference frequency provided by the DS1 drifted beyond a range that could be tracked by the TN2182. Therefore the TN2182 is no longer synchronized to that DS1 reference. If a second DS1 is available, the tone-clock may be synchronized to that reference. If no secondary DS1 reference is available, the tone-clock will run off of its internal clock. This may result in slips being reported by the tone-clock and all DS1 facilities.

- i. The tone-clock circuit pack in the master port network was unable to detect the incoming synchronization signal, but the other tone-clock was able to detect the references. If the aux data is 0, the problem is with the signal on the primary. If the aux data is 1, the problem is with the signal on the secondary. The system should switch clocks in this situation.
- 1.If this error is against a PPN clock board and the system is using a Stratum 3 clock, check the cabling that brings the stratum 3 signal to this clock board.
- 2.Replace the current standby Tone-Clock circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.

j. The indicated active Tone-Clock circuit pack, which is on a port network that does not contain the system synchronization reference (a **slave** Tone-Clock), has detected a loss of timing signal from its EXP-INTF synchronization source.

1. Enter **display errors** and **display alarms**, and follow the associated repair procedures for EXP-INTF, TDM-CLK, and TONE-BD error log entries that have on-board alarms.
2. If the 2305 errors persist, follow the repair procedures for EXP-INTF error log entries 257, 769, or 770, or any errors logged against SNI-BD, SNC-BD, or FIBER-LK.
3. If the 2305 errors persist:
  - a. *For Port Networks with more than one Tone-Clock circuit pack*, execute the command **test synchronization r 10**, and check to see if new 2305 errors against TDM-CLK were reported. If not, execute **reset PNC interchange** and then **test synchronization r 10** again, and recheck for new 2305 errors against TDM-CLK
  - b. *For Port Networks with a single Tone-Clock circuit pack*, execute the command **test synchronization r 10**, and check to see if new 2305 errors were reported.

If no new instances of the 2305 errors were logged for either test, then enter **test tone-clock UUC long clear** to clear the TDM-CLK errors and the procedure is complete.

4. For Port Networks with more than one Tone-Clock circuit pack, interchange Tone-Clocks with the **set tone-clock UUC**, then run **test synchronization r 10**, and check to see if new 2305 errors are reported against the new active Tone-Clock circuit pack. If not, replace the standby Tone-Clock circuit pack. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section. If this clears the error, the problem has been resolved.
  5. Replace the EI circuit pack for the active PNC. In the direct-connect case, use the **list fibers** command to identify which active EI connects with the PPN.
  6. If the problem is still not cleared, and the Tone-Clock circuit pack reported in the error log has not been replaced up to now, replace it. See *How to Replace the Tone-Clock Circuit Pack* in the TONE-BD section.
-

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *SAKI Reset Test* for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|----------------------|-------------------|
| SAKI Reset Test (#53) (a)                        |                     | X                  |                      | D                 |
| Clock Health Test (#46) (b)                      | X                   | X                  |                      | ND                |
| Control Channel Looparound Test (#52) (a)        | X                   | X                  |                      | ND                |
| Tone Generator Crosstalk Test (#90) (c)          |                     | X                  |                      | ND                |
| Tone Generator Transmission Test (#40) (c)       | X                   | X                  |                      | ND                |
| Tone Generator Audit/Update Test (#41) (c)       | X                   | X                  |                      | ND                |
| TDM Bus Clock Circuit Status Inquiry Test (#148) | X                   | X                  |                      | ND                |
| TDM Bus Clock Slip Inquiry Test (#149)(e)        | X                   | X                  |                      | ND                |
| TDM Bus Clock PPM Inquiry Test (#150)            | X                   | X                  |                      | ND                |
| TDM Bus Clock Parameter Update Test (#151)       | X                   | X                  |                      | ND                |
| Board Type Check Test (#574)                     | X                   | X                  |                      | ND                |
| Standby Reference Health Check Test (#651) (d)   |                     | X                  |                      | ND                |

1. D = Destructive; ND = Nondestructive

- Notes:
- a. Refer to “XXX-BD” for descriptions of these tests.
  - b. Refer to “TONE-BD” for a description of this test.
  - c. Refer to “TONE-PT” for descriptions of these tests.
  - d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above, or be a TN2182.
  - e. Test #149 is not run on the TN2182.

TDM Bus Clock Circuit Status Inquiry Test (#148)

The TDM Bus Clock circuitry is checked for sanity. Any problems that are found are reported via error codes

Table 10-431. TEST #148 TDM Bus Clock Circuit Status Inquiry Test

| Error Code     | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|----------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| None<br>1001   | ABORT       | The system could not allocate the necessary resources for the test.<br>1. Wait 1 minute, and retry the test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 2100           | ABORT       | System resources required to run this test are not available.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 1              | FAIL        | This error means the Tone-Clock circuit pack framing verification firmware reports an error in the clock synchronization signal coming into this Port Network.<br><br>1. If the Tone-Clock circuit pack reporting the problem is a master clock, then the system synchronization reference is providing a bad timing source. Refer to SYNC (Synchronization) or STRAT-3 (Stratum 3 Clock) Maintenance documentation to change the system synchronization reference.<br><br>2. If the Tone-Clock circuit pack is a slave clock, then the EI to which it is listening is providing a bad timing source. Follow the diagnostic procedures specified for TDM-CLK Error Code 2305.<br><br>3. If no problem can be found with the incoming synchronization signal, replace the Tone-Clock circuit pack. See <i>How to Replace the Tone-Clock Circuit Pack</i> in the TONE-BD section. |
| 2              | FAIL        | This error indicates that Tone-Clock circuit pack has inaccurately detected loss of signal on the incoming synchronization timing source.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 4<br>or<br>8   | FAIL        | The local oscillator on the Tone-Clock circuit pack has failed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 16<br>or<br>32 | FAIL        | The circuitry on the Tone-Clock circuit pack used to detect synchronization timing errors has failed.<br><br>1. Errors 2, 4, 8, 16, and 32 indicate that there is poor synchronization between port networks and external facilities. It may be noticeable to the customer in the form of errors in data communications. The Tone-Clock circuit pack is defective. See <i>How to Replace the Tone-Clock Circuit Pack</i> in the TONE-BD section.                                                                                                                                                                                                                                                                                                                                                                                                                                |

|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 64         | FAIL        | <p>This message is only sent when an uplink message has reported the loss of valid synchronization timing information coming into this Port Network. It has been reported in TDM-CLK Error Log entries; one or more of 1025, 1281, 1537, 2049 and 2305.</p> <p>1. Resolve the errors indicated. No separate corrective action is required.</p>                                                                                                                                                                                                                                                                                                                                                                                                    |
| 65         | FAIL        | <p>The tone-clock is currently not able to lock on to the current synchronization reference. If this tone-clock is in the master port network:</p> <p>1. Examine the error log for any DS1-BD, SYNC or other TDM-CLK errors and resolve as applicable.</p> <p>2. Run this test again via the test tone-clock UUC command.</p> <p>3. Examine the DS1 measurements to determine if the facility is healthy.</p> <p>4. Administer a new synchronization reference.</p> <p>5. Replace the DS1 board currently supplying the reference.</p> <p>If this tone-clock is in the slave port network:</p> <p>1. Examine the error log for any SYNC, EXP-INTF or other TDM-CLK errors.</p> <p>2. Run this test again via the test tone-clock UUC command.</p> |
| 66         | FAIL        | <p>There is an on-board failure of TDM clock hardware.</p> <p>1. Replace this faulty tone-clock circuit pack.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|            | PASS        | <p>TDM Bus Clock Circuit Status is sane. There are no clock-detection circuit problems on the Tone-Clock circuit pack.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

TDM Bus Clock Slip Inquiry Test (#149)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack.

 **NOTE:**  
This test does not apply to the TN2182

Table 10-432. TEST #149 TDM Bus Clock Slip Inquiry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Any        | FAIL        | <p>The error code represents the number of timing slips detected on the incoming synchronization source since the last slip inquiry was sent to the Tone-Clock circuit pack. The incoming synchronization signal can be from one of four sources:</p> <ol style="list-style-type: none"><li>1. A Stratum 3 Clock, if that option is administered and the circuit pack tested was the active Tone-Clock in the PPN.</li><li>2. A DS1 Interface circuit pack, if DS1 Synchronization is administered, and associated with the circuit pack tested.</li><li>3. The local oscillator on the master Tone-Clock circuit pack, if it is providing the system clocking signals.</li><li>4. An EXP-INTF circuit pack, if the port network on which the test was executed does not contain the current system synchronization reference.</li></ol> <p>The error code is a variable amount ranging from 1 to 255.</p> <ol style="list-style-type: none"><li>1. Small numbers of slips should not result in service degradation. If the error code is small (1 or 2), rerun the test. If the error only occurs infrequently, it may be ignored.</li><li>2. Otherwise, refer to the "Approach to Troubleshooting" section in the Synchronization (SYNC) Maintenance section of this manual.</li></ol> |
|            | PASS        | The Tone-Clock circuit pack does not detect any timing slips. This indicates that the incoming synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The <b>status synchronization</b> command should be used to verify that the desired synchronization reference is providing timing for the system.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

TDM Bus Clock PPM Inquiry Test (#150)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit pack

Table 10-433. TEST #150 TDM Bus Clock PPM Inquiry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Wait 1 minute, and retry the test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 255        | ABORT       | The Tone-Clock circuit pack was using its local oscillator rather than synchronizing to an external source.<br>1. Verify that this Tone-Clock circuit pack is expected to be the synchronization source. If not, correct the synchronization information and re-execute the test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 2100       | ABORT       | System resources required to run this test are not available.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| Any        | FAIL        | The error code represents the rate (in Parts Per Million, or PPM) at which clock slip errors have been detected on the incoming synchronization source since the last PPM inquiry was sent to the Tone-Clock circuit pack. A failure of this test indicates that we are outside of Stratum 4 or Stratum 3 timing specifications on the incoming timing source.<br><br>The error code is a variable amount ranging from 1 to 254.<br>1. If error 1537 is entered in the hardware error log against TDM-CLK, then the board has switched timing sources. Follow the procedures associated with hardware log error code 1537.<br>2. Otherwise, refer to "Approach to Troubleshooting" in the Synchronization (SYNC) Maintenance section of this manual. |
|            | PASS        | The Tone-Clock circuit pack does not detect timing any PPM errors. This indicates that the external synchronization timing source is valid or that the system synchronization reference is a Tone-Clock circuit pack. The <b>status synchronization</b> command should be used to verify that the desired synchronization reference is providing timing for the system.                                                                                                                                                                                                                                                                                                                                                                              |

TDM Bus Clock Parameter Update Test (#151)

This test updates the following internal parameters on the Tone-Clock circuit pack:

- Disable in-line duplication status messages.
- Disable in-line subrate frame maintenance messages (TN768, TN780 only).

- Set the PPM threshold at 60 PPM for TN768 and TN780. Set the PPM threshold at 85 PPM for TN2182.
- Enable PPM threshold switching
- Set the number of slips to trigger *loss of signal* - currently 30 per 5 millisecond period
- Enable the on-board synchronization switching algorithm (see above)
- Enable holdover operation (TN2182 only).

This is not a test and will always pass without identifying or reporting any Tone-Clock circuit pack errors

| Error Code | Test Result | Description/ Recommendation                                                                     |
|------------|-------------|-------------------------------------------------------------------------------------------------|
|            | PASS        | The proper (TN780) Tone-Clock circuit pack code is present for Stratum 3 Clock synchronization. |

Standby Reference Health Check Test (#651)

This test evaluates the quality of the external synchronization timing source for a standby Tone-Clock circuit pack. All administered synchronization timing sources must be valid for this test to pass. If the tone-clock circuit pack and the synchronization timing sources are in different port networks, the EI circuit packs transport the timing sources to the tone-clock.

Table 10-436. TEST #651 Standby Reference Health Check Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                     |

| MO Name As It<br>Appears in<br>Alarm Log | Alarm<br>Level | Initial System<br>Technician<br>Command to Run <sup>1</sup> | Full Name of MO        |
|------------------------------------------|----------------|-------------------------------------------------------------|------------------------|
| TIE-BD                                   | MIN            | test board PCSS sh                                          | Tie Trunk Circuit Pack |
| TIE-BD                                   | WRN            | test board PCSS sh                                          | Tie Trunk Circuit Pack |

- 
1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also TIE-TRK (Tie Trunk).

## TIE-DS1 (DS1 Tie Trunk)

| MO Name As It Appears in Alarm Log | Alarm Level        | Initial System Technician Command to Run | Full Name of MO |
|------------------------------------|--------------------|------------------------------------------|-----------------|
| TIE-DS1 <sup>1</sup>               | MAJOR <sup>2</sup> | test trunk <grp/mbr> l                   | DS1 Tie Trunk   |
| TIE-DS1                            | MINOR              | test trunk <grp/mbr> l                   | DS1 Tie Trunk   |
| TIE-DS1                            | WARNING            | test trunk <grp/mbr>                     | DS1 Tie Trunk   |

1. For additional repair information, see also DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

The DS1 tie trunk provides both voice and data inter-PBX communication. A 24 channel DS1 Interface circuit pack can support up to 24 digital tie trunks through a 1.544 Mbps DS1 link. A 32 channel DS1 Interface circuit pack can support up to 30 digital tie trunks through a 2.048 Mbps DS1 link. DS1 Interface circuit packs are described in DS1-BD. DS1 Tie Trunks are used widely in the DCS and Central Attendant Service (CAS) features of the system.

A DS1 tie trunk can also be used as an access endpoint which is a non-signaling channel with a bandwidth of voice-grade-data, 56K-data or 64K-data.

DS1 tie trunk maintenance provides a strategy to maintain a DS1 tie trunk via a port on the DS1 Interface circuit pack. The maintenance strategy covers logging DS1 tie trunk hardware errors, running tests for trunk initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution. Three different trunk service states are specified in the DS1 tie trunk maintenance. They are: *out-of-service* in which the trunk is in a deactivated state and cannot be used for either incoming or outgoing calls; *in-service* in which the trunk is in an activated state and can be used for both incoming and outgoing calls; *disconnect* (ready-for-service) in which the trunk is in an activated state but can only be used for an incoming call. If the DS1 Interface circuit pack is out-of-service, all trunks on the DS1 Interface circuit pack are placed into out-of-service state, and a Warning alarm is raised.

Hardware Error Log Entries and Test to Clear Values

DS1 Tie Trunk Maintenance Error Log Entries

|          |       |                                  |  |  |  |
|----------|-------|----------------------------------|--|--|--|
| 2562(j)  | 16665 |                                  |  |  |  |
| 2817(k)  | 52992 |                                  |  |  |  |
| 3840 (j) | Any   | Port Audit and Update (Test #36) |  |  |  |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
3. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the MINOR alarm is not downgraded by the **set options** values, the MINOR alarm is upgraded to a MAJOR alarm if 75 percent of the trunks in this trunk group are alarmed.
  - a. Error Type 1—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. This error can be caused by incompatible translations. Make sure the parameters administered on the DS1 circuit pack form match those administered on the far-end switch. See *DEFINITY Communications System Generic 3 V2 Implementation*, 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107, for details.

The Aux Data field indicates the following hardware error types:

- |       |                                                                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 57476 | On-hook before wink                                                                                                                                            |
| 57477 | On-hook before ready to receive digits                                                                                                                         |
| 57485 | Wink too short for valid signal                                                                                                                                |
| 57487 | The timer expired while waiting for an off-hook signal from the far end as a response at end of digits dialing. Check the far-end switch for related problems. |

If all administration errors between the switch and the far-end match, and these errors continue to recur, follow normal escalation procedures.

- b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).
- c. Error Type 18—The DS1 tie trunk has been busied out by a **busyout trunk** grp/mbf command. No calls can be made on this trunk except for the Facility Access Test Call. Facility Access Test Calls are described in *DEFINITY Communications System Generic 3 Feature Description*, 555-230-204.

- d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. Error Type 257—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. The trunk cannot communicate with the far end because it is unable to interpret digits sent from the far-end switch. The Aux Data field indicates the following:

57473            The rotary dial rate is below 8 pulses per second.

57474            The rotary dial rate is above 12 pulses per second.

Check with the far-end switch or operating company for proper trunk connection.

- f. Error Type 513—DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. The trunk is in-service/active and waiting for an “on-hook” from the far-end switch. No calls can be routed over the trunk while it is in this state. Aux Data 57392 indicates no external release on PBX disconnect. Check with the far-end switch or operating company for proper trunk connection.
- g. Error Type 769—The DS1 Interface circuit pack detects a hardware error on the DS1 tie trunk. This error usually occurs after one or more occurrences of error type 513. The trunk has received the belated “on-hook” that it has been waiting for from the far-end switch. The trunk is restored to in-service/idle and can be used for calls. Aux Data 57393 indicates delayed external release on PBX disconnect. This error can be ignored.
- h. Error Type 1793—The DS1 Interface circuit pack is out-of-service. See the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Interface Circuit Pack) Maintenance documentation for details.
- i. Error Type 2305—Reorder message. The trunk could not be seized. This error will cause the Trunk Seizure Test (#136) to run and is only considered a problem if the Seizure Test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in “Ready-for-Service” state (shown as “disconnected” by the status command), which allows only incoming calls. Run the Trunk Seizure Test (#136) and follow its outlined procedures.
- j. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- k. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the DS1 Tie Trunk Seizure Test (#136) and follow its outlined procedures.

- I. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter **status trunk** command and verify the status of the trunk. If the trunk is out-of-service, then enter **release trunk** command to put it back to in-service. Retry the test command. If the test continues to abort, then escalate the problem.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the

*NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)           |                     | X                  | ND                |
| Conference Circuit Test (#7)      |                     | X                  | ND                |
| DS1 Tie Trunk Seizure Test (#136) | X                   | X                  | ND                |
| Port Audit and Update Test (#36)  | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

**NPE Crosstalk Test (#6)**

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes on the order of 20 to 30 seconds to complete.

Table 10-437. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | System resources required for this test are not available.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1000       | ABORT       | System resources required to run this test were not available. The port may be busy with a valid call. Use the <b>display port UUCSSpp</b> command to determine the trunk group/member number of the port. Use the <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.<br><br>1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up.<br><br>2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times.<br><br>3. If the test continues to abort, escalate the problem. |
| 1001       | ABORT       | System resources required to run this test are not available.<br><br>1. Retry the command at 1 minute intervals for a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1002       | ABORT       | The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. Refer to the TDM-BUS (TDM bus) Maintenance Documentation to diagnose any active TDM-BUS errors.<br><br>1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                            |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1003       | ABORT       | <p>The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the <b>list measurements tone-receiver</b> command to display basic information about the system's tone receivers.</p> <ol style="list-style-type: none"><li>1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV Maintenance documentation.</li><li>2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT Maintenance documentation.</li><li>3. If neither condition exists, retry the test at 1 minute intervals for a maximum of 5 times.</li><li>4. If the test continues to abort, escalate the problem.</li></ol> |
| 1004       | ABORT       | <p>The port was seized by a user for a valid call. Use the <b>display port UUCSSpp</b> command to determine the trunk group/member number of the port. Use the <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.</p> <ol style="list-style-type: none"><li>1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                             |
| 1020       | ABORT       | <p>The test did not run because of a previously existing error on the specific port or a more general circuit pack error.</p> <ol style="list-style-type: none"><li>1. Examine the Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 2000       | ABORT       | <p>Response to the test request was not received within the allowable time period.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 2100       | ABORT       | <p>System resources required for this test are not available.</p> <ol style="list-style-type: none"><li>1. Retry the command at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2053       | ABORT       | <p>At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity.</p> <p>Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|            | FAIL        | <p>This can be due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane.</p> <ol style="list-style-type: none"><li>1. Look for EXP-PN and/or EXP-INTF errors in the error log. If present, refer to the EXP-PN Maintenance documentation and the EXP-INTF Maintenance documentation.</li><li>2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation.</li><li>3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation.</li><li>4. Retest when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.</li></ol> |
|            | PASS        | <p>The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.</li></ol> |

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 10-438. TEST #7 Conference Circuit Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | System resources required for this test are not available.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1000       | ABORT       | System resources required to run this test were not available. The port may be busy with a valid call. Use the <b>display port UUCSSpp</b> command to determine the trunk group/member number of the port. Use the <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.<br><br>1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up.<br><br>2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times.<br><br>3. If the test continues to abort, escalate the problem. |
| 1002       | ABORT       | The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. The <b>status health</b> command can be used to determine if the system is experiencing heavy traffic. Refer to the TDM-BUS (TDM bus) Maintenance Documentation to diagnose any active TDM-BUS errors.<br><br>1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                     |

| Error Code | Test Result      | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL<br>(con't.) | <p>6. Replace the circuit pack.</p> <p> <b>NOTE:</b></p> <p>If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.</p> |
|            | PASS             | <p>The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.</li></ol> |

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to ensure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk kept by the DS1 Interface circuit pack and the switch software.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | <p>System resources required to run this test were not available. The port may be busy with a valid call. Use the <b>display port UUCSSpp</b> command to determine the trunk group/member number of the port. Use the <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting.</p> <ol style="list-style-type: none"><li>1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up.</li><li>2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times.</li><li>3. If the test continues to abort, escalate the problem.</li></ol> |
| 1006       | ABORT       | <p>The test was aborted because the trunk is out of service.</p> <ol style="list-style-type: none"><li>1. Use the <b>status trunk</b> command to verify that the trunk is out of service.</li><li>2. If the trunk is out of service, determine why.</li><li>3. If it is OK to put the trunk back in service, issue the <b>release trunk</b> command to put the trunk back in service, and then retry the test.</li><li>4. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | <p>Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test does not run, but it does return PASS. To verify that the trunk is in-service:</p> <ol style="list-style-type: none"><li>1. Enter <b>status trunk</b> command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2.</li><li>2. Enter <b>release trunk</b> command to put trunk back into in-service.</li><li>3. Retry the test command.</li></ol>                                                                                                                                                                                        |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.</li></ol> |

DS1 Tie Trunk Seizure Test (#136)

The DS1 Tie Trunk Seizure Test is run to verify the trunk’s signaling capability. The test is composed of two parts. The first part queries the circuit pack for the following errors: Loss of Signal, Red Alarm, Blue Alarm, Yellow Alarm, and Hyperactivity Alarm. The second part of the test is performed by sending a seizure message to the DS1 Interface circuit pack and expecting an active reply by the DS1 Interface circuit pack. If maintenance software does not receive any

reply and the timer expires, the test is aborted. Once the active message is received, a dial pause message is sent to the DS1 Interface circuit pack. If the DS1 Interface circuit pack replies with a dial pulse tone message when the far end responds to the seizure, then the DS1 tie trunk Seizure Test passes. If the far end does not respond to the seizure and the timer expires, and the DS1 Interface circuit pack sends a reorder message back to the maintenance software, then the test fails.

This second part of this test **CANNOT** be run on a trunk if one of the following cases is true:

- 1. The trunk direction is administered as an incoming only trunk.
- 2. The trunk is the 24th port on a DS1 Interface circuit pack which is administered using 24th Common Channel Signaling.
- 3. The trunk has been seized by a normal trunk call.
- 4. The trunk is administered with maintenance test disabled.
- 5. The outgoing signal type of the trunk is either automatic or immediate-start.

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.</li></ol> |

(1) Earlier G1 Software Versions reported Error Code 2053 as a FAIL

## TIE-TRK (Tie Trunk)

| MO Name As It Appears in Alarm Log | Alarm Level        | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO |
|------------------------------------|--------------------|-------------------------------------------------------|-----------------|
| TIE-TRK <sup>2</sup>               | MAJOR <sup>3</sup> | test port PCSSpp l                                    | Tie Trunk       |
| TIE-TRK                            | MINOR              | test port PCSSpp l                                    | Tie Trunk       |
| TIE-TRK                            | WARNING            | test port PCSSpp sh                                   | Tie Trunk       |

- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).
- Not relevant to the TN497 circuit pack.
- A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. (This is not relevant to the TN497 circuit pack.

 **NOTE:**  
If ATMS testing is enabled, check the error log for ATMS Errors #3840 and #3841. If the error log indicates that measurements exceeded acceptable thresholds, and if no other trouble is found with the **test trunk** command, run the ATMS test call with the **test analog-testcall port PCCSSpp full** command.

The following circuit packs are covered by this section of TIE-TRK (Tie Trunk):

- TN760 series
- TN437 [G3iV2-386]
- TN439 [G3iV2-386]
- TN458 [G3iV2-386]
- TN497 [G3iV2-386]
- TN2140 [G3iV2-386]

The Tie Trunk circuit pack fits into a port slot and contains four trunk circuits (see [Figure 10-91](#)). Each of these circuits interface a digital PBX to an analog tie trunk going to another PBX across one-way dedicated circuits (except for the TN497 circuit pack) or across two-way dedicated circuits. Except for the TN439 and TN497 circuit packs, each tie trunk has a 4-wire audio connection and may have two signaling leads (E and M). Each tie trunk for the TN439 and TN497 circuit packs has 2-wire audio connection/signal leads (A and B).

In G3iV1.1-286 or G3iV2-386, a tie trunk port can also be administered as an access endpoint, which is a non-signaling channel with a voice-grade data bandwidth.

**Figure 10-91. Tie Trunk Interactions**

The number of tests to be implemented for Tie Trunk maintenance depends upon the TIE-TRK circuit packs involved. The test are as follows:

1. NPE Crosstalk Test—Verifies the switch connection operation of the circuit pack. It verifies that the trunk circuitry talks only on the selected time slot on the TDM Bus and that it never crosses over to time slots reserved for other connections.
2. Loop Around and Conference Circuit Test—Verifies the transmission operation of the circuit pack. It verifies that signals are transmitted to and from each port (Loop Around within the port), and it tests the conference capabilities of all ports.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration test field.

3. Several seizure tests, including the following:
  - Tie Trunk Seizure Test (not relevant to the TN439 and TN497 circuit packs)—Verifies the seizure capabilities of the circuit pack. For wink start and delay dial outgoing trunks only, (and, for the TN2140

- [G3iV2-386] circuit pack, also for continuous-seize-ack and discontinuous-seize-ack), this test activates the M lead and checks for a response from the distant end within 10 seconds. For G3iV1.1-286 or G3iV2-386, this test **ABORTS** on trunk ports administered as access endpoints.
- Seizure Test (for TN497 circuit packs only)—Verifies the seizure capabilities of the circuit pack. This test seizes the trunk and outpulses a "pause." The port reports the result of the seizure attempt uplink. The test can be disabled via Trunk Group Administration.
  - Tie Trunk Dial Test (for TN439 circuit packs only)—Verifies the seizure and dialing capabilities of the circuit pack. **This test ABORTS on trunk ports administered as access endpoints.**
4. EPF, M, and E Lead Test [G3iV1.1-286 and G3iV2-386 only]—ABORTS on trunk ports administered as access endpoints. This test consists of two parts:
- E lead test—Checks for the proper activation and deactivation of the port's E lead.
  - M lead test—Checks the M lead EPF current flow. The results of this test allow for distinguishing between circuit pack and external facility failures.
5. Port Audit Update Test (Audit & Update Test for the TN497 circuit pack)—Sends non-disruptive administrative updates to the circuit pack with no expected response. The test updates the translation information on individual ports of the Tie Trunk. Except for the TN497 circuit pack, these updates include:
- Immediate, automatic, wink start, or delay dial and for the TN2140 [G3iV2-386], continuous-seize-ack
  - For the TN2140 [G3iV2-386], continuous or discontinuous.
  - Rotary or DTMF senderization in or out
  - Disconnect timing
  - DMTF time slot

Additional in-line testing is performed while a call is in progress. Thus, many in-line errors may occur during operation. See the Error Log table for a description of these errors. These errors may be reproduced by using the trunk (making a call), and checking their occurrence in the Hardware Error Log.

Before a maintenance test can be run on a port, the port is required to be idle. Except for a TN497 circuit pack, if an incoming call seizes the port which is being tested by maintenance, the test is aborted, and the incoming call proceeds.

Non-TN497 circuit packs can be configured for back-to-back testing (also known as connectivity testing) by making translation and cross-connect changes. This

testing configuration allows for the connection of Tie Trunks back-to-back in the same switch to verify the operation of Tie Trunk ports. The tests can be performed in either the E&M or simplex modes. For details, refer to the "Analog Tie Trunk Back-to-Back Testing" section in [Chapter 5, "Routine Maintenance Procedures"](#)

Hardware Error Log Entries and Test to Clear Values

Table 10-441. TIE Trunk Error Log Entries

| Error Type           | Aux Data                               | Associated Test                                 | Alarm Level                                      | On/Off Board     | Test to Clear Value                  |

- 
- Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the MINOR alarm is not downgraded by the **set options** values, the MINOR alarm is upgraded to a MAJOR alarm if 75 percent of the trunks in this trunk group are alarmed.
  - Non-TN497 circuit packs only.
  - TN439 circuit packs only.
  - Non-TN439 and non-TN497 circuit packs only
  - TN497 circuit packs only.
  - TN439 and TN497 circuit packs only.

Notes:

- a. Digit time-out. This occurs when the far-end PBX begins transmitting digits too late (10 seconds) after receiving the signal indicating ready to receive digits (if any). This can occur on an incoming immediate, wink, or delay dial line. Check the far-end PBX to ensure a translation match at both ends.
- b. Rotary dial before wink. This occurs when the far-end PBX starts dialing before the PBX sends the wink on a wink-start or (for non-TN439 circuit packs) on a delay-dial line. Check the far-end PBX to ensure a translation match at both ends.
- c. Rotary dial too early. This occurs when the far-end PBX starts dialing too soon (about 50ms) after seizure on a wink start or (for non-TN439 circuit packs) on a delay-dial line. Check the far-end PBX to ensure a translation match at both ends.
- d. On hook before wink. This occurs when the far end goes on hook before a wink. Check the far-end PBX to ensure a translation match at both ends.
- e. On an outgoing wink-start or delay-dial trunk, the wink time was too short (less than 80ms) for a valid signal. Check the far-end PBX to ensure a translation match at both ends.
- f. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).
- g. This indicates that the trunk in question has been busied-out by maintenance personnel.
- h. This indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- i. The rotary dial rate was too slow (less than eight pulses per second.) Check the far-end PBX to ensure a translation match at both ends.
- j. The rotary dial rate was too fast (more than 12 pulses per second.) Check the far-end PBX to ensure a translation match at both ends.
- k. The time between digits was too short (less than 300ms). Check the far-end PBX to ensure a translation match at both ends.
- l. This indicates that the trunk is still seized with an incoming call. The far-end PBX is not releasing the trunk after the call is dropped. A Minor alarm is generated every four minutes until the far-end PBX releases the trunk. Check the far-end PBX for problems.

Once the trunk is released from the call, the severity of this problem is decreased. If Error Type 1025 does not appear again, this means that the problem has been corrected. Verify that Error Type 1025 does not reappear in the Error Log.

- m. Reorder message. Trunk could not be seized. This error causes the Tie Trunk Seizure Test (#73) to run, and it is considered a problem only if the Seizure Test fails (in which case Error Type 1793 also shows up). In this case, the trunk may be placed in the "Ready-for-Service" state (shown as "disconnected" by the status command), which allows only incoming calls. Run the Tie Trunk Seizure Test and follow its outlined procedures.
- n. Test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements that were outside the acceptable limits. Use the **list testcall detail** command to examine specific transmission parameters that are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, the limits administered on the "change trunk" screen should be changed.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Loop Around and Conference Circuit Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                                                                                      | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------------------------------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)                                                                                                     |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

2. Non-TN439 and non-TN497 circuit packs only

3. TN439 circuit pack only

4. TN497 circuit pack only

5. G3iV1.1-286 and G3iV2-386 only

6. Non-TN497 circuit packs only

Notes:

- a. ATMS test are not part of either sequence. They are run either on demand with the **test analog-testcall** command or via the ATMS schedule.

NPE Crosstalk Test (#6)

One or more NPE reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes 20 to 30 seconds to complete.

Table 10-442. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Translate the board, if necessary.</li><li>2. Issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board</b> command. This should re-establish the linkage between the internal ID and the port.</li></ol> |

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop around, and conference capabilities of a tie trunk port circuit. The test uses 404-Hz, 1004-Hz, and 2804-Hz tones. This is an on-board test only, and each tone is transmitted through the loop and checked upon return.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from the trunk administration Test field.

Table 10-443. TEST #33 Loop Around and Conference Circuit Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                  |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                |
| 7          | ABORT       | The conference circuit test was aborted.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                             |
| 129        | ABORT       | The 404-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.                                                                                                                                              |

| Error Code                       | Test Result       | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7, 129, 131, or 133<br>(cont'd.) | FAIL<br>(cont'd.) |  <b>NOTE:</b><br>If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.<br><br>If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see FAULT ISOLATION above. |
|                                  | PASS              | Tie trunk Loop Around and Conference Test is successful. This port is functioning properly.<br><br>1. If users are reporting troubles, examine loop connections to the port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Translate the board, if necessary.</li><li>2. Issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board</b> command. This should re-establish the linkage between the internal ID and the port.</li></ol> |

Audit Update Test (#36)

This test sends updates of the Tie Trunk port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the board. No response message is expected from the circuit pack once it receives translation updates. The port translation data for non-TN439 and non-TN497 circuit packs includes the following: Immediate, automatic, wink-start or delay dial trunk, rotary or DTMF senderization in or out, disconnect timing from 10 to 2550ms in 10ms increments, and DTMF time slot. (Continuous-seize-ack is also included for the TN2140 [G3iV2-386] circuit pack.) The port translation data for the TN439 circuit pack includes the following: Immediate or wink-start trunk, rotary or DTMF senderization in or out, disconnect timing from 10 to 2550ms in 10ms increments, and DTMF time slot.

|            | PASS        | <p>This test passed. Translation information was successfully updated on the circuit pack.</p> <p>1. If signaling troubles are reported, verify translation information for this port.</p> <p>(Non-TN439 and non-TN497 circuit packs only.) If the trunk is busied out, the test does not run, but it does return PASS.</p> <p>To verify that the trunk is in-service:</p> <p>1. Enter <b>status trunk</b> command to verify that the trunk is in-service.</p> <p>If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2.</p> <p>2. Enter <b>release trunk</b> command to put trunk back into in-service.</p> <p>3. Retry the test command.</p> |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>1. Check to ensure that the board translations are correct. Translate the board, if necessary.</p> <p>2. Issue the <b>busyout board</b> command.</p> <p>3. Issue the <b>reset board</b> command.</p> <p>4. Issue the <b>release busy board</b> command.</p> <p>5. Issue the <b>test board</b> command. This should re-establish the linkage between the internal ID and the port.</p>                                                                                                                                                                                                                                       |

Tie Trunk Seizure Test (#73), Tie Trunk Dial Test (#747). Seizure Test(#73)

The Tie Trunk Seizure Test activates the M lead and checks for a response from the external end within 10 seconds. This test is applicable only to wink start and delay dial outgoing trunks. (For the TN2140 [G3iV2-386] circuit pack, the trunk must also be continuous-seize-ack and discontinuous-seize-ack).

The Tie Trunk Dial Test seizes the trunk and outputs a pause digit.

For a port administered as TGU or a TGE, the Seizure Test internally seizes the trunk and outputs a "pause." The report reports the result of the seizure attempt uplink.

Table 10-445. Seizure Tests (#73, #747, #73)

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1004       | ABORT       | <p>(Non-TN497 circuit packs only.) The port was seized by a valid call during the test. The test has been aborted. Use the <b>display trunk xx</b> to determine the trunk group/member number of the port. Use the <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in <a href="#">Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"</a> for a full description of all possible states.) You must wait until the port is idle before retesting.</p> <ol style="list-style-type: none"><li>1. Retry the command at one minute intervals a maximum of five times.</li><li>2. If the test continues to abort, and the port is not in use, escalate the problem.</li></ol> |
| 1005       | ABORT       | <p>(Non-TN439 circuit packs only.) This test is not valid for this trunk translation. For this test to run, a delay dial trunk (or, for non-TN497 circuit packs, a wink-start trunk) must be in effect, and the trunk must be outgoing or two-way. Also, for the TN2140 [G3iV2-386], the trunk must be continuous-seize-ack or discontinuous-seize-ack.</p> <ol style="list-style-type: none"><li>1. Check trunk translation. If it is not a wink-start or delay dial trunk, this abort message should be ignored. (For the TN2140 [G3iV2-386], disregard this abort on a trunk that is not continuous-seize-ack or discontinuous-seize-ack.)</li></ol>                                                                                                                                                                                            |
| 1018       | ABORT       | <p>Test disabled via administration.</p> <ol style="list-style-type: none"><li>1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the <b>change trunk-group x</b> command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Translate the board, if necessary.</li><li>2. Issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board</b> command. This should re-establish the linkage between the internal ID and the port.</li></ol> |

Tie Trunk EPF Test (#74)

This test consists of an E lead and M lead test. The E lead test checks for the proper activation and deactivation of the port's E lead. The M lead test checks the M lead EPF current flow. The processor sends an M lead test request to the circuit pack and receives the results. The returned results are measured to see if a port or external tie trunk line fails.

Table 10-446. TEST #74 Tie Trunk EPF Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                                                                                                                                                                                                            |
| 2100       | ABORT       | Could not allocate the necessary system resources to run the test. This could be due to a failure to seize the port.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                               |
| 1          | FAIL        | The E lead test failed due to an on-board port problem.<br><br>1. Replace the circuit pack.                                                                                                                                                                                                                                                                                                                                                                |
| 2          | FAIL        | The M lead test failed. The EPF has experienced an overcurrent condition, perhaps due to the external M lead.<br><br>1. To make sure the problem is on-board, disconnect the facility from the pack and retry the test.<br><br>2. If the test fails, replace the circuit pack. Otherwise, check the external wiring toward the far-end PBX.                                                                                                                |
|            | PASS        | Tie Trunk EPF test is successful. This port is functioning properly.<br><br>1. If users are reporting troubles, examine loop connections to the port.                                                                                                                                                                                                                                                                                                      |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board).<br><br>1. Check to ensure that the board translations are correct. Translate the board, if necessary.<br><br>2. Issue the <b>busyout board</b> command.<br><br>3. Issue the <b>reset board</b> command.<br><br>4. Issue the <b>release busy board</b> command.<br><br>5. Issue the <b>test board</b> command. This should re-establish the linkage between the internal ID and the port. |

Transmission Test (#844-848)

This test is non-destructive.

**NOTE:**  
Tests #844-848 are not supported on a International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run on demand with the **test analog-testcall** command or as part of ATMS scheduled testing.

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of "marginal" or "unacceptable" thresholds. Detail and summary measurement reports are obtainable via the **list testcalls** command.

Table 10-447. TEST #844-848 Transmission Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | <p>System resources required to run this test are not available. The port may be busy with a valid call. Use <b>display port PCSSpp</b> to determine the trunk group/member number of the port. Use the "status trunk" command to determine the service state of the port. If the service state indicates that the port is in use, then the port unavailable for this test. (Refer to the "Status Commands" section in <a href="#">Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"</a> for a full description of all possible states.) You must wait until the port is idle before retesting.</p> <ol style="list-style-type: none"><li>1. If the port status is idle, then retry the command at 1 minute intervals for a maximum of 5 retries.</li><li>2. If the test continues to abort escalate the problem.</li></ol> |
| 1001       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1 minute intervals for a maximum of 5 retries.</li><li>2. If the test continues to abort escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

If the test continues to abort escalate the problem.                                                                                                                                                                                                                                                                        |
| 2053       | ABORT       | The test call could not be established, but no information on why is available.<br><br>1. Retry the command at 1 minute intervals for a maximum of 5 retries.<br><br>2. If the test continues to abort escalate the problem.                                                                                                                                                                                                                             |
| 2056       | ABORT       | An error occurred while trying to obtain results from the TN771 circuit pack.<br><br>1. Test the TN771 circuit packs.<br><br>2. If the test continues to abort escalate the problem.                                                                                                                                                                                                                                                                     |
|            | FAIL        | Measured transmission performance was in the unacceptable range as administered on the trunk group form. Retrieve a measurement report via the <b>list testcalls</b> command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. Besides the facility, test failures can be caused by faulty test lines or switch paths. If the measurements point to a facility problem, report the results to the trunk vendor.        |
| 8000       | FAIL        | Measured transmission performance was in the marginal range as administered on the trunk group form. This generally means that the trunk is usable but has an undesirable amount of noise or loss. If the user does not report unacceptable effects, it may not be necessary to take any action. Retrieve a measurement report via the <b>list testcalls</b> command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. |

## TONE-BD (Tone-Clock Circuit Pack)

| MO Name<br>As It<br>Appears in<br>Alarm Log | Alarm<br>Level | Initial System<br>Technician Command<br>to Run <sup>1</sup> | Full Name of MO         |

| TONE-BD                                     | MINOR          | test tone-clock PC                                          | Tone-Clock Circuit Pack |
| TONE-BD                                     | WARNING        | release tone-clock PC                                       | Tone-Clock Circuit Pack |

1. P is the port network number (1 for PPN, 2-3 for EPNs). C is the carrier designation (A, B, C, D, or E).

The Tone-Clock circuit pack functionality is provided by two independent objects in the same circuit pack. The tone generator provides all the tones needed by the system and the clock generates the system clocks for the Time Division Multiplex (TDM) Bus and aids in monitoring and selecting internal synchronization references.

When resolving errors/alarms on the Tone-Clock circuit pack, the following should be used also:

- TONE-PT (Tone Generator) Maintenance documentation.
- TDM-CLK (TDM Bus Clock) Maintenance documentation.
- SYNC (Synchronization) Maintenance documentation.

The TN2182 is a combined Tone-Clock-Detector circuit pack which contains a third independent function not available on the TN768 or TN780. The TN2182 contains 8 ports used for all-purpose tone detection. These ports are called Enhanced Tone Receiver ports (ETR-PT) and are described in the documentation for ETR-PT.

### Tone-Clock Circuit Packs and System Reliability Options

The following sections describe the relationship between the various System Reliability Options and Tone-Clock circuit pack configurations.

#### Standard Reliability Option

Systems with the Standard Reliability Option (no duplication options) have one Tone-Clock circuit pack in each port network (PPN and EPN). For the PPN or the EPN this is in the A carrier. This Tone-Clock circuit pack generates clocks and provides system tones for all carriers of the port network it resides on.

## High Reliability Option

---

Systems with the High Reliability Option (duplicated SPE, simplex PNC) have one Tone-Clock circuit pack in each PPN control carrier, A and B. One Tone-Clock circuit pack will be actively generating system clock signals for PPN components, while the other will be in standby mode, ready to take over in the event of a Tone-Clock interchange. Similarly, one Tone-Clock circuit pack will be actively providing system tones for the PPN, while the other will be in standby mode. Normally, the same Tone-Clock circuit pack will be active for both tones and clock signals, but these responsibilities may be divided if neither circuit pack is able to perform both functions. The **status port-network** command will indicate which Tone-Clock circuit pack is actively performing each function.

For systems using the TN2182 Tone-Clock-Detector circuit pack, tone generation and clock generation behaves the same as other clock boards with one being active and one being standby. But the tone detector ports (ETR-PTs) of the TN2182 are always considered available and in-service regardless of the active/standby state of the tones or clock for a specific circuit pack.

EPN Tone-Clock circuit pack configuration is the same as for the Standard Reliability Option. Each EPN Tone-Clock circuit pack will be active for both tones and clock signals for its port network.

## Critical Reliability Option

---

Systems with the Critical Reliability Option (SPE duplication and PNC duplication) have two Tone-Clock circuit packs associated with the PPN, as in the High Reliability Option case, and two more Tone-Clock circuit packs for each EPN. For the EPN, these are in carriers A and B. As in the previous case, one Tone-Clock in each Port Network is active, supplying system clocks and tones, and the other is in standby mode.

## Tone-Clock Interchange Strategy

---

The Tone-Clock circuit pack interchanges are controlled both by manual intervention and by maintenance software strategies.

The manual interchange strategy for Tone-Clock circuit packs differs slightly between the PPN and any EPNs on a system.

## Manual PPN Tone-Clock Interchange

---

In a PPN with more than one Tone-Clock circuit pack, the intention is to assure that the one considered most healthy is active at any given time. *This is independent of the SPE Duplication strategy*, in the sense that the active Tone-Clock circuit pack need not change with an interchange of SPE carriers. Rather, except for the effect of the manual intervention discussed earlier,

Tone-Clock interchanges occur only as a result of changes in the health of Tone-Clock circuit packs, as perceived by maintenance software. When both Tone-Clock circuit packs are equally healthy, no preference is given to one over the other, regardless of which SPE carrier is active.

It is possible to manually control Tone-Clock interchanges in three ways.

1. The **standby** Tone-Clock circuit pack may be made unavailable for most purposes by using the **busyout tone-clock PC** command. Such a Tone-Clock may not be selected with console commands, nor with normal maintenance software activities, until it has been made available again with the **restore tone-clock PC** command.

**NOTE:**

**busyout tone-clock** is not allowed for active Tone-Clock circuit packs.

2. The SPE processor lock switches may be used to force a particular SPE to be active. *This method overrides all other Tone-Clock interchange controls.* If there is a Tone-Clock circuit pack in the same carrier as the active SPE, it will become active, regardless of its health. If the Tone-Clock circuit pack in the selected SPE was in the *busyout* state (see item 1 above), it will automatically be released and made active. While the lock switches are set for a particular carrier, *no manual intervention or software error detection* will cause an interchange of Tone-Clocks; the Tone-Clock circuit pack in the standby SPE carrier can never become active. If there is no Tone-Clock circuit pack in the selected SPE at the time the switches are set, but one is later installed, the system will interchange to it regardless of its health. If the Tone-Clock circuit pack is removed from an SPE while the switches are set, *no interchange will occur*; the system will have no active tone-clock. When the lock switches are restored to the neutral position, a tone clock interchange will occur only if the standby Tone-Clock circuit pack is healthier than the active one.
3. A particular Tone-Clock circuit pack can be made active by issuing the **set tone-clock PC [override]** command. If the Tone-Clock to be made active is less healthy than the currently active one, no interchange will occur unless the **override** option is specified; without it a message will inform the user that it is required.

Once a Tone-Clock circuit pack is made active by the **set tone-clock PC** command, it will stay active until either the **set tone-clock PC** command is issued again to make the other circuit pack active, or until a fault occurs in the active Tone-Clock circuit pack, which causes the system to interchange Tone-Clocks.

## Manual EPN Tone-Clock Interchange

---

In an EPN with duplicated Tone-Clock circuit packs, one circuit pack is always *preferred* over the other. This is the Tone-Clock circuit pack in carrier **A**. The intention is that the preferred circuit pack be active whenever it is healthy. Once a failing preferred Tone-Clock circuit pack has been replaced or repaired, the system will make it active as soon as possible.

Control over interchanges for an EPN is accomplished in essentially the same ways as items 1 and 3 in the PPN case above. In addition, when the non-preferred Tone-Clock circuit pack in an EPN is active, and the preferred circuit pack is repaired and proven capable of filling its roles, the system will automatically interchange back to it as soon as possible.

## Software Maintenance Interchange

---

Interchanges may be instigated by software Tone-Clock maintenance in two ways.

1. A scheduled Tone-Clock circuit pack interchange occurs according to the parameters set by the **change system-parameters maintenance** command. This can be disabled or set to run weekly, but the standard (default) situation is for it to occur daily, at the time specified in the system-parameters list for scheduled maintenance to begin. This interchange will be blocked if the lock switches are set, if the non-preferred Tone-Clock circuit pack in an EPN has been selected with the **set tone-clock** command, if the standby Tone-Clock has been set to the busyout state, or if the clock generation capability of the standby Tone-Clock circuit pack is known to be impaired. When this scheduled interchange occurs, the standby Tone-Clock circuit pack becomes active for a period of 20 seconds to test its ability to generate clock signals, and then is returned to standby mode.
2. Unscheduled interchanges occur when on-board Tone-Clock circuit pack maintenance, or ongoing switch maintenance tests of **TONE-BD**, **TONE-PT**, or **TDM-CLK** uncover failures serious enough to raise any MAJOR or MINOR alarm against the active Tone-Clock circuit pack.

## International Settings [G3i V2]

---

The TN780 Tone-Clock circuit pack uses three firmware configuration parameters for international support [G3i V2]. The following two are automatically set by the software load for the targeted country:

- The circuit pack's country-code (USA, ITALY, AUSTRALIA, etc.)
- The circuit pack's companding mode (mu-Law or A-Law)

The third configuration parameter is used only for Italy (country code: ITALY), and selects whether *new* versus *old* ISPT (Istituto Superiore Poste Telegrafi)

tones will be used for dial and confirmation tones. Values for dial confirmation tone can be set independently on the **change system-parameters miscellaneous** form. Whenever such changes are made, the effects are immediately enforced on all TN780 Tone-Clock circuit packs without disrupting tone or timing services.

**Italian Tone Settings (New ISPT Value)**

---

| Tone         | Default    | Old ISPT Value |
|--------------|------------|----------------|
| Dial         | Continuous | Cadenced       |
| Confirmation | Cadenced   | Continuous     |

In addition the TN780 allows customization of up to six system tones in order to meet specific country needs. These changes are made via the **change system-parameters country-options** form.

The TN2182 allows the same International changes as the TN780 but allows the customization of up to 24 system tones in order to meet specific country needs. These changes are made via the **change system-parameters country-options** form.

**How to Replace a Tone-Clock Circuit Pack**

---

Replacing the Tone-Clock circuit pack is a service-disrupting procedure on Port Networks with a single Tone-Clock, because the Tone-Clock circuit pack is always needed to generate clocks for its network. For EPN Tone-Clock replacement where no second Tone-Clock circuit pack exists, only that EPN is affected. When the circuit pack is removed, all calls are dropped immediately, the EPN enters emergency transfer within one minute, and no calls can be set up from or to that EPN. However, if the PPN Tone-Clock is removed for replacement in a Standard Reliability Option system, the System Emergency Transfer feature is activated within milliseconds, and the entire system is disrupted; no calls can be placed, and existing calls are dropped.

When replacing the Tone-Clock circuit pack, always replace it with a comparable Tone-Clock circuit pack for the system. See the following table:

| System Type                                                                          | Tone-Clock Circuit Pack Code           |
|--------------------------------------------------------------------------------------|----------------------------------------|
| One-port network single-carrier cabinet system without High or Critical Reliability. | TN756, TN768, TN780 TN2182 [G3iV4-386] |
| One-port network system without High or Critical Reliability (multicarrier cabinet). | TN768, TN780                           |
| Two-port network single-carrier cabinet system without High or Critical Reliability. | TN768, TN780 TN2182 [G3iV4-386]        |
| One- or two-port network without High or Critical Reliability.                       | TN768, TN780 TN2182 [G3iV4-386]        |

- **TN768**—This is the general purpose Tone-Clock circuit pack for port networks on a G3i switch. It can be used in every situation except as the Master Tone-Clock circuit pack when a Stratum 3 Clock is administered.
- **TN780**—The Stratum 3 Clock feature requires the use of this circuit pack code for the PPN (in both carriers of High and Critical Reliability systems). The Stratum 3 Clock will operate only with this code as the Master Tone-Clock circuit pack. The TN780 circuit pack is upward compatible with the TN768 code, and can be used in any place a TN768 would be allowed. The TN780 is used in many countries outside the U.S. where the TN768 does not provide local tones.
- **TN2182**—This Tone-Clock-Detector may be used anywhere a TN768 or TN780 is used with the exception of configurations requiring Stratum 3 Clock. The TN2182 may be used in all country configurations.

Port Networks with a Single Tone-Clock Circuit Pack

This procedure is destructive.

1. Pull out the defective Tone-Clock circuit pack. This will remove the clocks and cause the system to activate emergency measures:
  - For the PPN Tone-Clock, the system will immediately go into the Emergency Transfer state.
  - For an EPN Tone-Clock, all calls to and from the EPN will drop and the EPN will activate Emergency Transfer within about one minute, but the rest of the system should operate normally.
2. Insert a new Tone-Clock circuit pack. The system will detect the return of the clocks and will automatically recover as follows:
  - If the Tone-Clock circuit pack being replaced is in the Processor Port Network, the system will perform a **reset system 2 (system cold 2 restart)** automatically. First, all red LEDs of the PPN will

come on and off within 30 seconds. Then, all red LEDs of any Expansion Port Networks will come on and go off within the next 30 seconds.

- If the Tone-Clock circuit pack being replaced is in an Expansion Port Network, the system will reset the EPN (**EPN cold restart**) and all the red LEDs of the EPN will come on and go off within 30 seconds.
3. If the red LEDs come on but do not go off within 30 seconds, pull the circuit pack out and reseat it. If the LEDs perform as expected this time, continue with step 6. Otherwise, there may be a problem with the TDM Bus; possibly a bent pin in the Tone-Clock circuit pack slot. Follow the directions in the TDM-BUS maintenance section.
  4. If the red LEDs did light, as explained above, then go to Step 6. If the red LEDs do NOT light, as explained above, then go on to Step 5.
  5. Restart the affected Port Network:
    - In the PPN, restart the system via the **reset system 2** command.
    - In an EPN, restart the EPN by resetting its Expansion Interface circuit pack via the **reset board** command, using the board address 1a01 for EPN1 and 1a02 for EPN2.

If this step should fail, follow normal escalation procedures.

6. Test the new Tone-Clock circuit pack to verify that it is functioning properly, using the **test tone-clock PC long** command, and verify that the system is operational by placing several phone calls. Where possible, try calls into, out from, and within the affected Port Network.

If the system is not operating properly, follow normal escalation procedures.

## Port Networks with Two Tone-Clock Circuit Packs:

---

1. If both Tone-Clock circuit packs in a Port Network need to be replaced, first replace and test the one that is in standby mode. Make sure that it is healthy and active before replacing the second one. Make sure the Tone-Clock circuit pack to be replaced is in Standby Mode by displaying its status via the **status port-network** command or making sure its yellow LED is off.

The active/standby state of a Tone-Clock circuit pack may also be determined by looking at its LED. A continuously lit red LED on the Tone-Clock circuit pack indicates a reported fault on one or more of the

maintenance objects on the circuit pack. Flashing patterns of the yellow and green LEDs correspond to the following service states: **Tone-Clock LED Flashing Codes**

| Condition                                                                                           | Tone-Clock Circuit State | Explanation                                                                                                                                      |
|-----------------------------------------------------------------------------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| "flashing yellow" 2.7 seconds on, .3 seconds off                                                    | active                   | An external timing source is being used as a synchronization reference. <sup>1</sup>                                                             |
| "flashing yellow" .3 seconds on, 2.7 seconds off                                                    | active                   | The local oscillator on the Tone-Clock circuit pack is being used as a synchronization reference.                                                |
| "yellow" on continuously                                                                            | active                   | The circuit pack has been reset but has not been told which synchronization source to use.                                                       |
| "yellow" LED off                                                                                    | standby                  | The circuit pack is in standby mode, (neither generating tones nor supplying clocks).                                                            |
| "jingle bells" green and yellow .1 sec on, .2 sec off, .1 sec on, .4 sec off, .4 sec on, .4 sec off | standby                  | Maintenance software is testing the standby circuit pack (the standby Tone-Clock is providing tones).                                            |
| "double blink yellow" .3 sec on, .3 sec off, .3 sec on, 2.4 sec off                                 | active                   | TN2182 has lost all external references and is in holdover mode.                                                                                 |
| "other green and yellow patterns"                                                                   | active                   | Maintenance software is testing the active circuit pack.                                                                                         |
| random yellow                                                                                       | standby                  | If the circuit pack is a TN2182, the yellow LED may come on and off intermittently as ETR-PTs on the board are used for tone detection services. |

1. For a Tone-Clock in the master port network, the external source is the primary or secondary DS1 source, or a Stratum 3 clock. For a Tone-Clzteock in a slave port network, the external source is the Expansion Interface circuit pack.
2. If the Tone-Clock circuit pack to be replaced is active, then switch to the other Tone-Clock circuit pack by doing the following:
  - **set tone-clock PC**—where PC is the Standby Tone-Clock circuit pack. Since the system is designed to operate primarily on the preferred tone clock, the set tone-clock PC command should be

used to make the preferred tone board active when maintenance activity is completed. There is no preferred tone clock for the PPN, but carrier A is preferred for EPNs.

- **status system**—verify the Tone-Clock circuit pack switched to the other Tone-Clock circuit pack or check the LEDs. The yellow LED of the new Standby Tone-Clock circuit pack should be off (provided maintenance is not running on it) and the yellow LED of the active Tone-Clock circuit pack should be blinking.
  - If the interchange was not successful, the standby Tone-Clock circuit pack may be defective. In particular, if the error message "must use override" is displayed, fix the standby Tone-Clock circuit pack before attempting to replace the active one.
3. If the Tone-Clock circuit pack to be replaced is in the PPN, it is recommended, but not required, that the SPE carrier containing it be locked in standby mode by executing an interchange if necessary, and locking the SPE-Select switches. This protects you from disrupting service in case of inadvertent errors in replacing the circuit pack.

 **NOTE:**

If the SPE-Select switches are locked, be sure to release them at the conclusion of the replacement procedure.

4. Pull out the defective Tone-Clock circuit pack. No calls should be affected. If this is a TN2182 circuit pack, some ETR-PTs may be in use and removal of the pack will affect some individual users. It may be less disruptive to busyout the standby TN2182 before removing it.
5. Insert a new Tone-Clock circuit pack of the appropriate code in the same slot where the defective Tone-Clock circuit pack was removed.
6. Test the new Tone-Clock circuit pack via the **test tone-clock PC** command to make sure it is functioning properly. If the Tone-Clock circuit pack is being replaced due to loss of clocks, the Clock Health Inquiry (#46) will still report a failure, proceed with the next step.
7. To verify that the new Tone-Clock circuit pack is able to generate clocks for the system, switch to the new Tone-Clock circuit pack via the **set tone-clock PC override** command, and execute **test tone-clock PC**. (In a PPN, the SPE-Select switches must be in the auto position.)

 **CAUTION:**

*If the new Tone-Clock circuit pack is not able to generate system clocks, this procedure becomes destructive. The system will detect a loss of clock and recover accordingly.*

In this case if the Tone-Clock circuit pack being replaced is in the PPN the system will perform a reset system 2 (cold 2 restart) automatically. If the Tone-Clock circuit pack being replaced is in an EPN, the system will reset the EPN (EPN cold restart). After either type of restart, the faulty

Tone-Clock circuit pack will be in standby mode. Since the replacement procedure was not successful, follow normal escalation procedures. **If the new Tone-Clock circuit pack is able to generate system clocks, there will be no system disruption.**

8. Place several phone calls.
9. After replacing a Tone-Clock circuit pack in an SPE, if the SPE lock switches were set during the procedure, they should be released. Additionally, after repairs in an EPN, the **set tone-clock PC** command should be used if required to make the preferred Tone-Clock circuit pack active.

Hardware Error Log Entries and Test to Clear Values

| Tone-Clock Circuit Pack Error Log Entries |          |                                                |                                |              |                            |

| 3840(n)                                   | Any      | None                                           |                                |              |                            |
| 3848(o)                                   | 0        | Clock Health Inquiry Test (#46)                |                                |              | set tone-clock PC override |
| 3872(p)                                   | 0        | None                                           |                                |              | set tone-clock PC override |
| 3999 (q)                                  | Any      | None                                           |                                |              |                            |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. Error Type 1—This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

**NOTE:**

The alarm is logged approximately 11 minutes after the circuit pack is removed/SAKI Sanity Test (#53) fails.

If the circuit pack is not present in the system, insert a circuit pack in the slot indicated by the error to resolve the error.

If the circuit pack is present in the system, it is faulty and must be replaced. See the preceding section, [“How to Replace a Tone-Clock Circuit Pack”](#).

If the faulty circuit pack is in standby mode, a MINOR alarm is raised, but no other system action is taken. If the circuit pack is the active Tone-Clock, further effects of this error depend on the Reliability Option for the switch.

**Table 10-448. Effect of Error Type 1 on an Active Tone-Clock Circuit Pack**

| Location of Tone-Clock Circuit Pack |                                                    |                                                       |
|-------------------------------------|----------------------------------------------------|-------------------------------------------------------|
| Reliability Option                  | PPN                                                | EPN                                                   |
| Standard                            | System Emergency Transfer (entire system affected) | Emergency Transfer in the affected EPN                |
| High                                | Interchange to standby Tone-Clock in the PPN       | Emergency Transfer in the affected EPN                |
| Critical                            | Interchange to standby Tone-Clock in the PPN       | Interchange to standby Tone-Clock in the affected EPN |

If an interchange is attempted and the system is unable to activate the standby Tone-Clock, Emergency Transfer is activated. If the problem is in the PPN the entire system is affected. Otherwise only the EPN in question is affected. When this happens, both circuit packs are faulty and must be replaced. See the preceding section, [“How to Replace a Tone-Clock Circuit Pack”](#).

If a successful interchange occurs in response to a failure of the active Tone-Clock, or if a standby Tone-Clock fails, the faulty Tone-Clock should be replaced.

- b. Error Type 18—The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock PC** command. This error applies only to High or Critical Reliability systems (an active Tone-Clock may not be busied out). To resolve this error, execute **release tone-clock PC**.

- c. Error Type 23—The circuit pack has been logically administered but not physically installed. Installing the circuit pack will resolve the alarm.
- d. Error Type 125—A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.
- e. Error Type 126—The port network specified in the PORT field of the error log entry booted up without a Tone-Clock circuit pack, or with a one that cannot communicate at all with the system. The error is logged five minutes after the port network is restarted. If no circuit pack is present, install one of the proper code. If there is a circuit pack present, replace it. See the preceding section, [“How to Replace a Tone-Clock Circuit Pack”](#). If replacement does not solve the problem, follow normal escalation procedures.
- f. Error Type 257—This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.
- g. Error Type 513—This circuit pack has an on-board hardware failure. Replace the circuit pack using the procedure described in preceding section, [“How to Replace a Tone-Clock Circuit Pack”](#).
- h. Error Type 769—This error can be ignored, but look for other errors on this circuit pack.
- i. Error Type 1025—This error is not service-affecting and no action is required.
- j. Error Type 1538—The circuit pack was taken out of service because of an excessive rate of uplink messages. Use **test tone-clock PC long** to reset the circuit pack and put it back into service. If the command is not successful, replace the circuit pack using the procedure described in the preceding section, [“How to Replace a Tone-Clock Circuit Pack”](#). If the alarmed circuit pack is the active Tone-Clock of a duplicated pair, first interchange Tone-Clocks via the **set tone-clock PC** command to avoid a service outage. If the error occurs again within 15 minutes, follow normal escalation procedures.
- k. Error Type 2049 or 2305—These errors indicate the loss of one or more clock signals from the reported Tone-Clock circuit pack, which was active at the time of the error. The effect of any of these errors is described in the table for error type 1. Diagnosis of the problem is the same for all four error types, with the exception noted below.
  - 1. Examine the Hardware Error Log for errors reported against circuit packs in the same Port Network, especially TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the repair or replacement procedures indicated for any such errors found.

- 2.If the error is not corrected by resolving errors found in step 1, the Tone-Clock circuit pack should be replaced. See the preceding section, ["How to Replace a Tone-Clock Circuit Pack"](#).

**NOTE:**

Replacing the circuit pack and retesting it with the **test tone-clock** command is not adequate to retire this alarm and return the Tone-Clock Circuit Pack to full service; the Clock Health Inquiry test (#46) will continue to fail. Because the ability to generate clocks was considered lost, once any repairs have been made it is necessary to execute the **set tone-clock PC override** command, forcing the circuit pack to become active. If the problem has not actually been corrected, this action may cause a disruption in service for active digital facilities users.

- 3.If error 2305 or 3848 persists, all clock signals from the indicated board were lost. If the reported Tone-Clock circuit pack is in a Port Network with duplicated Tone-Clocks, the problem may lie with the circuit pack responsible for selecting the active Tone-Clock circuit pack (the *t/c selector*).
  - For a PPN, the t/c selector is the DUPINT circuit pack on carrier A.
  - For an EPN, the t/c selector is the active EXP-INTF circuit pack that is connected to the PPN. This is EXP-INTF 2A01 or 2B02 for EPN1 and 3A01 or 3B02 for EPN2.

The t/c selector circuit pack of interest is the one which was active at the time the error was logged. This is the currently active t/c selector unless there has been an SPE interchange for PPN problem, or an EXP-INTF link switch for EPN problem. In order to determine whether an interchange has occurred since the TONE-BD error, examine the **display initcauses** log for SPE interchanges, and EXP-LNK entries in the hardware error log for expansion link interchanges.

If the t/c selector circuit pack was not replaced as part of the previous step, replace it now. Follow procedures described in ["Replacing Defective SPE Circuit Packs"](#) in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for the DUPINT circuit pack, or in the EXP-INTF section of this chapter for the Expansion Interface.

- 4.If the error has not been corrected at this point, there is a problem with the TDM Bus within the Port Network containing the reported Tone-Clock circuit pack. This may include TDM Bus intercarrier cables, Bus terminators, bent pins on the backplane, and errors on any circuit pack plugged into the same Port Network. Refer to the TDM-BUS section.
- 5.If the problem persists, follow normal escalation procedures.

- l. Error Type 2561—This error indicates that a Tone-Clock circuit pack, with a different circuit pack code as required for this system, has been inserted in the port slot as shown in the Hardware Error Log. To resolve this error, refer to the [“How to Replace a Tone-Clock Circuit Pack”](#) section for an appropriate circuit pack code and replace the Tone-Clock circuit pack according to the procedures indicated for this system. The meanings of the aux data values are as follows:

|      |                                                                                                                                                                                    |
|------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1001 | A TN756 Tone-Clock circuit pack is in the PPN of a one port network system without High or Critical Reliability (Multicarrier Cabinet).                                            |
| 1002 | A TN756 Tone-Clock circuit pack is in the EPN of a one port network system without High or Critical Reliability (Multicarrier Cabinet).                                            |
| 1003 | Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780 or TN2182) is in a one port network system without High or Critical Reliability (Multicarrier Cabinet). |
| 1004 | Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780 or TN2182) is in a High or Critical Reliability system.                                                 |
| 1005 | Same as for aux value 1004.                                                                                                                                                        |

- m. Error Type 3329—The system attempted but failed to interchange Tone-Clock circuit packs. (This error occurs only in Port Networks with duplicated Tone-Clocks.) The fault may lie in the standby Tone-Clock or in the circuit pack that controls selection of the active Tone-Clock (the *t/c selector*). The goal of the following procedure is to ensure that both Tone-Clocks can be interchanged into while either t/c-selector circuit pack is active.
- 1.Examine the Error Log for errors reported against circuit packs in the same Port Network, paying special attention to TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the procedures indicated for any such errors found. After eliminating the above potential problem sources, proceed with the following steps.
  - 2.Determine which circuit pack was controlling the choice of Tone-Clock at the time the error occurred.
    - For a PPN, the t/c selector is the DUPINT circuit pack on the A-carrier.
    - For an EPN, the t/c selector is the active EXP-INTF circuit pack that is connected to the PPN. This is EXP-INTF 2A01 or 2B02 for EPN1 and 3A01 or 3B02 for EPN2.

The t/c-selector circuit pack of interest is the one which was active at the time the error was logged. An EXP-LNK interchange since the time of the error may have made that circuit pack the current standby. Determine whether an interchange affecting the t/c

selector has occurred since the TONE-BD error. When investigation an EPN Tone-Clock, look for EXP-LNK entries in the hardware error log for PNC interchanges, which would affect the EXP-INTF.

3. If the t/c selector has not undergone an interchange since the error occurred, go to the next step. If such an interchange has taken place, interchange back to the formerly active t/c selector. Use the **set expansion-interface** command when investigating an EPN Tone-Clock.) If the interchange attempt fails due to other errors, resolve those problems first.
4. Interchange the Tone-Clock circuit packs using the **set tone-clock PC** command. If the command succeeds, the interchange which previously failed has been accomplished and the problem has been satisfactorily resolved. If it fails, proceed to the next step. (You may want to proceed in any case to definitively test all relevant components.)
5. Interchange the t/c selector using **set expansion-interface** if investigating an EPN. If errors prevent this interchange, resolve them first.
6. Attempt again to interchange Tone-Clocks with the **set tone-clock PC** command.
  - If the Tone-Clock interchange failed for both t/c selectors:

Replace the standby Tone-Clock circuit pack which could not be interchanged into and return to this step. (See ["How to Replace a Tone-Clock Circuit Pack"](#).) Test the new circuit pack as follows:

    - a. Execute the set tone-clock PC command.
    - b. Execute a set expansion-interface, if this is an EPN Tone-Clock.
    - c. Execute the set tone-clock PC command again.

If these commands successfully complete, the problem has been resolved.
  - If these commands successfully complete, the problem has been resolved.
  - If the Tone-Clock circuit packs successfully interchange when one EXP-INTF is active, but not when the other one is:

The t/c-selector circuit pack on the failing side is suspect.

    - a. Replace the A carrier DUPINT or EXP-INTF board that is active when the Tone-Clock interchange fails. (Follow procedures in ["Replacing Defective SPE Circuit Packs"](#) in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for the DUPINT circuit pack; for the Expansion Interface, see EXP-INTF.)

- b. Make sure the new t/c selector is active and execute the set tone-clock PC command.
    - If both Tone-Clocks can be interchanged into, and interchanges succeed when either t/c selector is active, the problem has been resolved. If the problem persists after following the above steps, follow normal escalation procedures.
- n. Error Type 3840—This error is not service-affecting and can be ignored. It indicates that the circuit pack has received a bad control message from the switch.
- o. Error Type 3848—This error indicates that the Tone/Clock circuit pack had a loss of clock. If error 2305 is also logged, see note (j).
- p. Error Type 3872—These errors indicate this Tone/Clock circuit pack had a loss of Data Clocks. This error will impact mainly users on station connected to Digital circuit packs. These users could be with out service. If error 2049 is also logged see note (i).
- q. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

---

## System Technician-Demanded Tests: Descriptions and Error Codes

---

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *SAKI Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Use the **list configuration control** command to find the Tone-Clock Circuit Pack Code of the system. Look for the Short and Long Test Sequences according to the Tone-Clock Circuit Pack Code.

For a system with a TN756 Tone-Clock Circuit Pack:

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| SAKI Sanity Test (#53) (a)                 |                     | X                  | D                 |
| Clock Health Inquiry Test (#46)            | X                   | X                  | ND                |
| Control Channel Loop Around Test (#52) (a) | X                   | X                  | ND                |
| Tone Detection Verification Test (#42) (b) | X                   | X                  | ND                |
| Tone Detection Audit/Update Test (#43) (b) | X                   | X                  | ND                |
| Tone Generator Crosstalk Test (#90) (b)    |                     | X                  | ND                |
| Tone Generator Transmission Test (#40) (b) | X                   | X                  | ND                |
| Tone Generator Audit/Update (#41) (b)      | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive
- a. Refer to XXX-BD (Common Port Circuit Pack) documentation for descriptions of these tests.

b. Refer to TONE-PT (Tone Generator) documentation for descriptions of these tests.

For a system with a TN768, TN780 or TN2182 Tone-Clock Circuit Pack:

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| SAKI Reset Test (#53) (a)                            |                     | X                  |                   |
| Clock Health Inquiry Test (#46)                      | X                   | X                  |                   |
| Control Channel Loop Around Test (#52) (a)           | X                   | X                  |                   |
| Tone Generator Crosstalk Test (#90) (b)              |                     | X                  |                   |
| Tone Generator Transmission Test (#40) (b)           | X                   | X                  |                   |
| Tone Generator Audit/Update (#41) (b)                | X                   | X                  |                   |
| TDM Bus Clock Circuit Status Inquiry Test (#148) (c) | X                   | X                  |                   |
| TDM Bus Clock Slip Inquiry (#149) (c) (e)            | X                   | X                  |                   |
| TDM Bus Clock PPM Inquiry Test (#150) (c)            | X                   | X                  |                   |
| TDM Bus Clock Parameter Update Test (#151) (c)       | X                   | X                  |                   |
| Board Type Check Test (#574) (c)                     | X                   | X                  |                   |
| Standby Reference Health Check Test (#651) (c,d)     |                     | X                  |                   |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to XXX-BD for descriptions of these tests.
- b. Refer to TONE-PT for descriptions of these tests.
- c. Refer to TDM-CLK for descriptions of these tests.
- d. This test runs only on the standby Tone-Clock circuit pack in a Port Network with duplicated Tone-Clocks (High or Critical Reliability systems). The circuit pack must be a TN780 with firmware version 2 or above or a TN2182.

Clock Health Inquiry Test (#46)

This inquiry reads special data stored in memory to determine if this Tone-Clock circuit pack had a loss of any of three clock types:

- SYSCLK

- SYSFM
- SYSDCLK

If this data indicates this Tone-Clock circuit pack had a loss of any of these clocks, the inquiry reports FAIL. In addition, if TDM-CLK error 1 is at threshold, this test will FAIL. TDM-CLK error 1 indicates a suspect clock is at the edge of its specified frequency. If the circuit pack did not have a loss of clock or TDM-CLK error 1 at threshold, the inquiry reports PASS.

This is not really a test, in the sense that it simply reports status held by the system, and does not generate new information or raise alarms. If this test fails with no error code, there is at least one Major alarm against a Tone-Clock circuit pack. If this test fails with an error code of 1, there is at least one Minor off-board alarm against a TDM-CLK.

**Table 10-449. TEST #46 Clock Health Inquiry Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                        |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal System Error.<br><br>1. Retry the command at 11-minute intervals for a maximum of 5 times.<br><br>2. If the test continues to abort, follow normal escalation procedures. |

Table 10-449. TEST #46 Clock Health Inquiry Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none       | FAIL        | <p>This Tone-Clock circuit pack had an apparent loss of clock. One or more of error types 2049, 2305, 3834, and 3872 will appear in the error log. Correct the problem according to the appropriate error log entries. Once this test fails, the only way to make it pass, and to retire the associated alarm, is to repair the problem and to execute the <b>set tone-clock PC override</b> command against the indicated Tone-Clock circuit pack.</p> <p> <b>NOTE:</b></p> <p>If power is removed from a carrier in a duplicated system, and that SPE has the active TONE-CLK, a MAJOR alarm is raised for the TONE-BD. The TONE-BD will be out of service and when running Test 46 (Clock Health Test) it will fail, indicating a loss of any of these three clocks, SYSCLOCK, YSFM, and SYSDCLK.</p> <p>To restore the TONE-BD to service you must execute the <b>set tone spe health-override</b> command.</p> |
| 1          | FAIL        | <p>This Tone-Clock circuit pack is suspect of having a clock at the edge of its specified frequency. A Tone-Clock circuit pack with this problem can cause Expansion Interface circuit packs to go out-of-frame or report no neighbor conditions, thus causing EPNs to go down</p> <ol style="list-style-type: none"><li>1. Replace the Tone-Clock circuit pack identified in the error log. Refer to the <a href="#">“How to Replace a Tone-Clock Circuit Pack”</a> section.</li><li>2. If the error persists, follow normal escalation procedures.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|            | PASS        | <p>This Tone-Clock circuit pack has not reported a loss of clock.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## TONE-PT (Tone Generator)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO |
|------------------------------------|-------------|------------------------------------------|-----------------|
| TONE-PT                            | MAJOR       | test tone-clock PC sh                    | Tone Generator  |
| TONE-PT                            | MINOR       | test tone-clock PC sh                    | Tone Generator  |
| TONE-PT                            | WARNING     | release tone-clock PC sh                 | Tone Generator  |

**NOTE:**  
Replacing the tone/clock circuit pack requires a special procedure which is described in the documentation for TONE-BD. That section also describes the LED display for this board.

The tone generator resides on the Tone/Clock circuit pack and provides all system tones such as dial tone, busy tone, and so on. If an active tone generator fails, its port network may not have tones (see the Tone Generator Transmission Test #40). For instance, a user may go off-hook and hear no dial tone. This problem will affect only users on the same port network in which the faulty Tone-Clock circuit pack resides. The system will be able to process certain type of calls (that is, internal calls will succeed while outgoing calls will not).

The Tone-Clock circuit pack also provides the clocks for the system and can serve as the synchronization reference. Therefore, when resolving alarms on the Tone-Clock circuit pack, the TDM-CLK (TDM Bus Clock) and SYNC (Synchronization) Maintenance documentation should be utilized as well as the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation.

See the section on TONE-BD Maintenance in this manual for a discussion of the relationship of Tone-Clock circuit packs with the various Reliability Options.

Hardware Error Log Entries and Test to Clear Values

| Tone Generator Error Log Entries |          |                                         |              |              |                          |
|----------------------------------|----------|-----------------------------------------|--------------|--------------|--------------------------|
| Error Type                       | Aux Data | Associated Test                         | Alarm Level  | On/Off Board | Test to Clear Value      |
| 0 <sup>1</sup>                   | 0        | Any                                     | Any          | Any          | test tone-clock PC r 1   |

| 1025                             |          | Crosstalk Test (#90)                    | MAJOR/ MINOR | ON           | test tone-clock PC l r 2 |
| 1281(g)                          | Any      | Tone Generator Audit/ Update Test (#41) | MINOR        | ON           | test tone-clock PC r 3   |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. A failure in the tone generation facility on the indicated circuit pack has been detected. Replace the circuit pack. See [“How to Replace a Tone-Clock Circuit Pack”](#) in the TONE-BD section.
- b. The indicated Tone-Clock circuit pack has been made unavailable via the **busyout tone-clock PC** command. It only applies to systems which have the High or Critical Reliability Option administered, because only a standby Tone-Clock circuit pack may be made busy by that command. To resolve this error, execute the **release tone-clock PC** command for the alarmed circuit pack.
- c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- d. The tone generation facility is having problems verifying that tones have been connected as requested.
- e. The tone generation facility may or may not be able to generate tones.

- f. Infrequent errors, at a rate which does not bring up an alarm, probably do not affect service, unless there are customer complaints of no tones, or incorrect tones which can not be explained in any other way. However, if an alarm is raised because this error is being repeatedly logged, then the circuit pack should be replaced. See ["How to Replace a Tone-Clock Circuit Pack"](#) in the TONE-BD section.
- g. The system-parameters country-options administration are setup such that a TN780 or TN2182 are required and the existing tone-clock circuit pack will not provide the needed functionality. The Base Tone Generation Set on page 1 or the custom tones beginning on page 2 of the system-parameters country options form may have values not supported by the existing tone-clock.

This error (1281) indicates that the system parameters country-options form has custom tones translated and that the alarmed tone board does not support the customized tones. TN768 tone boards do not support any customized tones. TN780 tone boards support up to 6 customized tones using the following frequencies/levels only:

Silence

350Hz at 17.25 dB

425Hz at 4.0 dB

425Hz at 11.0 dB

425Hz at 17.25 dB

440Hz at 17.25 dB

350Hz+425Hz at 4.0 dB

350Hz+440Hz at 13.75 dB

480Hz at 17.25 dB

620Hz at 17.25 dB

440Hz+480Hz at 19.0 dB

404Hz at 11.0 dB

404Hz at 16.0 dB

480Hz+620Hz at 24.0 dB

404Hz+425Hz at 11.0 dB

375Hz+425Hz at 15.0 dB

404Hz+450Hz at 11.0 dB

1000Hz at 0.0 dB

1000Hz at +3.0 dB

525Hz at 11.0 dB

1400Hz at 11.0 dB

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *SAKI Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Use the **list configuration control** command to find the Tone-Clock Circuit Pack Code of the system. Then look for the Short and Long Test Sequences according to the Tone-Clock Circuit Pack Code.

For a system with a TN756 Tone-Clock Circuit Pack

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| SAKI Sanity Test (#53) (a)                 |                     | X                  | D                 |
| Clock Health Inquiry Test (#46) (b)        | X                   | X                  | ND                |
| Control Channel Loop Around Test (#52) (a) | X                   | X                  | ND                |
| Tone Detection Verification Test (#42) (c) | X                   | X                  | ND                |
| Tone Detector Audit/Update Test (#43) (c)  | X                   | X                  | ND                |
| Tone Generator Crosstalk Test (#90)        |                     | X                  | ND                |
| Tone Generator Transmission Test (#40)     | X                   | X                  | ND                |
| Tone Generator Audit/Update Test (#41)     | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.
- b. Refer to TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for descriptions of these tests.
- c. Refer to Dual Tone Multifrequency Receiver Port (TTR) (DTMR-PT) or General Purpose Tone Detector (CPTR) (GPTD-PT) Maintenance documentation for descriptions of this test.

For a system with a TN768, TN780 or TN2182 Tone-Clock Circuit Pack:

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| SAKI Reset Test (#53) (a)                            |                     | X                  | D                 |
| Clock Health Test (#46) (b)                          | X                   | X                  | ND                |
| Control Channel Loop Around Test (#52) (a)           | X                   | X                  | ND                |
| Tone Generator Crosstalk Test (#90)                  |                     | X                  | ND                |
| Tone Generator Transmission Test (#40)               | X                   | X                  | ND                |
| Tone Generator Audit/Update Test (#41)               | X                   | X                  | ND                |
| TDM Bus Clock Circuit Status Inquiry Test (#148) (c) | X                   | X                  | ND                |
| TDM Bus Clock Slip Inquiry Test (#149)(e)(c)         | X                   | X                  | ND                |
| TDM Bus Clock PPM Inquiry Test (#150) (c)            | X                   | X                  | ND                |
| TDM Bus Clock Parameter Update Test (#151) (c)       | X                   | X                  |                   |
| Board Type Check Test (#574) (c)                     | X                   | X                  |                   |
| Standby Reference Health Check Test (#651) (c,d)     |                     | X                  |                   |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for descriptions of these tests.
- b. Refer to TONE-BD (Tone-Clock Circuit Pack) section for descriptions of these tests.
- c. Refer to TDM-CLK (TDM Bus Clock) section for descriptions of these tests.
- d. This test only runs on the Standby Tone-Clock circuit pack in a Port Network with more than one Tone-Clock circuit pack (High or Critical Reliability Option). The circuit pack must be a TN780 code with firmware revision 2 or above, or a TN2182.

## Tone Generator Transmission Test (#40)

The purpose of this test is to verify that the tone generation hardware on the tone-clock circuit pack is capable of generating a subset of system tones and a set of test tones. This test does not verify all system tones the tone generator produces during normal system operation.

The test is performed in two parts. For the first part, the Tone Generator is told to generate the touch-tone digits. The digits are received and checked by a Tone Detector touch-tone detector. If any of the digits fail, the test is repeated using a touch-tone detector in another Tone Detector circuit pack.

For the second part, the Tone Generator is told to generate call progress tones that are detected and identified by a tone detector. These tones are:

- 440 Hz
- 2225 Hz
- Digital Count

The tone generator is then told to generate a sequence of test tones whose output levels are measured by a tone detector. These tones are:

- 404 Hz at 0 dB
- 1004 Hz at -16 dB
- 1004 Hz at 0 dB
- 2804 Hz at 0 dB

A Tone Detector general purpose tone detector listens for the tones and measures the quality of the tone. If any of the measured values are not within limits, the test is repeated using a general purpose tone detector in a different Tone Detector circuit pack. If the values are still out of the limits, the test will fail.

For all the failure cases of Test #40, do the following:

1. Check that all Tone Detector circuit packs have the same companding mode as that administered for the system. Correct the situation if there is a mismatch.
2. Run the long test sequence: **test tone-clock PC long repeat 1.**
3. If the problem persists, replace the Tone-Clock circuit pack by following the steps outlined in the ["How to Replace a Tone-Clock Circuit Pack"](#) section.

Table 10-450. TEST #40 Tone Generator Transmission Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Table 10-450. TEST #40 Tone Generator Transmission Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                  |
|------------|-------------|------------------------------------------------------------------------------|
| 115 (b,c)  | FAIL        | Generation of digital count sequence invalid.                                |
| 120 (a)    | FAIL        | Generation of quiet tone failed.                                             |
| 1044 (a)   | FAIL        | DTMF generation failed to generate Digit 1 for the standby tone generator.   |
| 1045 (a)   | FAIL        | DTMF generation failed to generate Digit 5 for the standby tone generator.   |
| 1046 (a)   | FAIL        | DTMF generation failed to generate Digit 9 for the standby tone generator.   |
| 1047 (a)   | FAIL        | DTMF generation failed to generate Digit D for the standby tone generator.   |
|            | PASS        | The tone generation facility is able to generate and transmit all the tones. |

Notes:

Except in Port Networks containing more than one Tone-Clock circuit pack, replacing the circuit pack is a service disrupting procedure. The test should be run several times with more than one failure before the replacement policy specified in the following notes is executed. Use the procedure described in ["How to Replace a Tone-Clock Circuit Pack"](#) in the TONE-BD section.

- a. All the failure error codes marked with (a) may affect users if the failure is on the active tone generator. When this type failure is detected, the system will attempt to move the tone generation function to the alternate Tone-Clock circuit pack, if one is present in the affected Port Network. When the tone generation facility fails in this way, especially in a Port Network without duplicated Tone-Clock circuit packs, the faulty Tone-Clock should be replaced promptly.
- b. All the failure error codes marked with (b) are almost transparent to the user. Again, when this type failure is detected, the system will attempt to move the tone generation function to the alternate Tone-Clock circuit pack, if one is present in the affected Port Network. Users may or may not hear any noisy tones. This type of failure affects maintenance on other objects. Maintenance may not be able to run on other objects which use the tone generation facility (that is, Tone Detector Circuit Pack maintenance). In this case, the Tone-Clock circuit pack can be replaced as suitable to the customer.

- c. Error code 115 may also be caused by TDM Bus corruption. This normally means a physical problem with bent backplane pins, TDM/LAN Bus cabling, or TDM/LAN Bus terminators. Such physical problems should especially be suspected if board replacement or other physical activity has occurred just before this error is observed.

Use **display errors** to look for errors on other circuit packs in the carriers of the same Port Network as the indicated Tone-Clock. If any are found, they should be resolved if possible, and the Tone-Clock circuit pack retested. If this does not clear the problem, the Tone-Clock circuit pack should be replaced and the new one tested. If the problem persists, follow instructions for TDM Bus maintenance in this manual.

**Tone Generator Update/Audit Test (#41)**

The active tone generation facility is refreshed with all the time slot tone information. This test also triggers in-line error messages the Tone-Clock circuit pack generates when it detects problems by itself.

A check is also made between the type of tone-clock being tested and the type of tone-clock needed based on system administration. The administration on the system-parameters country-options form may imply that a TN780 or TN2182 is required.

**Table 10-451. TEST #41 Tone Generator Update/Audit Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                             |

Tone Generator Crosstalk Test (#90)

This test checks the ability of the Tone Generator to talk on a specific time slot. The tone generator is told to talk on a specific time slot. The other idle time slots are checked to make sure the Tone Generator put the tone on only the specified time slot.

Table 10-452. TEST #90 Tone Generator Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                             |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| None       | ABORT       | Internal System Error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, follow normal escalation procedures.                                                                                            |
| 1001       | ABORT       | The system was not able to put the tone generation facility in the appropriate mode to test it.                                                                                                                                                                         |
| 1002       | ABORT       | The system could not allocate time slots for the test connection. This can happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the <b>test tdm port-network PN#</b> command. Refer to TDM-BUS section for details. |
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                         |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, follow normal escalation procedures.                                              |

|            | PASS        | <p>The tone generation facility is able to put tones out.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

# TSC-ADM (Administered Temporary Signaling Connections)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO                              |
|------------------------------------|-------------|------------------------------------------|----------------------------------------------|
| TSC-ADM                            | none        | none                                     | Administered Temporary Signaling Connections |
| TSC-ADM                            | none        | none                                     | Administered Temporary Signaling Connections |

No alarms are generated for the TSC-ADM (Administered Temporary Signaling Connections) MO. Due to the unusual length of the full name of this MO (that is, Administered Temporary Signaling Connections), the abbreviation Administered TSC is used often in this Maintenance documentation.

In general, administered temporary signaling connections provide a path through ISDN-PRI switches for supplementary D-channel messages. ISDN-PRI applications [that is, Distributed Communications System (DCS)] use temporary signaling connections to exchange user information across an ISDN-PRI network. What makes Administered Temporary Signaling Connection unique is that these particular Temporary Signaling Connections stay active for an extended period time (that is, similar to a permanent data connection). These ADM Temporary Signaling Connections are used for DCS features that require a NCATSC, and the ADM TSC serves as the logical channel function in a DCS network.

A Non-Call Associated Temporary Signaling Connection (NCATSC) is a virtual connection established within a D-channel. The NCATSC connection provides user to user service by exchanging USER INFORMATION messages through the virtual connection in a D-channel without associating any B-channel connections.

An *Administered TSC* is a special NCA Administered TSC defined for the DCS over the ISDN-PRI D-channel application of G3iV1.1-286 or G3iV2-386. The Administered TSC connection is a special type of NCATSC that has an administratively defined endpoint and is established for an extended period of time.

There are two types of ADMTSCs:

- Permanent  

TSCs are established by the originating PBX (that is *Near-end* ADM TSC) or by the terminating PBX (that is, *Far-end* ADM TSC). Once these ADMTSCs are established, they remain active.
- As-Needed

TSCs are established on an as-needed basis. In this case, the ADMTSC is established whenever it is needed, and not before.

ADMTSC maintenance provides a strategy to verify that a far-end can respond to an ISDN-PRI USER INFORMATION TSC heartbeat message, thereby indicating that user to user signaling is functioning. In addition, maintenance can retrieve the status of the ADMTSC's connection state.

Since ADMTSCs are administered on a per signaling group basis, the health of an ADMTSC also depends on the state of the D-channel or D-channel pair administered per signaling group. Refer to ISDN-SGR (ISDN-PRI Signaling Group) Maintenance documentation for details on ISDN-PRI NFAS and D-channel Backup maintenance. The two administration commands for ADMTSCs are as follows:

- **add signaling group #**
- **change signaling group #**

The two maintenance commands for ADMTSCs are as follows:

- **test tsc-administered signaling group #[/tsc index]**
- **status tsc-administered signaling group #/tsc index**

Hardware Error Log Entries and Test to Clear Values

ADM TSC Error Log Entries

| Error Type   | Aux Data    | Associated Test       | Alarm Level | On/Off Board | Test to Clear Value |
|--------------|-------------|-----------------------|-------------|--------------|---------------------|
| 3840-3967(a) | tsc index # | test tsc-administered |             |              |                     |

Notes:

- a. There is no Test to Clear Value for error types 3840-3967. The error types provides the following additional data that may prove useful when tracking down problems.

This error indicates that a TSC Heartbeat Inquiry Test was run on an Active far-end Administered TSC from the switch. Upon receiving the heartbeat message, the network communicated to the switch that the call reference value is not currently in use on the ISDN interface. As a result, the error was logged. Check the signaling group status of the D-channel or D-channel pair via the **status signaling-group <group>** command for the Administered TSC. Check the status of the Administered TSC via the **status tsc-administered** command. Also check the administration of the Administered TSC on the switch.

- This error may only be affecting service for some DCS customers. Upon receipt of this error condition, the switch tears down and re-establishes the ADMTSC within 20 minutes.
- b. The port field in the error log contains the signaling group number for TSC-ADM errors.

**System Technician-Demanded Tests:  
Descriptions and Error Codes**

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *TSC Heartbeat Inquiry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------|---------------------|--------------------|-------------------|
| TSC Heartbeat Inquiry Test (#604) |                     |                    | ND                |

1. D = Destructive; ND = Nondestructive

**TSC Heartbeat Inquiry Test(#604)**

This test can be invoked by system technician personnel for any ADMTSC administered in the switch. The following table indicates the possible error conditions that might be encountered when the test is invoked. Most of the error conditions do not log an error, but switched services may take some type of recovery action in certain instances.

This test sends a USER INFORMATION TSC heartbeat message inquiry across an Administered TSC to determine if the far-end can respond to a USER INFORMATION TSC heartbeat message.

**Table 10-453. TEST #604 TSC Heartbeat Inquiry Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## TTR-LEV (TTR Level)

| MO Name As It<br>Appears in<br>Alarm Log | Alarm Level | Initial System<br>Technician<br>Command to Run | Full Name of MO |
|------------------------------------------|-------------|------------------------------------------------|-----------------|
| TTR-LEV                                  | WARNING     | See Note <sup>1</sup>                          | TTR Level       |

1. See the "Repair Procedure for the TTR Level Maintenance Object" section.

A TN748 Tone Detector circuit pack and the TN744 Call Classifier circuit pack provides touch tone receivers (TTRs or DTMR-PTs)) which are devices used to interpret touch tone calling signals and to translate the dual tones into the following valid digits: 0 through 9, \*, and #. A Tone Detector circuit pack is a resource shared by all PBX users. The term "touch tone" formerly bore an AT&T trademark while the term "dual tone multifrequency receiver" has been the generic term used for this kind of device. A Tone Detector circuit pack also has general purpose tone detector ports (GPTD-PTs) to detect call progress tones, modem answer tones, and transmission test tones. In G3iV1.1-286 or G3iV2-386, Call Classifier Ports (CLSFY-PTs) have also been added to detect voice or network intercept tones. A Call Classifier Port (CLSFY-PT) can function as either a DTMR-PT or as a GPTD-PT.

When a user places a call from a digital or analog voice terminal on the switch, a TTR is needed to interpret the dual tone multifrequency signals sent from the voice terminal. The TTR is in use until the total number of digits needed is collected or until a time-out occurs. Dial tone is supplied to a user after receipt of an off-hook signal which signifies that a TTR is connected and ready to receive digits. For example, if there are 20 TTRs in the system being used simultaneously by 20 users at a given time, then the 21st user would not receive dial tone until a TTR becomes available. It is for this reason that it is necessary to have sufficient tone detectors in the system to prevent delay in receiving dial tone. The TTR-LEV errors can be used to determine a shortage of tone detectors. Use the **list measurements tone-receiver** command to determine tone detector usage. For more information on this command, refer to the *DEFINITY. Communications System Generic 1—Administration and Measurement Reports*, 555-200-500. The minimum threshold values assigned on the Maintenance-Related System Parameters Form for TTRs (DTMR-PTs), CPTRs (GPTD-PTs), and CCRs (CLSFY-PTs) should match the number of touch tone receivers (TTR) and tone detectors (GPTD-PT) in the system. The numbers are four TTRs and two GPTDs for each Tone Detector circuit pack [TN748, TN748B, and TN748C, and (the TN756 Combined Tone Detector/Tone-Clock in a single-carrier cabinet system)] used in the switch and 8 CCRs for each Call Classifier Port (TN744) circuit pack. The threshold values are administered via the **change system-parameters maintenance** command on the Maintenance-Related System Parameters Form. The desired numbers are entered in the "TTR" (DTMR-PT), "CPTR" (GPTD-PT), and "Call Classifier" (CLSFY-PT) fields, respectively.

The TTR Level (Touch Tone Receiver Level) MO is used to represent the following possible events:

1. The total number of General Purpose Tone Detector Ports (GPTD-PTs), [also known as Call Progress Tone Receivers (CPTRs)], currently in service is less than the administered threshold number.
2. The total number of Dual Tone Multifrequency Receiver Ports (DTMR-PTs) [(also known as Touch Tone Receiver (TTRs)], currently in service is less than the administered threshold number.

The TTR Level maintenance performs a monitoring function. When one of the above events occurs, the switch reports it. At this point, the system is still operating properly, but the system capacity is reduced.

The above events can occur if:

1. The threshold number of General Purpose Tone Detector Ports (GPTD-PTs) for service or the threshold number of Dual Tone Multifrequency Receiver Ports (DTMR-PTs) for service is administered incorrectly on a Tone Detector circuit pack.
2. Too many General Purpose Tone Detector Ports (GPTD-PTs) or Dual Tone Multifrequency Receiver Ports (DTMR-PTs) have been taken out-of-service for a Tone Detector circuit pack (that is, the ports have been either busied-out by system technician or maintenance has taken them out-of-service).
3. Too many ports have been taken out-of-service for a Call Classifier circuit pack (that is, the ports have been busied-out by system technician or maintenance has taken them out-of-service).
4. There is an insufficient number of General Purpose Tone Detector Ports (GPTD-PTs) or Dual Tone Multifrequency Receiver Ports (DTMR-PTs) in the system for a Tone Detector circuit pack. Or there is an insufficient number of ports in the system for a Call Classifier circuit pack.

## Repair Procedure for the TTR Level Maintenance Object

---

The following is a step-by-step approach to resolve the TTR Level maintenance alarm.

1. Execute the **display error** command. Determine if the TTR-LEV warning alarm is raised against the GPTD-PT level, the DTMR-PT level, or the CLSFY-PT level. In the Hardware Error Log Table, the error type field of the TTR-LEV MO has a value of 2 for DTMR-PT level, a value of 4 for GPTD-PT level, or a value of 6 for CLSFY-PT level.

Perform the actions described in Step 2 for the DTMR-PT, the GPTD-PT, or the CLSFY-PT.

2. Issue the **change system-parameters maintenance** command. Check the administered value(s) for TTRs and CPTRs for service on the Tone Detector circuit packs or for CCRs on the Call Classifier Port (CLSFY-PT) circuit pack. If a threshold value is set too high, change it to a lower value via the **change system-parameters maintenance** command and wait one minute for the alarm to clear.

To determine the correct TTR, CPTR, and Call Classifier port values, check the total number of Tone Detector and Tone-Clock circuit pack and Call Classifier circuit packs (TN744) currently in the system. A Tone Detector circuit pack has two GPTD ports and four DTMR ports. A Call Classifier circuit pack has eight ports. Verify that the total number of GPTD-PTs, DTMR-PTs, and/or CLSFY-PTs in the system is greater than or equal to their respective administered threshold values. If not, then you must either (1) add more Tone Detector circuit packs and/or Call Classifier circuit packs to the system as required or (2) reduce the threshold to match the number in the system. If after (1) adding more Tone Detector circuit packs and/or Call Classifier circuit packs or (2) reducing the threshold, the TTR Level alarm is still present, then proceed to Step 3.

3. Execute the **display error** command. Look for a GPTD-PT, DTMR-PT, or CLSFY-PT that has been busied out. A port that has been busied out has a value of 18 in the error type field of the Hardware Error Log.

For each of the busied-out ports, use the following procedure:

- Determine why the port was busied out.
- If the port can be placed back into service, test the port via the **test port PCSSpp** command.
- If all the tests pass, release the port via the **release port PCSSpp** command. Then wait one minute for the TTR Level alarm to clear.

If this does not clear the TTR Level alarm, proceed to Step 4.

4. Execute the **display alarm** command. Determine the address of the Tone Detector circuit pack which contains the defective (alarmed) GPTD-PT or DTMR-PT.

Execute the **test board PCSS long rep 3** command where PCSS is the address (that is, port network number, carrier designation, and slot address) of the Tone Detector circuit pack or Call Classifier circuit pack containing the defective (alarmed) GPTD-PT or DTMR-PT.

If this does not clear the TTR Level alarm, proceed to Step 5.

5. At this point, the only way to clear the alarm is to replace the Tone Detector circuit pack or Call Classifier circuit pack containing the defective (alarmed) GPTD-PT, DTMR-PT or CLSFY-PT.

Hardware Error Log Entries and Test to Clear Values

TTR Level Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level                             | On/Off Board | Test to Clear Value |
|------------|----------|-----------------|-----------------------------------------|--------------|---------------------|
| 1 (a)      | 1        | None            |                                         |              |                     |
| 2 (b)      | 2        |                 | WARNING (See the WARNING message below) | OFF          |                     |

 **WARNING:**

*The Alarm is upgraded to MAJOR if the Base Tone Generator is set to 12 (France).*

Notes:

- a. Error code 1 does not indicate a current error condition. It indicates that the number of DTMR ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.
- b. The total number of DTMR ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure described above.
- c. Error code 3 does not indicate a current error condition. It indicates that the number of GPTD ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.
- d. The total number of GPTD ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure describe above.

- e. Error code 5 does not indicate a current error condition. It indicates that the number of Call Classifier ports (CLSFY-PT) in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.
  - f. The total number of Call Classifier ports currently in service is below the administered threshold. To clear the alarm, refer to the repair procedure described above.
  - g. There are currently no DTMR ports in service. To clear the alarm, refer to the repair procedure described above.
  - h. There are currently no GPTD ports in service. To clear the alarm, refer to the repair procedure described above.
  - i. There are currently no Call Classifier ports in service. To clear the alarm, refer to the repair procedure described above.
-

# UDS1-BD (UDS1 Interface Circuit Pack)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO             |
|------------------------------------|-------------|------------------------------------------|-----------------------------|
| UDS1-BD                            | MAJOR       | test board PCSSpp sh                     | UDS1 Interface Circuit Pack |
| UDS1-BD                            | MINOR       | test board PCSSpp l                      | UDS1 Interface Circuit Pack |
| UDS1-BD                            | WARNING     | test board PCSSpp sh                     | UDS1 Interface Circuit Pack |

The UDS1 Interface circuit pack provides an interface to the DS1 facility. UDS1 Interface circuit packs include the TN464B circuit pack and the TN464C circuit pack.

The TN464B circuit pack is designed to support 32 DS0 channels on a 2.048 Mbps DS1 link, and the TN464C (or greater vintage) circuit pack is designed to support either 24 DS0 channels on a 1.544 Mbps DS1 link or 32 DS0 channels on a 2.048 Mbps DS1 link. The TN464C (or greater vintage) circuit pack is optioned via a removable strap on the circuit pack. The 2 strap positions are labeled "24CHNL" or "32CHNL."

The DS0 channels can be administered either as trunks to other switches, lines to off-premises stations, ports to line-side PRI terminating devices, or as ports to other line-side non-PRI terminating devices.

 **NOTE:**  
DS0 channels on the TN464B circuit pack can be administered only as trunks to other switches.

UDS1 Interface Circuit Pack Maintenance documentation provides a strategy for maintaining the UDS1 Interface circuit pack. The maintenance strategy deals with logging the in-line errors reported by the UDS1 Interface circuit pack, running tests for error diagnosis and recovery, and raising or clearing maintenance alarms.

The TN464B and TN464C circuit packs support Tie trunks, CO trunks, DID trunks, OPS lines, narrowband access endpoint ports, the ISDN-PRI signaling channel (D-channel), and ISDN-PRI trunks (B-channels). The TN464C circuit pack can also support wideband access endpoint ports and PRI endpoint ports (B-channels).

The signaling (that is, the call setup) for the Tie trunks, CO trunks, DID trunks and OPS lines is done on the circuit pack by the UDS1 firmware. Signaling for the B-channels (ISDN-PRI trunks and PRI endpoint ports) is routed over the D-channel. ISDN-PRI Trunk and PRI endpoint port signaling (Q.921, Q.931), however, is not provided by the UDS1 Interface circuit pack. For the MIPS version of D92, the system software generates and/or receives the actual

ISDN-PRI signaling messages (Q.931). The system software sends and/or receives these ISDN-PRI messages via the TN1655 Packet Interface circuit pack. The Packet Interface circuit pack, in turn, communicates with the UDS1 circuit pack's D-channel via the Packet Bus. For the INTEL version of D92, the system software generates and/or receives the actual ISDN-PRI signaling messages (Q.931). The system software sends and/or receives these ISDN-PRI messages via the TN765 Processor Interface circuit pack. The Processor Interface circuit pack, in turn, communicates with the UDS1 circuit pack's D-channel via the TDM Bus.

The signaling over the DS1 link must be synchronized between the transmitting end and the receiving end to ensure error-free communication. Refer to SYNC (Synchronization) Maintenance documentation for details.

Each trunk, line, and port has its own maintenance strategy. However, each trunk, line, or port is dependent upon the health of the UDS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1 documentation for a DS1 Tie Trunk, CO-DS1 documentation for a DS1 CO Trunk, DID-DS1 documentation for a DS1 DID Trunk, OPS-LINE documentation for a DS1 OPS Line, WAE-PORT documentation for a Wideband Access Endpoint, ISDN-TRK documentation for a DS1 ISDN Trunk, PE-BCHL documentation for a PRI Endpoint Port, and ISDN-LNK documentation for an ISDN-PRI Signaling Link Port.

The maintenance strategy for the TN464 UDS1 Interface circuit pack (UDS1-BD) is very similar to the maintenance strategy for the TN767 DS1 Interface circuit pack (DS1-BD). The same commands are used for administering and testing the boards. The differences in maintenance strategy between the boards are due to the UDS1 circuit pack's direct interface to the Packet Bus which is used for ISDN-PRI signaling (ISDN-LNK). While both the TN464 and TN767 can support ISDN-PRI B-channels, ISDN-PRI D-channel signaling applications require a TN464 UDS1 circuit pack.

The TN464F (or later suffix) circuit pack combined with AT&T's new 120A1 CSU Module forms an Enhanced Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN464F hardware and firmware, and new switch software, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The 120A1 CSU Module connects to the TN464F circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module, thus becomes an integrated part of the DEFINITY. system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A1 CSU Module see *DEFINITY. Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation*, 555-230-193, Issue 1, December 1993.

The TN464F and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN464F circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this UDS1-BD section, but [Figure 10-92](#) gives a high level overview of the loopback points.

Figure 10-92. High Level Overview Of Loopback Points

## **Circuit Pack Administration and Options**

---

The DS1 configuration for each circuit pack is administered on the DS1 Circuit Pack form. *Bit Rate* is set to 1.544 Mbps for 24-channel systems, and 2.048 Mbps for 32-channel systems. *Country Protocol* is used to drive layer 3 protocol decisions based on PRI specifications specific to a given country (not those related to specific features). This Country Protocol is independent of the *Country* parameter administered on the country-options system-parameters form. Different UDS1 circuit packs may be administered with different Country Protocols, allowing the switch to act as a gateway between two incompatible ISDN-PRI implementations (for example, between two different countries). US systems use country protocol 1. *Near-End CSU Type* is set to *other* for no CSU installed, *or* for an external CSU such as an AT&T ESF T1 CSU, *or integrated* for the 120A1 CSU Module. Answering *integrated* will cause additional fields to be displayed for administering the Enhanced Integrated CSU Module. In addition to the above there are numerous other fields defining such parameters as framing modes, line coding companding mode and so on. For details, see *DEFINITY Communications System Generic 3 V2 Implementation*, 555-230-653, and *DEFINITY Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT/ISDN-PRI Reference*, 555-025-107.

[Figure 10-93](#) through [Figure 10-95](#) show how to configure the circuit pack for 24-channel or 32-channel DS1. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

Figure 10-93. TN464C/D DS1 Option Jumpers

Figure 10-94. TN464C/D DS1 Option Jumpers

The option switch located on the component side of the TN464E/F circuit pack must be set correctly. [Figure 10-95](#) shows how to configure the circuit pack for 24-channel or 32-channel DS1. The channel selection must match the

parameters administered on the corresponding DS1 Circuit Pack Form. (US applications use 24 Channels.)

Continued on next page

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.
3. Minor alarms on this MO may be downgraded to warning alarms based on values set in the **set options** command.
4. Major alarms on this MO may be downgraded to minor or warning alarms based on values set in the **set options** command.

Notes:

- a. Error 1 indicates that the circuit pack has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

To be fully administered, a UDS1 circuit pack must meet all of these 3 conditions:

1. Have an entry in the circuit plan via the **change circuit pack** command
2. Be administered via the **add ds1** PCSS command
3. Be physically inserted into the correct slot

If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning UDS1 circuit pack is inserted in the correct slot, or
2. Completely remove the UDS1-BD from the system using the following steps:
  - a. Remove any administered DS1 trunks, access endpoints or PRI endpoints associated with the circuit pack from their trunk groups.
  - b. Execute the **remove ds1** PCSS and **change circuit pack** PCSS commands.

If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions for LED Alarms with Error Type 1 in [Chapter 7, "LED Interpretation"](#).

- b. The UDS1 Interface circuit pack has been busied out by a **busyout board** PCSS command.
- c. The UDS1-BD circuit pack is not completely administered. To be fully administered, the UDS1 circuit pack must:
  1. Have an entry in the circuit plan via the **change circuit pack** command,

- 2.Be administered via the **add ds1** PCSS command, and
- 3.Be physically inserted into the correct slot.

A DS1 (UDS1-BD and DS1-BD) differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered with the **add ds1** command.

- d. No Aux Data: A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.

Aux Data 3: The 24/32-channel option jumper setting on the circuit pack does not match the option set on the DS1 circuit pack administration form. The circuit pack must be physically removed to see the setting of the jumper.

- e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for details.
- f. The UDS1 Interface circuit pack has detected a transient hardware problem. The value in the Aux Data field indicates the type of hardware problem.

|      |                      |
|------|----------------------|
| 4352 | External RAM failure |
| 4353 | Internal RAM failure |
| 4355 | Internal ROM failure |

If the UDS1 board detects only one of these hardware problems, then the error will disappear when none of these faults are detected for 10 minutes. If the same Aux Data value is logged more than once in a 24 hour period, the circuit pack should be replaced.

- g. LAN External RAM Error. This error occurs when there is a hardware fault in the PPE external RAM. The RAM is used for message buffering to and from the Packet Bus. This error should not occur regularly. If this error is seen quite frequently (10 times within 30 minutes), the circuit pack should be replaced.
- h. Transmit FIFO Underflow Error. This error occurs when the circuit pack cannot find the "end of frame" bit when transmitting a frame to Packet Bus. An alarm will be raised if this error occurs three times within 10 minutes. Clear the alarm via the following commands: **busyout board PCSS**, **reset board PCSS**, **test board PCSS long**, **release board PCSS**. If the error recurs within 10 minutes, then replace the circuit pack.
- i. Unable to Write LAN Translation RAM Error. This error occurs when a call is aborted because there are no available translation RAM locations for the call connection attempt. An alarm will be raised if this error occurs two times within 10 minutes. Clear the alarm via the following commands:

**busyout board PCSS, reset board PCSS, test board PCSS long, release board PCSS.** If the error recurs within 10 minutes, then replace the circuit pack.

- j. CSU Module missing. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the 120A1 CSU Module is not physically connected (or is improperly connected) to the TN464F board on the back of the port carrier.

If using the 120A1 CSU Module, plug (or replug) the CSU Module into the TN464F circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the *Near-End CSU Type* field using the *change ds1* form to *other*.

If this error remains after plugging the CSU Module into the board's connector, there could be a problem with the I/O connector panel.

- k. CSU Module not expected. The 120A1 CSU Module is physically connected to the TN464F board on the back of the port carrier but the *Near-End CSU Type* field on the *add ds1* form has not been administered as *integrated*.

If the 120A1 CSU Module is to be used, use the *change ds1* command to change the *Near-End CSU Type* field to *integrated*. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier.

- l. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN464F circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.
- m. DS1 circuit pack suffix incorrect for CSU Module. The *Near-End CSU Type* field on the *add ds1* form has been administered as *integrated* but the DS1 circuit pack is not a TN464F or later suffix UDS1 board.

If the 120A1 CSU Module is to be used, remove the circuit pack and replace it with a TN464F or later suffix board. Otherwise, use the ***change ds1*** command to change the *Near-End CSU Type* field to *other*.

- n. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: ***busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, release board PCSS***. If the BLB test continues to fail, then the TN464F circuit pack needs to be replaced.
- o. ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*.

Attempt to clear the alarm via the following commands: *busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, release board PCSS*. If the ELB test continues to fail, then either the TN464F board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate where the failure is occurring by reexecuting the test by replacing one piece of hardware at a time.

- p. RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command *test ds1-loop PCSS ds1/csu-loopback-tests*.

Attempt to clear the alarm via the following commands: *busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, release board PCSS*. If the RLB test continues to fail, then the CSU Module needs to be replaced.

- q. CPE Loopback Jack deactivation error. This error occurs when the TN464F circuit pack could not deactivate a CPE Loopback Jack loopback on power-up/reset or upon software request.

Attempt to clear the alarm via the following commands: *busyout board PCSS, test ds1-loop PCSS end-loopback/span-test, release board PCSS*. If the attempt to deactivate the CPE Loopback Jack loopback continues to fail, other steps must be taken to deactivate the loopback.

- r. Far CSU Loopback deactivation error. This error occurs when the TN464F circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

Attempt to clear the alarm via the following commands: *busyout board PCSS, test ds1-loop PCSS end-loopback/span-test, release board PCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

- s. LAN Bus Timeout Error. This error occurs when the circuit pack transmits too many bytes on the LAN bus for a single frame. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those maintenance objects.

If the error occurs three times within 10 minutes, the board will be isolated from the Packet Bus and the board will be alarmed. To clear the alarm and restore the board to the Packet Bus, use the following commands:  
**busyout board PCSS, reset board PCSS, test board PCSS long, release board PCSS.**

If the problem persists, and there are no PKT-BUS alarms or port alarms, then replace the circuit pack.

- t. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
  - 1.The common circuit pack level tests such as Test #50 and/or Test #52 are aborting with error code 2000.
  - 2.The tests run on the ports of this circuit pack are returning with a NO-BOARD.
  - 3.A busyout/release of the circuit pack has no affect on test results.
  - 4.A **list configuration** command shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and all trunks or ports on this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 20-30 minutes. When no faults are detected for 20-30 minutes, the UDS1 Interface circuit pack is restored to normal operation. All trunks or ports of the UDS1 Interface circuit pack are then returned to the in-service state. If the board is not restored to normal operation, or the error recurs after the board was restored to normal operation, escalate the problem.

- u. LAN Critical Error. A critical failure has been detected in the Packet Bus interface of the circuit pack. This failure may be due to an on-board fault or a Packet Bus fault. If the Packet Bus is alarmed, refer to the PKT-BUS Maintenance documentation for recommended repair procedures.

This error will isolate the board from the Packet Bus and raise an alarm. If the Packet Bus is not alarmed, enter the following commands: **busyout board PCSS, reset board PCSS, test board PCSS, release board PCSS**. This should clear the alarm and restore the board to the Packet Bus.

If the problem persists, and there are no PKT-BUS alarms, then replace the circuit pack.

- v. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving slips and the AUX data shows the last slip count that was reported.
- w. These errors are not service-affecting. No action is required. These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

|      |                     |
|------|---------------------|
| 4096 | Bad major heading   |
| 4097 | Bad port number     |
| 4098 | Bad data            |
| 4099 | Bad sub-qualifier   |
| 4100 | State inconsistency |
| 4101 | Bad logical link    |

- x. For later releases of G3V4 and beyond, only error 3585 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.
- y. The UDS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.
- z. Bad Translation RAM Location Found Error. This error is not service-affecting. No action is required. A Bad Translation RAM is detected, but the call continues by using another translation location.
- aa. LAN Receive Parity Error. This error occurs when the circuit pack detects an error in a received frame from the Packet Bus. These errors are most likely caused by a Packet Bus problem, but may be due to a circuit pack fault.

Refer to the PKT-BUS Maintenance documentation to determine if the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults.

- ab. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.
  - 1 — Test is currently running.
  - 2 — Test failed because loopback could not be activated.
  - 3 — Test failed because test pattern could not be detected.
  - 4 — Test has been terminated.
- ac. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.
  - 1 — Test is currently running.
  - 2 — Test failed because loopback could not be activated.
  - 3 — Test failed because test pattern could not be detected.
  - 4 — Test has been terminated.
- ad. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.
  - 1 — Test is currently running.
  - 2 — Test has failed because test could not be activated.
  - 3 — Test pattern was not received from the far end.
  - 4 — Test has been terminated.

- ae. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Connection Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-455. System Technician-Demanded Tests: Descriptions and Error Codes

| Order of Investigation                   | Short Test Sequence | Long Test Sequence | Reset Board Sequence | test ds1-loop Command | D/ND <sup>1</sup> |
|------------------------------------------|---------------------|--------------------|----------------------|-----------------------|-------------------|
| NPE Connection Audit Test (#50)          |                     | X                  |                      |                       | ND                |
| Control Channel Loop Test (#52)          |                     | X                  |                      |                       | ND                |
| Loss of Signal Alarm Inquiry Test (#138) | X                   | X                  |                      |                       | ND                |
| Blue Alarm Inquiry Test (#139)           | X                   | X                  |                      |                       | ND                |
| Red Alarm Inquiry Test (#140)            | X                   | X                  |                      |                       | ND                |
| Yellow Alarm Inquiry Test (#141)         | X                   | X                  |                      |                       | ND                |
| Major Alarm Inquiry Test (#142)          | X                   | X                  |                      |                       | ND                |
| Minor Alarm Inquiry Test (#143)          | X                   | X                  |                      |                       | ND                |

NPE Connection Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for the SCOTCH-NPE chip on the circuit pack.

Table 10-456. TEST #50 NPE Connection Audit Test

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

Table 10-458. TEST #53 SAKI Sanity Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| None       | ABORT       | System resources required for this test are not available.<br><br>1. Retry the <b>reset board</b> command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                  |
| 1005       | ABORT       | Wrong circuit pack configuration to run this test. This error applies only to DS1 Interface circuit packs. It means the DS1 Interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions.<br><br>1. If the circuit pack needs to be reset, then set synchronization to another DS1 Interface circuit pack or to the Tone-Clock circuit pack and try again. Refer to SYNC (Synchronization) Maintenance documentation. |
| 1015       | ABORT       | Port is not out-of-service.<br><br>1. Busyout the circuit pack.<br><br>2. Execute the <b>reset board</b> command again.<br><br>3. If the test aborts with this error code again, escalate the problem.                                                                                                                                                                                                                                                                                 |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Internal Loop Around Test (#135)

This test is destructive.

The Internal Loop Around Test is run by looping the transmitted DS1 bit stream back into the UDS1's board receiver. The loop occurs just before the DS1 facility interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Internal Loop Around Test. When the Internal Loop Around Test is initiated, maintenance software sends appropriate messages to the UDS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk or port are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the UDS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks or ports of the UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the UDS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the UDS1 Interface circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored.

The UDS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 3 seconds. It will not retire the alarm until the signal has returned for about 10 seconds.

This test is also used to maintain the new AT&T 120A1 CSU Module. This CSU Module, when combined with the functionality provided by the TN464F circuit pack, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The combination of the TN464F and 120A1 CSU Module is known as an Enhanced Integrated CSU (I-CSU).

If a TN464F circuit pack detects certain I-CSU hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the I-CSU error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN464F board to confirm the I-CSU error. A Minor or Warning alarm will be raised depending on the severity of the I-CSU error. The trunks on the board may be taken out of service if the I-CSU error is deemed serious.

If a Loss Of Signal alarm and an I-CSU error co-exist, the Loss Of Signal alarm condition will take priority and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the I-CSU hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other I-CSU errors or Loss Of Signal alarm exist).

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. |------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p>UDS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this UDS1 interface circuit pack are out-of-service. If the UDS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to the SYNC section in this chapter for details. If the UDS1 connects to a T1 network facility:</p> <ol style="list-style-type: none"><li>1. Check the physical connection of the UDS1 Interface circuit pack and the cable. If a 120A1 CSU Module is physically connected to a TN464F board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack.</li><li>2. If the UDS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint.</li></ol> <p>If the UDS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter:</p> <ol style="list-style-type: none"><li>1. Check the physical connection of the UDS1 Interface circuit pack to the terminating device. Check premise distribution system (or intra-premise wiring) for physical connection failures. If a 120A1 CSU Module is physically connected to a TN464F board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack.</li><li>2. Contact the vendor of the line-side terminating device to diagnose the equipment.</li></ol> |

| 1311       | FAIL        | <p>The Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test (#1210) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command <i>test ds1-loop PCSS ds1/csu-loopback-tests</i>.</p> <ol style="list-style-type: none"><li>1. Execute the <i>test ds1-loop PCSS ds1/csu-loopback-tests</i> command.</li><li>2. If the ELB test continues to fail, then either the TN464F board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module and running the <i>test ds1-loop PCSS ds1/csu-loopback-tests</i> command again.</li><li>3. If the ELB test continues to fail, then replace the TN464F board and run the <i>test ds1-loop PCSS ds1/csu-loopback-tests</i> command again.</li><li>4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module.</li></ol> |
| 1312       | FAIL        | <p>The Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test (#1211) failed. This test is executed by the I-CSU during I-CSU power-up/reset (i.e.- TN464F board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command <i>test ds1-loop PCSS ds1/csu-loopback-tests</i>.</p> <ol style="list-style-type: none"><li>1. Execute the <i>test ds1-loop PCSS ds1/csu-loopback-tests</i> command.</li><li>2. If the RLB test continues to fail, then replace the CSU Module.</li><li>3. Run this test again.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1324       | FAIL        | A non-service affecting CSU Module audit failure was detected by the TN464F UDS1 circuit pack. No ports should be affected. No immediate action is required. These errors indicate that the CSU Module hardware may have a problem, and that it should be replaced when practical to avoid further deterioration.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|            | PASS        | DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU errors are detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the UDS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote

DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The UDS1 Interface circuit pack takes 3 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the UDS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks or ports back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. When the switch DS1 is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. | 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Red Alarm Inquiry Test (#140)

A UDS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a UDS1 Interface circuit pack. A UDS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 10 seconds to recognize and report the resolution of a Red alarm.

When the UDS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks or ports of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the UDS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance

software restores all trunks or ports of the UDS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm

If the UDS1 Interface circuit pack is administered using DMI-BOS signaling, the UDS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once the UDS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A 'busyout' or a 'release' command has no affect on the test results.</li><li>4. A 'list config' command shows that the circuit pack and the ports are properly installed.</li></ol> <p><b>⇒ NOTE:</b></p> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

|            | PASS        | No Red alarm is detected on the UDS1 Interface circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The UDS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the UDS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software

places all trunks or ports on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks or ports on the UDS1 Interface circuit pack back to their previous service state before the Yellow alarm was raised.

This Yellow alarm corresponds to the yellow F2 state documented in CCITT Recommendation I.431.

Remote Multiframe Alarm

Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the UDS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 Fault Alarm

For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431.

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A 'busyout' or a 'release' command has no affect on the test results.</li><li>4. A 'list config' command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

|            | PASS        | Neither a Yellow alarm nor a Remote Multiframe Alarm nor a F5 state alarm is being received from the remote DS1 endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Major Alarm Inquiry Test (#142)

The Major alarm raised by a UDS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. The UDS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the UDS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. (32-channel interfaces send a YELLOW alarm to the far end). After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the

Major alarm on the UDS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks or ports on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks or ports on the circuit pack to their previous service state before a Major alarm occurs.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a UDS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the UDS1 Interface circuit pack takes 41 minutes to recognize and report a Minor alarm and 41 minutes to recognize and report that a Minor alarm condition has cleared. If ESF framing mode is selected, the UDS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition has cleared.

When the UDS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks or ports on the circuit

pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Slip Alarm Inquiry Test (#144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The UDS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips that have occurred on a DS1 link.

When the UDS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on a UDS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the UDS1 Interface circuit pack. All trunks or ports of the UDS1 Interface circuit pack

remain in the in-service state. If the UDS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See TDM-BUS (TDM Bus) and SYNC (Synchronization) Maintenance documentation for details.

|            | ABORT       | <p>Internal System Error</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a UDS1 Interface circuit pack are in error. The Misframe Alarm Inquiry Test queries the total number of misframes that have occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches a specified threshold (i.e.- 17), a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the UDS1 Interface circuit pack.

When the threshold of misframes is reached, if the UDS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus)

Maintenance documentation for details. A Minor alarm against the UDS1 Interface circuit pack is raised, but all trunks or ports of the UDS1 Interface circuit pack remain in the in-service state.

Table 10-467. TEST #145 Misframe Alarm Inquiry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 1 to 17    | FAIL        | <p>The test failed because the UDS1 interface circuit pack detected errors in the received framing bits pattern. The error code equals the number of misframes detected by the UDS1 interface circuit pack since the last misframe alarm inquiry test. Major bit and minor bit error rate (error types 2561 and 2817) error logs often accompany misframe alarms. Clearing the cause of these error logs may clear the misframes which are occurring.</p> <p>If the UDS1 connects to a T1 network facility or to another switch, do the following:</p> <ol style="list-style-type: none"><li>1. Retry the command at 1 minute intervals for a maximum of 5 times.</li><li>2. If the DS1 interface circuit pack is a TN464C, enter the <b>list measurement ds1-log PCSS</b> command to read the error seconds measurement.</li><li>3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding.</li><li>4. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors.</li><li>5. Contact T1 Network Service or the technician at the remote switch to diagnose the remote DS1 endpoint.</li><li>6. Check the physical connectivity of the UDS1 interface circuit packs and the cable.</li><li>7. Replace the local UDS1 interface circuit pack, and repeat the test.</li></ol> <p><i>More information continues on the next page.</i></p> |

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the UDS1 Interface circuit pack. Translation includes the following data administered for a UDS1 Interface circuit pack (see output of **display ds1 PCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

In G3V3, if a TN464F or later UDS1 circuit pack is combined with an AT&T 120A1 CSU Module to form an Integrated CSU Module, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module is done using the DS1 circuit pack administration form. Translation for the CSU Module includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, etc.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN464F DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1039       | ABORT       | <p>The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence:</p> <ol style="list-style-type: none"><li>1. Issue the <b>disable synchronization-switch</b> command.</li><li>2. Next, issue the <b>set synchronization PCSS</b> command.</li><li>3. Lastly, issue the <b>enable synchronization-switch</b> command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.</li></ol> |
| 1950       | ABORT       | <p>Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <i>test ds1-loop PCSS end-loopback/span-test</i> command in order to execute this test.</p>                                                                                                                                       |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|            | FAIL        | UDS1 Interface circuit pack failed the DS1 Board Loopback Test.<br><br>1. Retry the <i>test ds1-loop PCSS ds1/csu-loopback-tests</i> command.<br><br>2. If the BLB test continues to fail, then replace the UDS1 circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|            | PASS        | The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN464F DS1 board edge.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.<br><br>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.<br><br>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.<br><br>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.<br><br>4. Issue the <b>reset board</b> command.<br><br>5. Issue the <b>release busy board</b> command.<br><br>6. Issue the <b>test board long</b> command.<br><br>This should re-establish the linkage between the internal ID and the port. |

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local AT&T 120A1 CSU Module and tests the connection from the TN464F

DS1 board to the CSU Module (DS1 board edge, connection, and CSU Module edge). This test will only be performed if the AT&T 120A1 CSU Module is present, administered, and connected to a 1.544 Mbps TN464F DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern itself.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the local AT&T 120A1 CSU Module and tests the connection from the TN464F DS1 board to and including the CSU Module circuitry. This test will only be performed if the AT&T 120A1 CSU Module is present, administered, and connected to a 1.544 Mbps TN464F DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS ds1/csu-loopback-tests* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN464F UDS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern itself.

When the test is complete, all trunks or ports on the TN464F UDS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

**Table 10-471. TEST #1211 CSU Repeater Loopback Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1951       | ABORT       | The CSU Repeater Loopback Test could not be executed because the 120A1 CSU Module was not physically installed. Physically connect the 120A1 CSU Module to the TN464F board on the back of the port carrier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|            | PASS        | <p>The RLB test executed successfully. The test pattern was transmitted and received successfully over the connection from the TN464F DS1 board to the far-edge of the 120A1 CSU Module.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN464F DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded ***test ds1-loop PCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]*** command. The system technician has the choice of entering a loopback activation code on the command line or using the default code (0x47F).

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CSJ Loopback Test.

The CPE Loopback Test has the TN464F UDS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of Loopback/Span test executing (*Test* field), the type of pattern generated for the Loopback/Span test (*Pattern* field), and whether the pattern (*i.e.* 3-in-24 *Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

| 1950       | ABORT       | Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <i>test ds1-loop PCSS end-loopback/span-test</i> command in order to execute this test. |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Far CSU Loopback Test (#1213)

This test is destructive.

The Far CSU Loopback (R-LLB) Test causes a loopback at the far-end CSU and tests all circuitry and facilities from the local TN464F DS1 board to the far-end CSU.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS far-csu-loopback-test-begin* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Far CSU Loopback Test.

If the far-end CSU is not an AT&T 120A1 CSU Module, and the UDS1 is administered for ami-zcs line coding, one's density protection must be disabled

on the CSU during the test due to the large number of zero's in the 3-in-24 test pattern.

The Far CSU Loopback Test has the TN464F UDS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test will be available in the hardware error log via error type 3901. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of Loopback/Span test executing (*Test* field), the type of pattern generated for the Loopback/Span test (*Pattern* field), and whether the pattern(*i.e.* 3-in-24 *Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

|            | ABORT       | Internal System Error<br><br>1. Retry the <i>test ds1-loop PCSS far-csu-loopback-test-begin</i> command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                  |
| 1005       | ABORT       | Far CSU Loopback Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation. |

Table 10-473. TEST #1213 Far CSU Loopback Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1015       | ABORT       | <p>Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service.</p> <ol style="list-style-type: none"><li>1. Enter the <b>busyout board PCSS</b> command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state.</li><li>2. Retry the command.</li><li>3. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                  |
| 1039       | ABORT       | <p>The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence:</p> <ol style="list-style-type: none"><li>1. Issue the <b>disable synchronization-switch</b> command.</li><li>2. Issue the <b>set synchronization PCSS</b> command.</li><li>3. Issue the <b>enable synchronization-switch</b> command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.</li></ol> |
| 1950       | ABORT       | <p>Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <i>test ds1-loop PCSS end-loopback/span-test</i> command in order to execute this test.</p>                                                                                                                         |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

|            | PASS        | The Far CSU Loopback test has successfully began executing. The test will continue to run until the system technician enters the <i>test ds1-loop PCSS end-loopback/span-test</i> command or the <i>release board PCSS</i> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

One-Way Span Test (#1214)

This test is destructive.

The One-Way Span Test allows one-way span testing to and from remote test equipment or another DEFINITY communications system. This will test all circuitry and facilities from the local TN464F DS1 board to the remote test equipment or other DEFINITY communications system.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS one-way-span-test-begin* command.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the One-Way Span Test.

The One-Way Span Test has the TN464F UDS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempt to receive and verify the pattern. If the TN464F board receives a framed 3-in-24 test pattern sent from another DEFINITY G3V3 or test equipment at the far-end of the DS1, it will begin counting bit errors within the received pattern.

The status of the One-Way Span test will be available in the hardware error log via error type 3902. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being sent cleanly over the span from the far-end, the number of bit errors should be very low. The *Test Duration* field will show 0 until the test pattern is received from the far-end. Upon receiving the test pattern, the board will begin calculating the test duration and number of bit errors. The command will also display the type of Loopback/Span test executing (*Test Field*), the type of pattern generated for the Loopback/Span test (*Pattern Field*),and whether the pattern(*i.e.* 3-in-24 *Pattern*) is synchronized (*Synchronized Field*).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state.

If the test continues to abort, escalate the problem.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                  |
| 1039       | ABORT       | The UDS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the UDS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: <ol style="list-style-type: none"> <li>1. Issue the <b>disable synchronization-switch</b> command.</li> <li>2. Issue the <b>set synchronization PCSS</b> command.</li> <li>3. Issue the <b>enable synchronization-switch</b> command. Then rerun the test. If the test aborts again, a different ABORT error code will be generated. Follow the recommended maintenance procedures for that error code.</li> </ol> |

| 1950       | ABORT       | Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <i>test ds1-loop PCSS end-loopback/span-test</i> command in order to execute this test. |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|            | PASS        | <p>The One-Way Span test has successfully began transmitting a framed 3-in-24 test pattern. The test will continue to run until the system technician enters the <i>test ds1-loop PCSS end-loopback/span-test</i> command or the <i>release board PCSS</i> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Inject Single Bit Error Test (#1215)

This test is destructive.

The Inject Single Bit Error Test will cause a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS inject-single-bit-error* command. An attempt to use this command will be rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack Test, Far CSU Loopback Test, One-Way Span Test) are active on a TN464F circuit pack.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Inject Single Bit Error Test.

The *list measurements ds1 summary* command displays the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

**Table 10-475. TEST #1215 Inject Single Bit Error Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                          |

Table 10-475. TEST #1215 Inject Single Bit Error Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|            | PASS        | <p>A single bit error has been successfully injected into an active framed 3-in-24 test pattern.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Table 10-475. TEST #1215 Inject Single Bit Error Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

End Loopback/Span Test (#1216)

This test is destructive.

The End Loopback/Span Test will terminate an active loopback or span test on a TN464F UDS1 circuit pack. Bit error counting against the received test pattern stream is terminated and sending of the framed 3-in-24 test pattern is halted. If either the CPE Loopback Jack or the far-end CSU is looped, the appropriate loopback deactivate code is sent. If the loopback could not be deactivated, then the test will FAIL and a MINOR alarm will be noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by a system technician demanded Since only one of these three different long-duration loopback/span tests can be active at a time, the TN464F circuit pack knows which loopback/span test to terminate.

All trunks or ports on the UDS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running this End Loopback/Span Test.

The *list measurements ds1 summary* command will display the length of time the test ran (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field).

To restore the trunks or ports on the TN464F UDS1 Interface circuit pack to the in-service state, execute the **release board** command

**Table 10-476. TEST #1216 End Loopback/Span Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                          |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal System Error<br><br>1. Retry the <i>test ds1-loop PCSS end-loopback/span-test</i> command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                       |
| 1005       | ABORT       | End Loopback/Span Test cannot be executed in the current configuration. To run this, the TN464F or later suffix UDS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.                                                |
| 1015       | ABORT       | Ports on the UDS1 Interface circuit pack have not been busied out to out-of-service.<br><br>1. Enter the <b>busyout board PCSS</b> command to put all trunks or ports of the UDS1 Interface circuit pack into the out-of-service state.<br><br>2. Retry the command.<br><br>3. If the test continues to abort, escalate the problem. |

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The UDS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the UDS1 interface circuit pack is restored to normal operation. All of the trunks for the UDS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals for a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

ICSU Status LEDs Test (#1227)

The TN464F UDS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A1 Channel Service Unit (CSU) Module that can be connected to the TN464F board via the I/O connector panel on the back of the port carrier. The TN464F circuit pack combined with AT&T's new 120A1 CSU Module forms an Integrated CSU (ICSU).

This test is a visual test. It will light the four status LEDs red for 5 seconds, then light them green for 5 seconds, then light them yellow for 5 seconds, then turn the LEDs off and returns control of the status LEDs to the circuit pack.

This test will only be executed on a TN464F or later suffix UDS1 circuit packs administered for 24-channel operation (1.544 bit rate).

If the 120A1 CSU Module is not physically installed, the status LEDs are always off and this test will abort.

**Table 10-477. TEST #1227 ICSU Status LEDs Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal System Error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                         |
| 1005       | ABORT       | The ICSU Status LEDs test can not be executed for the current configuration. The test applies only to TN464F or later UDS1 circuit packs administered for 24-channel operation (1.544 bit rate).<br><br>1. If the circuit pack is a TN464F or later suffix UDS1 circuit pack, then retry the command.<br><br>2. If the test continues to abort, escalate the problem. |
| 1951       | ABORT       | The ICSU Status LEDs Test can not be executed because a 120A1 or later suffix CSU Module is not physically installed. If using a 120A1 CSU Module, physically connect it to the TN464F board on the back of the port carrier. Otherwise, ignore this abort.                                                                                                           |

Table 10-477. TEST #1227 ICSU Status LEDs Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | The ICSU Status LEDs test executed successfully. A PASS result, however, does not necessarily mean that the status LEDs behaved properly. It only means that the software successfully attempted to light the status LEDs. This is a visual test. The service technician must visually exam the behavior of the LEDs while the test is running. The LEDs are functioning properly if the four status LEDs are lit red for 5 seconds, then lit green for 5 seconds, then lit yellow for 5 seconds. If the LEDs behave differently, the board should be replaced at the customer's convenience.                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Ensure that the board translations are correct. Execute the <b>add ds1 PCSS</b> command to administer the UDS1 interface if it is not already administered.</li><li>2. If the board was already administered correctly, check the error log to determine whether the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, then issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

# VC-BD

| MO Name (in Alarm Log) | Alarm Level          | Initial Command to Run <sup>1</sup> | Full Name of MO                |
|------------------------|----------------------|-------------------------------------|--------------------------------|
| VC-BD                  | MAJOR                | test board PCSS l r#                | Voice Conditioner Circuit Pack |
| VC-BD                  | MINOR                | test board PCSS l r#                | Voice Conditioner Circuit Pack |
| VC-BD                  | WARNING <sup>2</sup> | test board PCSS s r#                | Voice Conditioner Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...).
2. Refer to XXX-BD (Common Port Board) Maintenance documentation.

 **CAUTION:**

*If the TN788 Voice Conditioner Circuit Pack (VC-BD) is not Vintage 2 or later, it must be replaced.*

The TN788 Voice Conditioner Circuit Pack (VC-BD) is a service circuit pack that provides conditioning for the audio signals from multimedia equipment based on the CCITT H.221 standard. The TN788 transcodes, gain adjusts, and bridges the audio bit streams demultiplexed by the TN787 (MMI) circuit pack and transmits encoded, exclusive audio conference sums onto the TDM bus so that the MMI can multiplex the audio, video, and data streams for the H.221 endpoints.

## Error Log Entries and Test to Clear Values

Table 10-478. VC-BD Error Log Entries

| Error Type     | Aux Data     | Associated Test                 | Alarm Level | On/Off Board | Test to Clear Value    |
|----------------|--------------|---------------------------------|-------------|--------------|------------------------|
| 0 <sup>1</sup> | 0            | Any                             | Any         | Any          | test board PCSS sh r 1 |
| 1 (a)          | Any          | None                            | MIN         | ON           |                        |
| 18 (b)         | 0            | busyout board PCSS              | WNG         | OFF          | release board PCSS     |
| 257 (c)        | Any          | Control Channel Loop Test (#52) | MIN         | ON           | test board PCSS r 20   |
| 513 (d)        | 4352 to 4357 |                                 |             |              |                        |

Table 10-478. VC-BD Error Log Entries — Continued

| Error Type       | Aux Data       | Associated Test        | Alarm Level | On/Off Board | Test to Clear Value |
|------------------|----------------|------------------------|-------------|--------------|---------------------|
| 769 (e)          | 4358           |                        |             |              |                     |
| 1025 (f)         | 4363           | NPE Audit Test (#50)   |             |              |                     |
| 1281 (g)         | Any            | SAKI Sanity Test (#53) | MAJ         | ON           |                     |
| 1293 to 1294 (h) | 46088 to 46096 | SAKI Sanity Test (#53) | MIN         | ON           | See note (g)        |
| 1538 (i)         | 46082          |                        | MIN         | ON           |                     |

1. Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The circuit pack stopped functioning or it was removed from the system. This alarm is logged approximately 11 minutes after the circuit pack is removed and/or the SAKI Sanity Test (#53) fails.

To resolve this error, insert a circuit pack in the same slot as the error indicates, if the circuit pack is not already in the system. Or, if the circuit pack is in the system and the red LED is on, then follow instructions for Red alarms.

 **CAUTION:**  
*If the TN788 Voice Conditioner Circuit Pack (VC-BD) is not Vintage 2 or later, it must be replaced.*

- b. This circuit pack is busied out by the **busyout board PCSS** command.
- c. Transient communication problems exist between the switch and this circuit pack. Execute the **test board PCSS** command and refer to the repair procedures for the Control Channel Loop Around Test (#52).
- d. The circuit pack detected an on-board hardware failure. The reported aux data values correspond to the following detected errors:

| Error | Description        |
|-------|--------------------|
| 4352  | External RAM error |

|      |                       |
|------|-----------------------|
| 4353 | Internal RAM error    |
| 4355 | ROM Checksum error    |
| 4357 | Instruction set error |

Reset the circuit pack by executing the **busyout board PCSS**, **reset board PCSS**, and **release board PCSS** commands. When it is reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedures in footnote (a) for error type 1.

- e. The circuit pack detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.
- f. The circuit pack cannot update NPE memory and read it back. This error type can be ignored, but it may lead to other error types being reported against this circuit pack.
- g. A critical hardware failure has been detected on the circuit pack. Use **busyout board PCSS**, **reset board PCSS**, followed by **release board PCSS**. If test #53 passes, the on-board circuitry is healthy. Use **test board PCSS long clear** to retire the alarm. If test #53 fails, replace the circuit pack.
- h. The circuit pack detected a critical hardware failure. Reset the circuit pack by issuing the **busyout board PCSS**, **reset board PCSS**, and **release board PCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm by issuing the **test board PCSS long clear** command. If the Circuit Pack Restart Rest (#594) fails, replace the circuit pack.

The reported error types correspond to the following detected errors:

| Error | Description                         |
|-------|-------------------------------------|
| 1293  | On-board auxiliary processor insane |
| 1294  | Internal memory access error        |

- i. The circuit pack is hyperactive — it is flooding the switch with messages sent over the control channel. The circuit pack is taken out of service when a threshold number of these errors is reported to the switch. Clear the alarm by using **busyout board PCSS**, **reset board PCSS**, **test board PCSS long clear**, and **release board PCSS**. If the error recurs within 10 minutes, then replace the circuit pack.

System Technician-Demanded Tests:  
Descriptions and Error Code

---

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| Control Channel Loop-Around Test (#52) (a) | X                   | X                  | ND                |

---

1. D = Destructive; ND = Nondestructive

 **CAUTION:**  
*If the TN788 Voice Conditioner Circuit Pack (VC-BD) is not Vintage 2 or later, it must be replaced.*

- Note:
- a. Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation for a description of this test.
- 

**Control Channel Loop Around Test (#52)**

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation as Control Channel Loop Around Test (#52).

VC-DSPPT

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO            |
|------------------------|-------------|-------------------------------------|----------------------------|
| VC-DSPPT               | MAJOR       | test port PCSSpp l r#               | Voice Conditioner DSP Port |
| VC-DSPPT               | MINOR       | test port PCSSpp l r#               | Voice Conditioner DSP Port |
| VC-DSPPT               | WARNING     | test port PCSSpp l r#               | Voice Conditioner DSP Port |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...).

Each Voice Conditioner Circuit Pack (VC-BD) provides two types of resources:

- 1. Transcoder Resources used for encoding and decoding audio formats
- 2. Summer Resources used for summing audio from different sources

The eight Voice Conditioner DSP ports are the transcoder resources on the VC-BD.

Error Log Entries and Test to Clear Values

Table 10-479. VC-DSPPT Error Log Entries

| Error Type     | Aux Data | Associated Test                             | Alarm Level | On/ Off Board | Test to Clear Value     |
|----------------|----------|---------------------------------------------|-------------|---------------|-------------------------|

| 778 to 781 (d) | Any      | VC Port Reset DSP Test (#1106)              | MAJ         | ON            | See note (d)            |
| 1025 (e)       |          |                                             | WNG         | ON            |                         |
| 1281 (f)       | Any      | VC DSP Port DSP Loopback Test # (1105)      | MIN         | ON            | test port PCSSpp sh r 3 |
| 3840 (g)       |          |                                             |             |               |                         |

1. Run the short test sequence first. If all test pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This port has been busied out by the **busyout port PCSSpp** command.
- b. The VC DSP Port NPE Crosstalk Test(#1103) failed.
- c. The VC DSP Port Local TDM Loopback Test(#1104) failed. Run the Long Test Sequence.
- d. A critical hardware failure has been detected on the circuit pack. Reset the port by the **busyout port PCSSpp** and **reset port PCSSpp** commands. If the VC Reset DSP Test (#1106) passes, then the on-board circuitry is healthy. Retire the alarm with the **test port PCSSpp long clear** command.
- e. The VC DSP port reported loss of framing on the Service Channel between the VC and MMI circuit packs.
- f. The VC DSP Port DSP Loopback Test (#1105) failed.
- g. The DSP corresponding to this port on the VC circuit pack reported a firmware error. No action is required.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the DSP NPE Crosstalk Test, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation         | Short Test Sequence | Long Test Sequence | D/ND* |
|--------------------------------|---------------------|--------------------|-------|
| DSP NPE Crosstalk Test (#1103) |                     | X                  | D     |
| TDM Loopback Test (#1104)      | X                   | X                  | D     |
| DSP Loopback Test (#1105)      | X                   | X                  | D     |

\* D = Destructive; ND = Nondestructive

VC DSP Port NPE Crosstalk Test (#1103)

This test is destructive.

The NPE controls port connectivity and gain and provides conferencing functions. The NPE Crosstalk test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 10-480. TEST #1103 VC DSP Port NPE Crosstalk Test

| Error Code   | Test Result    | Description/ Recommendation                                                                                                                                                                                                                                                              |

| 2012<br>2100 | ABORT<br>ABORT | Internal system error<br><br>Could not allocate the necessary resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                        |
| 0-3          | FAIL           | The NPE of the tested port was transmitting in error. This causes noisy and unreliable connections.<br><br>1. Replace circuit pack.                                                                                                                                                      |
|              | PASS           | The port is correctly using its allocated time slots.<br><br>1. To be sure that this is not an intermittent problem, repeat this test a maximum of 10 times to make sure that it continues to pass.<br><br>2. If complaints still persist, examine the station, connections, and wiring. |

VC DSP Port Local TDM Loopback Test (#1104)

This test is destructive.

This test verifies the connectivity of a VC DSP Port across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack. The Loopback Test runs the following tests:

- 1. A Looparound test across the TDM bus.
- 2. A conference Circuit Test.

The tests are run in the above order; if one test fails, an error code is returned and the remaining tests in the sequence are not executed.

VC-DSP Port DSP Loopback Test (#1105)

This test is destructive.

This test verifies the connectivity of a VC-DSPPT across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

VC Port Reset DSP Test (#1106)

This test is destructive.

This test resets the VC-DSPPT and the DSP associated with it. As part of the reset procedure, the VC-DSPPT will execute a series of self- tests on the hardware. If these self- tests fail, the test will fail; otherwise the test will pass.

Before executing the test, the VC-DSPPT must be busied out by executing the **busy port PCSSpp** command. After the completion of the test, the VC-DSPPT must be released by executing the **release port PCSSpp** command.

Table 10-483. TEST #1106 VC Port Reset DSP Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                     |

## VC-LEV (Voice Conditioner DSP Port Level)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run                               | Full Name of MO |
|------------------------|-------------|------------------------------------------------------|-----------------|
| VC-LEV                 | MAJOR       | See <a href="#">"Resolving VC-LEV Errors/Alarms"</a> | VC-LEV          |

Enable the MMCH feature on the System-Parameters Customer-Options form before changing the fields.

The Voice Conditioner (VC) Port Level MO monitors VC efficiency by tracking the number of VC ports that are in-service, and then comparing that number with the value entered in the VC field on the System-Parameters Maintenance form. This VCs field is located under the Minimum Maintenance Thresholds section. The VCs field contains the minimum number of VC ports needed for the Multimedia Call Handling (MMCH) feature, and is an administrable field. The VCs field must contain a number between 0 and 126, and is entered by the system administrator. The MMCH feature must be enabled on the System-Parameters Customer-Options form before the VCs field can be changed to a number greater than 0. For example, administering 8 in that field means 1 circuit pack. The algorithm for determining that a low level of VC resources exists uses the number entered in the VCs field, and the number of VCs that are in-service in the system.

Each VC circuit pack contains 16 physical ports: 8 ports are reserved for VC-DSPPT ports, and the remaining 8 ports are designated as VC-SUMPT ports. The 8 DSP ports are made up of 4 encoder and 4 decoder resources that encode and decode audio formats. Thus, *one VC circuit pack is required for every 8 ports of MMCH port capacity*. If the number of in-service VC ports falls below the MMCH port capacity (value entered on the System-Parameters Maintenance form under the Minimum Maintenance Thresholds section and in the VCs field), a VEC-LEV error is logged. If this outage continues for 15 minutes a MAJOR alarm is raised.

### Resolving VC-LEV Errors/Alarms

VC ports are a key part of the MMCH feature, any loss in the number of ports available for use degrades the MMCH customer defined service level.

If a VC circuit pack or port is busied out using the **busyout board** or **busyout port** command, these out-of-service ports are not included in the VC level calculation, thus allowing a technician to busy out a VC circuit pack for maintenance reasons without causing a MAJOR alarm to be raised.

**NOTE:**

When diagnosing a VC-LEV problem, resolve any alarms raised against VC-BD or VC-DSPPT maintenance objects. Clearing VC-BD or VC-DSPPT alarms may clear the VC-LEV alarm.

The VC circuit pack is maintained by the software similarly to the Tone Detector circuit pack. Tone Detector circuit packs may be removed and reinserted in any port board slot without administration. The same rule applies to VC circuit packs. If a VC circuit pack is removed from service logically (by failing the Archangel sanity scan test) or is removed from service physically (by physically removing the circuit pack from the carrier), no error/alarm is raised against VC-BD or VC-DSPPT maintenance objects. Therefore, if a VC-LEV error/alarm exists, and none has been raised against VC-BD or VC-DSPPT maintenance objects, a VC circuit pack may have been removed from service causing the VC-LEV error/alarm. To resolve a VC-LEV MAJOR alarm, restore the number of VC ports available for service to be equal to or more than the calculated port capacity (value entered in the VCs field).

To determine how many VC circuit packs are needed for the MMCH feature:

1. Display the System-Parameters Maintenance form by executing the command **display system-parameters maintenance**.
2. Locate the number listed in the Minimum Maintenance Threshold (VCs) field. The MMCH feature requires one VC circuit pack for each four ports listed in the Minimum Maintenance Threshold (VCs) field.
3. Divide the Minimum Maintenance Threshold value by 8 to determine the number of VC circuit packs needed. For example, a port capacity of 12 listed in the Minimum Maintenance Threshold (VCs) field would require 2 VC circuit packs.
4. Use the **list configuration** command to verify that the number of VC circuit packs listed agrees with the required number of VC circuit packs (determined in step 3). If the number of VC circuit packs listed in the step 3 differs from the calculated number, restore the number of VC circuit packs to the correct value, in order to resolve the VC-LEV alarm.

Error Log Entries and Test to Clear Values

Table 10-484. VC-LEV Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/ Off Board | Test to Clear Value |
|------------|----------|-----------------|-------------|---------------|---------------------|
| 1 (a)      | Any      | None            | MAJOR       | OFF           |                     |

Notes:

- a. The number of VC resources in the system that are in service has fallen below the calculated minimum value. If the number of in-service VC ports falls below the MMCH port capacity (value entered in the Minimum Maintenance Threshold VCs field on the system parameters maintenance form), a VEC-LEV error is logged. If this outage continues for 15 minutes a MAJOR alarm is raised. To resolve this alarm, correct the out-of-service problem by following the procedures below:
  - 1. See “VC-DSPPT” and “VC-BD” and resolve any associated alarms.
  - 2. If a VC-LEV error/alarm exist and none has been raised against VC-BD or VC-DSPPT maintenance objects, a VC circuit pack may have been removed from service causing the VC-LEV error/alarm. To resolve a VC-LEV MAJOR alarm, restore the number of VC ports available for service to be equal to or more than the calculated port capacity. See “Resolving VC-LEV ERRORS/ALARMS” for details.

System Technician-Demanded Tests:  
Descriptions and Error Code

There are no System Technician-Demanded test for VC-LEV.

# VC-SUMPT

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO               |
|------------------------|-------------|-------------------------------------|-------------------------------|
| VC-SUMPT               | MAJ         | test port PCSS l r#                 | Voice Conditioner Summer Port |
| VC-SUMPT               | MIN         | test port PCSS l r#                 | Voice Conditioner Summer Port |
| VC-SUMPT               | WNG         | test port PCSS s r#                 | Voice Conditioner Summer Port |

1. Where UU is the universal cabinet number (1 for PPN and 2-44 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...); and pp is the two digit port number (01, 02, 03, ...).

Each Voice Conditioner Circuit Pack (VC-BD) provides two types of resources:

1. Transcoder Resources that are used for encoding and decoding audio formats
2. Summer Resources that are used for summing audio formats from different sources.

The Voice Conditioner Summer ports (VC-SUMPT) are the summer resources on the VC-BD. There are 8 such ports on a VC-BD.

## Error Log Entries and Test to Clear Values

Table 10-485. VC-SUMPT Error Log Entries

| Error Type     | Aux Data | Associated Test                            | Alarm Level | On/Off Board | Test to Clear Value      |
|----------------|----------|--------------------------------------------|-------------|--------------|--------------------------|
| 0 <sup>1</sup> | 0        | Any                                        | Any         | Any          | test port PCSSpp sh r 1  |
| 18 (a)         | 0        | busyout port PCSS                          | WNG         | OFF          | release port PCSSpp      |
| 130 (b)        |          |                                            | WNG         | ON           | test port PCSSpp sh      |
| 257 (c)        | Any      | Control Channel Loop Test (#52)            | MIN         | ON           | test board PCSSpp 1 r 3  |
| 513 (d)        | Any      | VC Summer Port Local Loopback Test #(1100) | MIN         | ON           | test board PCSSpp sh r 3 |

1. Run the short test sequence first. If all test pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

- Notes:
- a. This port has been busied out with the **busyout port PCSSpp** command.
  - b. The circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.
  - c. The NPE Crosstalk Test(#1103) failed.
  - d. The VC Summer Port Local TDM Loopback Test(#1100) failed.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the Voice and Control Channel Local Loop Around Test, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation      | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6) (a) |                     | X                  | D                 |
| TDM Loopback Test (#1100)   | X                   | X                  | D                 |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

This test is destructive.

The NPE Crosstalk test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the port's long test sequence and takes approximately 20 to 30 seconds to complete.

| Error Code | Test Result | Description/Recommendation                                                                                                                                                    |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | System resources required to run this test are not available. The port may be busy with a valid call.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times. |

Table 10-486. TEST #6 NPE Crosstalk Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2012       | ABORT       | Internal system error                                                                                                                                                                                                                     |
| 2100       | ABORT       | Could not allocate the necessary resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                          |
|            | FAIL        | The NPE of the tested port was transmitting in error, causing noisy and unreliable connections.<br>1. Replace the circuit pack.                                                                                                           |
|            | PASS        | The port is correctly using its allocated time slots.<br>1. To be sure that this is not an intermittent problem, repeat this test a maximum of 10 times.<br>2. If complaints still persist, examine the station, connections, and wiring. |

VC Summer Port Local TDM Loopback  
Test (#1100)

This test is destructive.

This test verifies the connectivity of a VC Summer Port across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack. The Loopback Test runs the following tests:

- A Looparound test across the TDM bus.
- A conference circuit test.

The tests are run in the above order. If the first test fails, the switch returns an error code, and the second test is not executed.

Figure 10-98. VC Circuit Pack Summer Port Loopback Test

Table 10-487. TEST #1100 VC Summer Port  
Local TDM Loopback Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | System resources required to run this test are not available, or the port may be busy with a valid call.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                          |
| 1002       | ABORT       | The system could not allocate time slots for the test. The traffic load on the system is very high or time slots are out-of-service due to TDM-BUS errors. Refer to TDM-BUS maintenance documentation to diagnose any active TDM Bus errors.<br><br>1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times. |
| 1003       | ABORT       | The system could not allocate a Tone Detector for the test, the system is oversized for the number of Tone Detectors present, or some Tone Detectors are out-of-service.<br><br>1. Resolve any "TTR-LEV" errors.<br>2. Resolve any "TONE-PT" errors.<br>3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.                                        |
| 1004       | ABORT       | The port has been seized by a user for a valid call. Use the <b>status station</b> command for the station associated with this port to determine whether the port is available for testing.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                      |
| 2000       | ABORT       | Response to the test request was not received from the VC-BD circuit pack within the allowable time period.<br><br>1. If this result occurs repeatedly, reset the circuit pack if the other ports are not in use. Reset the circuit pack by issuing the <b>busyout board PCSS</b> and the <b>reset board PCSS</b> commands.<br>2. If this result occurs again, replace the circuit pack.  |
| 2012       | ABORT       | Internal system error                                                                                                                                                                                                                                                                                                                                                                     |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.                                                                                                                                                                                                                                                                                                                       |
| 2103       | ABORT       | The system could not make the conference connection for the test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                 |
| 0          | FAIL        | The TDM Loop Around Test failed.                                                                                                                                                                                                                                                                                                                                                          |
| 1          | FAIL        | The Conference Circuit Test failed.<br><br>1. Replace circuit pack.                                                                                                                                                                                                                                                                                                                       |
|            | PASS        | The VC Summer Port Local TDM Loopback Test passed.                                                                                                                                                                                                                                                                                                                                        |

# WAE-PORT (Wideband Access Endpoint Port)

|------------------------------------|-------------|------------------------------------------|-------------------------------|
| WAE-PORT <sup>1</sup>              | MINOR       | test access-endpoint <extension> I       | Wideband Access Endpoint Port |
| WAE-PORT                           | WARNING     | test access-endpoint <extension>         | Wideband Access Endpoint Port |

1.
- For additional repair information, see also UDS1-BD (UDS1 Interface Circuit Pack) Maintenance documentation.

The Wideband Switching capability supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. DEFINITY switching capabilities are extended to support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

The Wideband Switching capability extends the DEFINITY G3 Administered Connections feature to include non-signaling Wideband Access Endpoints. Endpoint application equipment with direct T1 or E1 interfaces may connect directly to the switch's line-side facilities. Application equipment without T1 or E1 interfaces requires a Terminal Adapter, such as a DSU/CSU. The terminal adapter or endpoint application equipment is connected to the Universal DS1 circuit pack (TN464C). These endpoints are administered as Access Endpoints, and they have no signaling interface to the switch. Instead, they simply transmit and receive data. (Some applications detect and respond to the presence or absence of data.) Calls are initiated from these endpoints using the Administered Connections feature.

Multiple Access Endpoints on one line-side UDS1 circuit pack (TN464C) facility are separate and distinct within the facility, and the endpoint application equipment must be administered to send and receive the correct data rate over the correct DS0s. All Administered Connections originating from Access Endpoints use the entire bandwidth administered for the Access Endpoint. An incoming call of a different data rate than that administered for the Access Endpoint cannot be routed to the Access Endpoint.

Although Wideband Access Endpoints are used primarily for line-side facilities, these endpoints can also be administered on network DS1 facilities to connect DEFINITY to non-switched network services, such as the AT&T fractional T-1 service. An example of this is the AT&T Static Integrated Network Access, where a trunk group to AT&T 4Ess Switched Services shares an access T-1 facility with a Wideband Access Endpoint. In this case, the Wideband Access Endpoint is

connected to the AT&T fractional T-1 service, and it does not terminate on local endpoint equipment but is connected to a far-end CPE (for example, another DEFINITY PBX) via the dedicated fractional T-1. All Wideband Access Endpoint functionality and operation is identical on both line-side and network facilities. However, because maintenance capabilities are limited to the Wideband Access Endpoint interface, and because faults can occur end-to-end, troubleshooting procedures based on an end-to-end view of the network is required.

Wideband Access Endpoint Port maintenance provides a strategy for maintaining a Wideband Access Endpoint Port via a port on the Universal DS1 interface circuit pack hardware. The maintenance strategy involves logging Wideband Access Endpoint Port hardware errors, running tests for port initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution. Two different port service states are specified in the Wideband Access Endpoint Port maintenance. These states include *out-of-service*, where the port is in a deactivated state and cannot be used for calls, and *in-service*, where the port is in an activated state and can be used for calls. If the Universal DS1 Interface circuit pack (TN464C) is out-of-service, all ports on the Universal DS1 Interface circuit pack (TN464C) are placed into the out-of-service state.

Hardware Error Log Entries and Test to Clear Values

| 3840 (f)       | Any      | Port Audit and Update (Test #36) |             |              |                                         |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The wideband access endpoint has been busied out by a **busyout access-endpoint <extension>** command. No calls can be made to this extension.
- b. The circuit pack has been removed, or it has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- c. The Conference Circuit Test (#7) failed on this port. See Test #7 for repair procedures.
- d. The NPE Crosstalk Test (#6) failed on this port. See Test #6 for repair procedures.
- e. There was a failure of the TN464C UDS1 Interface circuit pack. See UDS1-BD Maintenance documentation for details.
- f. The Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status access-endpoint <extension>** command and verify the status of the port. If the wideband access endpoint is out-of-service, enter the **release access-endpoint <extension>** command to put it back to in-service. Retry the test command. If the test continues to fail, escalate the problem.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)          |                     | X                  | ND                |
| Conference Circuit Test (#7)     |                     | X                  | ND                |
| Port Audit and Update Test (#36) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and it provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence, and it takes between 20 and 30 seconds to complete.

Table 10-488. TEST #6 NPE Crosstalk Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                        |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections.<br><br>1. Replace the circuit pack.                                                                |
|            | PASS        | The port is correctly using its allocated time slots.<br><br>1. User-reported troubles on this port should be investigated by using other port tests and by examining the terminal adapter or the external wiring. |

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and it provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and to conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

User-reported troubles on this port should be investigated by using other port tests and by examining the terminal adapter or the external wiring.</li></ol>                                                                                                                                                                                                         |

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the UDS1 Interface circuit pack to ensure that the wideband access endpoint port's translation is correct.

Table 10-490. TEST #36 Audit and Update Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                  |

## XXX-BD (Common Port Circuit Pack)

The Common Port Circuit Pack Maintenance is a set of common tests used by all the circuit packs with the generic hardware that interfaces with the TDM bus. Circuit packs included in this category are listed on the following pages.

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO                      |
|------------------------------------|-------------|-------------------------------------------------------|--------------------------------------|
| XXX-BD <sup>2</sup>                | MAJOR       | test board PCSS                                       | Common Port Circuit Pack Maintenance |
| XXX-BD <sup>2</sup>                | MINOR       | test board PCSS                                       | Common Port Circuit Pack Maintenance |
| XXX-BD <sup>2</sup>                | WARNING     | test board PCSS                                       | Common Port Circuit Pack Maintenance |

- 
- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02,...etc.)
  - Refer to the appropriate circuit pack documentation to get the correct MO name displayed in this field. It usually ends with BD.

Notes:

- 
- a.

All circuit pack suffixes (B,C, D, etc.) are also supported by the XXX-BD (Common Port Circuit Pack) Maintenance documentation.
- b.

The XXX-BD designation is also used in the SAT display in the case where a **reset board command** is issued to a circuit pack type which is in conflict to the actual circuit pack type administered for that slot or when a **reset board** command is issued to an empty circuit pack slot.

When any of the Common Port Circuit Packs (except the TN754 Digital Line and TN758 Pooled Modem circuit packs) are physically removed from the backplane, no alarm is logged for approximately 11 minutes. In the case of the Digital Line and Pooled Modem circuit packs, approximately 21 minutes elapse before an alarm is logged. When a circuit pack that has been removed is alarmed, the alarm type is minor and is classified as an on-board alarm. The time delay permits maintenance activity to be performed without triggering an additional alarm. **An alarm is logged only against a Common Port Circuit Pack on which ports have been administered.** See the next Note.

 **NOTE:**

In a heavily loaded system, the interval between the removal of a Common Port Circuit Pack and the logging of the alarm may be several minutes later.

XXX-BD Common Circuit Packs

The following list of circuit packs are listed by apparatus code, including circuit packs used in non-United States installations. .

Table 491. XXX-BD Common Circuit Packs

| Apparatus Code     | Name                                               | Type          |
|--------------------|----------------------------------------------------|---------------|
| (TN566)<br>(TN567) | DEFINITY AUDIX R3 System                           | Port Assembly |
| (TN2208)           | Call Visor ASAI over the DEFINITY (LAN) Gateway R1 | Port Assembly |
| TN417              | Auxiliary Trunk                                    | Port          |
| TN419B             | Tone-Clock                                         | Control       |
| TN420B/C           | Tone Detector                                      | Service       |
| TN429              | Direct Inward/Outward Dialing (DIOD) Trunk         | Port          |
| TN433              | Speech Synthesizer                                 | Service       |
| TN436B             | Direct Inward Dialing Trunk                        | Port          |
| TN437              | Tie Trunk                                          | Port          |
| TN438B             | Central Office Trunk                               | Port          |
| TN439              | Tie Trunk                                          | Port          |
| TN447              | Central Office Trunk                               | Port          |
| TN457              | Speech Synthesizer                                 | Service       |
| TN458              | Tie Trunk                                          | Port          |
| TN459B             | Direct Inward Dialing Trunk                        | Port          |
| TN464C/ D/E/ F     | DS1/E1 Interface - T1, 24 Channel - E1, 32 Channel | Port          |
| TN465/B/C          | Central Office Trunk                               | Port          |
| TN467              | Analog Line                                        | Port          |
| TN468B             | Analog Line                                        | Port          |
| TN479              | Analog Line                                        | Port          |
| TN497              | Tie Trunk                                          | Port          |
| TN553              | Packet Data Line                                   | Port          |
| TN556/B            | ISDN-BRI 4-Wire S/T-NT Line (A-Law)                | Port          |
| TN570/B/C          | Expansion Interface                                | Port          |
| TN572              | Switch Node Clock                                  | Control       |
| TN573/B            | Switch Node Interface                              | Control       |

| 769 (i)              | 4358     | None                                           |                   |              |                         |
| 1025 (j)             | 4363     | NPE Audit Test (#50)                           |                   |              | test board PCSS l r 20  |
| 1281 (k)             |          | Ringin Application Test (#51)                  | MINOR             | ON           | test board PCSS r 2     |
| 1538 (l)             | Any      | None                                           | WARNING/<br>MINOR | ON           |                         |
| 1793 (m)             |          | Neon Test (#220)                               | MINOR             | ON           | test board PCSS r 2     |
| 3840 (n)             | Any      | None                                           |                   |              |                         |
| 3999 (o)             | Any      | None                                           |                   |              |                         |

- 
- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
  - G3iV1-1.286 or G3iV2-386 only

Notes:

- a. This error indicates the circuit pack totally stopped functioning or it was physically removed from the system. This error type is not applicable to ANN-BD, DETR-BD, S-SYN-BD, M/T-BD, or CLSFY-BD.

**NOTE:**

The alarm is logged approximately 11 minutes after the circuit pack has been removed and/or SAKI Sanity Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, follow the instructions for "Red (alarm)" in the ["Control and Port Circuit Pack Status LEDs"](#) section in [Chapter 7, "LED Interpretation"](#) (See also the ["Handling Control Circuit Packs"](#) section in [Chapter 5, "Routine Maintenance Procedures"](#))

- b. This error indicates the circuit pack has been busied out. Release the circuit pack via **release board PCSS**.
- c. The circuit pack has been logically administered but not physically installed. The alarm should clear when the circuit pack is installed.

If the circuit pack is already installed:

1.Run **test board PCSS long** and look at any test failures or error codes generated.

2.If the test does not clear error 23, then execute **reset board PCSS** and run the long test again.

3.If the reset/test does not clear error 23, replace the circuit pack.

- d. This error applies only to the Maintenance/Test circuit pack (TN771B or TN771C). The error indicates that the hardware associated with the Analog Trunk Testing port of the circuit pack failed to initialize. This port is **not** used in G3iV1.1-286 or G3iV2-386. Note, however, that when this error occurs, the Maintenance/Test circuit pack may report an invalid vintage. Although this error is not service-affecting, the Maintenance/Test circuit pack should be replaced.
- e. A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.
- f. This error applies to the Maintenance/Test circuit pack (TN771D), Tone Detector (TN748B, TN748C, or TN748D), and Call Classifier (TN748) circuit packs. For the Maintenance/Test circuit pack, the error indicates that there is more than one Maintenance/Test circuit pack in the port network. For the Tone Detector or Call Classifier packs, the error indicates that there are more than 10 circuit packs in the system. Remove the circuit pack against which the error is logged.

- g. This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.
- h. This error, when reported with Aux data in the range of 4352 to 4358, indicates that the circuit pack has reported an on-board hardware failure. The circuit pack continuously tests the hardware and report the results approximately every 10 minutes. If the hardware problem is resolved, the "leaky bucket" strategy should clear the alarm in approximately 30 minutes. However, if the alarm does NOT clear in 30 minutes, the circuit pack should be replaced.
- i. This error can be ignored, but look for other errors on this circuit pack.
- j. This error is not service-affecting and no action is required.
- k. This error indicates that no ringing current is detected. Run Test #51, Ringing Application Test, and follow the procedures for Test #51. This error is only applicable to Analog Line circuit packs.
- l. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
  - 1.The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.
  - 2.The tests run on the ports of this circuit pack are returning with a NO-BOARD.
  - 3.A busyout/release of the circuit pack has no affect on test results.
  - 4.A **list configuration** command shows that the circuit pack and ports are properly installed.

If the XXX-BD is not a TN754 Digital Line Circuit Pack (DIG-BD), and if this error happens again within 15 minutes, replace the circuit pack. If the XXX-BD is a TN754 Digital Line Circuit Pack (DIG-BD), check the alarm level. If the alarm level is a WARNING, this indicates that users are probably causing the hyperactivity by playing with their digital stations. If the circuit pack is really hyperactive, this alarm is upgraded to a MINOR alarm within one hour. If the alarm level is a MINOR alarm, replace the circuit pack. (Refer to the "[Handling Control Circuit Packs](#)" section in [Chapter 5, "Routine Maintenance Procedures"](#).)

- m. This error indicates that no neon current is detected. Run Test #220, Neon Test, and follow the procedures for Test #220. This error is applicable only to TN769 and TN746 Analog Line circuit packs.
- n. This error is not service-affecting and no action is required.
- o. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may

be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Control Channel Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                 | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|----------------------------------------|---------------------|--------------------|----------------------|-------------------|
| NPE Audit Test (#50)                   |                     | X                  |                      | ND                |
| Ringing Application Test (#51) (a)     | X                   | X                  |                      | ND                |
| Control Channel Loop Around Test (#52) | X                   | X                  |                      | ND                |
| SAKI Sanity Test (#53)                 |                     | X                  | D                    |                   |
| Neon Test (#220) (b)                   | X                   | X                  |                      | ND                |

1. D = Destructive; ND = Nondestructive
- a. Only applicable to Analog Line circuit packs.

b. Only applicable to TN746 and TN769 Analog Line circuit packs.

NPE Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 10-492. TEST #50 NPE Audit Test

| Error Code   | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|--------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none or 2100 | ABORT       | System resources required for this test are not available.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 1019         | ABORT       | Test already in progress.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Ringing Application Test (#51)**

This test checks the ringing application circuitry common to all ports on an Analog Line circuit pack.

**Table 10-493. TEST #51 Ringing Application Circuit Test**

| Error Code   | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

SAKI Sanity Test (#53)

This test is destructive.

This test resets the circuit pack.

This test is executed as part of the long test sequence only for the Tone-Clock circuit pack and DS1 interface circuit packs. All other common circuit packs can be reset via the **reset board PCSS** command. The **reset** command executes this test.

Neon Test (#220)

This test checks the voltage required to light the neon lamp on an analog terminal. A relay connects a 150V DC source from the backplane of the circuit pack onto the voltage bus, and another relay connects a 2K shunt from the bus to ground. Current in the line is then monitored to determine if the voltage is present.

The neon test runs only for TN746 and TN769 Analog circuit packs. If the circuit pack is not a TN746 or TN769, the test returns PASS, but there is no testing done to the circuit pack.

Table 10-496. TEST #220 Neon Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1018       | ABORT       | <p>There are not any translated ports on the circuit pack, or if there are ports, then none are administered to have "neon."</p> <ol style="list-style-type: none"><li>1. Verify that there are ports administered on the circuit pack. If no ports are administered, no further action is required.</li><li>2. Make sure a TN755 or TN752 power unit circuit pack is installed.</li><li>3. Verify that you have neon sets connected (AT&amp;T sets that may be neon sets are 500 and 2500 series, also some non-AT&amp;T may also be neon sets). If no neon sets are connected to the circuit pack, the test continues to abort, but no further action is required.</li><li>4. If there are no neon sets connected to the circuit pack, at least one port needs to be translated with neon. To check if a port is translated with neon, use the <b>display port PCSSpp</b> command to determine the station extension of any station on this circuit pack. Use the <b>display station &lt;extension&gt;</b> to determine if the port is administered with neon. The field "Message Waiting Indicator:" must be set to "neon" for at least one of the administered ports. If this field is not administered to "neon" the test continues to abort. This is acceptable because not all stations have neon lamps on their analog terminals. If none of the terminals have neon lamps, the the test continues to abort, but no further action is required.</li></ol> |
