|            | PASS        | The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.                                                                                                                                                                                                                                                                                                                                                                                                     |

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop and conference abilities of a CO port circuit. The test uses 404 Hz, 1004 Hz, and 2804 Hz tones. Each tone is transmitted separately through the loop and checked.

Circuit Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7          | FAIL        | <div>1. Check for errors on TONE-BD or TONE-PT. If there are errors, take the appropriate actions.</div> <div>2. If the Reflective Loop Around Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, check the circuit pack for a red LED. If the red LED is on, then replace the appropriate power unit circuit pack. If neither the TN736 nor the TN752 power unit circuit pack is present, then the OLS631DB AC power unit may be defective. The system may contain a TN736 or TN752 power unit circuit pack OR an OLS631DB AC power unit, BUT NOT BOTH TYPES OF POWER UNITS.</div> <div>⇒ NOTE:<br/>To investigate problems with an OLD631DB AC power source, refer to CARR-POW Maintenance documentation.</div> <div>3. Rerun the test.</div> <div>4. If the test fails again, replace the circuit pack.</div> |
|            | PASS        | CO Trunk Loop Around and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Port Audit Update Test (#36)

This test sends updates of the CO port translation for all ports on the circuit pack which have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 10-143. TEST #36 Port Audit Update Test

| 2100       | ABORT       | Could not allocate the necessary system resources to run the test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|            | FAIL        | Internal System Error.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If test continues to fail, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|            | PASS        | This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service:<br><br>1. Enter <b>status-command</b> to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2.<br><br>2. Enter <b>release-trunk</b> command to put trunk back into in-service.<br><br>3. Retry the test command. |

## DLY-MTCE (MO-DAILY)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| DLY-MTCE               | MINOR       | NONE                   | DLY-MTCE        |
| DLY-MTCE               | MAJOR       | NONE                   | DLY-MTCE        |

The DLY-MTCE maintenance object monitors daily translation saves. If a translation save times out or fails to run, an error is logged against this maintenance object. If the save fails three times in a row, a MINOR alarm is raised; if the save fails for seven consecutive attempts, a MAJOR alarm is raised.

## DS1-BD (DS1 Interface Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO            |
|------------------------|-------------|-------------------------------------|----------------------------|
| DS1-BD                 | MAJOR       | test board PCSS sh                  | DS1 Interface Circuit Pack |
| DS1-BD                 | MINOR       | test board PCSS l                   | DS1 Interface Circuit Pack |
| DS1-BD                 | WARNING     | test board PCSS sh                  | DS1 Interface Circuit Pack |

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The DS1 Interface circuit pack provides an interface to an external DS1 facility and supports 24 DS0 channels carried on a 1.544 Mbps DS1 link. These DS0 channels can be administered as either trunks to other switches or lines to off-premises stations. The TN464C and later suffix Universal DS1 Interface also supports a 32-channel interface on a 2.048Mbps link. The functions and maintenance strategy for the TN464 circuit packs are covered under a separate maintenance object, UDS1-BD.

DS1-BD maintenance logs in-line errors reported by the DS1 Interface circuit pack, runs tests for error diagnosis and recovery, and raises and clears alarms. The following table shows the capabilities of each DS1 circuit pack. The TN722 and TN722B are not supported on G3r V1 or later systems.

| Circuit Pack Code | 24 Channel | 32 Channel | Tie Trunk Signaling | CO Trunk Signaling | DID Trunk Signaling | OPS Line Signaling |
|-------------------|------------|------------|---------------------|--------------------|---------------------|--------------------|
| TN722/B           | x          |            | x                   |                    |                     |                    |
| TN767/B/C/D/E     | x          |            | x                   | x                  | x                   | x                  |
| TN464C/D/E/F      | x          | x          | x                   | x                  | x                   | x<br>(24-chl only) |

ISDN-PRI Trunk signaling (for example, Q.921, Q.931) requires a TN464D and is handled by system software. The TN464 is covered in the "UDS1-BD (UDS1 Interface Circuit Pack)" section of Chapter 9.

Each trunk and line have their own maintenance strategies. However, they all depend on the health of the DS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1, CO-DS1, DID-DS1, OPS-LINE, ISDN-TRK, and ISDN-PLK. Signaling over the DS1 link must be synchronized between the transmitting and receiving ends to ensure error-free communication. Refer to "SYNC (Synchronization)" for details.

The TN767E circuit pack combined with AT&T's new 120A1 CSU Module forms an Enhanced Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN767E hardware and firmware, and new switch software, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The 120A1 CSU Module connects to the TN767E circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module, thus becomes an integrated part of the DEFINITY. system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A1 CSU Module see *DEFINITY. Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation, 555-230-193.*

The TN767E and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN767E circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this DS1-BD section, but Figure 10-28 gives a high level overview of the loopback points.

The following list of acronym definitions are for Figure 10-28:

- PLB = Payload Loopback
- BLB = Board Loopback
- ELB = Equipment Loopback
- LLB = Line Loopback
- RLB = Repeater Loopback
- CLJ = Loopback Jack Loopback
- R-LLB = Remote Line Loopback
- SMRT = Smart Jack
- LPBK = Loopback

For more information about DS1 interfaces, see the *DEFINITY Communications System DS1/CEPT1/ISDN-PRI Reference, 555-025-107.*

| 3999 (x)         | Any      | None                                     |                |              |                     |

- 
1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates that the circuit pack has stopped functioning or is not completely administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

To be completely administered, a DS1 circuit pack must meet all 3 of the following conditions:

1. Have an entry in the circuit plan via the **change circuit pack** command
2. Be administered via the **add ds1 PCSS** command
3. Be physically inserted in the appropriate slot

If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning DS1 circuit pack is inserted in the correct slot.
2. Completely remove the DS1-BD from the system using the following steps:
  - a. Remove any administered DS1 trunks or access endpoints associated with the circuit pack from their trunk groups.
  - b. Execute the **remove ds1 PCSS** and **change circuit pack PCSS** commands.

If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions for *LED Alarms with Error Type 1* in Chapter 7.

- b. The DS1 Interface circuit pack has been busied out by a **busy-out board PCSS** command.
- c. The DS1-BD circuit pack is not completely administered. A completely administered DS1-BD circuit pack should have an entry in the circuit plan via the **change circuit pack** command, should have been administered via the **add ds1 PCSS** command, and should have been inserted into the appropriate port slot.
- d. The circuit pack in the slot does not match the type administered to that position. Either replace the circuit pack with one of the type administered, or use **change circuit-pack** to readminister the slot. This error may also indicate that the 24/32-channel selection on the DS1 administration form does not match the configuration of the circuit pack.
- e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to "XXX-BD (Common Port Circuit Pack)" for details.
- f. The DS1 Interface circuit pack has detected a transient hardware problem (for example, external RAM failure, internal RAM failure, internal ROM failure, or instruction set failure). This error will disappear when no faults

are detected for 30 minutes. The value in the Aux Data field indicates the type of hardware problem. However, when this error is reported with Aux Data in the range of 4352 to 4358, it indicates the circuit pack has reported a hardware failure such that the circuit pack should be replaced.

- g. The DS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.
- h. CSU Module missing. The Near -End CSU Type field on the **add ds1** form has been administered as *integrated* but the 120A1 CSU Module is not physically connected (or is improperly connected) to the TN767E board on the back of the port carrier.

If using the 120A1 CSU Module, plug (or replug) the CSU Module into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the Near -End CSU Type field using the **change ds1** form to *other*.

If this error remains after plugging the CSU Module into the board's connector, there could be a problem with the I/O connector panel.

- i. CSU Module not expected. The 120A1 CSU Module is physically connected to the TN767E board on the back of the port carrier but the Near -End CSU Type field on the **add ds1** form has not been administered as *integrated*.

If the 120A1 CSU Module is to be used, use the **change ds1** command to change the Near -End CSU Type field to *integrated*. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier.

- j. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.
- k. DS1 circuit pack suffix incorrect for CSU Module. The Near -End CSU Type field on the **add ds1** form has been administered as *integrated* but the DS1 circuit pack is not a TN767E or later suffix DS1 board.

If the 120A1 CSU Module is to be used, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise, use the **change ds1** command to change the Near -End CSU Type field to *other*.

- l. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: **busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, release board PCSS**. If the BLB test continues to fail, then the TN767E circuit pack needs to be replaced.
- m. ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e., TN767E board physically inserted and

120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command **test ds1-loop PCSS ds1/csu-loopback-tests**.

Attempt to clear the alarm via the following commands: **busyout board PCSS**, **test ds1-loop PCSS ds1/csu-loopback-tests**, and **release board PCSS**. If the ELB test continues to fail, then either the TN767E board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate where the failure is occurring by re-executing the test by replacing one piece of hardware at a time.

- n. RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e., TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command **test ds1-loop PCSS ds1/csu-loopback-tests**.

Attempt to clear the alarm via the following commands: **busyout board PCSS**, **test ds1-loop PCSS ds1/csu-loopback-tests**, and **release board PCSS**. If the RLB test continues to fail, then the CSU Module needs to be replaced.

- o. CPE Loopback Jack deactivation error. This error occurs when the TN767E circuit pack could not deactivate a CPE Loopback Jack loopback.

Attempt to clear the alarm via the following commands: **busyout board PCSS**, **test ds1-loop PCSS end-loopback/span-test**, and **release board PCSS**. If the attempt to deactivate the CPE Loopback Jack loopback continues to fail, other steps must be taken to deactivate the loopback.

- p. Far CSU Loopback deactivation error. This error occurs when the TN767E circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

Attempt to clear the alarm via the following commands: *busyout board PCSS*, *test ds1-loop PCSS end-loopback/span-test*, *release board PCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

- q. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
  - 1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.
  - 2. The tests run on the ports of this circuit pack are returning NO BOARD.
  - 3. A busy-out/release of the circuit pack has no affect on test results.

4. A **list configuration** command shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and all trunks of this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 Interface circuit pack is restored to normal operation. All trunks of the DS1 Interface circuit pack are then returned to the in-service state. If the error recurs after 15 minutes, then replace the circuit pack.

- r. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving Slips and the AUX data shows the last Slip count that was reported.
- s. For later releases of G3V4 and beyond, only error 3329 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.
- t. This error is not service-affecting and can be ignored.
- u. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.

- 1 — Test is currently running.
- 2 — Test failed because loopback could not be activated.
- 3 — Test failed because test pattern could not be detected.
- 4 — Test has been terminated.

- v. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.

- 1 — Test is currently running.
- 2 — Test failed because loopback could not be activated.
- 3 — Test failed because test pattern could not be detected.
- 4 — Test has been terminated.

- w. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.

- 1 — Test is currently running.
- 2 — Test has failed because test could not be activated.
- 3 — Test pattern was not received from the far end.
- 4 — Test has been terminated.

- x. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then

the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order they are presented in Table 10-145. By clearing error codes associated with the *NPE Connection Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence

Table 10-145. System Technician-Demanded Tests: DS1-BD

| Order of Investigation                   | Short Test Sequence | Long Test Sequence | Reset Board Sequence | test ds1-loop Command | D/ND <sup>1</sup> |
|------------------------------------------|---------------------|--------------------|----------------------|-----------------------|-------------------|
| NPE Connection Audit Test (#50)          |                     | X                  |                      |                       | ND                |
| Control Channel Loop Test (#52)          |                     | X                  |                      |                       | ND                |
| Loss of Signal Alarm Inquiry Test (#138) | X                   | X                  |                      |                       | ND                |

1. D = Destructive, ND = Non-destructive

NPE Connection Audit Test (#50):

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 10-146. TEST #50 NPE Connection Audit Test

| Error Code   | Test Result | Description/ Recommendation                                                               |
|--------------|-------------|-------------------------------------------------------------------------------------------|
| None<br>2100 | ABORT       | System resources required for this test are not available.                                |
| 1019         | ABORT       | Test already in progress.                                                                 |

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p>The test failed because the circuit pack did not return the circuit pack code or vintage.</p> <p> <b>NOTE:</b><br/>Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as Test 138 and Test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test result.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> <ol style="list-style-type: none"><li>1. Retry the command for a maximum of 5 times.</li><li>2. If the problem continues, check for hyperactivity. Resolve the problem, as appropriate.</li><li>3. If there is no longer hyperactivity, retry the command for a maximum of 5 times.</li><li>4. If the test continues to fail, replace the circuit pack.</li></ol> |
|            | PASS        | Communication with this circuit pack is successful.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

SAKI Sanity Test (#53)

This test is destructive. This test resets the circuit pack.

Table 10-148. TEST #53 SAKI Sanity Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

|            | PASS        | The circuit pack initializes correctly.<br><br>1. Run the Short Test Sequence.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board).<br><br>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.<br><br>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.<br><br>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.<br><br>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.<br><br>4. Issue the <b>reset board</b> command.<br><br>5. Issue the <b>release busy board</b> command.<br><br>6. Issue the <b>test board long</b> command.<br><br>This should re-establish the linkage between the internal ID and the port. |

Internal Looparound Test (#135)

This test is destructive.

The Internal Looparound Test is run by looping the transmitted DS1 bit stream back into the DS1's board receiver. The loop occurs just before the DS1 facility

interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

All trunks on the DS1 Interface circuit pack must be busied out via the system technician **busy-out board** command before running the Internal Looparound Test. When the Internal Looparound Test is initiated, maintenance software sends appropriate messages to the DS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the DS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks of the DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

| 1039       | ABORT       | <p>The DS1 Interface circuit pack is providing timing for the system. Therefore, it cannot be reset without major system disruption.</p> <ol style="list-style-type: none"><li>1. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence:</li></ol> <ul style="list-style-type: none"><li>■ Issue the <b>disable synchronization-switch</b> command.</li><li>■ Next, issue the <b>set synchronization PCSS</b> command.</li><li>■ Lastly, issue the <b>enable synchronization-switch</b> command.</li></ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 2000       | ABORT       | <p>The test was aborted. Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as Test 139 and Test 140) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b></p> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 2100       | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. | 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the DS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the DS1 Interface

circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored. The DS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 1second. It will not retire the alarm until the signal has returned for about 10 seconds.

This test is also used to maintain the new 120A CSU Module. This Module, when combined with the functionality provided by the TN767E circuit pack, provides functionality equivalent to an external standalone ESF T1 CSU.

If a TN767E circuit pack detects certain ICSU hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the I-CSU error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN767E board to confirm the I-CSU error. A Minor or Warning alarm will be raised depending on the severity of the ICSU error. The trunks on the board may be taken out of service if the ICSU error is deemed serious.

If a Loss Of Signal alarm and an ICSU error co-exist, the Loss Of Signal alarm condition will take priority and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the ICSU hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other ICSU errors or Loss Of Signal alarm exist)

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | FAIL        | <p>DS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this DS1 interface circuit pack are out-of-service. If the DS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to "SYNC (Synchronization)" section for details.</p> <ol style="list-style-type: none"><li>1. If the DS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint.</li><li>2. Check the physical connection of the DS1 Interface circuit pack and the cable. If a 120A1 CSU Module is physically connected to a TN767E board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|            | PASS        | DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU errors are detected.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the DS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The DS1 Interface circuit pack takes 2 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the DS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the ICSU or DS1 into a loopback mode. When the ICSU or DS1 Board is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4-Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4-Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | FAIL        | <p>The remote DS1 endpoint is out-of-service.</p> <ol style="list-style-type: none"><li>1. | 1795       | FAIL        | The DS1 Interface circuit pack detects a Payload Loopback Alarm (PLB). If the DS1 Interface circuit pack connects to a leased T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to another DS1 board, call the system technician of the remote switch to diagnose the DS1 endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|            | PASS        | Remote DS1 endpoint is in-service. Neither a Blue alarm nor a Line Loopback alarm nor a Payload Loopback alarm is detected in the DS1 Interface circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

Red Alarm Inquiry Test (#140)

DS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a DS1 Interface circuit pack. DS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 10 seconds to recognize and report the resolution of a Red alarm.

When the DS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the DS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance software restores all trunks of the DS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm: If the DS1 Interface circuit pack is administered using DMI-BOS signaling, the DS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once DS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

| 2100       | ABORT       | Internal system error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b></p> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The DS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the DS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software places all trunks on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks on the DS1 Interface circuit pack back to their previous service state before the Yellow alarm is raised.

This Yellow Alarm corresponds to the yellow F2 state documented in CCITT recommendation I.431.

Remote Multiframe Alarm: Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the DS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 State Alarm: For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431

|            | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2000       | ABORT       | Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may appear.<br><br>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.<br><br>2. The tests run on the ports of this circuit pack are returning a no board result.<br><br>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.<br><br>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.<br><br> <b>NOTE:</b><br>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack. |

|            | PASS        | No Yellow alarm nor Remote Multiframe Alarm nor F5 State Alarm is received from the remote DS1 endpoint.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

Major Alarm Inquiry Test (#142)

The Major alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 16 seconds to recognize and report a Major alarm and 16 seconds to recognize and report that a Major alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the DS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the Major alarm on the DS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks on the circuit pack to their previous service state before a Major alarm occurs.

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | FAIL        | <p>The DS1 Interface circuit pack detects a Major alarm. The DS1 bit error rate is greater than 1/1000.</p> <ol style="list-style-type: none"><li>1. The performance of DS1 link between DS1 Interface circuit pack and remote DS1 endpoint is very poor. If the DS1 Interface circuit pack is TN767, enter <b>list measurement ds1-log PCSS</b> command to read the error seconds measurement.</li><li>2. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding.</li><li>3. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint.</li><li>4. Check the physical connectivity of the DS1 pack and of the cable.</li><li>5. Replace the local DS1 interface circuit pack, and repeat the test.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|            | PASS        | No Major alarm is detected in DS1 Interface circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 41 minutes to recognize and report a Minor alarm and 41 minutes to recognize and report that a Minor alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition is cleared.

When the DS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks on the circuit pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b></p> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

|            | FAIL        | <p>The DS1 Interface circuit pack detects a Minor alarm. The DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000.</p> <ol style="list-style-type: none"><li>1. The performance of DS1 link between DS1 Interface circuit pack and remote DS1 endpoint is poor. If DS1 Interface circuit pack is TN767, enter <b>list measurement ds1-log PCSS</b> command to read the error seconds measurement.</li><li>2. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding.</li><li>3. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint.</li><li>4. Check the physical connection of the DS1 pack and of the cable.</li><li>5. Replace the local DS1 interface circuit pack, and repeat the test.</li></ol> |
|            | PASS        | No Minor alarm is detected in DS1 Interface circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

Slip Alarm Inquiry Test (144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The DS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips occurred on a DS1 link.

When the DS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on DS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the DS1 Interface circuit pack. All trunks of the DS1 Interface circuit pack are still in the in-service state. If the DS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See "TDM-BUS" and "SYNC (Synchronization)" for details.

| 2100       | ABORT       | Internal system error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| 2000       | ABORT       | Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.<br><br>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.<br><br>2. The tests run on the ports of this circuit pack are returning a no board result.<br><br>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.<br><br>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.<br><br> <b>NOTE:</b><br>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack. |

Table 10-156. TEST #144 Slip Alarm Inquiry Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 to 88    | FAIL        | <p>The DS1 interface circuit pack detected a slip alarm. The error code equals the number of slips detected by the DS1 interface circuit pack since the last slip alarm inquiry test.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals a maximum of 5 times.</li><li>2. If the DS1 interface circuit pack is a TN767, enter the <b>list measurement ds1-log PCSS</b> command to read the error seconds measurement.</li><li>3. Verify that both endpoints and all intermediate equipment of the DS1 link are administered using the same signaling mode, framing mode, and line coding.</li><li>4. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint.</li><li>5. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors.</li><li>6. Check the physical connectivity of the DS1 pack and of the cable.</li><li>7. Replace the local DS1 interface circuit pack and repeat the test.</li></ol> |
|            | PASS        | No Slip alarm is detected on the DS1 Interface circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p>                                                                                                                                                                                                                                                   |

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a DS1 Interface circuit pack are in error. Misframe Alarm Inquiry Test queries the total number of misframes that occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches the threshold, a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the DS1 Interface circuit pack.

When the threshold of misframes is reached, if the DS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus) Maintenance documentation for details. A Minor alarm against the DS1 Interface circuit pack is raised, but all trunks of the DS1 Interface circuit pack are still in the in-service state.

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may appear.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b></p> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the DS1 Interface circuit pack. Translation includes the following data administered for a DS1 Interface circuit pack (see output of **display ds1 PCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

If a TN767E or later DS1 circuit pack is combined with a 120A CSU Module to form an Integrated CSU Module, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module is done using the DS1 circuit pack administration form. Translation for the CSU Module includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, and so forth.

|            | PASS        | Translation data has been downloaded to the DS1 Interface circuit pack successfully.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board).<br><br>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.<br><br>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.<br><br>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.<br><br>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.<br><br>4. Issue the <b>reset board</b> command.<br><br>5. Issue the <b>release busy board</b> command.<br><br>6. Issue the <b>test board long</b> command.<br><br>This should re-establish the link between the internal ID and the port. |

DS1 Board Loopback Test (#1209)

This test is destructive.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN767E DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | FAIL        | <p>DS1 Interface circuit pack failed the DS1 Board Loopback Test.</p> <ol style="list-style-type: none"><li>1. Retry <b>test ds1-loop PCSS ds1/csu-loopback-tests</b>.</li><li>2. If the BLB test continues to fail, then replace the DS1 circuit pack.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|            | PASS        | <p>The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN767E DS1 board edge.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local 120A CSU Module and tests the connection from the TN767E DS1 board to the CSU Module (DS1 board edge interconnecting cable, and CSU Module edge). This test will only be performed if the 120A CSU Module is present, administered, and connected to a 1.544Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board sets up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1950       | ABORT       | Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <b>test ds1-loop PCSS end-loopback/span-test</b> command in order to execute this test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 1951       | ABORT       | The CSU Equipment Loopback Test could not be executed because the 120A CSU Module was not physically installed. Physically connect the 120A CSU Module to the TN767E board on the back of the port carrier.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2100       | ABORT       | Internal system error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b></p> <p>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the local 120A CSU Module and tests the connection from the TN767E DS1 board to and including the CSU Module circuitry. This test will only be performed

if the 120A CSU Module is present, administered, and connected to a 1.544 Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

Table 10-161. TEST #1211 CSU Repeater Loopback Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1015       | ABORT       | <p>Ports on the DS1 Interface circuit pack have not been busied out to out-of-service.</p> <ol style="list-style-type: none"><li>1. Enter the <b>busyout board PCSS</b> command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state.</li><li>2. Retry the command.</li></ol>                                                                                                                                                                                                                                                                                                         |
| 1039       | ABORT       | <p>The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption.</p> <p>If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence:</p> <ol style="list-style-type: none"><li>1. Issue the <b>disable synchronization-switch</b> command.</li><li>2. Next, issue the <b>set synchronization PCSS</b> command.</li><li>3. Lastly, issue the <b>enable synchronization-switch</b> command.</li></ol>                    |
| 1950       | ABORT       | <p>Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log indicates whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <b>test ds1-loop PCSS end-loopback/span-test</b> command in order to execute this test.</p> |
| 1951       | ABORT       | <p>The CSU Repeater Loopback Test could not be executed because the 120A CSU Module was not physically installed. Physically connect the 120A1 CSU Module to the TN767E board on the back of the port carrier.</p>                                                                                                                                                                                                                                                                                                                                                                                                          |

| 2100       | ABORT       | Internal system error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | FAIL        | <p>DS1 Interface circuit pack failed the CSU Repeater Loopback Test.</p> <ol style="list-style-type: none"><li>1. | 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN767E DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]** command. The System technician has the choice of entering a loopback activation code on the command line or using the default code (0x47F).

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CPE Loopback Jack Test.

The CPE Loopback Jack Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully

sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback Jack test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*3-in-24 Pattern*) is synchronized (*Synchronized Field*).

To terminate the test, enter **test ds1-loop PCSS end-loopback/span-test** command or the **release board**. Using the **release board** command restores all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1950       | ABORT       | Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <i>test ds1-loop PCSS end-loopback/span-test</i> command in order to execute this test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2100       | ABORT       | Internal system error                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. | 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

If the CPE Loopback test continues to fail, the problem could be with the TN767E board, the CPE Loopback Jack equipment, or somewhere in between. Run <b>test ds1-loop PCSS ds1/csu-loopback-tests</b> to see if the loopback tests closer to the TN767E board are successful. If any of those loopback tests fail, follow the maintenance strategy associated with those loopbacks.</li></ol>                                                                                                                                                                                                                                                       |
|            | PASS        | <p>The CPE Loopback Jack test has successfully began executing. The test will continue to run until the system technician enters the <b>test ds1-loop PCSS end-loopback/span-test</b> command or the <b>release board PCSS</b> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

## Far CSU Loopback Test (#1213)

**This test is destructive.**

The Far CSU Loopback (R-LLB) Test causes a loopback at the far-end CSU and tests all circuitry and facilities from the local TN767E DS1 board to the far-end CSU.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS far-csu-loopback-test-begin** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Far CSU Loopback Test.

If the far-end CSU is not a 120A CSU Module, and the DS1 is administered for ami-zcs line coding, one's density protection must be disabled on the CSU during the test due to the large number of zero's in the 3-in-24 test pattern.

The Far CSU Loopback Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test will be available in the hardware error log via error type 3901. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter **test ds1-loop PCSS end-loopback/span-test** or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 10-163. TEST #1213 Far CSU Loopback Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |

| 2          | FAIL        | The far CSU Loopback Test was not set up properly. The DS1 Interface circuit pack could not put the far-end CSU into loopback mode.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3          | FAIL        | <p>The far CSU Loopback Test was not set up properly. The framed 3-in-24 test pattern, generated by the DS1 Interface circuit pack and looped back through the far-end CSU, could not be detected by the DS1 circuit pack.</p> <ol style="list-style-type: none"><li>1. Retry <b>test ds1-loop PCSS far-csu-loopback-test-begin</b>.</li><li>2. If the Far CSU Loopback test continues to fail with this error code, the problem could be with the TN767E board, the far-end CSU equipment, or somewhere in between. Run <b>test ds1-loop PCSS cpe-loopback-jack-test-begin</b> to see if the CPE Loopback Jack test which is closer to the TN767E board is successful. (If a CPE Loopback Jack device is not being used, then run <b>test ds1-loop PCSS ds1/csu-loopback-tests</b> to see if these even closer loopback tests succeed). If the closer loopback test fails, follow the maintenance strategy associated with that loopback</li></ol>                                                                   |
|            | PASS        | The Far CSU Loopback test has successfully began executing. The test will continue to run until the system technician enters <b>test ds1-loop PCSS end-loopback/span-test</b> or the <b>release board PCSS</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

One-Way Span Test (#1214)

This test is destructive.

The One-Way Span Test allows one-way span testing to and from remote test equipment or another DEFINITY communications system. This will test all circuitry and facilities from the local TN767E DS1 board to the remote test equipment or other DEFINITY communications system.

The test is destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS one-way-span-test-begin* command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the One-Way Span Test.

The One-Way Span Test has the TN767E DS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempt to receive and verify the pattern. If the TN767E board receives a framed 3-in-24 test pattern sent from another DEFINITY G3V3 or test equipment at the far-end of the DS1, it will begin counting bit errors within the received pattern.

The status of the One-Way Span test will be available in the hardware error log via error type 3902. Several distinct aux values will be used to give the user information of the status of the test.

The *list measurements ds1 summary* command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being sent cleanly over the span from the far-end, the number of bit errors should be very low. The *Test Duration* field will show 0 until the test pattern is received from the far-end. Upon receiving the test pattern, the board will begin calculating the test duration and number of bit errors. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*i.e. 3-in-24 Pattern*) is synchronized (*Synchronized* field).

To terminate the test, enter the *test ds1-loop PCSS end-loopback/span-test* command or the **release board** command. Using the **release board** command will restore all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 10-164. TEST #1214 One-Way Span Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                     |

|------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1005       | ABORT          | One-Way Span Test cannot be executed in the current configuration. To run this, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.                                                                                                                                                                                                                                                                                                                                          |
| 1015       | ABORT          | Ports on the DS1 Interface circuit pack have not been busied out to out-of-service.<br><br>1. Enter the <b>busyout board PCSS</b> command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state.<br><br>2. Retry the command.                                                                                                                                                                                                                                                                                                                                                       |
| 1039       | ABORT          | The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption.<br><br>If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence:<br><br>1. Issue the <b>disable synchronization-switch</b> command.<br><br>2. Next, issue the <b>set synchronization PCSS</b> command.<br><br>3. Lastly, issue the <b>enable synchronization-switch</b> command.                                                                   |
| 1950       | ABORT          | Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <b>test ds1-loop PCSS end-loopback/span-test</b> command in order to execute this test. |
| 2100       | ABORT<br>ABORT | Internal system error<br><br>Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals for a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Table 10-164. TEST #1214 One-Way Span Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | PASS        | <p>The One-Way Span test has successfully began transmitting a framed 3-in-24 test pattern. The test will continue to run until the system technician enters the <i>test ds1-loop PCSS end-loopback/span-test</i> command or the <i>release board PCSS</i> command.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

Inject Single Bit Error Test (#1215)

This test is destructive.

The Inject Single Bit Error Test will cause a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS inject-single-bit-error* command. An attempt to use this command will be rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack Test, Far CSU Loopback Test, One-Way Span Test) are active on a TN767E circuit pack.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the Inject Single Bit Error Test.

The *list measurements ds1 summary* command displays the number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

Table 10-165. TEST #1215 Inject Single Bit Error Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
|            | PASS        | A single bit error has been successfully injected into an active framed 3-in-24 test pattern.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

End Loopback/Span Test (#1216)

This test is destructive.

The End Loopback/Span Test will terminate an active loopback or span test on a TN767E DS1 circuit pack. Bit error counting against the received test pattern stream is terminated and sending of the framed 3-in-24 test pattern is halted. If either the CPE Loopback Jack or the far-end CSU is looped, the appropriate loopback deactivate code is sent. If the loopback could not be deactivated, then the test will FAIL and a MINOR alarm will be noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by a system technician demanded *test ds1-loop PCSS end-loopback/span-test* command. Since only one of these three different long-duration loopback/span tests can be active at a time, the TN767E circuit pack knows which loopback/span test to terminate.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running this End Loopback/Span Test.

The *list measurements ds1 summary* command will display the length of time the test ran (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field).

To restore the trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state, execute the **release board** command.

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | <p>Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited.</p> <ol style="list-style-type: none"><li>1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000.</li><li>2. The tests run on the ports of this circuit pack are returning a no board result.</li><li>3. A <b>busyout</b> or a <b>release</b> command has no affect on the test results.</li><li>4. A <b>list config</b> command shows that the circuit pack and the ports are properly installed.</li></ol> <p> <b>NOTE:</b><br/>When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.</p> |
| 1313       | FAIL        | <p>The TN767E DS1 circuit pack could not deactivate the loopback through the Customer Loopback Jack.</p> <ol style="list-style-type: none"><li>1. Retry the <i>test ds1-loop PCSS end-loopback/span-test</i> command at 1-minute intervals for a maximum of 5 times.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the link between the internal ID and the port.</p> |

ICSU Status LEDs Test (#1227)

The TN767E DS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A1 Channel Service Unit (CSU) Module that can be connected to the TN767E board via the I/O connector panel on the back of the port carrier.

This test is a visual test. It will light the four status LEDs red for 5 seconds, then light them green for 5 seconds, then light them yellow for 5 seconds, then turn the LEDs off and returns control of the status LEDs to the circuit pack.

This test will only be executed on TN767E or later suffix DS1 circuit packs administered for 24-channel operation (1.544 bit rate).

If the 1201 CSU Module is not installed, the status LEDs are always off and this test aborts.

|            | PASS        | The ICSU Status LEDs test executed successfully. A PASS result, however, does not necessarily mean that the status LEDs behaved properly. It only means that the software successfully attempted to light the status LEDs. This is a visual test. The service technician must visually exam the behavior of the LEDs while the test is running. The LEDs are functioning properly if the four status LEDs are lit red for 5 seconds, then lit green for 5 seconds, then lit yellow for 5 seconds. If the LEDs behave differently, the board should be replaced at the customer's convenience. |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board).</p> <p>This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>add ds1 PCSS</b> command to administer the DS1 interface if it is not already administered.</li><li>2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board.</li><li>3. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>4. Issue the <b>reset board</b> command.</li><li>5. Issue the <b>release busy board</b> command.</li><li>6. Issue the <b>test board long</b> command.</li></ol> <p>This should re-establish the linkage between the internal ID and the port.</p> |

DT-LN-BD (Data Line Circuit Pack)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO        |
|------------------------------------|-------------|-------------------------------------------------------|------------------------|
| DT-LN-BD                           | MIN         | test board PCSS sh                                    | Data Line Circuit Pack |
| DT-LN-BD                           | WRN         | test board PCSS sh                                    | Data Line Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also DAT-LINE (Data Line Circuit Port) Maintenance documentation for related line information.

# DTMR-PT [Dual Tone Multifrequency Port (TTR)]

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO                              |
|------------------------------------|-------------|-------------------------------------------------------|----------------------------------------------|
| DTMR-PT                            | MAJOR       | test port PCSSpp sh                                   | Dual Tone Multifrequency Receiver Port (TTR) |
| DTMR-PT                            | MINOR       | test port PCSSpp sh                                   | Dual Tone Multifrequency Receiver Port (TTR) |
| DTMR-PT                            | WARNING     | release port PCSSpp                                   | Dual Tone Multifrequency Receiver Port (TTR) |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Dual Tone Multifrequency Receiver Port (DTMR), also known as the Touch-Tone Receiver (TTR), resides on the Tone Detector circuit pack (TN748, TN420) or the TN756 Tone-Clock circuit pack. There are four Dual Tone Multifrequency Receiver (DTMR-PT) ports and two General Purpose Tone Detector (GPTD-PT) ports on a Tone Detector circuit pack. The DTMR port is used to detect touch-tone digits that are placed on the TDM bus. Examples of touch-tone digits are digits 0 through 9, digit #, and digit \*. The ability of the DTMR port to detect touch-tone digits is essential for maintenance of other circuit packs (for example, Tone-Clock circuit pack) and in placing a station-to-station call. Calls originating from a hybrid station **do not** require a DTMR port.

The Dual Tone Multifrequency Receiver Port maintenance object defines a set of tests to verify that the DTMF digits detection capability of the DTMR port is functioning properly. For all Tone Detector circuit pack level errors (DETR-BD), refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

Hardware Error Log Entries and Test to Clear Values

| Dual Tone Multifrequency Receiver Port (TTR) Error Log Entries |          |                                        |                  |              |                         |

| 513                                                            | Any      | Tone Detection Verification Test (#42) | MAJOR/ MINOR (a) | ON           | test port PCSSpp r 3    |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. There are two possible alarm levels for this error: Major alarm and Minor alarm. A Major alarm is raised if the total number of DTMR ports currently in service is less than or equal to one half of the administered threshold number. Otherwise, a Minor alarm is raised. In either case, run the Short Test Sequence against the DTMR port and follow the error code procedures for the individual tests.  
  
The threshold number of DTMR ports for service is administered using the **change system-parameters maintenance** command.
- b. This error indicates the DTMR port is having problems detecting touch-tone digits. If this error is being constantly logged, then the Tone Detector circuit pack containing the defective DTMR port should be replaced.
- c. The DTMR port lost its translation. Testing the DTMR port is sufficient to reload its translation. If testing the DTMR port does not clear the error, then the Tone Detector circuit pack containing the defective DTMR port should be replaced.
- d. This error type indicates that the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------|---------------------|--------------------|-------------------|
| Tone Detection Verification Test (#42) | X                   | X                  | ND                |
| Tone Detector Audit/Update Test (#43)  | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test verifies the "touch-tone digits detection" capability of the DTMR port is functioning properly.

Table 10-168. TEST #42 Tone Detection Verification Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none       | ABORT       | The system was not able to allocate all the resources needed for this test or there was an Internal System Error.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 1          | ABORT       | The system could not allocate all the resources needed to test the DTMR port.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 1001       | ABORT       | The system was unable to put the DTMR port in the appropriate mode to test it.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 1002       | ABORT       | <p>The system could not allocate time slots for the test connection. This could happen when the system is heavily loaded. If the system is not heavily loaded, then test the TDM Bus via the <b>test tdm [a b]</b> command. Refer to the TDM-BUS (TDM Bus) Maintenance documentation for details.</p> <ol style="list-style-type: none"><li>1. Retry the command at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                 |
| 1003       | ABORT       | <p>The system could not allocate a Tone Generator for the test connection. This could happen when the system is heavily loaded or there is not a Tone-Clock circuit pack in the port network when this test is being executed.</p> <ol style="list-style-type: none"><li>1. Make sure there is a Tone-Clock circuit pack in the same port network.</li><li>2. If a Tone-Clock circuit pack is missing, install one in the same port network.</li><li>3. Allow about one-minute for the Tone-Clock maintenance to run on the newly inserted Tone-Clock circuit pack.</li><li>4. Retry the command at one-minute intervals a maximum of five times.</li><li>5. If the test continues to abort, escalate the problem.</li></ol> |

# DUPINT (Duplication Interface Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO                    |
|------------------------|-------------|-------------------------------------|------------------------------------|
| DUPINT                 | MAJOR       | test duplication 1C                 | Duplication Interface Circuit Pack |
| DUPINT                 | WARNING     | test duplication 1C                 | Duplication Interface Circuit Pack |

1. Alarms on Duplication Interface circuit pack in the A carrier are always major alarms and alarms on Duplication Interface circuit pack in the B carrier are always warning alarms. Determine the carrier to test via the PORT field from the Alarm or Error Log.

In a High or Critical Reliability PPN system, there are two Duplication Interface circuit packs: one in carrier A and one in carrier B. Together, Duplication Interface circuit pack A and Duplication Interface circuit pack B provide memory shadowing (see “SHDW-CIR” for a full description) and communication between software on the Active and Standby SPEs. By itself, Duplication Interface circuit pack A provides control of the duplicated Processor circuit pack, environmental maintenance monitoring and control, and administration terminal connection.

Duplication Interface circuit pack A controls a lead that lets the Tone-Clock circuit packs know which of them is supposed to be active and additional leads that control which SPE is active. The system software can request that either the SPE Select lead or Tone-Clock lead be changed.

Duplication Interface circuit pack A controls and monitors the same environment leads that the Maintenance/Tape Processor does in a PPN a system without High or Critical Reliability. Duplication Interface circuit pack A also supports the serial channel to the PPN administration terminal in a high or critical reliability PPN. The administration terminal connects to Duplication Interface circuit pack A via a connector on the back of carrier A labeled DOT. At any time, the administration terminal may be disconnected from Duplication Interface circuit pack A and connected directly to the active Maintenance/Tape Processor by attaching the administration terminal to the connector marked TERM on the active carrier. This connection should only be made if the administration terminal fails to function since a problem with the Duplication Interface circuit pack A may be present.

The Duplication Interface circuit packs communicate over the Inter-Carrier Cable (ICC). The ICC connects the Duplication Interface circuit packs via pin fields on the backplane. The ICC consists of two 25-pin connector cables known as ICC-A and ICC-B. (**Note:** A single-carrier cabinet system has an ICC-C also.) The pin fields where ICC-A and ICC-B connect are clearly labeled on the backplane near the pin fields for the Duplication Interface circuit packs. The ICC carries several important leads related to maintaining a high or critical reliability system.

**NOTE:**

The ICC carries the following leads and their respective information: Tone-Clock select lead that indicates which Tone-Clock circuit pack is active; SPE Select Switch State leads which indicate the position of the SPE Select Switch; Emergency Transfer leads which indicate whether Emergency Transfer is on or off in the PPN cabinet; leads to tie INADS, CDR, and Customer-Provided Alarming Device.

Without the ICC properly attached, the system cannot function as a high or critical reliability system or as a standard system.

Figure 10-29 depicts the interconnection of the Duplication Interface circuit packs with the rest of the system. The dotted lines show the logical serial channel rather than actual physical implementation of the serial channel. For clarity, the UARTs are not shown. The following abbreviations are used in the figure:

- DUPINT for Duplication Interface circuit pack
- PR MAINT for Maintenance/Tape Processor
- PROCR for 80286 Processor circuit pack
- MEM BD for Memory

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates that an unexpected hardware reset has occurred on the Duplication Interface circuit pack. Appropriate action has been taken by the software to prevent malfunction. However, if this type error occurs with regular frequency, the DUPINT circuit pack may need to be replaced.
- b. There are several possible Aux Data fields for this error, including blank. All indicate loss of contact with the indicated Duplication Interface circuit packs. The following table summarizes the Aux Data fields.

| Aux Data               | Description                                                                                                                                                                                                                                                                                                                 |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1 or 3                 | Duplication Interface circuit pack A lost handshaking with Duplication Interface circuit pack B.                                                                                                                                                                                                                            |
| 2                      | MTP lost handshaking with the Duplication Interface circuit pack.                                                                                                                                                                                                                                                           |
| 221                    | Duplication Interface circuit pack reported the trouble.                                                                                                                                                                                                                                                                    |
| 65315 or 65503         | Duplication Interface circuit pack A lost contact with Duplication Interface circuit pack B.                                                                                                                                                                                                                                |
| Blank, 65313, or 65501 | <div>If reported against Duplication Interface circuit pack A, Duplication Interface circuit pack A lost handshaking with Maintenance/Tape Processor A.</div> <div>If reported against Duplication Interface circuit pack B, Duplication Interface circuit pack A lost handshaking with Maintenance/Tape Processor B.</div> |

- c. An Aux value of blank or 65317 is valid. The 65317 aux value means the Duplication Interface circuit pack reported the trouble, while the blank means the software detected the trouble.
- d. This could be caused by mismatched numbers of Processor Interface (TN765) or Packet Control (TN778) circuit packs in the two SPEs or by a defective Duplication Interface (TN772) Circuit Pack. If the Duplication Interface Circuit Pack is defective and becomes part of the Standby SPE, then memory shadowing does not work. Follow the procedures given for the FAIL case of Common Shadow Circuit M-Bus Time-Out Query Test (#285) in the SHDW-CIR section.

System Technician-Demanded Tests:

Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below. By clearing error codes associated with the *Duplication Interface Circuit Pack Status Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------------------|---------------------|--------------------|-------------------|
| Duplication Interface Circuit Pack Status Query Test (#315)      | X                   | X                  | ND                |
| Duplication Interface Circuit Pack Sanity Circuit Test (#273)(a) |                     | X                  | D                 |

| Order of Investigation                                                              | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

| SPE Select Switch Query Test (#278) (c)                                             | X                   |                    | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. When running the Long Test Sequence on Duplication Interface circuit pack A, the results of Test #273 may overwrite the results of Test #274.
- b. Refer to “SHDW-CIR” (Common Shadow Circuit) for a description of this test.
- c. Refer to “SPE-SELEC” (SPE Select Switch) for a description of this test.

Duplication Interface Circuit Pack Background Test Query (#271)

This test queries the Duplication Interface circuit pack for the results of its background tests. The response indicates the results of the last time the following background tests were run:

- ROM Checksum Test: This test verifies the correctness of the Duplication Interface circuit pack firmware.
- RAM Test: This tests verifies that the RAM on the Duplication Interface circuit pack is functioning properly.

Duplication Interface Circuit Pack Invalid  
Message Query Test (#272)

The Duplication Interface Circuit Pack Invalid Message Query Test sets the threshold for the number of bad checksum errors the Duplication Interface circuit pack detects before reporting the problem to maintenance and queries the Duplication Interface circuit pack for the number of checksum errors detected. The error threshold is set to 10. The query causes Duplication Interface circuit pack firmware to clear its bad checksum error counter. This test is run on both circuit packs, but has little meaning on Duplication Interface circuit pack B and should always pass.

Table 10-172. TEST #272 Duplication Interface Circuit Pack  
Invalid Message Query Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Duplication Interface Circuit Pack Sanity Circuit  
Test (#273)

This test is destructive.

This test checks the sanity hardware of a Duplication Interface circuit pack. The Duplication Interface circuit pack processor is instructed to allow the on-board circuit pack sanity timer to expire, which should cause the circuit pack to reset itself. The software then allows the Duplication Interface circuit pack 15 seconds to reset. After this time, the Duplication Interface circuit pack is queried for the results of its background tests (see Test #271). If the Duplication Interface circuit

pack responds to this query, then the reset passes. If performed on Duplication Interface A, this test can cause an SPE interchange to the SPE in the B carrier if the A carrier SPE was active when the test was executed. The B carrier Tone-Clock circuit pack is also selected on Duplication Interface circuit pack A processor reset. This test is run only when demanded by software and can be performed on either Duplication Interface circuit pack. There is no service-disruption when this test is run on Duplication Interface B.

Table 10-173. TEST #273 Duplication Interface Circuit Pack  
Sanity Circuit Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

Duplication Interface Circuit Pack  
Administration Terminal Loop Back Test (#274)

This test loops back data through the UART used to communicate with administration terminal. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

|            | FAIL        | The tested UART on the Duplication Interface circuit pack is defective.<br><div>1. If this is Duplication Interface circuit pack A, then the circuit pack must be replaced to restore duplication. If this is Duplication Interface circuit pack B, then this failure has no real impact on the system. However, since this Duplication Interface circuit pack can never be used in the A carrier, it should be replaced at some point.</div> <div>2. Follow the procedures for replacing Common Control circuit packs, and replace the Duplication Interface circuit pack.</div> <div>3. Rerun the test.</div>                                                                                    |
|            | NO BOARD    | The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or the Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B).<br><div>1. Refer to NO BOARD description for the Duplication Interface Circuit Pack Status Query Test (#315).</div>                                                                                                                                                                                                                                                                                                      |
|            | PASS        | The administration terminal UART on the Duplication Interface circuit pack is good. This implies that Duplication Interface circuit pack A should be able to communicate with the administration terminal. This implies that Duplication Interface circuit pack B has a good UART.<br><div>If there are problems bringing up the administration terminal, check the following:<br/><div>1. Verify the terminal is connected to the connector labeled <b>DOT</b> on the back of carrier A and that the connector is securely fastened.</div><div>2. Verify the terminal is set up for 9600 baud.</div><div>3. If the terminal still does not work, replace the administration terminal.</div></div> |

Duplication Interface Circuit Pack SPE A Loop  
Back Test (#275)

This test loops data back through the UART used to communicate with Maintenance/Tape Processor A. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

Duplication Interface Circuit Pack SPE B Loop  
Back Test (#276)

This test loops back data through the UART used to communicate with Maintenance/Tape Processor B. The data is generated by the Duplication Interface circuit pack processor and is looped through the UART. The test is done entirely on the Duplication Interface circuit pack. The test passes if the data sent matches the data received. This test does not check the physical serial channel that is printed on the backplane or carried by the ICC.

Duplication Interface Circuit Pack Sanity Maze  
Test (#277)

This test tests the Duplication Interface circuit pack processor's ability to write through the maze circuit. The Sanity Maze is a piece of circuitry on the Duplication Interface circuit pack that the Duplication Interface circuit pack

Processor must write through to get access to leads controlled by the Duplication Interface circuit pack (Tone-Clock Select Lead, 80286 Processor circuit pack Select Leads, etc.). This maze circuitry ensures that the processor on the Duplication Interface circuit pack is sane before any of these leads are changed. The Duplication Interface processor is instructed to write bit patterns through the maze circuit. The Duplication Interface processor examines the output of the maze circuit and compares it with the input.

Duplication Interface Circuit Pack Status Query  
Test (#315)

This test is used to detect the presence of Duplication Interface circuit packs A and B. To determine the status of Duplication Interface circuit pack B, a query is sent to the Duplication Interface circuit pack A. To determine the status of Duplication Interface circuit pack A, a query is sent to the Maintenance/Tape Processor on the active carrier. The response to either query indicates the status of the handshake to the appropriate Duplication Interface circuit pack.

Table 10-179. TEST #315 Duplication Interface Circuit Pack  
Status Query Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

| 2000       | ABORT       | The software timed out waiting for the reply message.<br><br>1. Rerun the test.<br><br>2. If the message times out again, then continue to the next step. If the query fails with a NO BOARD, then refer to NO BOARD on the next page of this table.<br><br>3. No response is being received from the Duplication Interface circuit pack or Maintenance/Tape Processor. If Duplication Interface circuit pack A is under-test, then check for and resolve all alarms against the active PR-MAINT (Maintenance/Tape Processor). If Duplication Interface circuit pack B is under test, then enter the <b>test dup a</b> system technician command and resolve problems with Test #315 for Duplication Interface circuit pack A first.<br><br>4. Rerun the test. If it still aborts, then a problem may exist with one of the serial links. If carrier B is active or Duplication Interface circuit pack B is under test, then the serial link to get to Duplication Interface circuit pack B is being carried by the ICC. Check for damage to the ICC, and verify that all four connectors for the ICC are plugged in. If the ICC has to be replaced, the system must be powered down.<br><br>5. If the ICC is not the problem, then that portion of the serial link wired into carrier A and/or carrier B may be defective, and the carrier pack may need to be replaced. |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p>The handshake to one of the Duplication Interface circuit packs has stopped. The circuit pack may be defective or communication to the circuit pack is hampered.</p> <ol style="list-style-type: none"><li>1. Look in the Hardware Error Log for error types against TAPE. If TAPE error types are present, resolve them since TAPE error types can cause Test #315 to fail. Refer to TAPE Maintenance documentation for recommended repair strategy.</li><li>2. After any TAPE error types are resolved, issue the <b>test duplication-interface</b> command on the suspect Duplication Interface circuit pack. If Test #315 fails on Duplication Interface A, Duplication Interface A is defective. Replace the Duplication Interface A circuit pack. If Test #315 fails on Duplication Interface B, Duplication Interface circuit pack A or Duplication Interface circuit pack B may be defective. In this case, it is necessary to determine which Duplication Interface circuit pack (A or B) is the defective one. To do this, issue the <b>test duplication-interface A</b> command. If Test #280 fails on Duplication Interface A, (and Test #315 has just failed on Duplication Interface B), Duplication Interface circuit pack A is defective and should be replaced. If Test #280 passes on Duplication Interface A (and Test #315 has just failed on Duplication Interface B), replace the Duplication Interface circuit pack B.</li><li>3. Reissue the <b>test duplication-interface</b> command on the Duplication Interface circuit pack that was replaced. If Test #315 still fails, check for problems with the Inter-Carrier Cables (ICCs). If any of the ICCs is defective, replace it.</li><li>4. Rerun the test.</li></ol> |
|            | NO BOARD    | <p>The Duplication Interface circuit pack has failed to handshake with either the active Maintenance/Tape Processor (in the case of Duplication Interface circuit pack A) or with Duplication Interface circuit pack A (in the case of Duplication Interface circuit pack B).</p> <ol style="list-style-type: none"><li>1. |            | PASS        | <p>The tested Duplication Interface circuit pack is present and sane enough to handshake.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## E-DIG-BD (Multi Application Platform Board)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO |
|------------------------|-------------|-------------------------------------|-----------------|
| DIG800-BD              | MIN         | test board PCSS sh                  | MO800DIG-BD     |
| DIG800-BD              | WRN         | test board PCSS sh                  | MO800DIG-BD     |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...).

The maintenance strategy for DIG800-BD is the same as the one described for MO-COMBD (MO-XXX-BD). Maintenance testing of the common circuit pack is handled by on-board firmware and SPE controlled tests. Maintenance software queries the firmware for error and alarm information, status, and test results. The firmware automatically reports error conditions that will result in SPE-controlled testing.

### Board Insertion

The switch makes an additional board query if any of the following circuit packs are inserted:

| Circuit Pack | Vintage              |
|--------------|----------------------|
| TN754        | 49                   |
| TN556        | 49,<br>80 or greater |
| TN800        | any                  |

For any of the above initial board up-links, the switch sends queries requesting additional data from the board for administration purposes, while also telling the board the switch software release and the system type.

For the native mode, the response to the board query downlink messages consists of several CCMS uplink messages that identify the true board code, vintage, suffix, emulation type, and the number of reserved slots it needs.

## Hyperactivity

The common circuit pack is considered "hyperactive" if the service dispatcher receives 200 up-link messages from the circuit pack in a 10-second period. Since MAPD has 32 ports, the hyperactivity limit is increased to 500 up-link messages per 10seconds. An alarm is issued and the board taken out of service when the limit reaches 400 or when it hits 500 up-link messages in 10 seconds.

## LED Use

The LED Control message 038x requests the Angel to drive the Red, Yellow, and Green LEDs on the face plate of typical port board on or off. On the MAPD, only the Red LED is controlled by this message. Yellow and Green change requests received from the switch by the MAPD drive LCD behavior rather than LED behavior. The switch continues to send the same LED control messages to the MAPD that it currently sends to all other port boards. The MAPD will handle proper interpretation of these messages. You should note that the PC on the MAPD, as well as the switch itself, can control the LEDs and the LCD on the MAPD.

## Port Administration

In administration without hardware, the switch allows administration of up to 32 MAPD ports of any port type. If the port type later reported by the board does not match the existing type, the switch assumes the board is a MAPD board with a different configuration and rejects the board. MAPD\_DCP\_STA and MAPD\_ASAI\_STA are the only two types of terminals are allowed on a MAPD board. Therefore, while administering ports on MAPD using **add station form**, it will allow only the terminals mentioned above.

### NOTE:

Refer to XXX-BD (Common Port Circuit Pack) maintenance documentation for circuit pack level errors. See also DIG-LINE maintenance documentation for related line information.

**E-DIG-RES (TN800 reserve slot)**

---

See ASAI-RES.

## E-DIG-STA (Emulated Digital Line)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO      |
|------------------------|-------------|-------------------------------------|----------------------|
| E-DIG-STA              | MINOR       | test port PCSSpp l                  | Emulated Digital St. |
| E-DIG-STA              | WARNING     | test port PCSSpp sh                 | Emulated Digital St. |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...).

There are 4 tests in the Emulated Digital Line station maintenance test sequence and only one test path in the test sequence. Once the test sequence is started, all tests in the test sequence are executed.

E-DIG-ST maintenance monitors and tests ports on the TN800 MAPD circuit pack and the hardware connected to those ports for lines administered as a digital station. These include stations with an emulated digital voice terminal and stations with an emulated digital voice terminal and a linked data module. Stand-alone data modules and data adaptors in stand-alone mode are not supported by the TN800 circuit pack. Circuit pack maintenance is covered by E-DIG-BD.

### Hardware Error Log Entries and Test to Clear Values

Table 10-180. Digital Line Error Log Entries

| Error Type     | Aux Data | Associated Test                         | Alarm Level              | On/Off Board | Test to Clear Value     |
|----------------|----------|-----------------------------------------|--------------------------|--------------|-------------------------|
| 0 <sup>1</sup> | 0        | Any                                     | Any                      | Any          | test port PCSSpp sh r 1 |
| 18 (a)         | 0        | busyout port PCSSpp                     | WNG                      | OFF          | rel port PCSSpp         |

Table 10-180. Digital Line Error Log Entries — Continued

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|------------|----------|-----------------|-------------|--------------|---------------------|
| 3840 (f)   | 40965    | None            |             |              |                     |
| 3841 (g)   | 41029    | None            |             |              |                     |
| 2304 (h)   |          | None            |             |              |                     |

Continued on next page

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. Maintenance personnel has busied out the port in question. Make sure that the port is released from busyout by using the **release port PCSSpp** command.
- b. The circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.
- c. The local loop test failed. Each failure increments the counter by 1 when the local loop test fails. The counter is decremented when the loop test passes. When the counter reaches a threshold of 3, an on-board MINOR alarm is raised. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No technician action is necessary.
- d. The NPE Cross talk test failed. The counter is incremented by 1 when the NPE Cross talk test fails. The counter is decremented by 1 when the NPE Cross talk test passes. When the counter reaches a threshold of 3, an on-board MINOR alarm is raised and the board is taken out of service.
- e. The station went off-hook while it was in the ready-for-service state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No technician action is necessary.
- f. No terminal is connected to the Digital Line board. No maintenance action is required.
- g. The circuit pack's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.

- h. Internal system error; no action is necessary. The error counters 1, 2, 3, 4, 5, 6, 10, 11, 12, 13, 14, 15, and 16 do not have any significance for this MO.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the Voice and Control Channel Local Loop Around Test, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| Voice and Control Channel Local Loop Around Test (#13) |                     | X                  | D                 |
| NPE Crosstalk Test (#9)                                |                     | X                  | ND                |
| Station Lamp Updates Test (#16)                        |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

**Digital Line NPE Crosstalk Test (#9)**

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete. Crosstalk testing occurs on both the primary information channel (voice) and the secondary information channel (data) associated with each digital station port. If this test fails on either channel, the station and the DTDM are taken out-of-service.

Table 10-181. TEST #9 Digital Line NPE Crosstalk Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | ABORT       | <p>During testing of the primary information channel, system resources may not have been available or the port was busy during the test.</p> <ol style="list-style-type: none"><li>1. Check the port status. Use the <b>display port PCSSpp</b> command to determine the station extension of the port. Use the <b>status station</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for this test. You will have to wait until the port is idle.</li><li>2. Voice and Control Channel Local Loop Test (#13)

These tests check the information and control channels between the Switch Processing Element (SPE) and the Digital Line port circuit. The SPE sends a message to loop around both the information and control channels for the port. First, the primary information (voice) channel loopback test sends a digital count from the Tone-Clock circuit pack on the primary information channel time slot and receives the same digital count with a general purpose tone detector.

While the primary information channel is still looped around, the Control Channel Loop Around Test sends four different transparent patterns to the on-board microprocessor, receives them back, and compares them.

The Loop Around Test for the secondary information (data) channel is the same as the primary information channel loop around test and is performed only if a DTDM is administered.

Next, a Conference Test checks the primary information channel. This test is the same as Conference Test #6.

The four tests will generate only one resulting value (Pass, Fail, or Abort). If any test fails or aborts, the test sequence stops.

If noisy connections for voice or corrupted data for data transfer persist, examine the station, connections, and wiring.</li></ol>                                                                                                                                                                                                                                                                                  |

Station Lamp Updates Test (#16)

This test lights all lamps on the terminal as specified. The lamp updates will run only if the station is in-service. The status of the station is checked and the lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | <p>The message to light all of the station lamps was sent successfully to the port.</p> <ol style="list-style-type: none"><li>1. Observe the station lamps being lit when running the test. If all lamps do not light successfully, the other Digital Line test results may indicate related problems that will not allow the lamps to light.</li><li>2. Investigate by using other Digital Line port tests and by examining the station, wiring, and connections.</li></ol> |

# EMG-XFER

## Emergency Transfer (SCC Cabinets)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO    |
|------------------------|-------------|-------------------------------------|--------------------|
| EMG-XFER               | MAJOR       | test environment P                  | Emergency Transfer |
| EMG-XFER               | WARNING     | test environment P                  | Emergency Transfer |

1. Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

The system provides the ability to cut designated analog phones through to CO trunks if the switch cannot provide even minimal phone service. This ability is known as Emergency Transfer. Each port network PPN and EPN can have a separate Emergency Transfer capability. The EMG-XFER MO tracks the control of Emergency Transfer. There is one EMG-XFER MO for each port network. Emergency Transfer can be controlled by the system or can be manually controlled within each port network via the Emergency Transfer switch(es) which is (are) located on the Processor circuit pack and the EPN Maintenance circuit pack. If the Emergency Transfer switch or switches in a high or critical reliability system on the Processor circuit pack or EPN Maintenance circuit pack are in a manual position, the system cannot change the state of Emergency Transfer within that port network. A manual ON position (to the right) generates a Major alarm. A manual OFF position (to the left) generates a Warning alarm. Unless a technician is currently working on the system, the switches should be left in the auto position ().

On a high or critical reliability system, the switches on BOTH Processor circuit packs must be in the ON position to manually invoke Emergency Transfer. However, if EITHER switch is in the OFF position, Emergency Transfer cannot be controlled by the system and is in the manual OFF state. The **status system** system technician command displays the current state of the Emergency Transfer switches in the system. Valid states for the switches are: *manual ON*, *manual OFF*, *auto ON* (the switch is in the auto position and the system has invoked Emergency Transfer), or (the switch is in the auto position and the system has invoked Emergency Transfer), or *auto OFF* (the switch is in the auto position and the system has not invoked Emergency Transfer).

Error Log Entries and Test to Clear Values

Table 10-184. Emergency Transfer Error Log Entries

| Error Type     | Aux Data | Associated Test                 | Alarm Level | On/Off Board | Test to Clear Value       |
|----------------|----------|---------------------------------|-------------|--------------|---------------------------|
| 0 <sup>1</sup> | 0        | Any                             | Any         | Any          | test environment P sh r 1 |
| 1              | Any      | Emergency Transfer Query (#124) | MAJOR       | ON           | test environment P r 3    |
| 257            | 0        | Emergency Transfer Query (#124) | WARNING     | ON           | test environment P r 3    |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence. For example, you may also clear errors generated from other tests in the testing sequence.

Single Carrier System

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| Power Query Test (#79) (a)                           | X                   | X                  | ND                |
| Emergency Transfer Query Test (#124)                 | X                   | X                  | ND                |
| External Alarm Lead Query Test (#120) (b)            | X                   | X                  | ND                |
| Analog Ring Generator Initialization Test (#117) (c) | X                   | X                  | ND                |
| Analog Ring Generator Query Test (#118) (c)          | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to “DC-POWER” for a description of this test.
- b. Refer to “EXT-DEV” for a description of this test.
- c. Refer to “RING-GEN” for a description of this test.

➤ **NOTE:**

These tests only show up in the test sequence if there is a TN768 Tone-Clock Board in the port network being tested.

Emergency Transfer Query Test (#124)

This test queries the hardware for the state of the Emergency Transfer switch (or switches in a High or Critical Reliability system) and reports the result. If the switch(es) is (are) in a position where the system software can control Emergency Transfer, then the test passes. If the switch(es) is (are) in a position where the system software cannot control Emergency Transfer, then the test fails. In the PPN, the Maintenance/Tape Processor controls Emergency Transfer and, in the EPN, the EPN Maintenance circuit pack controls Emergency Transfer. The system software does not have control of Emergency Transfer within a cabinet if the switch(es) is (are) in the manual ON or manual OFF state for that cabinet.

Table 10-185. TEST #124 Emergency Transfer Query Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000       | ABORT       | System resources required to run this test are not available.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br>2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Resolve all DC-POWER alarms. Then, repeat the test.<br>3. If the test continues to ABORT with a 2000 error code, check for and resolve all DUPINT (Duplication Interface) errors in a PPN for a high or critical reliability system, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Repeat the test. |
| 2029       | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1          | FAIL        | Emergency Transfer is manually turned OFF via the Emergency Transfer switch(es).                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 2          | FAIL        | Emergency Transfer is manually turned ON via the Emergency Transfer switch(es).<br>1. Place the switch (or switches in a PPN for a High or Critical Reliability system) in the AUTO position.                                                                                                                                                                                                                                                                                                                                                                                                      |

Table 10-185. TEST #124 Emergency Transfer Query Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | <p>The system software has control of Emergency Transfer within this port network. If Emergency Transfer is invoked, then there can be a Major alarm in the system that is invoking Emergency Transfer. The following table lists the error types and MOs that may cause Emergency Transfer. If any or all of these errors appear in the log, then refer to the appropriate Maintenance documentation and resolve those problems first.</p> <p>If none of these errors appear in the log, then check the Emergency Transfer hardware. Specifically, on the EPN, if Emergency Transfer is invoked while call processing is permitted, verify that the current limiter card (982LS) is in the correct slot on the backplane. If the current limiter card is not in the correct slot, move it to the correct location and rerun this test.</p> |

Table 10-186. Test #124 Error Log Entries That Cause Emergency Transfer

| MO Name | Error Type | Aux Data |
|---------|------------|----------|
| SW-CTL  | 1          |          |
| SW-CTL  | 2          |          |
| TONE-BD | 1          | 0        |
| TONE-BD | 2305       | 0        |

## EPN-SNTY (EPN Sanity Audit)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO  |
|------------------------------------|-------------|------------------------------------------|------------------|
| EPN-SNTY                           | None        | None                                     | EPN Sanity Audit |

The EPN Sanity Audit feature enhances the system’s ability to recover from failure conditions that disable an entire EPN. In such situations, not only is the affected EPN unable to provide service to the system, but the system itself has not detected the condition. The EPN Sanity Audit feature recognizes an EPN as unable to provide service when the software cannot receive control messages from EPN circuit packs. When such a failure is detected by the EPN Sanity Audit, a sequence of recovery actions is triggered to restore the EPN to service.

For a Standard system, the recovery sequence is as follows:

- 1. TDM Bus Switch
- 2. EPN Reset

For a duplicated system, the recovery sequence is as follows:

- 1. TDM Bus Switch
- 2. Expansion Interface Link Switch
- 3. Tone/Clock Switch within the EPN
- 4. EPN Reset

The EPN Sanity Audit feature activates only when all existing maintenance operations have failed to detect the EPN problem. Therefore, the EPN Sanity Audit serves as a safety net for the EPN.

 **NOTE:**

It is not clear why certain types of EPN problems activate this feature. Thus, error log entries related to these problems do not specify which hardware to replace. The error log entries only indicate that some drastic recovery action occurred due to an unknown problem. However, clues as to the root cause of the EPN outage may be present in the Error Logs and the Alarm Logs of the following MOs: Switch Control (SW-CTL), TDM Bus (TDM-BUS), Expansion Interface (EXP-INTF), and TDM Bus Clock (TDM-CLK). Therefore, it is recommended that you refer to these maintenance sections during trouble shooting operations.

Hardware Error Log Entries and Test to Clear Values

EPN-SNTY Error Log Entries

| Error Type     | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-----------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any             |             |              | None                |
| 8801 (a)       | Any      | None            |             |              |                     |
| 8802 (b)       | Any      | None            |             |              |                     |
| 8803 (c)       | Any      | None            |             |              |                     |
| 8804 (d)       | Any      | None            |             |              |                     |
| 9901 (e)       | Any      | None            |             |              |                     |
| 9902 (f)       | Any      | None            |             |              |                     |
| 9903 (g)       | Any      | None            |             |              |                     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error occurs whenever the EPN is unable to send up-link control messages and the control channel of the TDM Bus in the EPN has been switched as part of the recovery procedure.
- b. This error occurs whenever the EPN is unable to send up-link control messages and an EI link switch has been invoked as part of the recovery procedure.
- c. This error occurs each time whenever the EPN is unable to send up-link control messages and the EPN Tone-Clock has been switched as part of the recovery procedure.
- d. This error occurs whenever the EPN is unable to send up-link control messages and the EPN has been reset as part of the recovery procedure.
- e. This error occurs whenever the EPN is unable to send up-link control messages, but recovers after the control channels of the TDM Bus in the EPN are switched.
- f. This error occurs whenever EPN is unable to send up-link control messages, but recovers after the Expansion Interface Links to the EPN are switched.
- g. This error occurs whenever the EPN is unable to send up-link control messages, but recovers after the active Tone-Clock in the EPN is switched.

ERR-LOG (Error Log)

| MO Name As It<br>Appears in<br>Alarm Log | Alarm Level | Initial System<br>Technician<br>Command to Run | Full Name of MO |
|------------------------------------------|-------------|------------------------------------------------|-----------------|
| ERR-LOG                                  | none        | none                                           | Error Log       |

Functional Description

The ERR-LOG MO is responsible for the sanity of the Alarm Log, the Hardware Error Log, and the Software Error Log. If an inconsistency is detected in any one of these logs, all logs are re-initialized and a hardware error is logged against ERR-LOG indicating the time of inconsistency. There are no tests and no alarms for the Error Log MO. This MO exists solely for the purpose of allowing errors to be logged against it.

Hardware Error Log Entries and Test to Clear Values

| Error Log Error Log Entries |          |                 |             |              |                     |
|-----------------------------|----------|-----------------|-------------|--------------|---------------------|
| Error Type                  | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
| 0 <sup>1</sup>              | Any      | Any             | Any         | Any          | none                |
| 510 (a)                     | Any      | none            | none        | none         | none                |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates that an inconsistency was detected in either the Alarm Log, the Hardware Error Log, or the Software Error Log. To recover from this error, all of the logs were cleared and re-initialized. Any alarms that were active at the time of this error have been cleared. There is no associated test for this error. If the error persists, escalate the problem.

The Aux data value indicates when the inconsistency was found:

|   |                                                |
|---|------------------------------------------------|
| 0 | Found during a periodic audit of the Error Log |
| 1 | Found after an extended reboot                 |

|     |                                        |
|-----|----------------------------------------|
| 2   | Found after a reboot                   |
| 3   | Found after a Reset System 3 (Cold_1)  |
| 4   | Found after a Reset System 2 (Cold_2)  |
| 16  | Found after a Warm Start               |
| 100 | Found after an internal software audit |

# ETR-PT (Enhanced Tone Receiver Port)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO             |
|------------------------------------|-------------|-------------------------------------------------------|-----------------------------|
| ETR-PT(a)                          | MAJOR       | test port PCSSpp sh                                   | Enhanced Tone Receiver Port |
| ETR-PT                             | MINOR       | test port PCSSpp sh                                   | Enhanced Tone Receiver Port |
| ETR-PT                             | WARNING     | test port PCSSpp sh                                   | Enhanced Tone Receiver Port |

1. P is the port network number (1 for PPN, 2 - 3 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

**NOTE:**  
Replacing the tone/clock circuit pack requires a special procedure which is described in the documentation for TONE-BD. That section also describes the LED display for this board.

The TN2182 is a combined Tone Generator/Tone Detector board. It provides 8 Enhanced Tone receiver (ETR) ports. Each of these ports provides the functions previously found individually on DTMR-PTs, GPTD-PTs and CLAS-PTs ports. Thus each port on the TN2182 may be used for any tone detection function that was previously done by TN748, TN420 or TN744 Tone detection boards.

The TN2182 provides Mu-law or A-law tone detection capability.

Since the TN2182 also provides Tone/Clock function only one (or two if your system is duplicated) TN2182 circuit packs may be present in a port network. Thus if more tone detection resources are needed, the additional resources must be provided by TN748, TN420 or TN744 circuit packs.

Hardware Error Log Entries and Test to Clear Values

Enhanced Tone Receiver Port (ETR-PT) Error Log Entries

| Error Type | Aux Data | Associated Test                        | Alarm Level         | On/Off Board | Test to Clear Value  |
|------------|----------|----------------------------------------|---------------------|--------------|----------------------|
| 1          | any      | Tone Detector Audit/Update Test (#43)  | MAJOR/<br>MINOR (a) | ON           | test port PCSSpp r 2 |
| 18         |          | busyout port                           | WARNING             | OFF          | release port PCSSpp  |
| 257 (b)    | 17666    | Tone Detection Audit Update Test (#43) | MAJOR/<br>MINOR (a) | ON           | test port PCSSpp r 3 |
| 513 (c)    | any      | Tone Detection Verification Test (#42) | MAJOR/<br>MINOR (a) | ON           | test port PCSSpp r 3 |

Notes:

- a. There are two possible alarm levels for this error type: major alarm and minor alarm. These alarm levels are dependent on the administered thresholds for TTR, CPTR and CCTR. Each ETR port is capable of operating an any of these.  
  
A major alarm is raised if the total number of ports capable of TTR, CPTR or CCTR detection currently in-service is less than or equal to 1/2 of the administered TTR, CPTR or CCTR threshold number.  
  
Otherwise, a minor alarm is raised. In either case, run the short test sequence against the port (ETR-PT) and follow the error code procedures for the individual tests.  
  
The threshold number of ports for service is administered using the **change system-parameters maintenance** command. For details, refer to "Chapter 5, "Routine Maintenance Procedures".
- b. The ETR-PT lost its translation. Testing the ETR-PT is sufficient to reload its translation. If testing the ETR port does not clear the error, then the TN2182 circuit pack containing the defective ETR port should be replaced at a time when it is convenient to remove a clock board from the system. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.
- c. This error indicates the (ETR-PT) Enhanced Tone Receiver port is having problems detecting touch tones, call progress or MFC tones. If this error type is persistently logged, then the TN2182 circuit pack containing the defective ETR-PT should be replaced at a time it is convenient to remove a clock board from the system. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.
- d. The ETR-PT lost its translation. Testing the ETR-PT is sufficient to reload its translation. If testing the ETR port does not clear the error, then the TN2182 circuit pack containing the defective ETR port should be replaced

at a time when it is convenient to remove a clock board from the system. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------|---------------------|--------------------|-------------------|
| Tone Detection Verification Test (#42) | X                   | X                  | ND                |
| Tone Detection Audit/Update Test (#43) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks out a single ETR port in the touch-tone receiver mode MFC tone detection/generation mode and general purpose tone detection mode. During the first portion of the test, the touch-tone receiver mode is tested. Then general purpose call progress and maintenance tones are tested and lastly MFC tones are tested.

Table 10-187. TEST #42 Tone Detection Verification Test

| Error Code | Test Result | Description/ Recommendation                                                                                       |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------|
| none       | ABORT       | The system was not able to allocate all the resources needed for this test OR there was an Internal System Error. |
| 1          | ABORT       | The system could not allocate all the resources needed to test the tones.                                         |
| 1001       | ABORT       | The system was unable to put the ETR-PT in the appropriate mode to test it.                                       |

In order to restore performance to normal, replace the TN2182 circuit pack containing the defective ETR-PT. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack. |
|            | PASS        | Tone Detection Verification is successful. The ETR Port is able to detect/generate all necessary tones.                                                                                                                                                                                                                                                                                                                                                                                                        |

Tone Detector Audit/Update Test (#43)

A Digital Signal Processor sanity audit is performed on the ETR-PT.

Table 10-188. TEST #43 Tone Detector Audit/Update Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| none       | ABORT       | The system was not able to allocate all the resources needed for this test.<br><br>1. Wait 1 minute, and repeat the command a maximum of 5 times.                                                                                                                                                                                                                                                                                       |
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                                                                                                                                                                                         |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                             |
|            | FAIL        | Hardware audit failed.<br><br>1. Run the short test sequence via the <b>test port PCSSpp sh r 1</b> command.<br><br>2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the circuit pack containing the defective ETR-PT. Follow the procedures described in the TONE-BD section for replacing a tone/clock circuit pack. |
|            | PASS        | The ETR Port has passed the sanity inquiry.                                                                                                                                                                                                                                                                                                                                                                                             |

## EXP-INTF (Expansion Interface Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO                  |
|------------------------|-------------|-------------------------------------|----------------------------------|
| EXP-INTF               | MAJOR       | test board PCSS sh                  | Expansion Interface Circuit Pack |
| EXP-INTF               | MINOR       | test board PCSS sh                  | Expansion Interface Circuit Pack |
| EXP-INTF               | WARNING     | test board PCSS sh                  | Expansion Interface Circuit Pack |

- Where P is the port network number 1, 2, or 3, C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth).

### CAUTION:

A detailed flowchart for isolating and resolving Packet Bus faults is included in Chapter 9, "Packet Bus Fault Isolation and Correction". This flowchart, along with the other information presented in the chapter, can help in resolving problems relevant to the Packet Path of the TN570 Expansion Interface. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9, "Packet Bus Fault Isolation and Correction" in addition to the relevant MO documentation.

The TN570 or the TN776 Expansion Interface circuit pack is used to provide connectivity between the Processor Port Network (PPN) and either Expansion Port Network (EPN) (network 2 or 3) or between the two Expansion Port Networks. The TN776 Expansion Interface is used in G1 systems to provide connectivity between the Processor Port Network and the (single) Expansion Port Network. This connectivity is provided via a 32 Mbps fiber optic cable. The TN776 supports circuit-switched connections and the control channel to and from the EPN. The TN570 also supports packet-switched connections for those systems that use the Packet Bus. The TN776 and TN570 circuit packs must only be used in matched pairs. A TN776 circuit pack does not function if connected via fiber to a TN570 circuit pack and vice versa.

The EPN(s), if present, are always under the control of the TN777 Processor circuit pack in the PPN. Therefore, if the Expansion Interface circuit packs to the EPN are not functioning correctly, service may be unavailable in that EPN, but is available in the PPN. If the Expansion Interface circuit packs between EPNs are not functioning properly, there is service in all networks, but connectivity between EPN and EPN is not available.

A system with EPN(s) may have one or two pairs of Expansion Interface circuit packs connecting any two cabinets. If two pairs exist, one pair operates as the Active pair and provides the required connectivity. The second pair acts as a hot

Standby. When a problem arises on the Active pair, the Standby pair may be called upon to take over and provide continuous service with stable calls being preserved. The Expansion Interface circuit packs must be inserted into fixed slots. The valid slots for Expansion Interface circuit packs are: 1A01, 1A02, 1B01, 1B02, 2A01, 2A02, 2B02, 2B03, 3A01, 3A02, 3B02, or 3B03. It is also a requirement that the fiber cables be connected according to the following table:

Table 10-189. Expansion Interface Circuit Pack Connections

| EXP-INTF in slot  | connected to EXP-INTF in slot | Description                              |
|-------------------|-------------------------------|------------------------------------------|
| 1A01              | 2A01                          | Network 1 to Network 2                   |
| 1B01              | 2B02                          | Network 1 to Network 2 (Duplicated Link) |
| 1A02 <sup>1</sup> | 3A01                          | Network 1 to Network 3                   |
| 1B02 <sup>1</sup> | 3B02                          | Network 1 to Network 3 (Duplicated Link) |
| 2A02 <sup>1</sup> | 3A02                          | Network 2 to Network 3                   |
| 2B03 <sup>1</sup> | 3B03                          | Network 2 to Network 3 (Duplicated Link) |

1. G3iV1.1-286 and G3iV2-386 only.

 **NOTE:**  
If Expansion Interface circuit packs are connected in any other way, they do not function properly.

The Active Expansion Interface Link may be selected by system technician via the **set expansion-link PCSS** command, where PCSS is the address of either Standby Expansion Interface circuit pack. System Technician may prevent the system from switching Expansion Interface Links by using the **busyout board PCSS** command, where PCSS is the address of either Standby Expansion Interface circuit pack. These two commands are described later in greater detail in the "Expansion Interface Link Switch Command" section (located at the end of this EXP-INTF Maintenance documentation).

A G3MT terminal connected to an EPN [G3i] provides the same maintenance and administrative capabilities as the local administration terminal, but at a slower transmission speed. The EPN Maintenance circuit pack also provides Emergency Transfer and environmental monitoring functions for the EPN.

The abbreviations have the following meanings:

- **PROC** The TN773 Processor circuit pack (the Active TN773 Processor circuit pack in a High or Critical Reliability system)
- **NETCON** The SW-CTL portion of the Network Control circuit pack (the Active Network Control circuit pack in a High or Critical Reliability system)

- **TDM BUS** The Time Division Multiplex Bus that connects circuit packs within a cabinet
- **EXP-INTF** The Expansion Interface (EXP-INTF) circuit pack
- **FIBER** The optical fiber used to connect Expansion Interface circuit packs
- **MAINT** EPN Maintenance (MAINT) circuit pack
- **PKT-BUS** The Packet Bus used to carry ISDN-BRI signalling information
- **MGR 1** The local administration terminal

To determine which Expansion Interface Link is active and which is standby for each Expansion Interface pair, the **status system** command can be used. Alternately, visual inspection shows that the Active Expansion Interface circuit packs have the yellow LED on solid or blink a pattern two seconds on, 200 milliseconds off. The Standby Expansion Interface circuit packs have the yellow LEDs off.

| Condition                       | LED on     | LED off    |
|---------------------------------|------------|------------|
| Fiber Out-of-Frame (a)          | 0.1 second | 0.1 second |
| In frame, No Neighbor (b)       | 0.5 second | 0.5 second |
| Expansion Interface Active (c)  | 2 second   | 0.2 second |
| Expansion Interface Active (d)  | solid on   | never off  |
| Expansion Interface Standby (e) | never on   | solid off  |

Notes:

- a. This flashing code corresponds to error codes 769 and 770 from the Hardware Error Log and indicates a failure of Test #238. These error codes are usually accompanied by error code 1281 (no Expansion Interface detected on opposite end of fiber). This condition may be caused by the absence of the opposite end Expansion Interface circuit pack, a broken or missing fiber, or a missing lightwave transceiver on either Expansion Interface circuit pack.
- b. This flashing code corresponds to error code 1281 from the Hardware Error Log and indicates a failure of Test #237. This condition is usually due to a failed Expansion Interface circuit pack on the opposite end of the fiber.
- c. This is the normal state for an EPN Active Expansion Interface circuit pack that is also the bus master in the EPN.
- d. This is the normal state for an Active Expansion Interface circuit pack that is not the bus master. It is also the state of the TN776 Expansion Interface circuit pack immediately after circuit pack initialization when the system has not yet assigned a role to it (that is, Active or Standby). To distinguish between these two situations, use the **status system** command. If the link

which contains this Expansion Interface circuit pack is in-service (up), the Expansion Interface circuit pack is active; if it is out-of-service (down), the Expansion Interface circuit pack is neither active nor standby.

- e. This is the normal state for a Standby Expansion Interface circuit pack. It is also the state of the TN570 Expansion Interface circuit pack immediately after circuit pack initialization when the system has not yet assigned a role to it (that is, Active or Standby). To distinguish between these two situations, use the **status system** command. If the link which contains this Expansion Interface circuit pack is in-service (up), the Expansion Interface circuit pack is standby; if it is out-of-service (down), the Expansion Interface circuit pack is neither active nor standby.

---

When testing Expansion Interface circuit packs to investigate problems, tests should always be run on both circuit packs of an Expansion Link. This provides a better indication of where a problem is located. Hardware errors for all Expansion Interface circuit packs (EXP-INTF) may be displayed by using the category "infc" on the Display Errors form.

In the EPN, the EPN TN775 Maintenance (MAINT) circuit pack monitors the sanity of the Expansion Interface circuit pack. If the Expansion Interface circuit pack should cycle between sane and insane several times, the Maintenance circuit pack holds the Expansion Interface circuit pack reset. If a new Expansion Interface circuit pack is installed in the EPN, the EPN Maintenance circuit pack should be removed because it may attempt to hold the new Expansion Interface circuit pack reset. The Maintenance circuit pack may be reinstalled after the Expansion Interface circuit pack has been inserted and the Expansion Interface circuit pack's red LED has gone off.

The Active Expansion Link is also involved in synchronization between the two cabinets. The Expansion Interface circuit pack reports slip errors if the two cabinets are not correctly synchronized. When diagnosing synchronization problems, the Expansion Interface circuit packs should be examined as a possible cause.

## Relationship Between Expansion Interface and Tone-Clock Circuit Packs

---

The Expansion Interface fiber link depends on the system clock that is provided by the Active Tone-Clock circuit pack on each network. (See TDM-CLK and TONE-BD Maintenance documentation.) Each Expansion Interface circuit pack transmits over the fiber at a rate derived from the system clock on its network. If the Active Tone-Clock is defective to the point where the system clock frequency it produces is out of the specified range ("out of spec"), an Expansion Interface Link might go down even though the Expansion Interface circuit packs are healthy. In a High or Critical Reliability system, both links could go down if there is a defective Active Tone-Clock.

Whether or not a link goes down, depends on certain characteristics of the Expansion Interface circuit packs. An Expansion Interface circuit pack should not be replaced if the link on which it resides goes down because of a defective Active Tone-Clock circuit pack. The defective Tone-Clock circuit pack should be replaced instead. The Expansion Interface circuit packs are more sensitive to a defective system clock than the rest of the components of the system. Therefore, testing of the Tone-Clock circuit pack might not reveal a problem.

The symptoms of the problem in which an invalid system clock causes an Expansion Link to go down are as follows:

1. If the Active PPN Tone-Clock circuit pack is providing an invalid system clock:
  - a. The EPN Expansion Interface circuit pack yellow LED blinks quickly.  
(Fiber Out-of-Frame condition).  
If the EPN is up, Test #238 fails on this Expansion Interface circuit pack.
  - b. The PPN Expansion Interface circuit pack yellow LED blinks slowly.  
(In-frame, No Neighbor condition).  
Test #237 fails on this Expansion Interface circuit pack, but Test #238 passes.
2. If the EPN Tone-Clock circuit pack is providing an invalid system clock:
  - a. The PPN Expansion Interface circuit pack yellow LED blinks quickly  
(Fiber Out-of-Frame condition).  
Test #238 fails on this Expansion Interface circuit pack.
  - b. The EPN Expansion Interface circuit pack yellow LED blinks slowly  
(In-frame, No Neighbor condition).  
If the EPN is in-service, Test #237 fails on this Expansion Interface circuit pack, but Test #238 passes.

These symptoms can also be the result of other problems (for example, one half of the fiber being unable to transmit data). If the system exhibits these symptoms, execute the following procedure:

1. Verify that the EPN stays down for at least one minute.

If the Expansion Interface Link comes back in service after a short time, without switching the Active Tone-Clock, the problem probably was the on-line synchronization source became invalid (see SYNC Maintenance documentation for more information).

However, if the Expansion Interface Link(s) has not come back into service after one minute, the synchronization source is not the cause of the problem. Proceed to Step 2.

2. Check for errors via the **display errors** command with the Category field set to "tone" and the Active alarms field set to "n." Some of the alarms on EPN objects might have been resolved if the EPN went down. Refer to the appropriate MO Maintenance documentation for descriptions of any of the errors occurring at about the same time as the EXP-LINK errors. Resolve any active alarms. Also, if Error Type 18 was logged against the SYNC MO when the EPN went down, the problem was probably that the synchronization on-line reference became invalid. Since reference switching was disabled, the Tone-Clock did not switch from the invalid reference. Therefore, the Tone-Clock circuit pack put out a system clock that was "out of spec." Issue the **enable synchronization-switch** command. If the EPN is down, reseal the Tone-Clock circuit packs on the EPN. This action should restore the EPN to service.

Execute Steps 3 and 4 in the order most convenient to you and least destructive to the customer.

3. Check if the fiber optic cable is transmitting properly via the following procedure on one of the out-of-service links:
  - a. Carefully record the symptoms (yellow LED pattern and tests failing) that were occurring on the PPN Expansion Interface circuit pack and the EPN Expansion Interface circuit pack. Clearly indicate which symptoms are occurring on which Expansion Interface circuit pack.

**WARNING:**

*Before proceeding, note which is the current transmit fiber and which is the current receive fiber for proper reconnection.*

- b. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the PPN Expansion Interface circuit pack slot (see Figure 10-30 on page 10-657).
- c. Connect what was formerly the transmit fiber to the receive jack.
- d. Connect what was formerly the receive fiber to the transmit jack.
- e. Perform Steps b, c, and d on the opposite end of the fiber and the lightwave transceiver on the back of the EPN Expansion Interface circuit pack slot.

**NOTE:**

If it is more convenient for you, execute Steps b, c, and d on the EPN Expansion Interface circuit pack first.

- f. If the symptoms which were formerly occurring on the PPN Expansion Interface circuit pack are now occurring on the EPN Expansion Interface circuit pack and vice versa, the fiber is defective and should be replaced.

4. Determine if the problem is due to a defective Active Tone-Clock circuit pack. Refer to the preceding list of symptoms to decide which network contains the suspect Active Tone-Clock. See Warning.

**WARNING:**

*If you remove the EPN Expansion Interface circuit pack that is active or that was active when the EPN was last in-service, then the 2A/3A Tone-Clock circuit pack becomes the Active Tone-Clock. This characteristic can be deceiving. Replacing or reseating the Active EPN Expansion Interface circuit pack might restore the Expansion Interface Links temporarily. However, if the 2B/3B Tone-Clock circuit pack was really the source of the problem and not the Expansion Interface circuit pack, then the Expansion Interface Link(s) goes down again the next time a Tone-Clock switch to the 2B/3B Tone-Clock is attempted (probably when the scheduled Tone-Clock switch occurs).*

**WARNING:**

*If, after all the Expansion Interface Links are restored, you suspect the problem might have been due to a defective Tone-Clock circuit pack, switch to this Tone-Clock at an appropriate time. If the Tone-Clock circuit pack was the cause of the problem and the same Expansion Interface circuit packs are in place, the same Expansion Interface Link(s) goes down again.*

- a. On a High or Critical Reliability system in which the network containing the suspect Tone-Clock circuit pack is in-service:

Switch to the Standby Tone-Clock on this network. If the suspect Tone-Clock circuit pack is defective, the Expansion Interface Link(s) should be restored to service at this point. Switching back to the defective Tone-Clock should make the same Expansion Interface Link(s) go out-of-service. Such a Tone-Clock circuit pack is defective and should be replaced as soon as possible. If switching Tone-Clocks does not bring up the EPN, then this Tone-Clock is not the source of the problem. Make sure to switch back to the original Tone-Clock.

**WARNING:**

*If the defective Tone-Clock circuit pack is left as the Standby Tone-Clock, then a scheduled Tone-Clock switch causes the same Expansion Link(s) to go out-of-service again.*

- b. On a system in which the EPN containing the suspect Tone-Clock circuit pack is out-of-service:

Replace the Active Tone-Clock circuit pack on this network. In a High or Critical Reliability system, the Active Tone-Clock is the Tone-Clock circuit pack whose yellow LED is: 1) blinking and 2) blinking slower if both Tone-Clocks have blinking yellow LEDs. If the Expansion Interface Link(s) comes up after replacing this Tone-Clock circuit pack, then this Tone-Clock circuit pack should be replaced as soon as possible. See Warning.

**WARNING:**

*If the defective Tone-Clock circuit pack is left as the Standby Tone-Clock, then a scheduled Tone-Clock switch causes the same EPN to go out-of-service again.*

If replacing the Active Tone-Clock did not bring up the Expansion Interface Link(s), then this Tone-Clock circuit pack is not the source of the problem.

- c. On a standard system in which the PPN contains the suspect Tone-Clock circuit pack:

Replace the PPN Tone-Clock circuit pack **at a time when bringing down the system is most convenient to the customer.**

**WARNING:**

*Replacing the PPN Tone-Clock circuit pack stops call processing on that network and also brings down stable calls. This action eventually causes a Reset System 2 (Cold 2 restart).*

If replacing the Tone-Clock circuit pack restores the Expansion Interface Link(s), then the Tone-Clock circuit pack is defective and should be replaced. Otherwise, the problem is not with the PPN Tone-Clock circuit pack.

## **Expansion Interface Manual Loop Back Procedure**

This procedure is to be used when an Expansion Interface circuit pack cannot be tested by software. This is usually when the Expansion Interface circuit pack is in the EPN and the EPN is down. A spare length of fiber jumper cable is required for this procedure.

If this procedure is run on both Expansion Interface circuit packs of a link, and both check out fine, then the failure is most likely in the fiber itself if neither Expansion Interface circuit pack is busied out, but the link remains inactive.

1. Busyout the Expansion Interface circuit pack using the **busyout board PCSS** command.

2. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the Expansion Interface circuit pack slot. **Note which is the transmit fiber and which is the receive fiber for proper reconnection at the end of this procedure.**
3. Using a spare fiber jumper cable, interconnect the transmit and receive jacks of the lightwave transceiver as shown in Figure 10-30 on the following page.
4. Go to the front of the cabinet and inspect the yellow LED.
  - If the yellow LED is on steady, this Expansion Interface circuit pack and the lightwave transceiver are functioning properly.
  - If the yellow LED is off, reseal the circuit pack. For the TN776, if the yellow LED comes on steady after the red LED has gone off, the Expansion Interface circuit pack and the lightwave transceiver are functioning properly. For the TN570 [G1V5], if the yellow LED is off steady after the red and green LEDs have gone off, the Expansion Interface circuit pack and the lightwave transceiver are functioning properly.
  - If the yellow LED flashes on at a rate of once per second, the Expansion Interface circuit pack or transceiver should be replaced.
  - If the yellow LED flashes on at a rate of five times per second, the Expansion Interface circuit pack or the lightwave transceiver may need replacement. This condition may also be due to a faulty system clock on the network containing this Expansion Interface circuit pack. Refer to the procedure described in the preceding "Relationship Between Expansion Interface and Tone-Clock Circuit Packs" on page 10-651 section for further details.
5. Replace faulty component(s) and reconnect the original fiber. Be sure to reconnect the fibers properly as noted in Step 3.
6. Release Expansion Interface circuit pack with the **release board PCSS** command.

**Figure 10-30. Interconnection of Lightwave Transceiver Transmit/Receive Jacks**

**Error Log Entries and Test to Clear Values**

**Table 10-190. Expansion Interface Circuit Pack Error Log Entries**

| Error Type     | Aux Data | Associated Test                                       | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-------------------------------------------------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any                                                   | Any         | Any          | test board PCSS     |

| 10004 (v)  | 0        | None            |             |              |                     |
| 11000 (w)  | 0        | None            |             |              |                     |
| 11000 (x)  | 2        | None            |             |              |                     |
| 11000 (y)  | 3        | None            |             |              |                     |
| 11000 (z)  | 4        | None            |             |              |                     |
| 11000 (aa) | 5        | None            |             |              |                     |
| 11000 (ab) | 8        | None            |             |              |                     |
| 11001 (ac) | 0        | None            |             |              |                     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. Expansion Interface (EI) circuit pack has been busied out by system technician.
- b. EI circuit pack has been administered on the Circuit Pack form, but has not been physically inserted into the system. Insert the circuit pack.
- c. A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to re-administer this slot to match the circuit pack inserted.

- d. This alarm is raised after an EI circuit pack has been removed from a slot for 11 minutes. The alarm is resolved when the EI circuit pack is inserted into this slot. Another way to resolve or prevent this alarm is to use the **change circuit pack** command to remove the EI circuit pack administrative entry for this slot after the EI circuit pack has been removed from the slot. Or, if the circuit pack is in the system and the red LED is on, then follow the instructions for "Red (alarm)" in the "Control and Port Circuit Pack Status LEDs" section in Chapter 7, "LED Interpretation".
- e. Error Type 257 with Aux Data 85 through 88 indicates that this EI circuit pack is detecting incorrect data on the incoming fiber bit stream. The data is originating at the opposite EI circuit pack. These errors could result from a bad timing reference on the network which contains the EI circuit pack on the opposite end of the fiber. For example, if the error is logged against the 1B01 (PPN) EI circuit pack, then the bad timing reference is on the EPN. Resolve any EXP-INTF errors 2305, 769, or 770. Resolve any TONE-BD, TDM-CLK, or SYNC errors. Finally, if the errors continue to occur, perform the following procedure:
  1. If the EI circuit pack reporting the error is part of the Active link and a Standby link exists, switch to the Standby link.
  2. Reset the EI circuit pack at the opposite end of fiber.
  3. Issue the **test board PCSS repeat 10** command, where PCSS is the address of the EXP-INTF circuit pack reporting the error. If Tests #241 or #316 fail even once, follow the procedures associated with the failures.
  4. Wait 15 minutes. Then check the Error Log to see if new errors of type 257 have been detected.
  5. If errors are present, reset the EI circuit pack reporting the errors.
  6. Wait five minutes. Then check the Error Log to see if new errors of type 257 have been detected.
  7. If errors are present, replace the EI circuit pack or transceiver at the opposite end of the fiber.
  8. Wait 15 minutes. Then check the Error Log to see if new errors of type 257 have been detected.
  9. If errors are present or if this error occurs intermittently (over one week's time), replace the EI circuit packs or transceivers on this link.
- f. Error Type 513 with Aux Data 5 through 7 indicates an ON BOARD hardware failure of the circuit packs RAM or ROM. Replace the EI circuit pack or transceiver.
- g. Error Type 1538 indicates a hyperactive EI circuit pack that is generating an abnormal amount of control messages to the Processor circuit pack. When this error was generated, the EI was automatically reset by the system. If this system does not have duplicate EI Links, service to the EPN

is disrupted. If this system does have duplicate EI Links, the system should have switched to the Standby EI Link. Reset the EI. If error 1538 is detected again, replace the EI circuit pack or transceiver.

- h. Error Type 2049 indicates that the last time the EI circuit pack was reset, its initialization tests failed. The number in the Aux Data field is the error code with which Reset Test (#336) failed. Follow the procedure specified in the Reset Test (#336) FAIL section for this error code.
- i. Error Type 2305 with aux data 118 indicates that the EI circuit pack has detected slips on the incoming fiber data stream. Thus, the EPN and PPN are not synchronized. Examine the Error Log for any SYNC, TDM-CLK, TONE-BD, and DS1-BD errors. If these errors exist, refer to the appropriate MO for repair procedures. If the errors do not exist, refer to "SYNC" for general information on diagnosing synchronization problems. If there are no active EI circuit pack errors with Error Types 769 and 770, Error Type 2305 resolves when fewer than nine slips are detected in a 5- to 10-minute period (that is, Error Type 2305 resolves within 10 minutes of the last slip.) If the Error Log has an active EI error with type 769 or 770, then Error Type 2305 is resolved when Error Types 769 and 770 are resolved.

**⇒ NOTE:**

These errors may be ignored if they occur during clock interchanges.

- j. Error Type 2561 indicates an on-board failure of EI circuitry related to handling packet data from the fiber interface and from the Packet bus interface. If this error has generated a minor alarm, replace the EI circuit pack or transceiver.
- k. Error Type 2817 indicates an on-board failure of EI circuitry related to transmission of data to the fiber interface. If this error has generated a minor alarm, replace the EI circuit pack or transceiver.
- l. Error Type 3074 and 3075 indicates failures of EI circuit pack packet path tests. These packet path tests do exercise circuitry on both EI circuit packs of the expansion link. If Error Type 3075 is present without Error Type 3074, the fault probably lies with the EI circuit pack that reported the error. Replace the EI circuit pack or transceiver. If Error Type 3074 exists with or without 3075, the fault is probably on the neighbor of the EI circuit pack that reported this error. Replace the neighbor EI circuit pack or transceiver.

**⇒ NOTE:**

Certain Packet Bus failures can cause this error. In that case the EI is not defective. If PKT-BUS errors are also present, refer to Chapter 9, "Packet Bus Fault Isolation and Correction" and the PKT-BUS section for fault isolation procedures. If PKT-BUS errors are not present and replacing the EI does not solve the problem this error can still be the result of a Packet Bus failure.

- m. Error Type 3330 indicates a failure of a diagnostic component on the Expansion Interface circuit pack. The failed component does not impair service, but it may leave the EI circuit pack in a state where the EI circuit pack cannot detect errors.
- n. Error Type 3585 indicates that the EI circuit pack experienced a series of very short out-of-frame conditions within several minutes. This may indicate transmission difficulties over the fiber link. If this is a duplex system, and if no other alarms exist, the system should have switched away from the fiber link using this EI circuit pack. If this condition ceases, the warning alarm should be resolved within 15 minutes. In the meantime, make sure all lightwave transceivers are firmly secured to the back of the cabinet. Thereafter, if the alarm is not resolved during the next four 15-minute segments, replace the following (the first after the first 15-minute segment, the second after the second 15-minute segment, and so forth):
  - 1. Lightwave transceiver attached to the EI reporting the alarm
  - 2. Lightwave transceiver on the opposite end of the fiber
  - 3. Expansion Interface board reporting the alarm
  - 4. Expansion Interface board on the opposite end of the fiber

Since the counter is active only due to a transient condition, there is no test that can be run to clear the counter. However, the counter automatically decrements by one every five minutes. Once the condition causing the transient Fibers Out-of-Frame (FOOFs) has been fixed, it will take 15 minutes for the counter to be cleared if the alarm was raised.

- o. Error Type 3841 indicates that the EI (TN570 only) has reported a loss of lock with the backplane system clock.
- p. Error Type 3842 indicates that the test that queries the EI (TN570 only) for the state of the lock to the system clock has failed. This means that a loss of lock condition is present. A link switch is then attempted, and the alarm is raised. When both links report this error, the link switch is not attempted because, in this case, the problem is more likely to occur with the backplane clock than with the Expansion Interface circuit pack.
- q. The counter associated with Error Types 3841 and 3842 is cleared when the query for the state of the lock-to-system-clock passes. Once the alarm is raised, this test is run every five minutes. However, the test is not part of any sequence that can be run on demand.
- r. Error Type 10000 is a report from the EI circuit pack that its internal data has become corrupted. The EI circuit pack has lost track of control messages destined for the EPN. When this error is detected, the system automatically resets the EI circuit pack and brings the EPN down. Service to the EPN is unavailable for several minutes after detection of this error. No system technician action is required.

- s. Error Type 10001 is a report that the EI circuit pack dropped one control message to the EPN. This condition may have been observed as a call that did not complete correctly. No system technician action is required.
- t. In response to Error Type 10002, the system denied all calling services for up to 10 seconds.

If EI Error Type 257 is logged at the same time against an Expansion Interface circuit pack on this link, first try to resolve this error. The error associated with Error Type 257 could be the cause of this error.

If Error Type 257 is not logged at the same time as this error, then Error Type 10002 indicates that heavy call traffic was encountered involving EPN endpoints.

No system technician action is required; however, should this error recur frequently, the system should be examined for traffic engineering. The PPN and EPNs may not be equipped with sufficient trunks and Tone Detectors for the number of stations in each cabinet.

- u. Error Type 10003 indicates that heavy call traffic involving EPN endpoints has returned to normal levels. This Error Type should always appear after Error Type 10002 or 10004. No system technician action is required.
- v. Error type 10004 indicates that an extreme backup of traffic was present on the EI circuit pack. The EPN served by this link was most probably not providing service when this error was logged. If this is a high or critical reliability system, the system should have switched to the Standby Expansion Link in order to restore service. Error type 11000 with an Aux value of 5 should have been logged against EXP-INTF to indicate this condition.

In a standard system, the system should have reset the EPN in order to restore service. EXP-LINK Error Type 122 with an Aux value of 6 should have been logged to indicate this condition.

- w. Error Type 11000 with an Aux value of 0 appears when an EI Link switch takes place. Data calls between the PPN and EPN may have experienced some data loss or, in severe cases, the data calls may have dropped. The link that became active is the link with the circuit pack address given in the Error Log entry. The link switch may have occurred for several reasons:
  - 1. System Technician demanded the Expansion Interface Link switch. This can be verified by using the **list history** command.
  - 2. The Expansion Interface Link switch may have been scheduled. Check the Maintenance-Related System Parameters form.
  - 3. An Expansion Interface circuit pack error may have been detected. Examine the Error Log for other EI circuit pack errors with the same approximate time as this error.
  - 4. An EPN Maintenance circuit pack error may have been detected. Examine the Error Log for MAINT errors with the same approximate time as this error. MAINT Error Type 2561 indicates that the Active Expansion Interface circuit pack on the EPN could not

communicate with the EPN Maintenance circuit pack. MAINT Error Type 3329 means the EPN Maintenance circuit pack cannot talk to the EPN Expansion Interface circuit pack in the A carrier. MAINT Error Type 3585 means the EPN Maintenance circuit pack cannot talk to the EPN Expansion Interface circuit pack in the B carrier.

5. Synchronization (SYNC) maintenance may have detected an inability of the Active Expansion Interface Link to provide synchronization between cabinets. Examine Error Log for SYNC Error Type 2305 with the same approximate time as this error.
- x. Error Type 11000 with an Aux value of 2 appears when a system technician-demanded Expansion Interface Link Switch is issued. No further action is required.
- y. Error Type 11000 with an Aux value of 3 appears when a scheduled EI Link Switch has occurred. No further action is required.
- z. Error Type 11000 with an Aux value of 4 appears when an Expansion Interface Link Switch has occurred due to a Special EPN recovery strategy. The software has forced an Expansion Interface switch because the new Expansion Interface Link contains new features which support EPN recovery in case of a bad tone/clock board. This error code appears when there is a periodic/scheduled tone/clock switch.
- aa. Error Type 11000 with an Aux value of 5 appears when the system has detected an excessive backup of traffic on the Active Expansion Link. This condition may have been due to communication difficulties on the Expansion link. To restore normal service, the system switched Expansion Links to the link identified in the Error Type 11000 with an Aux Data value of 5. Error Type 10004 should be present against the Expansion Interface circuit pack that reported the traffic congestion.
- ab. Error type 11000 with an Aux value of 8 indicates that the EI link was switched as part of the recovery action taken by EPN-SNTY. This error should be accompanied by EPN-SNTY error 8802 0. If EPN-SNTY error 9902 0 is also present, this indicates that the switching of the EI link was the recovery action that restored sanity to the EPN. In this case, the fault was with the link that was switched away from. The relevant EIs and connections should be tested and examined to determine the cause of the problem. Look for EPN-SNTY errors in the error log, and refer to the EPN Sanity Audit (EPN-SNTY) section for more details.
- ac. Error Type 11001 occurs when an Expansion Link switch was attempted but for unknown reasons could not be completed.

---

## Expansion Interface LED Usage

The EI circuit pack has the standard red, green, and yellow LEDs. The red and green LEDs have the traditional use, where red means some alarm condition and green indicates maintenance testing in progress. The yellow LED is used to

provide useful visual status information. The state of the yellow LED is very important when executing the EI Manual Loop Back Procedure previously described.

Upon power-up, the TN776 red LED comes on and off, followed by the yellow LED coming on solid. The TN570 red and green LEDs comes on and off. The yellow LED remains off.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below. By clearing error codes associated with the *Expansion Interface Reset Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                                      | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| Expansion Interface Reset Test (#336)                                       |                     |                    | D                 |
| Expansion Interface Fiber Out-of-Frame Query Test (#238)                    | X                   | X                  | ND                |
| Expansion Interface Lightwave Transceiver Interface Loop Around Test (#242) |                     | X                  | D                 |
| Expansion Interface Control Channel Test (#316)                             | X                   | X                  | ND                |
| Expansion Interface Neighbor Query Test (#237)                              | X                   | X                  | ND                |
| Expansion Interface Local Loop Around Test (#240)                           | X                   | X                  | ND                |
| Expansion Interface 2-Way Transmission Test (#241)                          | X                   | X                  | ND                |
| TN570 Expansion Interface Packet Interface Test (#589)                      | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Expansion Interface Neighbor Query Test (#237)

The Expansion Interface Neighbor Query Test is a request to an EI circuit pack to determine if it has established communication with the EI circuit pack on the opposite end of the fiber.

Table 10-191. TEST #237 EI Neighbor Query Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                           |

| 0          | NO BOARD    | No board was detected by the test.<br><br>1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable.<br><br>2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the <b>reset board PCSS</b> command.<br><br>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. |

Expansion Interface Fiber Out-of-Frame (FOOF)  
Query Test (#238)

This test is a request to an Expansion Interface circuit pack to determine if it is currently detecting the framing sequence on the incoming fiber data stream. If it cannot detect this framing signal, the Expansion Interface circuit pack is not able to establish a link with the opposite Expansion Interface circuit pack.

Table 10-192. TEST #238 EI Fiber Out-of-Frame Query Test

| Error Code       | Test Result | Description/Recommendation                                                                                                                |

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p>Expansion Interface circuit pack could not detect framing sequence.</p> <ol style="list-style-type: none"><li>1. Check if the Expansion Interface circuit pack on the opposite end of the fiber is present and if its cabinet has power.</li><li>2. Verify that the lightwave transceiver is connected to the correct slot on the back of the cabinet and that the fiber is connected to the lightwave transceiver. Verify this connection on both ends of the fiber. Check that an Expansion Interface circuit pack detects its lightwave transceiver by executing the <b>reset board PCSS</b> command, where PCSS refers to the Expansion Interface circuit pack. If the reset passes, the Expansion Interface circuit pack detects a lightwave transceiver. Refer to the description of the Expansion Interface Reset Test (#336) if the reset fails.</li><li>3. Verify that fiber transmit and receive ends have not been crossed when connected to the lightwave transceiver.</li><li>4. The problem may be due to a synchronization timing loop. Use the <b>status sync</b> command to determine which circuit pack is the synchronization reference. If the reference is a DS1 Interface circuit pack, use the <b>set sync</b> command to make a Tone-Clock circuit pack the reference. If this action causes the Expansion Interface to go into frame, synchronization must be examined for a possible timing loop. Refer to SYNC (Synchronization) Maintenance documentation for repair procedures. If the DS1 Interface circuit pack is not a reference, and the Expansion Interface circuit pack that is failing Test #238 is in the PPN, run tests on Tone-Clock circuit pack in the PPN to determine if clocks are present. If the Expansion Interface circuit pack that is failing Test #238 is in the EPN, and the red LEDs are ON on a large number of circuit packs, then reseal any Tone-Clock circuit packs in the EPN.</li></ol> <p><i>More information follows.</i></p> |

Table 10-192. TEST #238 EI Fiber Out-of-Frame Query Test — Continued

| Error Code | Test Result       | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL<br>(cont'd.) | <p>5. Execute the <b>test tone-clock PC</b> command where P is the port network which contains the Expansion Interface circuit pack's neighbor Expansion Interface on the OPPOSITE end of the fiber and C refers to the carrier which contains the Active Tone-Clock on port network P. Also, look for SYNC errors in the Error Log. If there are any tests failing or errors found, resolve these problems and then rerun Test #238. If the test still fails and the system has a Standby Tone-Clock, switch the Active Tone-Clock on this network (<b>set tone-clock PC</b> command, where P is the port network containing the Expansion Interface circuit pack on the OPPOSITE end of the fiber and C is the carrier containing the Standby Tone-Clock). Also, if the EPN is down, replace the EPN Tone-Clock circuit pack in carrier A of the EPN.</p> <p>6. Check for errors using the <b>display errors</b> command with the Category field set to "tone" and the Active alarms field set to "n." Some of the alarms on EPN objects might have been resolved if the EPN went down. Refer to the documentation for descriptions of any of the error types occurring at about same time as the EXP-LINK error types. Resolve any active alarms. Also, if Error Type 18 was logged against the SYNC MO when the EPN went down, the problem was probably that the Synchronization on-line reference became invalid. Since, reference switching was disabled, the Tone-Clock did not switch away from the invalid reference. Therefore, the Tone-Clock put out an "out-of-spec" system clock. Execute the <b>enable synchronization-switch</b> command. If the EPN is down, reseal the Tone-Clock circuit packs on the EPN. This action should restore the EPN to service.</p> <p>7. Follow the procedure described in "Relationship Between Expansion Interface and Tone-Clock Circuit Packs" near the beginning of this section if the symptoms match those described there.</p> |
|            | PASS              | <p>The Expansion Interface circuit pack has detected the valid framing signal on the fiber.</p> <p>1. Refer to errors from other Expansion Interface circuit pack tests if the link is still not functioning.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| 0          | NO BOARD    | <p>No board was detected by the test.</p> <ol style="list-style-type: none"><li>1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable.</li><li>2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the <b>reset board PCSS</b> command.</li><li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li></ol> |

Expansion Interface Local Loop Around Test (#240)

This test is similar to the Lightwave Transceiver Loop Around Test described in Test #242. A test tone from TDM Bus A is received by the Expansion Interface circuit pack under test, but is not transmitted out to the lightwave transceiver before being looped back onto TDM Bus A again. The test is then repeated using TDM Bus B. Thus, this loop back test is performed on each TDM Bus on the network containing the Expansion Interface circuit pack to verify that the Expansion Interface circuit pack is able to loop back data on each TDM Bus. Since this loop back is internal to the circuit pack, this test does not interfere with the normal fiber data stream.

Table 10-193. TEST #240 EI Local Loop Around Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | ABORT       | Could not allocate time slot on TDM Bus A. Loop back passed on TDM Bus B.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 2          | ABORT       | <p>Could not allocate time slot on TDM Bus B. Loop back passed on TDM Bus A.</p> <ol style="list-style-type: none"><li>1. If there is no reason to doubt that the Expansion Interface circuit pack can transfer data to or from a TDM Bus, then since the test passed on one bus, assume that the test passes on the other bus as well.</li><li>2. If EXP-INTF circuit pack Error Types 1, 2, 1537, or 1793 are present in the Error Log and/or if Expansion Interface circuit pack Tests #240, #241, or #242 have failed previously, there is reason to doubt that the Expansion Interface circuit pack can transfer data to or from a TDM Bus. To determine if the test can pass on both TDM Buses, perform the following procedure: For Error Code 1, issue the <b>set tdm PC</b> command, where P is the network containing the Expansion Interface circuit pack being tested and C is the TDM Bus A. Execute the <b>test board PCSS</b> command again. If this test passes or aborts with Error Code 2, this test is considered to have passed. For Error Code 2, issue the <b>set tdm PC</b> command, where P is the network containing the Expansion Interface circuit pack being tested and C is the TDM Bus B. Execute the <b>test board PCSS</b> again. If this test passes or aborts with error code 1, this test is considered to have passed.</li><li>3. If this test continues aborting with the same error after setting the TDM Bus as indicated in Step 2, rerun the test at 1-minute intervals a maximum of 5 times. Apply the passing criteria for Step 2 to each result.</li><li>4. If the test still does not pass on the other TDM Bus, follow the procedure for abort error code 3.</li></ol> |
| 3          | ABORT       | <p>The system could not allocate time slots for the test on either TDM Bus. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Enter <b>display errors</b> and follow associated repair procedures for TDM-BUS errors.</p> <ol style="list-style-type: none"><li>1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 3 times.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Table 10-193. TEST #240 EI Local Loop Around Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1002       | ABORT       | <p>The system could not allocate time slots for the test on either TDM Bus. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors.</p> <ol style="list-style-type: none"><li>1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 1003       | ABORT       | <p>The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service.</p> <ol style="list-style-type: none"><li>1. Look for TTR-LEV errors in the Error Log. If these errors are present, refer to TTR-LEV (TTR Level) Maintenance documentation. Even if there are no TTR-LEV errors, there still may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If not, this test always aborts for this Expansion Interface circuit pack. This does not harm the system in any way.</li><li>2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation.</li><li>3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.</li></ol> |
| 1031       | ABORT       | <p>A query of the Expansion Interface circuit pack aborted. The purpose of this query was to see if the Expansion Interface circuit pack could detect the framing signal.</p> <ol style="list-style-type: none"><li>1. If Test #238 aborted, follow the procedure associated with this abort code.</li><li>2. If Test #238 did not abort, rerun Test #240 at 1-minute intervals a maximum of 5 times.</li><li>3. If Test #240 continues to abort without Test #238 aborting, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 1032       | ABORT       | <p>The Expansion Interface circuit pack cannot detect the framing signal and cannot run the test.</p> <ol style="list-style-type: none"><li>1. Resolve either of these issues, if applicable.</li><li>2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the <b>reset board PCSS</b> command.</li><li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li></ol> |

Expansion Interface 2-Way Transmission Test (#241)

This test is a basic connectivity test between the two cabinets. The test first sends a test tone from the cabinet of the Expansion Interface circuit pack under test through the opposite Expansion Interface circuit pack to a Tone Detector in the opposite cabinet. The connections are then reversed and the tone is passed in the opposite direction. This test should be run once from each Expansion Interface circuit pack on the fiber.

Table 10-194. TEST #241 Expansion Interface 2-Way Transmission Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 1003       | ABORT       | <p>The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service.</p> <ol style="list-style-type: none"><li>1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. Even if there are no TTR-LEV errors, there still may not be a Tone Detector available on the network that contains the circuit pack being tested. Verify that there is at least one Tone Detector on this network. If there is not at least one Tone Detector, this test always aborts for this Expansion Interface circuit pack. This does not harm the system in any way.</li></ol> <p> <b>NOTE:</b><br/>G3 systems require that Tone Detector circuit packs (TN768) must be of vintage "B" or newer. If older Tone Detector circuit packs are installed in the system, this test well always abort with this abort code.</p> <ol style="list-style-type: none"><li>2. Look for TONE-PT errors in the Hardware Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation.</li><li>3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.</li></ol> |
| 1033       | ABORT       | <p>The test cannot run because either one or both of the Expansion Interface circuit packs on this link are busied out or an Expansion Interface circuit pack is not present on the opposite end of the fiber.</p> <ol style="list-style-type: none"><li>1. If Expansion Interface is busied out, issue the <b>release board PCSS</b> command.</li><li>2. Examine results of Tests #237 and #238.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

If hyperactive, use the <b>reset board PCSS</b> command.</li><li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Expansion Interface Lightwave Transceiver Loop Around Test (#242)

This test is destructive and requires that the Expansion Interface circuit pack first be busied out. Busying out an Expansion Interface circuit pack denies service to the EPN if the Expansion Interface circuit pack supports a PPN to EPN link and duplicate Expansion Interface Links are not in use. If the Expansion Interface circuit pack is part of an EPN to EPN link, service between the two EPNs are denied if duplicate Expansion Interface links are not in use. This test is NOT DESTRUCTIVE if the Expansion Interface circuit pack to be busied out is in Standby Mode.

This is a two part connectivity test. The first portion of the test applies to both TN776 and TN570 Expansion Interface circuit packs. In the first part of the test, a test tone is transmitted from the cabinet of the Expansion Interface circuit pack under test, through the Expansion Interface circuit pack under test, out to its lightwave transceiver. The connection then loops back into the lightwave transceiver through the same Expansion Interface circuit pack again and into the originating cabinet. If the test tone is detected by a tone detector, the first part of the test passes.

The second portion of the test applies only to the TN570 Expansion Interface circuit pack. In this part of the test, a data packet is sent from the TN778 Packet Control circuit pack to the Expansion Interface circuit pack under test; the packet is then looped back through the lightwave transceiver and sent back to the Packet Control circuit pack. If the Packet Control circuit pack receives the same packet it transmitted, the second part of the test passes. If the entire test has passed, the Expansion Interface circuit pack, its backplane wiring, and the electrical portion of the lightwave transceiver are healthy.

### NOTE:

When the Expansion Interface circuit pack under test is an EPN, the data packet must also pass through the Active Expansion Interface circuit packs of the Active link connecting the EPN to the PPN.

This test requires the Expansion Interface circuit pack to ignore incoming data from its neighbor Expansion Interface circuit pack on the opposite end of the fiber. Thus, this test disturbs any inter-cabinet connections that currently exist and disrupts signaling between the two cabinets.

Table 10-195. TEST #242 Expansion Interface Lightwave Transceiver Loop Around Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | <p>➡ <b>NOTE:</b></p> <p>If the Expansion Interface is a TN570 and the system does not have the Packet Bus enabled field set to yes on the Maintenance-related system parameters form, then this test does not execute the packet bus portion of the loop around.</p> <p>When this test (#242) and the Expansion Interface Local Loop Around Test #240 pass, this indicates that the Expansion Interface circuit pack is functioning properly, but it does not verify that the optical portion of the lightwave transceiver is functioning properly. Remove the Expansion Interface circuit pack from the busyout state using the <b>release board PCSS</b> command.</p> <p>1. If duplicate Expansion Interface Links are available, issue the <b>test board PCSS</b> command on the Standby Expansion Interface circuit packs on both ends of fiber. If this test passes from both sides, but other tests fail, such as Test #241, this condition indicates either a faulty lightwave transceiver or a faulty fiber cable. To determine if either a lightwave transceiver or the fiber itself has failed, execute the Expansion Interface Manual Loop Back Procedure described in the section preceding the "Hardware Error Log Entries and Test to Clear Values" table for this MO.</p> <p>➡ <b>NOTE:</b></p> <p>This test can only be run from both Expansion Interface circuit packs if they are the Standby pair, and if the Active pair is working properly.</p> <p>2. If this Expansion Interface circuit pack is failing other tests, the Expansion Interface Manual Loop Back Test should be executed.</p> <p>If problems still exist after the Expansion Interface Manual Loop Back Procedure indicates that both Expansion Interface circuit packs and both lightwave transceivers are healthy, manually check out the building fiber. Verify that each optical fiber is connected to a transmitter at one end and a receiver at the other.</p> |

Expansion Interface Control Channel Test (#316)

If an Expansion Interface circuit pack is a Standby Expansion Interface circuit pack (yellow LED off) or if the Expansion Interface is active in the PPN (yellow LED on), this test queries the Expansion Interface circuit pack for its circuit pack type and vintage information. If the Expansion Interface circuit pack is an Active Expansion Interface circuit pack in the EPN (yellow LED on long, off short), the Expansion Interface Control Channel Test checks to see if the Expansion Interface circuit pack can communicate with other circuit packs in the EPN using the EPNTDM Bus.

Expansion Interface Reset Test (#336)

**This test is potentially very destructive and requires the Expansion Interface circuit pack to be busied out prior to execution of this test.**

The Expansion Interface Reset Test, which is not a part of either the Short or the Long Test Sequences, is executed via the **reset board PCSS** command where PCSS is the address of the Expansion Interface circuit pack to be reset.

If the system only has one working Expansion Interface Link between a pair of port networks and one of the Expansion Interface circuit packs must be reset, the action of busying out the desired Expansion Interface circuit pack WILL DISRUPT SERVICE TO THE EPN until the Expansion Interface circuit pack is released from the busyout state. If the Expansion Interface circuit pack is part of a PPN to EPN link, the EPN WILL BE WITHOUT SERVICE. If the Expansion Interface circuit pack is part of an EPN to EPN link CALLS BETWEEN THE TWO EPNs WILL BE DENIED.

If the system has working duplicate Expansion Interface Links, and the Expansion Interface circuit pack to be reset is part of the Active Expansion Interface Link, the system does not allow the busyout and instructs system technician to switch Expansion Interface Links via the **set expansion-link PCSS** command where PCSS is the address of either Standby Expansion Interface circuit pack on the Standby link. After executing the Expansion Interface Link switch, it is possible to busyout and then reset the original Expansion Interface circuit pack.

However, if the EPN Maintenance (MAINT) circuit pack determines that the Expansion Interface (EXP-INTF) circuit pack is cycling between sane and insane several times within several minutes, MAINT may inhibit operation of the EXP-INTF by holding the Expansion Interface circuit pack in a reset state. This condition may result in an unsuccessful reset of the Expansion Interface circuit pack.

If the reset command returns with "EPN is unavailable," execute the following steps:

1. Use the **change circuit-pack P** command where P is the port network number of the EPN.
2. For the Expansion Interface circuit pack you wish to reset, add an entry to the Circuit Pack form for the TN776 or TN570 Expansion Interface circuit pack. Be sure to enter the appropriate carrier and slot (that is, A01 or B02).
3. Enter the form.
4. Repeat the **reset board** command.

Table 10-197. TEST #336 Expansion Interface Reset Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3          | FAIL        | <p>The reset over the optical fiber failed.</p> <ol style="list-style-type: none"><li>1. Execute the <b>test board PCSS</b> command on the PPN neighbor Expansion Interface circuit pack located on the opposite end of the fiber from this Expansion Interface circuit pack. If Test #238 does not pass, follow the maintenance procedure associated with this test result. Then perform the reset again.</li><li>2. If the Expansion Interface circuit pack is in the EPN, temporarily remove the EPN Maintenance circuit pack.</li><li>3. Repeat the <b>reset board PCSS</b> command.</li><li>4. Reinsert EPN Maintenance circuit pack if it was removed.</li><li>5. Follow the procedure described in the "Relationship Between Expansion Interface and Tone-Clock Circuit Packs" section if the symptoms match those described there.</li><li>6. Check the Hardware Error Log for the EPN Tone-Clock errors that were resolved about when the EPN went down. These EPN Tone-Clock errors may have been resolved BECAUSE the EPN went down. When there is no Tone-Clock generating the system clock on an EPN, then an Expansion Interface circuit pack can only be reset once. All subsequent reset attempts fail. It is also possible that the system itself may have already tried to reset the Expansion Interface circuit pack. Refer to the TONE-BD (Tone-Clock) Maintenance documentation for recommended maintenance strategy for Tone-Clock problems.</li><li>7. If the reset still fails, execute the Manual Loop Back Procedure on the opposite PPN Expansion Interface circuit pack. This procedure is described in the section preceding the "Hardware Error Log Entries and Test to Clear Values" table for this MO. If the Expansion Interface circuit pack and the lightwave transceiver are healthy, the problem must lie with the Expansion Interface circuit pack and its lightwave transceiver on the EPN end of the fiber or with the fiber itself. Test the EPN Expansion Interface circuit pack with the manual loop back procedure and investigate the test results.</li></ol> |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | <p>The Expansion Interface was successfully reset, and it did restart execution. Also, it passed all its initialization tests and detected a lightwave transceiver. Remove the Expansion Interface circuit pack from the busyout state by using the <b>release board PCSS</b> command.</p> <p>1. Execute <b>test board PCSS short</b> command. Refer to errors for each test.</p>                                                                               |
| 0          | NO BOARD    | <p>No board was detected by the test.</p> <p>1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable.</p> <p>2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the <b>reset board PCSS</b> command.</p> <p>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</p> |

Expansion Interface Packet Interface Test (#589)

This test attempts to send a data packet from the TN778 Packet Control circuit pack through any intervening Expansion Interface circuit packs and through the Expansion Interface circuit pack to be tested. The path the data packet takes is dependent on the location of the Expansion Interface circuit pack to be tested and whether the Expansion Interface circuit pack is par of the Active link or Standby link.

If the Expansion Interface circuit pack to be tested is part of an Active link from PPN to either EPN, the path shown in Figure 10-31 is used.

If the Expansion Interface circuit pack to be tested is on either EPN and is part of a Standby link from PPN to either EPN, the path shown in Figure 10-32 is used. The path in this figure is also used if the Expansion Interface circuit pack to be tested is on the PPN.

If the Expansion Interface circuit pack to be tested is part of a link from EPN to EPN, the path shown in Figure 10-33 is used.

|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1005       | ABORT       | This test does not apply to the current system configuration. Either the system is not administered to have the Packet Bus activated, the Maintenance-Related System Parameters form has the Packet Bus Enabled field set to "n," or the system is administered to have the Packet Bus activated, but there exist TN776 Expansion Interface circuit packs that prevent this test from running. The TN776 Expansion Interface circuit packs do not support Packet Bus capabilities. |

| 0          | NO BOARD          | <p>No board was detected by the test.</p> <ol style="list-style-type: none"><li>1. Check the error log for wrong board (error 125) or no board (error 131). Resolve either of these issues, if applicable.</li><li>2. Check that the board is properly translated and inserted. If so, check for hyperactivity (error 1538). If hyperactive, use the <b>reset board PCSS</b> command.</li><li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li></ol>                                                                                                                                                                                             |

Expansion Interface Link Switch Command

This action is potentially destructive.

The Expansion Interface switch command enables system technician to choose which set of Expansion Interface Links should be the Active link when duplicate Expansion Interface Links are available.

The command line entry is **set expansion-link PCSS**, where PCSS is the Expansion Interface address of *either* Expansion Interface circuit pack on the

Standby link. If the **status system** command indicates that the Standby link is up, the **set expansion-link** command makes the Standby link the Active link.

This action is destructive because it must temporarily disable all connections between PPN and EPN. This break in the connections is not detectable by normal voice users.

**CAUTION:**

*Data connections lose a small amount of data. Depending on the data transmission speed, the lost data is anywhere from zero to several bytes.*

It is recommended that system technician switch links when it is necessary to run the more destructive tests on Expansion Interface circuit packs. Most significantly, Test #242 requires the Expansion Interface circuit pack to be busied out and, therefore, the link with the Expansion Interface to be tested should be made the Standby link.

To prevent the system from automatically switching Expansion Interface Links during system technician-demanded tests, busyout one or both of the Standby Expansion Interface circuit packs.

**CAUTION:**

*This introduces a small risk. If the remaining Active Expansion Link should fail while the Standby Expansion Link is busied out, service to the EPN is lost.*

The **set expansion-link** command has no error codes to return. It displays one of following messages upon completion:

1. **Command completed successfully**

Link switch was successful. This may be verified by visually inspecting the new yellow LED states or by the **status system** command.

2. **Command did not complete successfully**

This indicates that the system attempted to switch links, but for unknown reasons the software or hardware was unable to complete the action. The system may have switched and determined that the new link could not provide service and thus returned to the original link.

3. **Standby EXP-INTF Link is unable to take over**

Because the Expansion Interface circuit pack pair on the Standby link has enough errors logged against it as to be unable to provide service, the system did not attempt to switch links.

4. **EXP-INTF is already on active link**

The Expansion Interface circuit pack address given in the **set expansion-link** command is an Active Expansion Interface. The address must be a Standby Expansion Interface circuit pack in order to switch links.

#### 5. Address is not a valid Expansion Interface Board

The link switch could not be attempted because the address in the **set expansion-link** command did not correspond to any known Expansion Interface circuit pack.

EXP-LINK (Expansion Interface Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run      | Full Name of MO          |
|------------------------|-------------|-----------------------------|--------------------------|
| EXP-LINK               | MAJOR       | display errors <sup>1</sup> | Expansion Interface Link |

1. Display errors for "infc" category and investigate EXP-INTF errors.

The EXP-LINK (Expansion Interface Link) Maintenance strategy is covered in the EXP-INTF (Expansion Interface Circuit Pack) Maintenance documentation.

Error Log Entries and Test to Clear Values

Table 10-199. Expansion Interface Circuit Pack Error Log Entries

| Error Type | Aux Data   | Associated Test | Alarm Level | On/Off Board | Test to Clear Value                                                                 |
|------------|------------|-----------------|-------------|--------------|-------------------------------------------------------------------------------------|
| 0          | 0          | Any             | Any         | Any          | disp err                                                                            |
| 122 (a)    |            | None            | MAJOR       | ON           |                                                                                     |
| 122 (b)    | None, 1-10 | None            | MAJOR       | ON           |                                                                                     |
| 122 (c)    | 30-40      | None            | MAJOR       | ON           |                                                                                     |
| 122 (d)    | 6          | None            | MAJOR       | ON           |  |
| 122 (e)    | 8          | None            | MAJOR       | ON           |                                                                                     |

- a. This alarm is used only to indicate that all Expansion Interface Links between a pair of Port Networks (PNs) are down. This condition is indicated by the EXP-LINK Error Type 122 in the Error Log. When this condition occurs, examine all EXP-INTF errors to resolve the alarm.
- The pair of PNs is specified in the port fields as follows: 1-2 (PPN to EPN1), 1-3 (PPN to EPN2), and 2-3 (EPN1 to EPN2).
- b. Aux Data values of blank and 1 through 10 mean that the link is down due to a defective Expansion Interface Link. Look for and resolve Expansion Interface circuit pack errors.
- c. Aux Data values of 30 through 40 mean that the EPN was reset because of a temporary loss of system timing reference on the EPN. Execute the **display errors** command with the category "tone" to determine what caused the loss or restoration of the clock.
- d. The system detected an excessive backup of traffic on the Active Expansion Link. This condition may have been due to communication difficulties on the Expansion Link. To restore normal service, the system

had to reset the Expansion port network served by the Expansion Link.  
Error type 10004 should have been logged against the Expansion  
Interface circuit pack that reported the traffic congestion.

- e. Aux Data value of 8 means that the link is down due to the recovery  
feature of the EPN Sanity Audit. Look for EPN-SNTY errors in the error log,  
and refer to the EPN-SNTY section for more details.

## EXT-DEV ADMIN? N (External Device Alarm)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO       |
|------------------------------------|-------------|-------------------------------------------------------|-----------------------|
| EXT-DEV                            | MAJOR       | test environment UU                                   | External Device Alarm |
| EXT-DEV                            | MINOR       | test environment UU                                   | External Device Alarm |

1. where UU is an appropriate cabinet number determined via the PORT field from the Alarm or Error Log.

**⇒ NOTE:**  
Use this Maintenance Object when the *External Device Alarm Admin?* field on the *change system-parameters customer-options* form is set to **(n)**.

In the Standard Reliability PPN the Maintenance Processor (TN786B or TN790) in carrier (A) monitors the EXT-DEV alarm leads. In the High or Critical PPN, the Duplication Interface (TN772) circuit pack in carrier (A) monitors the EXT-DEV alarm leads, and provides status to the Maintenance processor (TN786B or TN790) in the active SPE. In the EPN the Maintenance Board (TN775) monitors the EXT-DEV alarm leads. The system only recognizes pairs connected to the 1M and 1m (ALARM MONITOR) leads. Pairs connected to the 2M, 2m, 3M, 3m, and 3w are not recognized by the system. Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111, for more details.

Hardware Error Log Entries and Test to Clear Values

Table 10-200. Hardware Error Log Entries and Test to Clear Values

| Error Type     | Aux Data | Associated Test                   | Alarm Level              | On/Off Board | Test to Clear Value          |
|----------------|----------|-----------------------------------|--------------------------|--------------|------------------------------|
| 0 <sup>1</sup> | 0        | Any                               | Any                      | Any          | test environment UU r2 or 6  |
| 1 or 5         | Any      | External Device Alarm Test (#120) | MAJOR MINOR <sup>2</sup> | OFF          | test environment UU r 2 or 6 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. One port generates a MAJOR alarm; the other port generates a MINOR alarm.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, you may also clear errors generated from other tests in the testing sequence.

| Multicarrier Cabinet Tests                     |                     |                    |                   |
|------------------------------------------------|---------------------|--------------------|-------------------|
| Order of Investigation                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
| Battery & Battery Charger Query Test (#5) (a)  | X                   | X                  | ND                |
| AC Power Query Test (#78) (b)                  | X                   | X                  | ND                |
| OLS Query Test (Carrier E) (#127) (c)          | X                   | X                  | ND                |
| OLS Query Test (Carrier D) (#127) (c)          | X                   | X                  | ND                |
| OLS Query Test (Carrier A) (#127) (c)          | X                   | X                  | ND                |
| OLS Query Test (Carrier B) (#127) (c)          | X                   | X                  | ND                |
| OLS Query Test (Carrier C) (#127) (c)          | X                   | X                  | ND                |
| Emergency Transfer Query Test (#124) (d)       | X                   | X                  | ND                |
| Cabinet Sensors Query Test (#122) (e)          | X                   | X                  | ND                |
| External Device Alarm Test (MAJOR port) (#120) | X                   | X                  | ND                |

| Multicarrier Cabinet Tests — Continued               |                     |                    |                   |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
| External Device Alarm Test (MINOR port) (#120)       | X                   | X                  | ND                |
| Analog Ring Generator Initialization Test (#117) (f) | X                   | X                  | ND                |
| Analog Ring Generator Query Test (#118) (f)          | X                   | X                  | ND                |

External Device Alarm Test (#120)

The External Device Alarm Test requests the state of the External Device Alarm from the Maintenance circuit pack and reports the results. The test has no effect on the external device itself.

Table 10-201. TEST #120 External Device Alarm Test

| Error Code                   | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

Table 10-201. TEST #120 External Device Alarm Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ANY        | FAIL        | <p>The External Device Alarm has been activated by the external device.</p> <ol style="list-style-type: none"><li>1. Clear the major alarm on the external device, and rerun the test.</li><li>2. If the test still fails, then disconnect the External Device Alarms from the Maintenance circuit pack and rerun the test.</li><li>3. If the test still fails, then there is a problem with the Maintenance circuit pack that is reporting the alarm. This circuit pack should be replaced. There are failures that can occur on Maintenance circuit pack's that <i>will not</i> be detected by their respective maintenance, but which will cause many environment tests to fail. If many environment tests are failing, the suspect circuit pack should be replaced and the test rerun.</li><li>4. If the test still fails, escalate the problem.</li></ol> |
|            | PASS        | <p>If there is a problem with the external device, but the Maintenance circuit pack connected to the device reports no alarm, then the External Device may not be properly reporting the problems or the External Device may not be properly connected to the External Device.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## EXT-DEV ADMIN? Y (External Device Alarm)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO       |
|------------------------------------|-------------|-------------------------------------------------------|-----------------------|
| EXT-DEV                            | MAJOR       | test<br>eda-external-device-alm<br>physical location  | External Device Alarm |
| EXT-DEV                            | MINOR       | test<br>eda-external-device-alm<br>physical location  | External Device Alarm |
| EXT-DEV                            | WARNING     | test<br>eda-external-device-alm<br>physical location  | External Device Alarm |

1. where UU is an appropriate cabinet number determined via the PORT field from the Alarm or Error Log.

**⇒ NOTE:**  
Use this Maintenance Object when the *External Device Alarm Admin?* field on the *change system-parameters customer-options* form is set to **(y)**. You must have INADS or INIT login permission to administer EXT-DEV Alarm.

Generic 3i Maintenance circuit packs each have alarm leads which can be connected to external devices such as Uninterruptible Power Supplies (UPS) or adjuncts such as AUDIX. Certain conditions on the external device close the contacts on the alarm leads to notify the switch which in turn originates an EXT-DEV alarm.

The special locations UUmajor and UUminor are used to designate the major or minor maintenance board alarm connection for cabinet UU. The major/minor designation specifies the port, not the alarm level associated with the connection; *for example*, the “major” port can be administered as a major, minor, or warning alarm, and the “minor” port can be administered as a major, minor or warning alarm. In addition Analog line ports can also be administered as external device alarms.

**⇒ NOTE:**  
An unadministered maintenance board external device alarm port, that is sensing a contact closure will have an entry in the Error Log and in the Alarm Log. INADS will not receive warning alarms.

In the Standard Reliability PPN the Maintenance Processor (TN786B or TN790) in carrier (A) monitors the EXT-DEV alarm leads. In the High or Critical PPN, the

Duplication Interface (TN772) circuit pack in carrier (A) monitors the EXT-DEV alarm leads, and provides the status to the Maintenance processor (TN786B or TN790) in the active SPE. In the EPN the Maintenance Board (TN775) monitors the EXT-DEV alarm leads. The system only recognizes pairs connected to the 1M and 1m (ALARM MONITOR) leads. Pairs connected to the 2M, 2m, 3M, 3m, and 3w are not recognized by the system. Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111, for more details.

Hardware Error Log Entries and Test to Clear Values

Table 10-202. Hardware Error Log Entries and Test to Clear Value

| Error Type | Aux Data | Associated Test                   | Alarm Level | On/Off Board | Test to Clear Value                                     |
|------------|----------|-----------------------------------|-------------|--------------|---------------------------------------------------------|
| 0          | 0        | Any                               | Any         | Any          | test eda-external-device-alm physical location r 2 or 6 |
| 1 or 5     | Any      | External Device Alarm Test (#120) | Any         | OFF          | test eda-external-device-alm physical location r 2 or 6 |

 **NOTE:**  
The loss of -48 volt power will prevent detection of an external device alarm. AC-POWER, CARR-POW, and DC-POWER alarms could indicate the loss of the external device alarm -48 volt power source. ALARM-PT alarms may also indicate a loss of power. When analog line ports are administered as analog line external device alarms loss of -48 volts will prevent detection of an external device alarm.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| External Device Alarm Test (MAJOR port) (#120)   | X                   | X                  | ND                |
| External Device Alarm Test (MINOR port) (#120)   | X                   | X                  | ND                |
| External Device Alarm Test (WARNING port) (#120) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

External Device Alarm Test (#120)

The External Device Alarm Test requests the state of the External Device Alarm from a Maintenance circuit pack and reports the results. The test has no effect on the external device itself.

Table 10-203. TEST #120 External Device Alarm Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                          |

## FL-DATA (Flash Data Consistency)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO        |
|------------------------|-------------|------------------------|------------------------|
| FL-DATA                | MAJOR       | test card-mem a b l    | Flash Data Consistency |
| FL-DATA                | MINOR       | test card-mem a b l    | Flash Data Consistency |
| FL-DATA                | WARNING     | test card-mem a b l    | Flash Data Consistency |

In systems with high or critical reliability, the software and the hard patch update files are stored in the on-board flash memory in both the Active SPE and Standby SPE. The translations and announcements are stored in the memory cards in both the Active SPE and Standby SPE. Flash Data Consistency flags problems when files become mismatched by monitoring the translations, announcements, update files, and software vintage number in a High or Critical Reliability PPN system. If the software vintage numbers on both SPEs are mismatched, a MAJOR alarm is raised. If the announcement files on both memory cards are mismatched, a WARNING alarm is raised. For all other problems, a MINOR alarm is raised. The software vintage can be displayed via the **list configuration software-vintage long** command. The Flash Data Consistency Test is run on system technician command and as part of daily Standby SPE maintenance.

 **NOTE:**  
Flash Data Consistency is not applicable to Standard systems.

### Error Log Entries and Test to Clear Values

Table 10-204. Flash Data Consistency Error Log Entries

| Error Type                                                 | Aux Data | Associated Test                    | Alarm Level | On/Off Board | Test to Clear Value |
|------------------------------------------------------------|----------|------------------------------------|-------------|--------------|---------------------|
| 0 <sup>1</sup>                                             | 0        | Any                                | Any         | Any          | test card-mem a/b l |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- a. The Aux Data field records which SPE was active at the time the Flash Data Consistency Test failed. An "8" in the log refers to carrier A and a "16" refers to carrier B.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Memory Card Insertion Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| 12 Volt Power Supply Test (#701) (b)                   | X                   | X                  | ND                |
| Memory Card Insertion Test (#695) (a)                  | X                   | X                  | ND                |
| Memory Card Format and Read Test (#696) (a)            | X                   | X                  | ND                |
| Memory Card Match Test (#697) (a)                      | X                   | X                  | ND                |
| Memory Card Write-Protected Test (#698) (a)            | X                   | X                  | ND                |
| Memory Card Directory Recovery Test (#699) (a)         | X                   | X                  | ND                |
| Memory Card Translation Data Integrity Test (#694) (a) |                     | X                  | ND                |
| Memory Card Erase/Write/Read Test (#693) (a)           |                     | X                  | ND                |
| Flash Data Consistency Test (#421) (c)                 |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

- Notes:
- a. See “CARD-MEM” for this test description.
  - b. See “12V-PWR” for a description of this test.
  - c. The Flash Data Consistency Test does not run in a Standard system.

Flash Data Consistency Check Test (#421)

The software vintage number, translation time stamps, announcement time stamps, and update file time stamps and identifiers are read off of both memory cards or SPEs and then compared. If the comparison shows any discrepancy, FL-DATA is alarmed. This test is only run in a High or Critical Reliability system. The test is run as part of the **test card-mem long** and as part of the standby PE scheduled maintenance.

Table 10-205. TEST #421 Flash Data Consistency Check Test

| Error Code                                                                                                                                   | Test Result | Description/Recommendation                                                                                                                                                                                                                               |

| GPTD-PT                | MINOR       | test port PCSSpp sh                 | General Purpose Tone Detector Port (CPTR) |
| GPTD-PT                | WARNING     | release port PCSSpp                 | General Purpose Tone Detector Port (CPTR) |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The General Purpose Tone Detector (GPTD) Port, also known as Call Progress Tone Receiver (CPTR), resides on the Tone Detector circuit pack (TN748 [all suffixes], TN420B [and greater suffixes], and TN756 combined tone detector and tone clock [all suffixes]). There are two GPTD ports and four Dual Tone Multifrequency Receiver (DTMR) ports on a Tone Detector circuit pack. The GPTD port is used to perform level measurements of test tones and to detect call progress tones. Examples of call progress tones are dial tone, ring back, busy, alert, confirmation, and recall dial. The abilities of the GPTD port to perform level measurements of test tones and to detect call progress tones are essential for maintenance of other circuit packs (for example, Tone-Clock).

The GPTD maintenance feature defines a set of tests to ensure that the general purpose tone detection capability of the GPTD port is functioning properly. For all Tone Detector circuit pack level errors (DETR-BD), refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

## HYB-BD (Hybrid Line Circuit Pack)

| MO Name As It<br>Appears in<br>Alarm Log | Alarm<br>Level | Initial System<br>Technician<br>Command to Run <sup>1</sup> | Full Name of MO          |
|------------------------------------------|----------------|-------------------------------------------------------------|--------------------------|
| HYB-BD                                   | MIN            | test board PCSS sh                                          | Hybrid Line Circuit Pack |
| HYB-BD                                   | WRN            | test board PCSS sh                                          | Hybrid Line Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also HYB-LINE (Hybrid Line) Maintenance documentation for related line information.

## HYB-LINE (Hybrid Line)

| MO Name As It<br>Appears in<br>Alarm Log | Alarm<br>Level | Initial System<br>Technician<br>Command to Run <sup>1</sup> | Full Name of MO |
|------------------------------------------|----------------|-------------------------------------------------------------|-----------------|
| HYB-LINE                                 | Minor          | test port PCSSpp l                                          | Hybrid Line     |
| HYB-LINE                                 | Warning        | test port PCSSpp l                                          | Hybrid Line     |

1.
- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

Hybrid Line is the user-friendly name for Hybrid Line, which was previously used to denote the Multifunction Analog Telephone. The Hybrid Line set is also known as an SCS (Small Communications System).

The TN762B Hybrid Line circuit pack supports eight of these multifunction analog telephone sets, as shown in the following figure. The Hybrid Line sets use three pairs of wires: an analog voice pair, a transmit/receive pair, and a power pair.

**Figure 10-34. Hybrid Station Interactions**

This section refers only to the HYB-LINE (Hybrid Line) maintenance that is performed. Please note that the HYB-LINE (Hybrid Line) maintenance is closely related to, and interacts with, the HYB-BD (Hybrid Line circuit pack) maintenance in some instances. Some of the results of maintenance testing of the Hybrid Line may be affected by the health of the Hybrid Line circuit pack. This interaction should be kept in mind when investigating the cause of reported Hybrid Line problems.

There are instances in this section where "service states" of a station are mentioned. It is helpful to understand what is meant by the different service states that may exist. An explanation of these service states follows:

- **Out-of-Service**—The port, and thus the station, have been removed from service. A busyout of a port causes it to be out-of-service.
- **Ready-for-Service**—Once a port on the circuit pack has been put into service, the voice terminal must communicate that it is present. The time between these two events is the time when the terminal is in the ready-for-service state.
- **In-Service**—Once the system has received a message from the voice terminal communicating that it is present, the station is put into the in-service state. The terminal can also be forced into the in-service state if it goes off-hook while it is in the ready-for-service state.

When the **status station** command has been run, and the status screen appears, the status is reported as either out-of-service or in-service, which mean exactly as stated in the above list, or disconnect, which means the station is in the ready-for-service state.

Hardware Error Log Entries and Test to Clear Values

Table 10-206. Hybrid Line Error Log Entries

| Error Type     | Aux Data | Associated Test                      | Alarm Level          | On/Off Board | Test to Clear Value     |

| 1793           |          | TDMNPE Crosstalk Test (#6)           | MIN/WRN <sup>2</sup> | ON           | test port PCSSpp l r 3  |
| 2049 (j)       | 32770    | None                                 |                      |              |                         |
| 2049 (k)       | 40967    | None                                 |                      |              |                         |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major or Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. Indicates a defective data link. An off-board problem was detected by port circuit. Verify that the Hybrid set is connected and that the EPF test passes. If data transmission problems are experienced, check for defective wiring or a defective voice terminal, or move terminal closer to

the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired after a predetermined period of time.

- b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).
- c. This error type is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout via the **release port PCSSpp** command.
- d. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. This indicates that the EPF has been turned off due to an overcurrent condition at the voice terminal. Check for defective wiring or a damaged jack, and make sure the voice terminal is a Hybrid set. Once the problem has been resolved, the alarm is retired after a predetermined period of time.
- f. This indicates that the voice terminal has probably been disconnected or that there is a problem in the wiring to the terminal. Make sure that the voice terminal is connected or check for defective wiring to the voice terminal.
- g. Note that Error Types 769 and 1281 by themselves create Warning alarms only, but if both are present, a Minor alarm is logged.
- h. This indicates that there is something wrong with the data link to the voice terminal. An in-line maintenance error has generated an off-board warning. Ignore it if there are no complaints. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack.
- i. This indicates that the station went off-hook while in the disconnect state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to in-service. No system technician action is necessary.
- j. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No system technician action is necessary.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Local Digital Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| Local Digital Loop Around Test (#58)             |                     | X                  | ND                |
| NPE Crosstalk Test (#6)                          |                     | X                  | ND                |
| Hybrid Electronic Power Feed Test (#56)          |                     | X                  | ND                |
| Hybrid Circuit and Conference Circuit Test (#57) |                     | X                  | ND                |
| Remote Digital Loop Around Test (#59)            | X                   | X                  | ND                |
| Station Lamp Update Test (#60)                   | X                   | X                  | ND                |
| Station Audits Test (#61)                        | X                   | X                  | ND                |
| Ringer Update Test (#62)                         | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-207. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | <p>Could not allocate the necessary system resources to run this test.</p> <ol style="list-style-type: none"><li>1. Retry the command at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 1000       | ABORT       | <p>System resources required to run this test are not available. The port may be busy with a valid call. Use the <b>display port PCSSpp</b> command to determine the station extension number of the port. Use the <b>status station</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.</p> <ol style="list-style-type: none"><li>1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol> |
| 1001       | ABORT       | <p>Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port.</p> <ol style="list-style-type: none"><li>1. Retry the command at 1-minute intervals a maximum of 5 times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1002       | ABORT       | <p>The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors.</p> <ol style="list-style-type: none"><li>1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                       |

| Any        | FAIL        | <p>This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane.</p> <ol style="list-style-type: none"><li>1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation.</li><li>2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation.</li><li>3. Retest the board when the faults from steps 1 and 2 are cleared.</li></ol>                                                                                          |
|            | PASS        | <p>The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol> |

Hybrid Electronic Power Feed Test (#56)

In this test, the software requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit from the station. If no current is being drawn, this probably indicates that the station is not connected. If an overcurrent condition is sensed (that is, too much current is being drawn), this may indicate a short in the loop or a defective voice terminal. Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This test is repeated once more five seconds later. If either test is not successful, the test aborts (see first ABORT entry in the table below).

Table 10-208. TEST #56 Hybrid Electronic Power Feed Test

|            | PASS        | <p>EPF test passed. The message to turn on the power to the station was successfully sent to the port.</p> <ol style="list-style-type: none"><li>Although this test never returns a FAIL result, after running this test, the Error Log should be checked for any entries with Error Type 257 to examine the real results of this test.</li><li>If Error Type 257 does not appear in the Error Log within 10 seconds after completion of this test, it is safe to assume that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that all the feature buttons are operating.</li><li>If Error Type 257 appears in the Error Log, this indicates some problem with the power to the station. The system technician should check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.</li></ol> |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>Issue the <b>reset board</b> command.</li><li>Issue the <b>release busy board</b> command.</li><li>Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol>                                                                                                                               |

Hybrid Circuit and Conference Circuit Test (#57)

This test checks the amount of reflection from the Hybrid loop around circuitry and a Conference Test. Please be aware that if no station is connected to the port being tested, the results of the test are not valid. The Tone-Clock circuit pack places a 1004-Hz tone on a time slot that the port circuit is listening on. A GPTD is connected to another time slot that the same port circuit is talking on. The on-board microprocessor places the port in the loop around mode and the GPTD measures the level of the reflected signal.

The Conference Test is performed after the Circuit Test. The Conference Circuit Test verifies that the NPE is able to listen to several test tones and correctly conference them together. The test is executed in two parts. The first half of the test checks the operation of the NPE's first three conference channels. The NPE is put in the loop around mode and instructed to talk on a selected time slot and listen to the 1004-Hz tone using the first three Conference Channels. The signal level and noise level of the conferenced output are then measured using a GPTD and checked to verify that they are within an acceptable range.

The second half of the Conference Test checks the operation of the NPE's remaining four Conference Channels and follows the same procedure as the preceding paragraph.

| 57         | FAIL        | <p>Hybrid Circuit Test failed. This could result in noisy or bad connections.</p> <ol style="list-style-type: none"><li>1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK.</li><li>2. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using the <b>test board PCSS short</b> command.</li><li>3. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack.</li><li>4. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Hybrid Line circuit pack.</li></ol> <p> <b>NOTE:</b></p> <p>If the Hybrid Circuit and Conference Circuit Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, the 631DB AC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain either a TN736 or a TN752 power unit circuit pack OR a 631DB AC power unit, <i>but not both types of power units</i>. To investigate problems with a 631DB AC power unit, refer to CARR-POW (Carrier Port Power Unit for AC-Powered Systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to CARR-POW (Carrier Port Power Unit for DC-Powered Systems) Maintenance documentation.</p> |

Circuit Test — *Continued*

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | Hybrid Circuit and Conference Circuit Test passed. The hybrid circuitry is transmitting properly.<br><br>1. If complaints still exist, investigate by using other port tests, and by examining the station, wiring, and connections.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.<br><br>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.<br><br>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.<br><br>3. Issue the <b>reset board</b> command.<br><br>4. Issue the <b>release busy board</b> command.<br><br>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. |

Hybrid Line Local Digital Loop Around Test (#58)

This test checks the control channel between the SPE and the port's digital circuitry. The SPE sends transparent data to the on-board microprocessor and compares the data echoed back. This test is repeated three times.

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol> |

Hybrid Line Remote Digital Loop Around Test  
(#59)

This test checks the digital control pair from the port circuit to the terminal. The on-board microprocessor sends a message to the terminal and checks for a proper return message. This test is repeated three times, with two out of the three attempts passing being sufficient for this test to pass. [G1] This test will run if the station is in-service or out-of-service.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal System Error.<br><br>1. Retry the command at 1-minute intervals for a maximum of 5 times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| 1          | ABORT       | A request for a remote station audit aborted even though all internal resources were correctly allocated.<br><br>1. Look in the error log for error type 18 (port busied out) for this port. If this error type is present, release the port via the <b>release port UUCSSpp</b> command or the <b>release station extension</b> command, and then run the test again.<br><br>2. Make sure that the terminal is connected.<br><br>3. Retry the command at 1-minute intervals for a maximum of 5 times.<br><br>4. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                              |
| 1000       | ABORT       | System resources required to run this test are not available. The port may be busy with a valid call. Use the <b>display port PCSSpp</b> command to determine the station extension number of the port. Use the <b>status station</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.<br><br>1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem. |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol> |

Hybrid Line Lamp Updates Test (#60)

For this test, the software lights the lamps on the terminal based on the status record contained in the processor. The lamp updates run only if the station is in-service.

Table 10-212. TEST #60 Hybrid Line Lamp Updates Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Hybrid Line Audits Test (#61)

This is a series of three tests that are classified as audits. These audits abort if attempted on an out-of-service station. The tests are as follows:

- Switchhook Audit - This is an update of the SPE records according to the circuit packs' records.
- Bad Scan Inquiry - A message is sent uplink that contains a count that is generated due to certain events relating to the data link conditions. This is an indication of data transmission problems between the Hybrid circuit pack and the voice terminal.
- EPF Inquiry - The status of the Electronic Power Feed is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, EPF-no-load, and EPF-on-overcurrent.

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | Internal System Error.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|            | PASS        | Hybrid Line Audits Test passed.<br><br>1. Although this test always return a PASS result, it may enter Error Types 257 or 513 into the Error Log. To determine if there are any problems that don't show up in the test result, look for these error types in the Error Log.<br><br>2. If these errors appear in the Error Log, or if user complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.                                                                                                                                                                                                                                                                                                                           |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.<br><br>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.<br><br>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.<br><br>3. Issue the <b>reset board</b> command.<br><br>4. Issue the <b>release busy board</b> command.<br><br>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. |

Hybrid Line Ringer Update Test (#62)

In this update, a "ringer on" or a "ringer off" message is sent to the firmware to start and stop the ringer on the set.

Table 10-214. TEST #62 Hybrid Line Ringer Update Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## INADS (INADS Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| INADS                  | none        | test inads-link        | INADS Link      |

The INADS Link MO represents the software and communications link required by the switch to make a call to the Initialization and Administration System (INADS). The purpose of the INADS Link MO is to check the communications link between the DEFINITY Generic 1 and INADS and verify that the alarm notification process works correctly. An INADS technician can test the process remotely to verify that alarms are reported to INADS, or a system technician may want to test the connection while on-site at installation time or during subsequent service calls.

Although the INADS Link MO is never alarmed, the errors are logged. The errors are only logged as a result of the **test inads-link** command being issued.

### Error Log Entries and Test to Clear Values

The Hardware Error Log entries are described as part of the INADS Link Test description.

### Short and Long Test Sequences

The **test inads-link** command is different from other test commands. This command does not have a long or short option, and the test on the INADS Link does not have an associated test number. When the command is different from other test commands. This command does not have a long or short option, and the test on the INADS Link does not have an associated test number. When the **test inads-link** command is issued, the user immediately sees either the "Command successfully completed" or "Command failed" message command is issued, the user immediately sees either the "Command successfully completed" or "Command failed" message.

### INADS Link Test (no test number)

The INADS Link Test attempts to place a call to INADS (in the background) to verify the communications link to INADS. When the **test inads-link** command is entered, the user immediately sees either "Command successfully completed" or "Command failed." The "Command failed" message appears when a previously run command is entered, the user immediately sees either "Command successfully completed" or "Command failed" The "Command failed" message appears when a previously run **test inads-link** command is in progress or the system has active alarms which must be reported to INADS. The "Command successfully completed" means the switch will start the attempt to call INADS in

two minutes (the test still runs even if Alarm Origination is disabled). The two-minute delay allows a remote INADS technician time enough to hang up the call and thus free up the INADS line so that the switch can call INADS back. As error conditions are encountered, errors are logged against INADS. Error codes 1 through 9 can be logged if the test result was "Command successfully completed" and Error Codes 10 and 11 can be logged if the test result was "Command failed." An error is also logged against INADS if the call to INADS finally succeeds. The INADS software (release 3.2 or later) recognizes this special "test inads" type of alarm and automatically opens and then closes a trouble ticket which indicates that the reason for the trouble ticket is a command is in progress or the system has active alarms which must be reported to INADS. The "Command successfully completed" means the switch will start the attempt to call INADS in two minutes (the test still runs even if Alarm Origination is disabled). The two-minute delay allows a remote INADS technician time enough to hang up the call and thus free up the INADS line so that the switch can call INADS back. As error conditions are encountered, errors are logged against INADS. Error codes 1 through 9 can be logged if the test result was "Command successfully completed" and Error Codes 10 and 11 can be logged if the test result was "Command failed." An error is also logged against INADS if the call to INADS finally succeeds. The INADS software (release 3.2 or later) recognizes this special "test inads" type of alarm and automatically opens and then closes a trouble ticket which indicates that the reason for the trouble ticket is a **test inads-link** command. The trouble ticket alarm contains a **TESTING INADS LINK** description field.

After entering the command, it may take as long a nine minutes for the switch to place the call and for INADS to respond. The Error Log should be examined (use the category **inads**) 10 minutes after successfully entering the command to determine if the call was successful.

Use the following table to interpret the Error Log entries.

Table 10-215. INADS Link Error Log Entries Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                    |

# ISDN-LNK (ISDN-PRI Signaling Link Port)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO              |
|------------------------|-------------|-------------------------------------|------------------------------|
| ISDN-LNK <sup>2</sup>  | MINOR       | test port PCSSpp l                  | ISDN-PRI Signaling Link Port |
| ISDN-LNK               | WARNING     | test port PCSSpp sh                 | ISDN-PRI Signaling Link Port |

- Where 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.
- For additional repair information, see also DS1-BD (DS1 Interface Circuit Pack) or UDS1-BD (Universal DS1 Interface Circuit Pack) Maintenance documentation.

**NOTE:**

Use this Maintenance Object (ISDN-LNK) for maintenance tests, alarms, and hardware errors when the “ISDN-PRI over PACCON” option on the *system-parameters customer* form is set to a “n”. When the ISDN PRI over PACCON is set to “y” use Maintenance Object ISDN-PLK.

When the ISDN-PRI over PACCON option is set to “n”, the ISDN-PRI D-channel call control messages are transmitted over the TDM bus to the Processor Interface circuit pack and you must use this Maintenance Object for PRI Link problems.

An ISDN-PRI Signaling Link is known as a D-channel. D-channels are used to transmit call control signaling for B-channels. The call control signaling for the B-channels is combined and carried over separate ISDN-PRI D-channels. User information (for example, digitized voice, digital data) channels are known as bearer channels (B-channels); DS1 ISDN Trunks are B-channels and they carry the user traffic. PRI endpoint ports are also B-channels that can carry Wideband traffic.

The ISDN-PRI Signaling Link Port (ISDN-LNK) and the associated DS1/UDS1 ISDN Trunk (ISDN-TRK) or PRI endpoint port (PE-BCHL) use ports on a TN767 or TN464B or later DS1/UDS1 interface circuit pack (the TN722 cannot be used for this application). The TN767 is used for 24 channel 1.544 Mbps systems. The TN464B is used for 32 channel 2.048 Mbps systems. The TN464C or later can be used for either 24 or 32 channel systems. A description of these circuit packs appears in “DS1-BD” or “UDS1-BD”.

In a 24 channel system, the DS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the first 23 ports. The ISDN-PRI Signaling Link Port must be the 24th port. In certain configurations (NFAS), the 24th port may be used as a B-channel. Refer to “ISDN-PRI Signaling Group” for further details.

In a 32 channel system, the DS1/UDS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the ports 1-15 or 17-31, but the ISDN-PRI Signaling Link Port must be the 16th port. In certain configurations (NFAS), the 16th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

ISDN-LNK handles maintenance and recovery for the D-channel port on the DS1 carrying the signaling link. A problem with the ISDN-PRI Signaling Link Port (D-channel) has an effect on all of the associated DS1 ISDN Trunks or PRI endpoint ports (B-channels) since no call control information can be conveyed to the far-end switch without it. Stable calls may remain operational, but no new calls can be made.

The ISDN-PRI Signaling Link Port itself depends on two other entities: the DS1/UDS1 Interface circuit pack it resides on, and the Processor Interface Link that provides the link to the processor. If there are problems with the ISDN-PRI Signaling Link Port, also investigate the DS1/UDS1 interface circuit pack and the Processor Interface Link.

Error Log Entries and Test to Clear Values

Table 10-216. ISDN-PRI Signaling Link Port Error Log Entries

| Error Type     | Aux Data | Associated Test         | Alarm Level | On/Off Board | Test to Clear Value         |
|----------------|----------|-------------------------|-------------|--------------|-----------------------------|
| 0 <sup>1</sup> | 0        | Any                     | Any         | Any          | test port PCSSpp sh r 1 (c) |
| 18             | 0        | busyout port PCSSpp (c) | WARNING     | OFF          | release port PCSSpp (c)     |
| 130 (a)        |          | None                    | WARNING     | ON           | test port PCSSpp sh (c)     |
| 1537 (b)       |          | NPE Crosstalk Test #6   | MINOR       | ON           | test port PCSSpp l r 3 (c)  |

1. Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. Indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear, reinsert or replace the circuit pack.
- b. The actual alarming level depends on the options chosen via the **set options** command on the Manager terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option "y" on the Set Options form).
- c. 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence. The command line entry to test the ISDN-LNK MO is: **test port PCSSxx (sh or l)**, where 'xx' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

| Order of Investigation            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)           |                     | X                  | ND                |
| Signaling Link Board Check (#643) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete. This test runs only if the Processor Interface link corresponding to this ISDN-LNK MO is busied out by system technician. The Processor Interface link number can be determined from the Communication-Interface Links form.

Table 10-217. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1000       | ABORT       | System resources for this test are not available. The ISDN-PRI link may be up and servicing calls. First obtain the ISDN-PRI link number (lnk-no) from the Communication-Interface Links form by issuing the <b>display communication-interfaces links</b> command. Then, determine the status of the ISDN-PRI link via the <b>status link lnk-no</b> command. If the link is in-service, this test aborts. Therefore, to run this test, the link must be busied out. No new ISDN-PRI calls can be made while the link is in the busied-out state.<br><br>1. If the test must be run, busyout the link.<br>2. Retry the command. |
| 1001       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 1002       | ABORT       | The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance to diagnose any active TDM-BUS errors.<br><br>1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                               |

Signaling Link Board Check (#643)

This ISDN-PRI Signaling Link Port D-channel depends on the health of the DS1 Interface circuit pack. This test checks the state of the DS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port.

Table 10-218. TEST #643 Signaling Link Board Check

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|            | PASS        | The DS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port is in-service.                                                                                                                                                                                                                                                                                                                                                                                                         |

# ISDN-PLK (ISDN-PRI Signaling Link Port)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO              |
|------------------------|-------------|-------------------------------------|------------------------------|
| ISDN-PLK <sup>2</sup>  | MINOR       | test port PCSSpp l                  | ISDN-PRI Signaling Link Port |
| ISDN-PLK               | WARNING     | test port PCSSpp sh                 | ISDN-PRI Signaling Link Port |

1. Where 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.
2. For additional repair information, see also PKT-CTRL (Packet Control), DS1-BD (DS1 Interface Circuit Pack) or UDS1-BD (Universal DS1 Interface Circuit Pack).

 **NOTE:**

Use this Maintenance Object (ISDN-PLK) for maintenance tests, alarms, and hardware errors when the “ISDN-PRI over PACCON” option on the *system-parameters customer* form is set to a “y” When the ISDN PRI over PACCON is set to “n” use Maintenance Object ISDN-LNK.

The ISDN-PRI over PACCON option allows the PRI Links to be carried over the PACCON (Packet Controller TN778 circuit board), increasing the system ISDN-PRI capacity to the possible number of D-channels. An ISDN-PRI Signaling Link is known as a D-channel. The D-channel is used to transmit call-control signaling for the B-channels. B-channels (User information channels) are known as bearer channels (B-channels for example, transmit digitized voice, digital data); DS1 ISDN Trunks are B-channels and they carry the user traffic. PRI endpoint ports are also B-channels that can carry Wideband traffic. The call control signaling for the B-channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-channel.

The ISDN-PRI Signaling Link Port is the port on a TN464C or later UDS1 Interface circuit pack that carries D-channel messages to the processor. The ISDN-PRI interface uses out-of-band signaling as opposed to robbed-bit, in-band signaling. For G3s, and G3i, this port can be used as an interface to the TDM bus or to the Packet bus. This is controlled by the “ISDN-PRI over PACCON” option. When the option is set to “y” the ISDN-PRI D-channel messages are transmitted over the Packet bus to the Packet Control circuit pack. The associated maintenance object name of the UDS1 port used to carry the D-channel over the Packet Bus is ISDN-PLK.

The B-channels associated with a ISDN-PRI D-channel can use ports on the same circuit pack or ports on other TN464C or later or TN767 DS1 Interface circuit packs (the TN722 cannot be used for this application).

The TN767 DS1 interfaces is used for 24 channel 1.544 Mbps systems. The TN464C or later can be used for either 24 or 32 channel systems. The 32-channel

(31 DS0 channels + 1 framing channel on a 2.048 Mbps link) are only supported on TN464 series circuit packs. A description of these circuit packs appears in DS1-BD or UDS1-BD maintenance documentation.

In a 24 channel system, the DS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the first 23 ports. The ISDN-PRI Signaling Link Port must be the 24th port. In certain configurations (NFAS), the 24th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

In a 32 channel system, the DS1 ISDN Trunk or PRI endpoint port (B-channels) may use any of the ports 1-15 or 17-31, but the ISDN-PRI Signaling Link Port must be the 16th port. In certain configurations (NFAS), the 16th port may be used as a B-channel. Refer to the ISDN-PRI Signaling Group (ISDN-SGR) Maintenance documentation for further details.

ISDN-PLK handles maintenance and recovery for the D-channel port on the DS1 carrying the signaling link. A problem with the ISDN-PRI Signaling Link Port (D-channel) has an effect on all of the associated DS1 ISDN Trunks or PRI endpoint ports (B-channels) since no call control information can be conveyed to the far-end switch or Terminal Adapter without it. Stable calls may remain operational, but no new calls can be made.

The ISDN-PRI Signaling Link Port (ISDN-PLK) itself depends on two other entities: the UDS1 interface circuit pack (TN464) it resides on, and the Packet bus which provides the link to the processor. If there are problems with the ISDN-PLK, also investigate the TN464 UDS1 interface circuit pack (UDS1-BD) and the packet bus (PKT-BUS).

\*TN464 C or later

| 3843 (h)       |          | Signaling Port Packet Bus (LAN) Loopback test (#939) |             |              | test port PCSSpp <sup>2</sup> 1  |

1. Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.
2. pp is 24-channel interfaces and 16 for 32-channel interfaces.

Notes:

- a. The D-channel is demand busied out. No calls can be made over this D-channel.
- b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- c. "Link error" This error occurs when the port receives an invalid frame over the D-channel. This error normally indicates an off-board problem usually related to transmission errors on the DS1 facility. Execute the **list measurements ds1-log** command for the UDS1 TN464 circuit pack on which the D-channel resides. If the UDS1 is reporting some errors, then the DS1 facility has experienced transmission problems which could have caused the ISDN-PLK to report a Link Error. If the UDS1 is not reporting errors, execute the long test sequence for the D-channel (ISDN-SGR). Investigate any errors, if there are none execute a long test sequence for the UDS1 circuit pack (UDS1-BD) and investigate any errors.

If no errors are reported, the Link Error is probably not affecting service.

- d. The UDS1 Interface circuit pack is out-of-service. Look for and resolve UDS1-BD errors in the Hardware Error Log.
- e. "Transmit FIFO Overflow error" This error indicates that the circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signaling information over the D-channel. Specifically, this error occurs when the Packet Bus transmit buffers overflow. This condition probably indicates a hardware problem.

The actual alarming level depends on the options chosen via the **set options** command on the G3-MT terminal. ISDN-PRI Signaling Link Port alarms are treated as Station alarms, and their default alarming option is to downgrade all alarms to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option "y" on the *Set Options* form).

- f. "Bad DLCI error" This error occurs when a LAPD frame is received across the DS1 facility which contains a DLCI which does not have a valid entry in the on-board translation memory. This error normally indicates an off-board problem usually related to a broken endpoint or a state mismatch between a remote endpoint and the local call processing software. Maintenance will not start any testing or generate any alarms in response to this error.
- g. "Receive FIFO Overflow error" This error occurs when the circuit pack detects an overflow of its receive buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch between the two end-points of a packet switched connection. LAPD should be able to recover from this problem, but it may degrade the performance of the Packet Bus. Maintenance will not start any testing or generate any alarms in response to this error.
- h. This error occurs when the *Signaling Port Packet Bus Loopback Test* (#939) fails. Run the long test sequence and pay particular attention to the results of *Test #939*.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. REMINDER: The command line entry to test the ISDN-PLK MO is: **test port PCSSpp (sh or l)**, where 'pp' is '24' for 24-channel interfaces, and '16' for 32-channel interfaces.

| Order of Investigation                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------------|---------------------|--------------------|-------------------|
| Signaling Port Bus Loopback Test (#939) |                     | X                  | D                 |
| Signaling Link Board Check (#643)       | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Signaling Link Board Check (#643)

This test checks the state of the UDS1 Interface circuit pack (TN464C or later) transporting the ISDN-PRI Signaling Link.

Table 10-220. TEST #643 Signaling Link Board Check

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

|            | PASS        | The UDS1 Interface circuit pack transporting the ISDN-PRI Signaling Link Port is in-service.                                                                                                                                                                                                                                                                                                                                                                                                              |

Signaling Port Packet Bus Loopback Test (#939)

This test verifies the connectivity of an ISDN-PRI Signaling Port (D-channel) across the Packet Bus, also known as the LAN bus. It will execute only if the port is busied out. Failure of this test indicates a fault associated with the port hardware on the circuit pack.

# ISDN-SGR (ISDN-PRI Signaling Group)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO          |
|------------------------|-------------|-------------------------------------|--------------------------|
| ISDN-SGR               | MINOR       | test sig-group <group>              | ISDN-PRI Signaling Group |
| ISDN-SGR               | WARNING     | test sig-group <group>              | ISDN-PRI Signaling Group |

1. Where <group> is a number 1-8 and the test sequence can be either s (short) or l (long).

An ISDN-PRI Signaling Group is a collection of DS1/UDS1 ISDN Trunks or PRI endpoint ports (B-channels) for which a given ISDN-PRI Signaling Link Port (D-channel) carries signaling information. ISDN-PRI requires the use of one of the following DS1 interface circuit packs:

|                 |                                                                           |
|-----------------|---------------------------------------------------------------------------|
| TN767           | 24-channel with ISDN-PRI D-channel over PI-BD                             |
| TN464B          | 32-channel with ISDN-PRI D-channel over PI-BD                             |
| TN464C or later | 24- or 32-channel with ISDN-PRI D-channel over PI-BD or PKT-CTRL (PACCON) |

See DS1-BD and UDS1-BD Maintenance documentation for a description of these circuit packs. See *DS1/CEPT1/ISDN-PRI Reference*, 55-025-101, for more information on ISDN.

**NOTE:**  
If a ISDN-PRI over PACCON (Packet Control Circuit pack) is to be used then only the TN464C or later may be used for the D-channel Signaling.

For 24 channel interfaces, the first 23 ports on the circuit pack are used as B-channels. The 24th port may be used as a B-channel or as a D-channel depending on the type of Signaling Group used, as described below.

For 32 channel interfaces, ports 1-15 and 17-31 on the circuit pack are used as B-channels. The 16th port may be used as a B-channel or as a D-channel depending on the type of Signaling Group used, as described below.

There are two types of Signaling Groups:

- Facility Associated Signaling (FAS) (supported by all country protocols)
- Non-Facility Associated Signaling (NFAS) (supported by country protocol 1 only)

The figures following this discussion illustrate each of the configurations.

In an FAS Signaling Group, the 24th port of the DS1 Interface circuit pack (for 24 channel interfaces) or the 16th port of the DS1 Interface circuit pack (for 32 channel interfaces) is always the D-channel that carries signaling information for the other ports (B-channels) on the circuit pack. If a Packet Control circuit pack is used then only the TN464C or later circuit pack may be used.

In an NFAS Signaling Group, the 24th port of a DS1 Interface circuit pack (for 24 channel interfaces) or the 16th port of a DS1 Interface circuit pack (for 32 channel interfaces) is administered as a D-channel. The D-channel carries signaling information for the other ports (B-channels) on that circuit pack. That D-channel can also carry signaling information for any of the ports on other DS1 Interface circuit packs in the NFAS Signaling Group. As a result, the 24th port on other 24-channel DS1 Interface circuit packs and the 16th port on other 32-channel DS1 Interface circuit packs can be used as B-channels. A D-channel in an NFAS Group can signal for B-channels on a total of 20 DS1 Interface circuit packs. This configuration is known as NFAS Simplex. If a Packet Control circuit pack is used then only the TN464C or later circuit pack may be used to carry the D-channel, however other DS1/UDS1 interface circuit packs may be used to carry only B-channels.

In addition to NFAS Simplex, there is another type of NFAS Group called NFAS Duplex. This provides the user with more reliability, which is desirable because NFAS permits the D-channel to signal for so many B-channels. NFAS Duplex allows the administration of a backup D-channel, which remains in a Standby state until the Active D-channel goes down. If the Active D-channel does go down, the backup D-channel takes over and provides signaling for all the B-channels in the signaling group. In the case that a Packet Control circuit pack is used then only the TN464C or later may be used to carry the D-channels. B-channels may be carried by any DS1/UDS1 interfaces.

The ISDN-PRI Signaling Group itself depends on three other entities: the DS1 Interface circuit pack on which the D-channel(s) resides, the ISDN-PRI Signaling Link Port(s), and the interface link that provides connectivity to the processor (either the Processor Interface Link or the Packet Control circuit pack). If there are any problems with the ISDN-PRI Signaling Group, also investigate the ISDN-PRI Signaling Link Port(s), the DS1 Interface circuit pack(s), and either the Processor Interface Link or the Packet Control circuit pack.

| 3840-3928 (h)  | port number |                                                |             |              | none                   |

1. Run the Short or Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This switch sent a message to the far-end switch or terminal adapter, and the far-end did not respond in the allotted time. Possible causes include link failure and congestion or outage at the far-end. The Aux Data field contains Layer 3 protocol information used by internal counters.

If no other symptoms are not present, no action is required. If Layer 3 communication is down, there should be indications in the form of alarms and errors for link components. Check out other errors against ISDN-SGR, ISDN-TRK, and other hardware components on the link.

There is no test to clear these errors. The error counter is decremented by 1 every 15 minutes.

- b. This error indicates that the primary signaling channel connection has been lost for more than 90 seconds. If a secondary signaling channel does not exist or is not in-service, the associated B-channels will be placed in the ISDN Maintenance/Far-End state. The B-channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Pay particular attention to the results of Test #636 (Primary Signaling Link Hardware Check) in the test sequence. When the link does recover, the B-channels will be negotiated back to the In-Service state and their alarms will be retired.

When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

- c. This error indicates that the secondary signaling channel connection has been lost for more than 90 seconds. If the primary signaling channel is not in-service, B-channels will be placed in the ISDN Maintenance/Far-End state. The B-channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Pay particular attention to the results of Test #639 (Secondary Signaling Link Hardware Check) in the test sequence. When the link does recover, the B-channels will be negotiated back to the In-Service state and their alarms will be retired.

When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the **status sig-group** command).

- d. This error indicates a failure of the Layer 2 Status Query Test for the primary signaling channel
- e. This error indicates a failure of the Layer 2 Status Query Test for the secondary signaling channel.
- f. A specific message was sent to the far-end switch, and it did not respond within the allotted time. Investigate elements of the ISDN PRI D-channel(s) (ISDN-LNK, ISDN-PLK, ISDN-SGRP, PI-LINK, PI-PT, PKT-CTRL) for both this switch and the Far-end switch. If Test #637 fails twice in a row, the B-channels will be alarmed and made unavailable for outgoing calls (although incoming calls will still be accepted). When Test #637 succeeds and the Far-end switch starts responding properly, the DS1 ISDN Trunk (B-channels) will be placed back into normal operation and their alarms will be retired.

- g. A SERV or SERV ACK ISDN D-channel message has been received by a non-US-type interface (country option other than 1 on the DS1 administration form). However, these messages are used only for duplex NFAS signaling which is supported only by country protocol 1.
- Thus, there may be a mismatch in administration between the local and far-end switches. Consult with the customer's network provider to determine whether the D-channel is set up correctly on the far-end switch.
- h. These error codes are used to report certain error messages received by the ISDN-PRI Signaling Group for one of its associated B-channels. The aux data field shows for which B-channel (port number) the message was received.
- The error code generated equals 3840+x, where x is a Cause Value defined by the ISDN PRI Specification. Note that there is no Test to Clear Value for these error types; selected ISDN cause values are placed in the log when they are received, but no direct action or alarming is performed solely in response to receiving them. They provide added data that may prove useful when tracking down obscure networking and routing problems. The following table provides more information:

Table 10-223. Descriptions of Error Codes 3840-3928

| Error Code | Description                                                                                 | Recommendation                                                                                                                                                                                                                                                                  |
|------------|---------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3842       | A request has been made to use a transit network or common carrier that cannot be accessed. | <div>1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported.</div> <div>2. Check all routing patterns containing this trunk group for validity of interexchange carriers requested (IXC field).</div> |

Table 10-223. Descriptions of Error Codes 3840-3928 — Continued

| Error Code | Description                                                                                                                                                                                                              | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3846       | The far-end switch has indicated that the B-channel (trunk) is not acceptable for use in the call for which it was requested.                                                                                            | <p>This could indicate an administration problem (for example, the local switch and the far-end switch have different B-channels administered), or could reflect the occurrence of a normal race condition (for example, the local switch has requested use of a B-channel which the far-end switch had just reserved for use on another call).</p> <ol style="list-style-type: none"><li>1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li><li>2. Issue the <b>status trunk</b> command for the indicated trunk.</li><li>3. Refer to the “DS1 ISDN Trunk Service States” and “ISDN-PRI Trunk Service States” sections of ISDN-TRK for recovery suggestions.</li></ol> |
| 3858       | The switch sent an ISDN message to the far-end switch or terminal adapter which did not respond in the allotted time.                                                                                                    | <p>Possible causes include link failure and congestion or outage at the far-end.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3878       | The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful). | <ol style="list-style-type: none"><li>1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li><li>2. Consult with the network provider to determine the nature and expected duration of the out of service condition.</li><li>3. Consider modifying all routing patterns containing this trunk group, to route calls around the network which is out of service.</li></ol>                                                                                                                                                                                                                                                                                                   |

Table 10-223. Descriptions of Error Codes 3840-3928 — Continued

| Error Code | Description                                                                                                                                                                                              | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3890       | A request to use a network service (e.g., SDN) has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk. | <p>This could be a local administration problem only, or a mismatch between the local administration and that of the network provider.</p> <ol style="list-style-type: none"><li>1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li><li>2. Display the trunk group form: If the trunk group is Call-by-Call (Service Type is "cbc"), check all routing pattern forms containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the Service Type field contains the single network service purchased for this trunk.</li><li>3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.</li></ol> |
| 3892       | Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.                                                                                             | If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, provide the next tier with this Error Log information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
| 3894       | Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.                                                                                             | First, eliminate any transitory state mismatch problems by issuing the <b>test port PCSSpp</b> command for the trunk port shown in the aux data field. Test #256 (Service State Audit) is the important test in the sequence. If this passes satisfactorily, yet the customer continues to complain of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, provide the next tier with this Error Log information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 10-223. Descriptions of Error Codes 3840-3928 — Continued

| Error Code | Description                                                                                                                                                        | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3905       | Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.                                                       | If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, provide the next tier with this Error Log information.                                                                                                                                                                                                                                                                                             |
| 3906       | Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.                                                       | If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, provide the next tier with this Error Log information.                                                                                                                                                                                                                                                                                             |
| 3909       | A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented.                       | Follow the recommendations listed above for error type 3890.                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 3928       | A call was denied because of a basic incompatibility between the type of call and either the facilities selected by the routing pattern or the called user itself. | This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks or PRI endpoints. Determine the trunk group from the circuit pack and port number (in the aux data field) and then check the BCC fields of the pertinent routing patterns. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension). |

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Primary Signaling Link Hardware Check*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------|---------------------|--------------------|-------------------|
| Primary Signaling Link Hardware Check (#636)   | X                   | X                  | ND                |
| Secondary Signaling Link Hardware Check (#639) | X                   | X                  | ND                |
| Layer 2 Query Test (#647)                      | X                   | X                  | ND                |

Primary Signaling Link Hardware Check (#636)

The ISDN-PRI Signaling Link Port itself depends on the health of the DS1/UDS1 Interface circuit pack on which it resides. This test will fail if there are problems with either the ISDN-PRI Primary D-channel port or the DS1/UDS1 circuit pack. The ISDN-PRI Primary D-channel also depends on the health of either the Processor Interface Link or the Processor Control circuit pack providing connectivity to the DS1/UDS1 circuit pack.

If there are problems with the ISDN-PRI Signaling Link, also investigate the DS1/UDS1 circuit pack (DS1-BD/UDS1-BD) and the Processor Interface Link or Packet Control (PI-LINK/PACCON) dependent upon which is used

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1700       | ABORT       | Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is a normal abort when the rollabout video feature is enabled. To complete test on this port, either:<br><br><div><div>1. Re-attach the disconnected PRI terminal adapter and retry test command, or</div><div>2. Disable the rollabout video feature on this circuit pack by entering <b>change ds1 PCSS</b> and set the field "<b>Alarm when PRI Endpoint Detached?</b>" to "y".</div></div> |
| 4          | FAIL        | There is a problem with the Processor Interface Link. No DS1 ISDN Trunk (B-channel) or wideband PRI Endpoint calls can be made until the problem is resolved.<br><br><div><div>1. Display the Communication-Interface Links Form via the to determine which link is down (find the one that matches the DS1 interface circuit pack this ISDN-PRI Signaling Link Port is on) and then consult the procedures for Processor Interface Link.</div></div>                                                                      |
| 8          | FAIL        | There is a problem with the DS1/UDS1 Circuit Pack, or the ISDN-PRI Signaling Channel (D-channel). No DS1 ISDN Trunk (B-channel) or wideband PRI Endpoint calls can be made until the problem is resolved.<br><br><div><div>1. Consult the procedures for DS1/UDS1 Circuit Pack and the ISDN-PRI Signaling Channel (ISDN-LNK/ISDN-PLK).</div></div>                                                                                                                                                                         |
|            | PASS        | The basic physical connectivity of the primary D-channel is intact and functional. Try this test repeatedly to ensure the link is up and to uncover any transitory problems.                                                                                                                                                                                                                                                                                                                                               |

Remote Layer 3 Query (#637)

This test will query the far-end switch or terminal adapter to determine if the signaling connection is functioning properly at Layer 3. It will select a B-channel in the in-service or maintenance service state and send an ISDN Layer 3 SERVICE message, which requires a response from the far end (similar to performing Test #256 on an ISDN trunk. The test will not be performed if there are no B-channels in an appropriate ISDN service state (as when none are administered or they are all out of service).

**NOTE:**  
The service state can be displayed by using the **status trunk <trunk group/trunk member>** or **status pri-endpoint** command.

As is the case with Test #256 for an ISDN trunk, a PASS only indicates that a message was composed and sent to the far-end switch or terminal adapter. The ISDN PRI Specification allows up to 2 minutes for a response. Check the Error Log for ISDN-SGR (ISDN-PRI Signaling Group) errors of type 2305 for evidence of a Remote Layer 3 Query failure.

Tests #639 and #636 check the health of the D-channels and DS1/UDS1 Interface Circuit Packs. As shown in the figures below, Test #637 goes one step further by checking the communication path from the processor, through the Processor Interface or Packet Control circuit pack over the TDM or Packet Bus through the DS1/UDS1 Interface circuit pack, and on to the far-end switch or terminal adapter. A special ISDN message is sent to the far-end switch or terminal adapter, which must respond within a specified amount of time. This test is designed to ensure that the communication path between the switch and the far-end is up and operational, and that the two endpoints can properly exchange ISDN control messages.

If there is still a problem with a particular DS1 ISDN Trunk or PRI Endpoint Port (B-channel), busyout the trunk or port and run the long test sequence, paying particular attention to the results of Test #258 (ISDN Test Call).</li></ol> |

Secondary Signaling Link Hardware Check (#639)

The ISDN-PRI Signaling Group D-Channel port depends on the health of the DS1/UDS1 Interface circuit pack on which it resides. This test will fail if there are problems with either the ISDN-PRI Primary D-channel port or the DS1/ UDS1 circuit pack. If there are problems with the ISDN-PRI Secondary Signaling Channel port (ISDN-LNK or ISDN-PLK), also investigate the DS1/UDS1 circuit pack.

Layer 2 Status Test (#647)

The Layer 2 Status Test checks the layer 2 status of the ISDN-PRI Signaling Channel (D-channel). This test will fail if there is a hardware failure or a facility problem, or if the primary and secondary ISDN-PRI D-channels are not administered correctly.

The Primary and Secondary Signaling Link Hardware tests (test 636 and 639) and the Remote Layer 3 Query test (test 637) will detect most problems caused by hardware failures or incorrect administration. However, the Layer 3 test (test 637) cannot detect end-to-end transmission problems with the Standby D-channel since Layer 3 messages are not sent on the standby channel.

For G3r, the SYS-LINK Maintenance Object reports Layer 2 ISDN-PRI D-channel problems and for G3i/s/vs, the PI-LINK Maintenance Object reports Layer 2 ISDN-PRI D-channel problems (if the D-channel is connected to the Processor Interface circuit pack). However, the PI-LINK Maintenance Object does not monitor the Layer 2 status of the ISDN-PRI D-channel when the D-channel is connected to the Packet Control circuit pack for the ISDN-PRI over PACCON

feature. The Layer 2 Query test is provided to detect D-Channel Layer 2 failures and generate an associated Warning alarm independent of the hardware configuration used for the D-channels.

## ISDN-TRK (DS1 ISDN Trunk)

| MO Name (in Alarm Log) | Alarm Level        | Initial Command to Run | Full Name of MO |
|------------------------|--------------------|------------------------|-----------------|
| ISDN-TRK <sup>1</sup>  | MAJOR <sup>2</sup> | test port PCSSpp l     | DS1 ISDN Trunk  |
| ISDN-TRK               | MINOR              | test port PCSSpp l     | DS1 ISDN Trunk  |
| ISDN-TRK               | WARNING            | test port PCSSpp sh    | DS1 ISDN Trunk  |

- For additional repair information, refer to the [“DS1-BD \(DS1 Interface Circuit Pack\)”](#) maintenance object.
- A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

A DS1 ISDN Trunk is known as a B-channel. It is a 64 kbps Bearer channel that can be used to transmit digital traffic, be it voice or data. These trunks use a separate channel for signaling (for example, for call setup); this mode of operation is known as out-of-band signaling, as opposed to in-band, robbed-bit signaling, where the signaling traffic flows over the same channel as the voice or data traffic. The separate signaling channel is called a D-channel in ISDN terminology, and it carries all the call control signaling messages for the DS1 ISDN Trunk B-channels. The D-channel for these B-channels is an ISDN-PRI (Primary Rate Interface) Signaling Link Port (ISDN-LNK/ISDN-PLK).

On 24-channel interfaces, any of the first 23 ports on the DS1/UDS1 interface circuit pack can be a B-channel. The 24th port may be used as a B-channel or as a D-channel depending on the type of ISDN-PRI Signaling Group (ISDN-SGR) to which it belongs. On 32 channel interfaces, any of ports 1-15 and 17-31 on the DS1 interface circuit pack can be a B-channel. The 16th port may be used as a B-channel or as a D-channel depending on the type of ISDN-PRI Signaling Group (ISDN-SGR) to which it belongs. For more details, refer to the ISDN-SGR and DS1-BD/UDS1-BD Maintenance documentation.

 **NOTE:**  
If a Packet Control circuit pack is used instead of a Processor Interface Link as the interface of the PBX SPE to the D-channel, then the signaling link port on the UDS1 circuit pack is referred to as ISDN-PLK and only the TN464C or later may be used to carry D-channel Signaling. The B-channels may be carried by any DS1/UDS1 interface circuit pack. If a Processor Interface is used for connectivity then the Signaling Link port is referred to as a ISDN-LNK and the TN767 or TN464B or later DS1 interface circuit pack may be used to carry D-channels Signaling.

For interfaces using country protocol 1 on the DS1 Circuit Pack administration form (including US), the signaling protocol used for the maintenance of the B-channel is defined by the AT&T ISDN-PRI Specification.

For interfaces using country protocols other than 1, the signaling protocol used for the maintenance of the B-channel is defined by the CCITT ISDN-PRI Specification.

There are five possible SERVICE STATES for a B-channel. The service state is negotiated with the far-end switch, changes over time, and may have a far-end or near-end component. The service state is initialized to Out-Of-Service/Far-End state and an attempt is made to negotiate it to In-Service.

#### NOTE:

The service state of a particular DS1 ISDN Trunk B-channel can be displayed by issuing the **status trunk <trunk\_group/trunk\_member>** system technician command.

If a call is present, the Specification defines the permissible CALL STATES as well. There are tests in the Short and Long Test Sequences for DS1 ISDN Trunk designed to audit these states and ensure agreement between both ends of the PRI connection.

## Alarming Based on Service States

A warning alarm is logged against a DS1 ISDN B-channel trunk when it is placed in the Maintenance/Far-End or Out-Of-Service/Far-End states, during which the trunk is unusable for outgoing calls. When a warning alarm is present, use **status trunk group#/member#** command to determine the exact state. Other alarms can be diagnosed by using the short and/or long test sequences. Note that an ISDN B-channel trunk can be placed in a Far-End service state by either action taken by the far-end switch or by failure of the far-end switch to respond. For example, if the far-end does not respond to a Remote Layer 3 Query (Test #637 for ISDN-SGR), the associated DS1 ISDN trunk B-channels will be placed in the Maintenance/Far-End service state.

As a port on a DS1 circuit pack (DS1-BD or UDS1-BD), and as part of a signaling group dependent on a D-channel (ISDN-LNK/ISDN-PLK) for signaling, operation of the ISDN-TRK is dependent on the health of these other maintenance objects. The ISDN D-channel in turn depends on the Packet Bus (PKT-BUS)/Processor Interface Link (PI-LINK) (dependent on setup) for transmission through the system. Keep this hierarchy of dependencies in mind when diagnosing problems.

### DS1 ISDN Trunk Service States

This section defines the possible service states of a DS1 ISDN trunk, explains the reason for each service state, and provides the recommended recovery procedures (when required).

#### Service States

- **In-Service (INS)**  
The B-channel is in its normal operating state.
- **Out-of-Service/Far-end (OOS/FE)**  
A B-channel is initialized to this state when administered and it may also be in this state if there is a failure on the B-channel attributed to a problem on the far-end switch. The switch sends messages to the far-end to negotiate the B-channel into service. If the far-end does not respond to the messages within a certain time period, then the service state remains out-of-service and maintenance will periodically resend the messages. The trunk is unusable for outgoing calls. On US interfaces, the trunk is unusable for incoming calls, but on non-US interfaces, incoming calls will be accepted.

- Out-of-Service/Near-end (OOS/NE)

This is the state of the trunk when a hardware failure exists on the link, the NPE Crosstalk Test fails, or when the trunk is busied out by system technician. In this state, the trunk is unusable for incoming or outgoing calls. No messages are sent to the far-end until the signaling link comes back into service or the trunk is released by system technician.

- Maintenance/Far-end (MTC/FE)

This state is reached when the far-end does not respond to messages sent over the signaling link for a particular trunk after a certain amount of time. This state is different from OOS/FE since the signaling link must have initially been up and the B-channels in-service. The switch will periodically send messages to the far-end to try to negotiate the trunk (B-channel) into service. The trunk is unusable for outgoing calls but will service incoming call requests from the far-end. Note that transitions into MTC/FE do not drop stable calls. Therefore, if the service state changes from in-service to MTC/FE, then stable calls are unaffected.

- Maintenance/Near-end (MTC/NE)

The trunk (B-channel) is in this state if the signaling link (PI-LINK) is busied out by system technician. The trunk (B-channel) is also temporarily in this state if system technician has issued a **test trunk trunk\_group/trunk\_member long** command. This command will execute the ISDN-PRI test call. This test will change the state of the trunk member to MTC/NE for the duration of the test unless a call request comes in from the far-end. In that case, the test would abort. Note that transitions into MTC/NE do not drop stable calls. Therefore, a system technician- demanded **busyout link Ink-no** command will not drop stable trunk calls. In this state, the B-channel is not usable for new outgoing calls, but is available for incoming calls and outgoing test calls.

- Pending States

If the near-end is expecting a timed response from the far-end for a request to change the service state of a trunk, then the state of the trunk reflects a Pending State.

- Pending-in-service (PINS)

The near-end has sent a B-channel maintenance message to the far-end, requesting that the B-channel service state be transitioned to in-service. The far-end has a certain amount of time to respond to the message. The service state will be PINS until either a response is received or the timer expires.

- Pending-maintenance (PMTTC)

This state is supported only by systems using country protocol 1 (including US). The near-end has sent a B-channel maintenance message to the far-end, requesting that the B-channel service state

be transitioned to maintenance. The far-end has a certain amount of time to respond to the message. The service state will be PMTC until either a response is received or the timer expires.

— Call Activity States

In addition to the service and pending state, the state of a B-channel also reflects its call activity. If a call is connected over the B-channel, then the state of the trunk will reflect the "active" call state, for example, "in-service/active." If there is no call on the B-channel, then the trunk will reflect the "idle" call state, for example, "OOS/FE-idle."

The following diagram of the DS1 ISDN Trunk service states shows the common progression from one service state to another and the event that caused the change of state.

Figure 10-60. Common Progressions in Service States

ISDN-PRI Trunk Service States

The following chart summarizes each of the different DS1 ISDN Trunk service states that can result when the **status trunk <trunk\_group/trunk\_member>** command is issued.

**NOTE:**  
Refer to [Chapter 5, “Routine Maintenance Procedures”](#) for a layered approach to the processing of ISDN-PRI problems.

Table 10-228. ISDN-PRI Trunk Service States (Test #161 Loop Around Test)

| Service State                     | Alarm*  | Possible Cause                                                                                    | Possible Solution                                                                                                                                             |
|-----------------------------------|---------|---------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| out-of-service/NE                 | Warning | Trunk is demand busied out.                                                                       | Enter <b>release trunk</b> grp#/mbr#.                                                                                                                         |
|                                   | Minor   | NPE Crosstalk Test (#6) failed.                                                                   | Replace DS1/UDS1 circuit pack.                                                                                                                                |
|                                   | None    | DS1 or UDS1 circuit pack lost its signal.                                                         | Is the DS1/UDS1 circuit pack or cable removed? Is the far-end switch restarting? Check circuit pack using procedures in DS1-BD or UDS1-BD.                    |
| out-of-service/FE                 | Warning | Unadministered far-end                                                                            | Administer corresponding trunk on far-end switch.                                                                                                             |
|                                   | Warning | The far-end trunk is busied out.                                                                  | Check the status of the far-end switch.                                                                                                                       |
| pending-in-service, pending-maint | None    | Maintenance message was sent and the switch is waiting up to 2 min. for a reply from the far-end. | Wait 2 minutes and check service state after the pending state has cleared.                                                                                   |
| maint-NE<br><br>maint-FE          | None    | ISDN test call in progress ( <b>test trunk long</b> and <b>test isdn-testcall</b> commands)       | Wait several minutes for test to finish and check status again.                                                                                               |
|                                   | None    | System link has been busied out by command.                                                       | Check link status. Release link with <b>release link</b> link#.                                                                                               |
|                                   | Warning | Signaling channel has been down for over 90 sec.                                                  | Consult ISDN-SGR and/or ISDN-LNK. Far-end signaling channel may be busied out, or the far-end switch may currently be restarting.                             |
|                                   | Warning | Repeated failure of far end to respond to messages.                                               | Maintenance software will periodically try to resend messages. You can speed the process with <b>test trunk grp#/mbr#</b> and/or <b>test signaling-gr #</b> . |
|                                   | Warning | The far-end trunk is being tested.                                                                | Check status of the far-end switch. Wait for testing to finish.                                                                                               |
| in-service                        | None    | Normal operating state                                                                            |                                                                                                                                                               |

Error Log Entries and Test to Clear Values

Table 10-229. DS1 ISDN Trunk Error Log Entries

| Error Type     | Aux Data | Associated Test              | Alarm Level           | On/Off Board | Test to Clear Value       |
|----------------|----------|------------------------------|-----------------------|--------------|---------------------------|
| 0 <sup>1</sup> | 0        | Any                          | Any                   | Any          | test port PCSSpp sh r 1   |
| 1 (a)          | Any      | None                         |                       |              | test port PCSSpp sh r 1   |
| 15 (b)         | Any      | Audit and Update Test (#36)  |                       |              |                           |
| 18             | 0        | busyout trunk <grp>/<mbr>    |                       |              | release trunk <grp>/<mbr> |
| 129 (c)        |          | None                         | WARNING               | OFF          | test port PCSSpp          |
| 130 (d)        |          | None                         | WARNING               | ON           | test port PCSSpp          |
| 257 (e)        | Any      | None                         |                       |              | test port PCSSpp          |
| 513 (f)        | Any      | None                         | WARNING               | OFF          | test port PCSSpp          |
| 769 (e)        | Any      | None                         |                       |              | test port PCSSpp          |
| 1281           | Any      | Conference Circuit Test (#7) | MIN/ WRN <sup>2</sup> | ON           | test port PCSSpp l r 4    |
| 1537           | Any      | NPE Crosstalk Test (#6)      | MIN/WRN <sup>2</sup>  | ON           | test port PCSSpp l r 3    |
| 1793 (g)       | Any      | None                         |                       |              | test port PCSSpp          |
| 3073 (h)       | Any      | Service State Audit (#256)   |                       |              | test port PCSSpp          |
| 3585 (i)       | Any      | None                         |                       |              | None                      |
| 3841 (j)       | Any      | None                         |                       |              | None                      |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, then the Minor alarm will be upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

- a. These error types indicate a disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN *call* state of the DS1 ISDN Trunk. This switch will automatically try to recover by clearing the call, (that is, the call will be torn down). You can use the **status trunk <trunk\_group/trunk\_member>** command to determine the state of the trunk.

When running the Short Test Sequence of tests, pay close attention to the results of the Call State Audit Test (#257).

- b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).
- c. The far-end switch changed its ISDN *service* state to either out-of-service or maintenance. This may be a temporary condition due to testing of that trunk by the far-end *or* a hardware problem with the trunk. Outgoing calls will not be allowed over the trunk. To investigate the status of the trunk, issue the **status trunk <trunk\_group/trunk\_member>** command.
- d. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. These error types indicate a disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN service state of the DS1 ISDN Trunk. This switch will automatically try to recover by performing a service state audit. You can use the **status trunk <trunk\_group/trunk\_member>** command to determine the state of the trunk.

When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

- f. This trunk is not recognized by the far-end switch. Investigate the trunk administration for both switches and make changes as necessary.
- g. This error indicates a failure of the DS1/UDS1 Interface circuit pack. When running the Short Test Sequence, the results of the Signaling Link State Check Test (#255) are important.
- h. Two Service State Audit attempts have failed (see Test #256). The trunks will not be usable for any outgoing calls (although incoming calls will be accepted) until the test passes and the trunk state is changed to in-service (use **status trunk trunk\_group/trunk\_member** to investigate trunk status).
- i. Error Type 3585 appears when the switch receives an ISDN RESTART message for an ISDN trunk. Calls are cleared with the RESTART message. Therefore, this error type may be associated with a dropped call report from a user.

The following Aux Data values for Error Type 3585 represent the trunk's ISDN call state at the time the unexpected request to restart the channel was received from the remote switch. This information can be useful if dropped calls (cutoffs) are being reported by users of the ISDN-PRI trunks. The meanings of the various Aux Data values are shown below.

**Aux Data values of concern; any others can be ignored.**

|   |                                  |
|---|----------------------------------|
| 0 | A idle trunk received a restart. |
|---|----------------------------------|

| Aux Data values of concern; any others can be ignored. |                                                                                                                                                                                                                                                                                                                  |
|--------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10                                                     | A call in a stable, talking state was cleared unexpectedly by the far-end with an ISDN RESTART message. This state is called the "active" state.                                                                                                                                                                 |
| 4, 7, 8<br>260,<br>263                                 | A call that has not reached the active state, but has at least reached a ringing state, was cleared unexpectedly by the far-end with an ISDN RESTART message.                                                                                                                                                    |
| 1, 3, 6<br>9, 265                                      | A call that has not yet reached a ringing state was cleared unexpectedly by the far-end with an ISDN RESTART message.                                                                                                                                                                                            |
| 11, 12<br>19,<br>531,<br>267,<br>268                   | A call that was in the process of clearing anyway has been cleared by the far-end with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end is attempting to clear trunks that it thinks are in a "hung" state. The RESTART message brings the trunk to an idle condition. |

- j. An ISDN trunk selected by the near-end has been rejected 10 times by the far-end without a successful call. This may indicate a service state mismatch between the near-end and far-end for this trunk that is effecting the end user (that is, customer receives unexpected intercept tones when accessing ISDN trunks). This may indicate that the ISDN trunk is not administered on the far-end.

The Aux field contains the physical name of the ISDN trunk in decimal. Then, verify that the far-end has this trunk administered. If problems persist, then busy-out the ISDN trunk to take it out of the hunt group.

The Warning alarm will be retired automatically whenever an outgoing or incoming call that uses this trunk is answered by the called endpoint. If problems persist, then busy-out the ISDN trunk to take it out of the hunt group.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

---

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-230. System Technician-Demanded Tests: ISDN-TRK

| Order of Investigation                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)                |                     | X                  | ND                |
| Conference Circuit Test (#7)           |                     | X                  | ND                |
| Audit and Update Test (#36)            | X                   | X                  | ND                |
| Signaling Link State Check Test (#255) | X                   | X                  | ND                |
| Service State Audit Test (#256)        | X                   | X                  | ND                |
| Call State Audit Test (#257)           | X                   | X                  | ND                |
| ISDN Test Call Test (#258)             |                     | X                  | ND                |

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

 **NOTE:**  
The TN464C or later UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                           |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                               |
| 1000       | ABORT       | System resources required for this test are not available. The port may be in use on a valid call. Use <b>status station</b> or <b>status trunk</b> commands to determine when the port is available for testing.<br>1. Retry the command at 1-minute intervals a maximum of 5 times. |

Table 10-231. TEST #6 NPE Crosstalk Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1001       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                      |
| 1002       | ABORT       | The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-Bus errors. Refer to TDM-Bus Maintenance to diagnose any active TDM-Bus errors.<br>1. If the system has no TDM-Bus errors and is not handling heavy traffic, repeat the test at 1-minute intervals a maximum of 5 times.                                                                                                         |
| 1003       | ABORT       | The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service.<br>1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation.<br>2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation.<br>3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times. |
| 1004       | ABORT       | The port has been seized by a user for a valid call. Use <b>status station</b> or <b>status trunk</b> commands to determine when the port is available for testing.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                      |
| 1018       | ABORT       | Maintenance is disable on this trunk.<br>1. Enable maintenance by entering “y” in the “Maintenance Tests?” field on page 2 of the <b>change trunk-group</b> form.                                                                                                                                                                                                                                                                                                                            |
| 1117       | ABORT       | A service state audit message is outstanding.<br>1. Wait two minutes and then try again.                                                                                                                                                                                                                                                                                                                                                                                                     |
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                          |
| 2020       | ABORT       | The test did not run due to an already existing error on the specific port or a more general circuit pack error.<br>1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.                                                                                                                                                                                                                                       |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                      |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                     |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Any        | FAIL        | The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. The ISDN-TRK is moved to out-of-service/near-end state.<br><br>1. Replace the circuit pack. |
|            | PASS        | The port is able to communicate over the TDM Bus.                                                                                                                                                               |

Conference Circuit Test (#7)

The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

 **NOTE:**  
The TN464C or later UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.

|            | PASS        | The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.                                                             |

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 interface circuit pack to assure that the trunk’s translation is correct. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 interface circuit pack and in the switch software.

|            | PASS        | Trunk translation has been updated successfully. The current trunk states kept in the DS1 interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run, but will return PASS. To verify that the trunk is in-service:<br><br>1. Enter <b>status-command</b> to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2.<br><br>2. Enter <b>release-trunk</b> command to put trunk back into in-service.<br><br>3. Retry the test command. |

Signaling Link State Check Test (#255)

As noted in the general description for a DS1 ISDN Trunk, it depends on the health of the DS1/UDS1 interface circuit pack and the ISDN-PRI D-channel (ISDN-LNK/ISDN-PLK) trunk for proper operation. This test checks the status of those critical elements.

|            | PASS        | The signaling link hardware is OK.                                                                                                                                                                                                                                                                                                                                                                       |

Service State Audit (#256)

These trunks may be in one of several service states. This test performs a Service State Audit with the far-end switch.

For interfaces using country protocol 1 (including US), the Service State Audit executes in all trunk service states. A message is sent to the far-end switch to ensure that both sides agree on the service state. A PASS for this test simply means that the message has been successfully sent. Two minutes are allowed for a reply. If no reply is received within that 2 minute window, the message is sent out again. If that attempt fails, an error is logged (Error Type 3073) and the switch then attempts another Service State Audit every 15 minutes. If the trunk was initially INS (in-service), it is then placed in the MTC/FE (maintenance state, far-end problem) state. No outgoing calls are placed over this trunk, but incoming calls are accepted. If an incoming call is presented while in such a state, a Service State Audit attempt is immediately attempted (that is, the switch does not wait for the 15-minute cycle, but tries to recover immediately).

For interfaces not using country protocol 1, the Service State Audit executes only if the trunk is in the OOF/FE state. A message is sent to the far-end switch to

attempt to bring the trunk back into the in-service state. A PASS for this test simply means that the message has been successfully sent. Two minutes are allowed for a reply. If no reply is received within that two minute window, the message is sent out once again. If no response is received in the next two minute window, then the trunk remains in the OOS/FE state. The switch will attempt another Service State Audit in another hour.

To investigate the service state of the DS1 ISDN Trunk, issue the **status trunk trunk-group/trunk-member** command.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | Wait 4 minutes and then check the Error Log for any new errors of type 3073. If there are none, then both sides of the ISDN connection agree on the service state; the negotiation succeeded. If there is a new 3073 error, then the negotiation failed (the far-end switch twice failed to respond within 2 minutes). The switch will automatically retry every 15 minutes. If the trunk was initially in-service, it is now placed in the maintenance/far-end state. Incoming calls will be accepted, but no outgoing calls can be originated. If an incoming call is presented, another Service State Audit will be immediately performed in an attempt to put the DS1 ISDN Trunk in the proper state. |

Call State Audit Test (#257)

If a call is active on the trunk, the switches on both sides of the connection should agree on the ISDN state of the call, as defined in the ISDN Protocol Specification. This test audits internal call state data by querying the far-end switch as to the ISDN state of the call. It can be helpful when trying to clear a hung call. If the internal call state data on the near-end switch is different than that of the far-end switch, then **the call will be torn down**.

As with Test #256 (Service State Audit), a PASS simply means that an appropriate message was composed and sent to the far-end switch. The ISDN Specification allows up to two minutes for a reply. If a reply is not received within the two minute window, a protocol time-out violation will be recorded in the error log against the associated signaling channel (ISDN-PRI Signaling Link Port, which is listed in the Error Log as ISDN-LNK/ISDN-PLK; the Error Type is 1).

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1113       | ABORT       | The signaling link has failed, so the system cannot send any messages on behalf of this trunk.<br>1. Check the results of Test #255 (Signaling Link State Check).                                                                                                  |
| 1114       | ABORT       | The signaling link is in a transitional state.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                 |
| 1116       | ABORT       | The trunk is in an out-of-service ISDN service state.<br>1. A call cannot be present if the trunk is in an ISDN out-of-service state, so a call state audit would be inappropriate. No action necessary. (Use the <b>status trunk</b>                              |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                            |
|            | FAIL        | Internal system error<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                          |
|            | PASS        | This switch sent a call state auditing message to the far-end switch to verify the state of the call active on this trunk. If a call state mismatch is found, then the call will be torn down within two minutes. If no call was active, then no message was sent. |

ISDN Test Call Test (#258)

This test performs a far-end loop around to a far-end switch over an ISDN trunk. The trunk's service state must be in-service, maint-NE, or out-of-service/NE, and no call can be active on the trunk. The test call can be initiated as part of a long test sequence, or as an individual test, as described below. This test is valid only for systems using country protocol 1 (including US), or when the far end has loop-around capability.

A test call connection is established to a far-end switch over the ISDN trunk to be tested. The digital port on a TN711D Maintenance/Test circuit pack generates a test-pattern bit stream which is sent to the far-end switch and echoed back. The received pattern is then compared to the sent pattern and checked for errors that indicate a loss of integrity on the communications path.

If a test call is running when scheduled maintenance starts, the green LED is turned off. To determine if a test call is still running, use the **list isdn-testcall** and **status isdn-testcall** commands. A lit yellow LED on the Maintenance/Test circuit pack also indicates that a test call is running.

There are two methods available to place an outgoing ISDN-PRI test call in G3iV1.1-286 and G3iV2-386.

In the first method, the test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN-PRI trunk to a data channel. This method is selected when no Maintenance/Test circuit pack resides in the system.

In the second method, the test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN-PRI trunk to a digital trunk testing port on the Maintenance/Test circuit pack. The Maintenance/Test Digital Port generates a pseudo bit stream. A pictorial description of the outgoing ISDN-PRI test call connectivity is contained in the following figure.

Figure 10-61. ISDN-PRI Outgoing Test Call

Synchronous Commands

You can demand a synchronous outgoing test call by using the following maintenance commands:

- test trunk trunk-group-no/member-no long [repeat number]
- test board board-location long [repeat number]
- test port port-location long [repeat number]

Whenever a circuit translates to an ISDN-PRI trunk during a Long Test Sequence, an outgoing test call is invoked. If the B-channel is unrestricted (B8ZS or HDB3) the default duration of the test call is 8.6 seconds. Otherwise, if the B-channel is restricted (ZCS) the default duration of the test call is 9.4 seconds. Once the test call completes, the bit error rate is retrieved from the Maintenance/Test Digital Port. A bit error rate greater than zero is reported as a failure to the Manager I terminal (MGRI). A failure indicates the need to run further diagnostics, such as the **test isdn-testcall** command.

If no Maintenance/Test circuit pack exists, the outgoing ISDN-PRI test call is established over a high speed data channel on the Network Control (NETCON) circuit pack (DATA-BD).

Asynchronous Commands

You can start, query, and stop an outgoing test call by using the following maintenance commands:

- **test isdn-testcall trunk-group-no/member-no [ minutes ]**  
This command enables you to start an outgoing ISDN-PRI test call for a maximum of two hours (120 minutes).
- **status isdn-testcall trunk-group-no/member-no**  
This command displays the progress of the outgoing test call by reporting the bit and block error rates of the tested B-channel specified by the "trunk group no/member no" identifier.
- **clear isdn-testcall trunk-group-no/member-no**  
This command enables you to stop an outgoing test call already in progress. The **trunk-group-no/member-no** identifier specifies the B-channel used to stop the test call. The measurements are not cleared until the next test call begins.

 **NOTE:**  
Only one trunk can be tested in a given port network, until the test call is canceled or completes.

Table 10-237. TEST #258 ISDN TEST Call — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | The call worked. A test pattern was sent and received properly; the communications path is OK if the synchronous test call command was issued. If the <b>test isdn-testcall</b> command was issued, a PASS indicates that the test call was established. A <b>status isdn-testcall</b> command must be invoked to query the bit and block error rates to determine if the test call passed. An in-depth analysis of the DS1 facility including the transmission facility and any external equipment such as DACs, CSUs, etc., should take place if the bit and block error rates are not acceptable. |

## LOG-SVN (Login Security Violation)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO          |
|------------------------------------|-------------|-------------------------------------------------------|--------------------------|
| LOG-SVN                            | MAJOR       | enable login <login ID>                               | Login Security Violation |

1. Where <login ID> is the AT&T services login ID for which the security violation was detected. The *Alt Name* field indicates the login ID associated with the security violation and the major alarm.

The Security Violation Notification (SVN) feature provides notification when the number of failed attempts to access the system administration/maintenance interface meets or exceeds customer administered threshold parameters.

A major alarm is logged whenever a security violation is detected involving an AT&T services login ID and that login ID has been disabled as a result of the security violation. The capability to disable a login ID following detection of a security violation involving that login ID is administrable on a per login ID basis.

Refer to *DEFINITY Communications System Generic 3 Version 5 Implementation*, Issue 1 (555-230-656) for information on administration required for the Security Violation Notification feature and the option to disable a login ID following detection of a security violation involving the affected login ID.

### Hardware Error Log Entries and Test to Clear Values

Table 10-238. Hardware Error Log Entries and Test to Clear Value

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value     |
|------------|----------|-----------------|-------------|--------------|-------------------------|
| 1-15       | None     | None            | Major       | OFF          | enable login <login ID> |

### General Information about log-svn Error Log Entries

- a. The number (1 - 15), that appears in the error type field, corresponds to the location the login in the internal login data structure.
- b. The *Alt Name* field on the alarm report indicates the login ID associated with the security violation and major alarm.

- c. These errors/alarms are associated with a number of failed attempts to access the system management/maintenance interface using an AT&T services login ID that meet or exceed the customer administered threshold parameters. The associated alarm is immediately raised as a major alarm.
- d. The affected login ID will be disabled as a result of detection of the security violation, unless it is the last enabled INADS type login on the system. The provision to disable a login ID following detection of a security violation involving that login ID is administrable on a login ID basis.
- e. The *enable login* command is used to both enable a login that has been disabled, and to retire any login security violation alarms associated with the login ID.
- f. Use of the *enable login* command to enable a login and/or retire alarms must be executed using a login ID with greater service level hierarchy permissions.
- g. Access to the *enable login* command is controlled through the Administer Permissions field on the Command Permission Categories form. This field (Administer Permissions) must be set to "y" to access the enable login command.
- h. The *Port* alarm report field will set to the port where the final invalid login attempt, involving the alarmed login ID, was detected. Valid port values for G3i products include:
  - MGR1 — Dedicated manager 1 or G3 management terminal connection
  - NET-n — Network controller dial up port
  - INADS — INADS port
  - EPN — EPN maintenance EIA port
  - EIA — Other EIA port

Valid port value for G3r products include:

- SYSAM\_LOC — Local administration port
  - YSAM\_RMT — Remote administration port
  - SYS\_PORT —
  - MAINT — Maintenance port
- i. The *Svc State* alarm report field will be set to OUT if the login ID is in the disabled state as a result of detection of a security violation involving the login ID. Once the login ID has been enabled, the field will be set to IN.
  - j. The source or reason of the failed login attempts should be identified and the cause corrected prior to re-enabling a login ID and/or retiring any alarms associated with the login ID. The cause may be something as

innocuous as the failure of AT&T services automatic login software, to something as insidious as a hacker attempting to gain access to the switch system management interface.

The login ID associated with that alarm is displayed in the *Alt Name* field of the alarm report.

Prior to retiring an SVN alarm and enabling the associated login ID, the *monitor security-violations login* command can be used to access information about the invalid login attempts that caused the security violation. This information can be useful in determining the source of the invalid attempts and analyzing why they occurred.

The *list logins* command provides status information about logins on the system. If a login has been disabled as a result of a security violation, the status will be "svn-disabled."

## **Procedure to Retire an SVN Alarm**

---

To retire a SVN alarm:

1. Enter the command **enable login <login ID>**.

The login ID associated with that alarm is displayed in the *Alt Name* field of the alarm report and the alarm is retired.

## JNL-PRNT (Journal Printer Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run          | Full Name of MO      |
|------------------------|-------------|---------------------------------|----------------------|
| PMS-PRNT/JNL-PRNT      | MINOR       | test journal pms-log/wakeup-log | Journal Printer Link |
| PMS-PRNT/JNL-PRNT      | WARNING     | test journal pms-log/wakeup-log | Journal Printer Link |

 **NOTE:**  
Since the maintenance strategy for both the JNL-PRNT (Journal Printer Link) and PMS-PRNT (PMS Printer Link) MO is the same, both of these MOs are described in the PMS-PRNT/JNL-PRNT Maintenance documentation.

# MAINT (EPN Maintenance Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO              |
|------------------------|-------------|------------------------|------------------------------|
| MAINT                  | MINOR       | test maintenance sh    | EPN Maintenance Circuit Pack |
| MAINT                  | MAJOR       | test maintenance l     | EPN Maintenance Circuit Pack |

The EPN Maintenance circuit pack monitors and supports environmental maintenance for the EPNs. The EPN Maintenance circuit pack provides the switch software, a mechanism to enable and disable Emergency Transfer in the EPN (assuming the Emergency Transfer Switch is in the AUTO position). The EPN Maintenance circuit pack invokes Emergency Transfer when the EPN loses contact with the PPN or the EPN Maintenance circuit pack loses contact with all Expansion Interface circuit packs. When AC power fails in the EPN cabinet, no power holdover is available. If an Expansion Interface circuit pack goes insane and is reset six times within 15 minutes, the EPN Maintenance circuit pack holds the Expansion Links reset (which prevents the Expansion Interface circuit pack from running).

The EPN Maintenance circuit pack provides system level alarm LEDs which indicate the absence or presence of Major, Minor, and Warning alarms within the entire system (PPN and EPN).

The EPN Maintenance circuit pack supports a G3MT terminal which runs at 9600 baud. However, the system software throttles the rate of data flow to the EPN Maintenance circuit pack for display on the terminal to about 1200 baud. All system commands can be executed via the EPN terminal. However, due to the slow speed at which the software runs the terminal, it is recommended that the EPN terminal's primary use be for system maintenance rather than system administration.

The PPN communicates with the EPN Maintenance circuit pack using the following path (messages from the EPN Maintenance circuit pack to the PPN take exactly the reverse path). From the PPN, TN773 Processor circuit pack, EPN Maintenance circuit pack messages are passed to the Switch Control on the Network Control circuit pack over the Memory Bus (MBUS) and then over the TDM Bus to the Active PPN Expansion Interface circuit pack. The Active PPN Expansion Interface circuit pack passes the message across the fiber to the Active EPN Expansion Interface circuit pack. The Active EPN Expansion Interface circuit pack then passes the message over a serial link to the EPN Maintenance circuit pack. [Figure 10-62](#) illustrates this path.

In [Figure 10-62](#), PROCR means a TN790 for a RISC Processor circuit pack, NETCON is the Network Control circuit pack (TN777B) (the Active NETCON circuit pack in a high or critical reliability system), and MB stands for the EPN Maintenance circuit pack. [Figure 10-62](#) shows the connectivity for a system with duplicated Expansion Interface Links.

**Figure 10-62. EPN Maintenance Circuit Pack Message Flow**

The EPN Maintenance circuit pack must be physically inserted into the dedicated slot marked Maintenance in the A carrier of the EPN. The serial links from the EPN Maintenance circuit pack to the Expansion Links physically connect from this dedicated slot to slots 2A01 and 2B02 (2B02 is used only if there are redundant Expansion Links). The serial link from slot 2A01 to the maintenance slot is hard-wired into the backplane of carrier A, whereas the serial link from slot 2B02 to the maintenance slot is a ribbon cable connecting the two slots. The serial link from the EPN Maintenance circuit pack to the terminal is also a ribbon cable which plugs into a connector labeled TERM on the back of carrier A.

The maintenance strategy for the EPN Maintenance circuit pack consists of checking the integrity of the communications path to/from the EPN Maintenance circuit pack, testing individual hardware components on the EPN Maintenance circuit pack, and keeping the system level LEDs up-to-date. The individual hardware components include the serial interfaces which handle the serial links connected to the EPN Maintenance circuit pack. There are three serial interfaces, one for each possible Expansion Interface circuit pack and one for the Manager I (G1) or G3MT terminal.

Since the EPN Maintenance circuit pack supports environmental maintenance in the EPN, trouble with the EPN Maintenance circuit pack can cause environmental maintenance to falsely detect problems. These environmental MOs include DC-POWER, EMG-XFER, EXT-DEV, and CUST-ALM.

Since communication to the EPN Maintenance circuit pack flows through the SW-CTL (Switch Control) and the EXP-INTF (Expansion Interface) circuit packs, any problems with these MOs can prevent communication with the EPN Maintenance circuit pack.

If a repair procedure calls for the EPN Maintenance circuit pack to be replaced, and the EPN has redundant Expansion Links, use the following procedure to prevent an Expansion Links switch when the new EPN Maintenance circuit pack is plugged in.

1. Determine the Standby Expansion Links by using the **status system** command.
2. Busyout the Standby Expansion Links by issuing the **busyout board PCSS** command where PCSS is the 4-character circuit pack address of the Expansion Interface circuit pack in the EPN on the Standby link.
3. Replace the EPN Maintenance circuit pack.
4. Release the Standby Expansion Links by issuing the **release board PCSS** command, where PCSS is the 4-character circuit pack address of the Expansion Interface circuit pack in the EPN on the Standby link.

Error Log Entries and Test to Clear Values

Table 10-239. EPN Maintenance Circuit Pack Error Log Entries

| Error Type     | Aux Data | Associated Test                                | Alarm Level | On/Off Board | Test to Clear Value     |

- 
1.

Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2.

Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a.
- A value of 0 indicates the Expansion Link in the A carrier was active when this error occurred. A value of 1 indicates the Expansion Link in the B carrier was active when this error occurred. To clear this problem, make sure the Active Expansion Link is the same as that indicated by the Aux Value.
- b.
- Multiple values can appear in the Aux Data field. There are other errors in the log if there is a real problem. Use these other errors to troubleshoot the problem.
- c.
- The serial link between the Expansion Link in the A carrier and the EPN Maintenance circuit pack is defective.
- d.
- The serial link between the Expansion Link in the B carrier and the EPN Maintenance circuit pack is defective.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Sanity Handshake Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| Sanity Handshake Test (#106)                         | X                   | X                  | ND                |
| Network Control Circuit Pack DPR Test (#104) (a)     |                     | X                  | D                 |
| EPN Maintenance Circuit Pack Reset Test (#306)       |                     | X                  | D                 |
| Serial Channel Local Loop Around Test (#229)         | X                   | X                  | ND                |
| MGR I Channel Local Loop Around Test (#228)          |                     | X                  | D                 |
| EPN Maintenance Circuit Pack Sanity Maze Test (#303) | X                   | X                  | ND                |
| EPN Maintenance Circuit Pack Serial Link Test (#337) | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

- Note:
- a. If you are invoking the Long Test Sequence from the EPN terminal, Test #104 causes the system technician terminal to be logged off, and Test #306 is not run as part of the test sequence. Test #104, however, causes Test #306 to run in an attempt to bring the EPN Maintenance circuit pack back to a known state. After the test sequence runs, the Error Log should be examined for MAINT errors of type 1 and 3073 to determine if the Network Control Circuit Pack DPR Test and EPN Maintenance Circuit Pack Reset Test failed.
- If you are invoking the Long Test Sequence from the PPN, all tests listed are run and their results are displayed on the PPN terminal. The EPN terminal is still logged off.

Network Control Circuit Pack Dual Port Ram  
(DPR) Test (#104)

This test is destructive.

When executed, this test drops the EPN Manager I (G1) or G3MT terminal login. The login prompt reappears if the test passes successfully.

The Dual Port Ram (RAM), memory shared by the TN777 Processor circuit pack and the Network Control circuit pack, is tested to ensure that it can be read from

and written to. EPN Maintenance circuit pack maintenance utilizes the DPR on the Network Control circuit pack for placing messages that eventually get passed along to the Expansion Interface circuit pack in the EPN cabinet and subsequently to the EPN Maintenance circuit pack in the EPN cabinet.

**Table 10-240. TEST #104 Network Control Circuit Pack Dual Port Ram (DPR) Test**

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                        |

| 10401      | ABORT       | Test disabled using a software patch.                                                                                                                                                                                                                                                                                                                             |
|            | FAIL        | The test failed.<br><br>1. Since a portion of the Network Control circuit pack (the Dual Port Ram) is actually being tested here, run the Short Test Sequence against the Network Control circuit pack (SW-CTL) and follow the maintenance procedures for Test #325.                                                                                              |
| 2000       | FAIL        | Response to the test request was not received within the allowable time period.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                           |
|            | PASS        | The communication to the EPN Maintenance circuit pack is good at least up to the Network Control circuit pack. If there are still problems communicating with the EPN Maintenance circuit pack, then these problems must be with either the EXP-LINK (Expansion Links), EXP-INTF (Expansion Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack. |

**Sanity Handshake Test (#106)**

This test checks the EPN Maintenance circuit pack's ability to respond to queries. A message is sent to the EPN Maintenance circuit pack which then sends a message back. If the response message is received, then the EPN Maintenance circuit pack is queried for the EPN cabinet type. The EPN Maintenance circuit pack reads pins on the backplane of carrier A that identify the type of cabinet and report this information. If a valid cabinet type is returned, then the test passes.

Table 10-241. TEST #106 Sanity Handshake Test

| Error Code                   | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

| Error Code | Test Result       | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL<br>(cont'd.) | <div>2. If the -5 volt unit is good and this test continuously fails, background maintenance automatically escalates to an EPN Maintenance circuit pack Reset (Test #306). Otherwise, you can manually invoke an EPN Maintenance circuit pack Reset by issuing the <b>test maintenance long</b> command and evaluating any generated error codes from Test #306. If Test #306 passes, this test should also PASS. Otherwise, use the following steps to determine if the EPN Maintenance circuit pack, or the serial link to the EPN Maintenance circuit pack, is defective:</div> <div><div>■ Duplicated Expansion Links:</div><div><div>1. Determine which serial link is the standby by issuing the <b>status system</b> system technician command.</div><div>2. Switch Expansion Links by entering <b>set expansion-link PCSS</b> where PCSS is the 4-character Expansion Interface circuit pack location for the Standby link.</div><div>3. Run the Short Test Sequence against the EPN Maintenance circuit pack. If Test #106 still fails, replace the EPN Maintenance circuit pack and retest. Otherwise, follow the error routines for any errors that are logged by this Short Test.</div></div><div><div>■ Single Expansion Interface Link Switch:</div><div><div>1. Replace the EPN Maintenance circuit pack and invoke the Short Test Sequence.</div><div>2. If error persists, replace the EPN Expansion Interface circuit pack, <b>at a time when the EPN can go down with minimal inconvenience</b>.</div><div>3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the EPN Maintenance circuit pack.</div></div></div></div> |
|            | PASS              | The communications path to and from the EPN Maintenance circuit pack is sane, and the EPN Maintenance circuit pack can read and report the correct EPN cabinet type. The EPN Maintenance circuit pack may still have problems related to Tests #228, #229, #303, or #306.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

MGR I Channel Local Loop Around Test (#228)

This test is destructive.

This test checks the on-board circuitry of the EPN Maintenance circuit pack associated with the serial link for the terminal connection. This test does not cause the terminal to become disconnected. However, any data being displayed

on the terminal while the test is running is lost. [Figure 10-63](#) shows the three serial interfaces on the EPN Maintenance circuit pack and is meant to clarify that only the one dealing with the EPN terminal is being tested.

Figure 10-63. EPN Manager I (G1) or G3MT Connection

Table 10-242. TEST #228 MGR I Channel Local Loop Around Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                              |

|            | PASS        | <p>The serial interface circuitry on the EPN Maintenance circuit pack which controls the EPN Manager I (G1) or G3MT terminal is functioning properly. If there are still troubles with the EPN Manager I (G1) or G3MT terminal, the problem may be one of the following:</p> <ol style="list-style-type: none"><li>1. The EPN Manager I (G1) or G3MT terminal is not configured properly. The connection between the EPN Manager I (G1) or G3MT and the EPN Maintenance circuit pack must be set up at 9600 baud.</li><li>2. The serial link from the back of carrier A to the EPN management terminal may be defective. The serial link consists of the connector on the back of carrier A labeled TERM and the ribbon cable running to the EPN terminal.</li><li>3. The EPN terminal may be defective. Try another terminal.</li><li>4. Since this test is not 100 percent accurate, there may still be problems with the EPN Maintenance circuit pack.</li></ol> |

Serial Channel Local Loop Around Test (#229)

This test checks the on-board circuitry of the EPN Maintenance circuit pack associated with the serial links to the Expansion Interface circuit pack. [Figure 10-64](#) shows the three serial interfaces on the EPN Maintenance circuit pack and is meant to clarify that the two dealing with the Expansion Links are being tested. A request is sent to the EPN Maintenance circuit pack over the Active link via the Active Expansion Interface circuit pack serial interface circuitry to test the serial interface circuitry of the standby Expansion Interface circuit pack link. If a response is received, then by definition the serial interface circuitry associated with the Active link is good.

|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p>The on-board circuitry associated with the Standby serial link is defective. Since the EPN Maintenance circuit pack reported this failure, the on-board circuitry associated with the Active serial link is functional.</p> <ol style="list-style-type: none"><li>This test checks the circuitry on the EPN Maintenance circuit pack associated with the Standby Expansion Interface link.<ul style="list-style-type: none"><li>In a switch without duplicated Expansion Links, current service is not affected because the circuitry failing is not being used. Nevertheless, a Minor alarm remains in the Alarm Log against MAINT. Therefore, the EPN Maintenance circuit pack must be replaced.</li><li>In a switch with duplicated Expansion Links, service is not affected as long as you DO NOT SWITCH LINKS; otherwise, the connection to the EPN Maintenance circuit pack is lost. Losing the EPN Maintenance circuit pack connection means loss of the EPN Manager I (G1) or G3MT and EPN Environment maintenance. If an Expansion Links switch does occur, the software probably switches the links back, based on the relative health of each link. The EPN Maintenance circuit pack must be replaced to correct this problem.</li></ul></li></ol> |
|            | PASS        | <p>The on-board circuitry associated with both Expansion Interface circuit pack serial links is good. If there is still a problem communicating with the EPN Maintenance circuit pack, check the following:</p> <ol style="list-style-type: none"><li>The cable comprising the serial link (B carrier Expansion Interface circuit pack to EPN Maintenance circuit pack only) may be defective.</li><li>The EPN Maintenance circuit pack may actually be defective.</li></ol> <p> <b>NOTE:</b><br/>This test may not be 100 percent accurate.</p> <ol style="list-style-type: none"><li>The Expansion Interface circuit pack on the Standby link may be defective.</li></ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

EPN Maintenance Circuit Pack Sanity Maze Test  
(#303)

The EPN Maintenance circuit pack processor has direct access to special registers in the EPN Maintenance circuit pack. These registers are tied to such things as the Expansion Interface circuit pack reset leads and Carrier Port Power Unit reset leads (which enable the EPN Maintenance circuit pack to recycle carriers). To prevent an insane EPN Maintenance circuit pack from inadvertently controlling these external devices, a special interface called the Sanity Maze is provided that must first be navigated by the EPN Maintenance circuit pack

processor prior to any register access. There are two parts to the test. Part 1 involves navigating the Sanity Maze to toggle an unused lead. Part 2 attempts to toggle an unused lead without first navigating the Sanity Maze. The Sanity Maze test passes if Part 1 is successful and Part 2 fails.

Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|            | FAIL        | The Sanity Maze of the EPN Maintenance circuit pack is defective.<br>1. Replace the EPN Maintenance circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|            | PASS        | The Sanity Maze is working properly, and the EPN Maintenance circuit pack can access the unused register. If <b>recycle carrier</b> commands (for EPN carriers) do not work, the following problems may still exist:<br><br>1. The Carrier Port Power Unit or wiring to the Carrier Port Power Unit may be defective. Refer to CARR-POW (Carrier Port Power Unit) Maintenance documentation.<br><br>2. Since this test only tests the EPN, there is a very small probability that the EPN Maintenance circuit pack cannot access those registers that deal with EPN devices. The EPN Maintenance circuit pack may need to be replaced. |

EPN Maintenance Circuit Pack Reset Test (#306)

This test is destructive.

The EPN management terminal is dropped and, if the Emergency Transfer switch is in the AUTO position, Emergency Transfer is disabled for the duration of the test.

The EPN Maintenance circuit pack is reset by the Active Expansion Interface circuit pack. After the Expansion Interface circuit pack reports that the EPN Maintenance circuit pack has reset, a handshake message is sent to the EPN Maintenance circuit pack. If the EPN Maintenance circuit pack responds to the handshake, the test passes. If not, it fails. If the test passes, the EPN Manager I (G1) or G3MT is brought back up, and Emergency Transfer is restored to its previous state.

Table 10-245. TEST #306 EPN Maintenance CP Reset Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2005       | FAIL        | <p>EPN Maintenance Circuit Pack Reset passed, but the EPN Maintenance circuit pack did not respond to subsequent handshake message. Retry this command three more times. If it continues to fail, the EPN Maintenance circuit pack, the Active Expansion Interface circuit pack, or the serial link is defective. To determine which is defective, follow the appropriate procedures outlined below.</p> <ul style="list-style-type: none"><li>■ Duplicated Expansion Links:<ol style="list-style-type: none"><li>1. Determine which serial link is the Standby by issuing the <b>status system</b> system technician command.</li><li>2. Switch Expansion Links by entering <b>set expansion-link PCSS</b> where PCSS is the 4-character Expansion Interface circuit pack location for the Standby link.</li><li>3. Run the Short Test Sequence against the EPN Maintenance circuit pack. If Test #306 still fails, replace the EPN Maintenance circuit pack and retest. Otherwise, follow the error routines for any errors that are logged by this Short Test Sequence.</li></ol></li><li>■ Single Expansion Interface Link Switch:<ol style="list-style-type: none"><li>1. Replace the EPN Maintenance circuit pack and invoke the Short Test Sequence.</li><li>2. If the error persists, replace the EI circuit pack, <b>at a time when the EPN can go down with minimal inconvenience</b>.</li><li>3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the EPN Maintenance circuit pack.</li></ol></li></ul> |
|            | PASS        | <p>The Active Expansion Interface circuit pack can reset the EPN Maintenance circuit pack. This implies the EPN Maintenance circuit pack, the Active Expansion Interface circuit pack, and Active serial link are sane. There could still be a problem with the Standby Expansion Interface circuit pack and Standby serial link in a High or Critical Reliability system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

EPN Maintenance Circuit Pack Serial Link Test  
(#337)

This test is destructive.

This test checks the serial link from the Standby Expansion Interface circuit pack to the EPN Maintenance circuit pack. If there is no Standby link, or the Standby link is down at the time of the test, this test aborts.

**⇒ NOTE:**  
The status of the link is changed to "down" when the Standby Expansion Interface circuit pack begins initialization tests (for example, after being resealed). The link status is then updated at the conclusion of these tests.

**Table 10-246. TEST #337 EPN Maintenance Circuit Pack Serial Link Test**

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## MEM-BD (Memory)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| MEM-BD                 | MAJOR       | test memory l c        | Memory          |
| MEM-BD (a)             | WARNING     | test memory sh c       | Memory          |
| MEMORY (b)             | MAJOR       | test memory a/b sh c   | Memory          |

 **NOTE:**  
For memory problems on systems with a TN790 RISC processor circuit pack, see "PR-MEM."

Notes:

- a. Non-TN790 is on the processor circuit pack and not on a separate memory circuit pack. The maintenance object is "MEMORY" and not "MEM-BD." However, all references to MEM-BD in this section are applicable to "MEMORY" as well.

The Memory contains the DEFINITY software and firmware. The Processor circuit pack is the most critical component of all system operations.

- b. Non-TN790 systems contain memory that is integrated with the processor. For testing purposes, the circuit pack is logically separated into PR-MAINT, PROCR, and MEMORY. This means that a memory problem on 386 systems requires that the Processor be replaced. 386 systems contain two types of memory: Flash ROM and DRAM. Flash ROM is permanent memory that contains the boot image, PI firmware, and PACCON firmware. This type of memory is not erased during circuit pack resets. It can be reprogrammed only via the **upgrade software** command. DRAM is used for software data storage, and it changes constantly. DRAM loses its value during circuit pack resets. Both types of memory are present on the Processor circuit pack. The diagnostics run appropriate tests on both memories.

For all system activity, the Processor must be able to access the Memory. If the Processor cannot do this, the system goes into SPE-down mode. In SPE-down mode, fatal Memory errors may show up as Processor errors. This merely indicates that the Processor and the Memory are very closely linked as a matter of course.

If the initialization diagnostics fail, refer to the "Procedure for SPE-Down Mode" section in [Chapter 4, "Initialization and Recovery"](#).

Memory faults usually indict the Processor circuit pack (TN790) or the CPP1 circuit pack, however the problem may be on the TN786B.

Error Log Entries and Test to Clear Values

Table 10-247. MEM-BD (Memory) Memory Error Log Entries

| Error Type     | Aux Data | Associated Test               | Alarm Level | On/Off Board | Test to Clear Value   |
|----------------|----------|-------------------------------|-------------|--------------|-----------------------|
| 0 <sup>1</sup> | 0        | Any                           | Any         | Any          | test memory a/b l r 1 |
| 1-256          | Any      | Read All Memory Test (#85)    | MAJOR       | ON           | test memory a/b l r 5 |
| 257-512 (b)    | Any      | Read All Memory Test (#85)    | MAJOR       | ON           | test memory a/b l r 1 |
| 513 (c)        | 0        | Memory Detection/ Test (#87)  | MAJOR       | ON           | test memory a/b r 3   |
| 769 (d)        | Any      | Text Checksum Test (#86)      | MAJOR       | OFF/ON       | test memory a/b l r 2 |
| 1025 (e)       | Any      | Memory Functional Test (#332) | MAJOR       | ON           | test memory a/b l r 1 |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The "clear" option can replace the "repeat" option in a **test memory** command. For a High or Critical Reliability system, the carrier (a or b) must be specified. In all other systems, there is no need to specify the carrier.
- b. The Read All Memory Test (#85) failed. Refer to the FAIL section of this test. The error is associated with MEM-BD 1.
- c. The Memory Error Detection Test (#87) failed. Refer to the FAIL section of this test. The error is associated with MEM-BD 1.
- d. The Text Checksum Test (#86) failed. Refer to the FAIL section of this test. The error is associated with MEM-BD 1 and is an ON board alarm.
- e. There are Functional Test errors against both the Processor circuit pack and Memory. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate errors in the order in which they are presented in [Table 10-248](#). By clearing error codes associated with the *Read All Memory Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-248. MEM-BD (Memory) Order of Investigation

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|-------------------|
| Processor Non-maskable Interrupt Test (#82)(a)        | X                   | X                  | ND                |
| Processor ROM Checksum Test (#80) (a)                 | X                   | X                  | ND                |
| Processor Software Initiated Interrupt Test (#77) (a) | X                   | X                  | ND                |
| Processor Sanity Timer Test (#83) (a)                 |                     | X                  | D                 |
| MTP Outpulse Relay Test (#102) (b)                    | X                   | X                  | ND                |
| MTP Analog Loop Around Test (#103) (b)                | X                   | X                  | ND                |
| MTP Sanity Handshake Test (#106) (b)                  | X                   | X                  | ND                |
| MTPSAT Loop Around Test (#228) (b)                    | X                   | X                  | ND                |
| MTP Aux Loop Around Test (#229) (b)                   | X                   | X                  | ND                |
| MTP Reset Test (#101) (b)                             |                     | X                  | D                 |
| MTP Dual Port Ram Test (#104) (b)                     |                     | X                  | D                 |
| Read All Memory Test (#85)                            |                     | X                  | ND                |
| Memory Error Detection Test (#87)                     | X                   | X                  | ND                |

| Memory Functional Test (#332) (c)                     |                     | X                  | D                 |
| Memory Board Check Test (#631)                        | X                   | X                  | ND                |

Continued on next page

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to PROCRA (Processor) Maintenance documentation for a description of these tests [386 systems only].
- b. Refer to PR-MAINT (Maintenance/Tape Processor) Maintenance documentation for a description of these tests [386 systems only].

- c. This test is run only on the Standby SPE in a High or Critical Reliability system. On other systems or on the Active SPE, the test is run only via a **reset system 4** command or a **reset system 5** command.

Read All Memory Test (#85)

This test is a nondestructive test. The test reads every memory location in memory and writes it back. A failure of this test indicates a failure in the Processor or Memory circuit pack.

Table 10-249. TEST #85 Read All Memory Test

| Error Code                                                                           | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

Otherwise, the circuit pack and/or the two connectors that are used to connect the Expansion Memory circuit pack (if available) might become damaged.</i></p> |
|                                                                                      | PASS        | The Memory is healthy.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Text Checksum Test (#86)

This test is a nondestructive test. The test computes the checksum of the DEFINITY software text module, and it validates the operation of the flash ROM. A failure of this test indicates corruption of the Text.

Table 10-250. TEST #86 Text Checksum Test

| Error Code                                                                           | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

| 2058                                                                                 | FAIL        | <b>(G3iV1.1-286 system only).</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|                                                                                      | PASS        | The checksum is correct.                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

Memory Error Detection Test (#87)

This test is a nondestructive test. This test determines if the parity circuitry is working. Accordingly, the test determines if parity errors can be detected. The parity circuitry is used to detect DRAM memory failures.

Memory Functional Test (#332)

This test is destructive.

This test ensures that every DRAM memory location can be accessed and changed independently. Running this test wipes out all data in DRAM memory. This test is performed during a **reset system 4** or **reset system 5**. If the test fails during a **reset system** command, refer to the "Procedure for SPE-Down Mode" section of [Chapter 4, "Initialization and Recovery"](#), for the recommended maintenance strategy.

Table 10-251. TEST #332 Memory Functional Test

| Error Code                                                                           | Test Result | Description/Recommendation                                                                                                                                     |
|--------------------------------------------------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1000                                                                                 | ABORT       | System resources required to run this test are not available.<br>1. Repeat the command at 1-minute intervals a maximum of three times.                         |
| 1029<br>2014<br>2015<br>2016<br>2017<br>2018<br>2020<br>2022<br>2024<br>2025<br>2051 | ABORT       | Refer to "STBY-SPE" for a description of these error codes.                                                                                                    |
|                                                                                      | FAIL        | The Standby SPE Memory is defective.<br>1. Repeat the command at 1-minute intervals a maximum of 5 times.<br>2. The Processor circuit pack should be replaced. |
|                                                                                      | PASS        | The Standby SPE Memory circuit pack(s) is healthy.                                                                                                             |

Memory Board Check Test (#631)

This test always passes.

# MEMORY

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO |
|------------------------|-------------|------------------------|-----------------|
| MEMORY                 | MAJOR       | test memory a/b l c    | memory          |

Refer to MEM-BD (Memory Circuit Pack) for circuit pack level errors.

## MET-BD (MET Line Circuit Pack)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO       |
|------------------------------------|-------------|-------------------------------------------------------|-----------------------|
| MET-BD                             | MIN         | test board PCSS sh                                    | MET Line Circuit Pack |
| MET-BD                             | WRN         | test board PCSS sh                                    | MET Line Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also MET-LINE (MET Line) Maintenance documentation for related line information.

## MET-LINE (MET Line)

| MO Name As It<br>Appears in<br>Alarm Log | Alarm<br>Level | Initial System<br>Technician<br>Command to Run <sup>1</sup> | Full Name of MO |
|------------------------------------------|----------------|-------------------------------------------------------------|-----------------|
| MET-LINE                                 | MINOR          | test port PCSSpp l                                          | MET Line        |
| MET-LINE                                 | WARNING        | test port PCSSpp sh                                         | MET Line        |

1.
- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

Electronic Station is the user-friendly term to denote the MET (Multibutton Electronic Telephone) Station Set. The MET sets were originally introduced for use in earlier PBX systems but can now be used in Generic 1 switches.

The TN735 MET Line circuit pack supports four of these Multifunctional Electronic Sets. Each MET set uses three pairs of wires: an analog voice pair, a transmit pair, and a receive pair. Power is sent over the transmit and receive pairs. The MET Line circuit pack supports all 10-, 20-, and 30-button sets.

MET Line interactions are shown in [Figure 10-65](#).

**Figure 10-65. MET Line Interactions**

A change in the use of the Recall button on the MET set needs to be noted. Instead of being used as it was in earlier PBX systems, the Recall button is used in this system as a self-test button and, when pressed, lights all of the lamps on the MET set and runs the ringer update.

This section refers only to the MET-LINE (MET Line) maintenance that is performed. Note that MET-LINE (MET Line) maintenance is closely related to, and interacts with, the MET-BD (MET Line circuit pack) maintenance in some instances. Some of the results of maintenance testing of the MET Line may be affected by the health of the MET Line circuit pack. This interaction should be kept in mind when investigating the cause of reports of MET Line problems.

There are instances in this section where service states of a station are mentioned. It is helpful to understand what is meant by the different service states that may exist. An explanation of these service states follows:

- **Out-of-Service**—The port, and thus the station, have been removed from service. A busyout of a port causes it to be out-of-service.
- **Ready-for-Service**—Once a port on the circuit pack has been put into service, the voice terminal must communicate that it is present. The time between these two events is the time when the terminal is in the ready-for-service state.

- In Service—Once the system receives a message from the voice terminal communicating that it is present, the station is put into the in-service state. The terminal can also be forced into the in-service state if it goes off-hook while it is in the ready-for-service state.

When the **status station** command has been run, and the status screen appears, the status is reported as either out-of-service, in-service (as stated in the preceding list), or disconnect (the station is in the ready-for-service state).

Hardware Error Log Entries and Test to Clear Values

| MET Line Error Log Entries |          |                                       |                      |              |                         |
|----------------------------|----------|---------------------------------------|----------------------|--------------|-------------------------|
| Error Type                 | Aux Data | Associated Test                       | Alarm Level          | On/Off Board | Test to Clear Value     |
| 0 <sup>1</sup>             | 0        | Any                                   | Any                  | Any          | test port PCSSpp sh r 1 |

| 2049(g)                    | 32770    |                                       |                      |              |                         |
| 2049(h)                    | 40967    |                                       |                      |              |                         |
| 3840(i)                    | 40989    |                                       |                      |              |                         |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

2. Major or Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

### Notes:

- a. Indicates a defective data link. An off-board problem detected by port circuit. Make sure the MET set is connected, and that the EPF test passes. If data transmission problems are experienced, check for defective wiring, check for a defective voice terminal, and move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired due to the passing of time.
- b. This error is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout.
- c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- d. This indicates that the EPF has been turned off due to the overcurrent condition at the voice terminal. Check for defective wiring, check for a damaged jack, and make sure the voice terminal is a MET set. Once the problem has been resolved, the alarm is retired due to the passing of time.
- e. The particular station audit that causes this error type to be produced is the EPF inquiry audit. If the EPF inquiry receives an "epf-no-load" message a certain number of times, this error occurs and, if the EPF inquiry receives an "epf-on-ok" or an "epf-off-ok" message, it contributes to the resolution of this alarm.

This indicates that the voice terminal has probably been disconnected or that there is a problem in the wiring to the terminal. Make sure that the voice terminal is connected or check for defective wiring to the voice terminal.

- f. This indicates that something is wrong with the link to the voice terminal. An in-line maintenance error has generated an off-board Minor alarm. Ignore if there are no complaints. Otherwise, verify that the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack.
  - g. This indicates that the station went off-hook while it was in the ready-for-service state. Use the **status system** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No action is necessary.
  - h. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No action is necessary.
  - i. An uplink message being logged that the EPF is one with no load on it. No action is necessary.
-

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Port Diagnostic Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)                          |                     | X                  | ND                |
| Port Diagnostic Test (#35)                       |                     | X                  | ND                |
| MFAT Electronic Power Feed Test (#56)            |                     | X                  | ND                |
| Hybrid Circuit and Conference Circuit Test (#57) |                     | X                  | ND                |
| Station Lamp Update Test (#60)                   | X                   | X                  | ND                |
| Station Audits Test (#61)                        | X                   | X                  | ND                |
| Ringer Update Test (#62)                         | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-252. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.</li></ol> |

Port Diagnostic Test (#35)

This test checks a port's battery feed circuitry. The battery feed circuitry is tested for proper battery voltage by testing the switchhook state. In response to the test message, the on-board firmware terminates the line and checks for switch-hook presence. The termination is then removed, and a check is made for no switch-hook presence. The MET set must be on-hook for the test to execute.

Table 10-253. TEST #35 Port Diagnostic Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.</li></ol> |

MET Electronic Power Feed (#56)

In this test, the software requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit to the station. If no current is being drawn, this probably indicates that the station is not connected. If an overcurrent condition is sensed (that is, too much current is being drawn), this may indicate a short in the loop or a defective voice terminal. Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This test is repeated once more five seconds later. If either test is not successful, the test aborts.

Although this test will never actually return a fail result (except for the internal system error), an error type 257 entry will be made in the error log when the test has completed if the overcurrent case is detected by the hardware.

Table 10-254. TEST #56 MET Electronic Power Feed Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

| 1000       | ABORT       | <p>System resources required to run this test are not available. The port may be busy with a valid call. Use the <b>display port PCSSpp</b> command to determine the station extension, attendant number, or trunk group/member number of the port. Use the <b>status station</b>, <b>status attendant</b>, or <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in <a href="#">Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"</a> for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.</p> <ol style="list-style-type: none"><li>1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.</li><li>2. If the test continues to abort, escalate the problem.</li></ol> |

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted.</li></ol> |

MET Circuit and Conference Circuit Test (#57)

The MET Circuit Test checks the amount of reflection from the MET loop around circuitry and a Conference Test. The Tone-Clock circuit pack places a 1004-Hz tone on a time slot that the port circuit is listening on. A General Purpose Tone Detector (GPTD) is connected to another time slot that the same port circuit is talking on. The on-board microprocessor places the port in the loop around mode and the GPTD measures the level of the reflected signal.

The Conference Test is performed after the Circuit Test. The Conference Circuit Test verifies that the NPE is able to listen to several test tones and correctly conference them together, and the test is executed in two parts. The first half of the test checks the operation of the NPE's first three conference channels. The NPE is put in the loop around mode and instructed to talk on a selected time slot and to listen to the 1004-Hz tone using the first three conference channels. The signal level and noise level of the conferenced output are then measured using a GPTD and checked to verify that they are within an acceptable range.

The second half of the Conference Test checks the operation of the NPE's remaining four conference channels and follows the same procedure as above.

|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7          | FAIL        | <p>The conference circuit test failed. The conference circuit test is performed only if the hybrid test passes. The conference circuit test verifies that the network processing element (NPE) is able to correctly conference several test tones together. The test is executed in two parts. The first half of the test verifies the operation of the NPE's first three conference channels, while the second half verifies the NPE's remaining four conference channels. The test puts the NPE in loop around mode and instructs it to talk on a specified time slot while listening to a 1004 Hz tone, using the conference channels. A GPTD then measures the signal and noise levels of the conferenced output and reports whether or not these are within an acceptable range. The failure may be due to off-board circumstances, the most common of which is an off-hook occurring during the test. It is possible that the port may still be functional from a user's point of view. Also, check the error logs against the GPTD-BD, the TONE-BD, and the TONE-PT.</p> <ol style="list-style-type: none"><li>1. This error can be caused by a disconnected terminal. First, ensure that the terminal is connected and the wiring is OK.</li><li>2. Then, issue the <b>display port</b> and the <b>station status</b> commands to determine if the station is idle. If it is idle, issue the <b>test port</b> command for this port.</li><li>3. If test continues to fail, issue the <b>busyout port</b> and the <b>release port</b> commands, and then retest the port.</li></ol> |

MET Line Station Lamp Updates Test (#60)

For this test, the software lights the lamps on the terminal based on the status record contained in the processor. The lamp updates run only if the station is in-service.

Table 10-256. TEST #60 MET Line Station Lamp Updates Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

MET Line Station Audits Test (#61)

This is a series of three tests that are classified as audits. These audits abort if attempted on an out-of-service station. The tests are as follows:

- Switchhook Audit—This is an update of the SPE records according to the circuit packs' records.
- Bad Scan Inquiry—A message is sent uplink that contains a count that is generated due to certain events relating to the link conditions. This is an indication of data transmission problems between the MET Line circuit pack and the voice terminal.
- EPF Inquiry—The status of the EPF is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, EPF-no-load, and EPF-on-overcurrent.

Although this test will never actually return a fail result (except for the internal system error), it is possible that it will enter error types 257 (over current) or 513 (open circuit) into the error log. To determine if there are any problems that do not show up in the test result, look for these error types in the error log. If these errors appear in the error log or if user complaints still exist, investigate by using other circuit pack tests and by examining the station, the wiring, and the connections.

Table 10-257. TEST #61 MET Line Station Audits Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | Hybrid Line Station Audits passed.<br><br>1. Although this test always returns a PASS result, it may enter Error Types 257 or 513 into the Error Log. To determine if there are any problems that don't show up in the test result, look for these error types in the Error Log.<br><br>2. If these errors appear in the Error Log, or if user complaints still exist, investigate by using other circuit pack tests, and by examining the station, wiring, and connections.                                                                                                                                                                                                                                                                                                           |
| 0          | NO BOARD    | The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.<br><br>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.<br><br>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.<br><br>3. Issue the <b>reset board</b> command.<br><br>4. Issue the <b>release busy board</b> command.<br><br>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted. |

MET Line Ringer Update Test (#62)

In this update, a "ringer on" or a "ringer off" message is sent to the firmware to start and stop the ringer on the set.

**Table 10-258. TEST #62 MET Line Ringer Update Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3          | ABORT       | <p>This port may have been busied out by system technician.</p> <ol style="list-style-type: none"> <li>1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the <b>release station &lt;extension&gt;</b> command and run the test again.</li> <li>2. Make sure that the terminal is connected.</li> <li>3. Retry the command at one-minute intervals a maximum of five times.</li> <li>4. If the test continues to abort, escalate the problem.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 1000       | ABORT       | <p>System resources required to run this test are not available. The port may be busy with a valid call. Use the <b>display port PCSSpp</b> command to determine the station extension, attendant number, or trunk group/member number of the port. Use the <b>status station</b>, <b>status attendant</b>, or <b>status trunk</b> command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in <a href="#">Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"</a> for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.</p> <ol style="list-style-type: none"> <li>1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.</li> <li>2. If the test continues to abort, escalate the problem.</li> </ol> |
|            | FAIL        | <p>Internal System Error.</p> <ol style="list-style-type: none"> <li>1. Retry the command at one-minute intervals a maximum of five times.</li> <li>2. If the test continues to abort, escalate the problem.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

Use the <b>list config</b> command, and resolve any problems that are found.<br><br>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.<br><br>3. Issue the <b>reset board</b> command.<br><br>4. Issue the <b>release busy board</b> command.<br><br>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to ensure that there is a valid board inserted. |

# MIS (Management Information System)

| MO Name (In Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO               |
|------------------------|-------------|------------------------|-------------------------------|
| MIS                    | WRN         | release mis            | Management Information System |

The Management Information System (MIS)/Call Management System (CMS) MO is used only for administering MIS translations, such as trunks and stations. There are no hardware failures associated with this MO.

 **NOTE:**  
To diagnose MIS link hardware errors and alarms, see PI-LINK (Processor Interface Link) and PI-SCI (System Communication Interface) maintenance information.

The MIS/CMS is an adjunct processor that collects ACD data sent from the system. To change MIS translations, a system administrator must first enter a **busyout mis** command at the terminal. When the MIS is busied out, the system stops sending ACD data to the MIS, and a Warning alarm is raised. When finished, a **release mis** command should be entered at the terminal. This clears the Warning alarm and allows the switch to send ACD data to the MIS.

## Error Log Entries and Test to Clear Values

Table 10-259. Management Information System Error Log Entries

| Error Type     | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|----------|-----------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0        | Any             | Any         | Any          | release mis         |
| 18(a)          | 0        | busyout mis     | WARNING     | ON           | release mis         |

Continued on next page

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

- a. When the **busyout MIS** command is issued, no data is sent to the MIS/CMS regardless of the link state. To allow data to be sent to MIS/CMS, a **release mis** command must be issued from the terminal.

# MODEM-BD (Modem Pool Circuit Pack)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO         |
|------------------------------------|-------------|-------------------------------------------------------|-------------------------|
| MODEM-BD                           | MIN         | test board PCSS sh                                    | Modem Pool Circuit Pack |
| MODEM-BD                           | WRN         | test board PCSS sh                                    | Modem Pool Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also MODEM-PT (Modem Pool Port) Maintenance documentation for related port information.

## MODEM-PT (Modem Pool Port)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO |
|------------------------------------|-------------|-------------------------------------------------------|-----------------|
| MODEM-PT                           | MINOR       | test port PCSSpp sh                                   | Modem Pool Port |

1.
- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Modem Pool Port provides an interface for digital and analog data communication devices or ports connected to the PBX. It may be thought of as a PBX data communications "conversion resource" because it converts analog modem signals typically used in the telephone network into digital signals that are compatible with the internal PBX network and vice versa.

There may be a number of these conversion resources available in the PBX, each assigned to one of five available Modem Pool Groups. Only one conversion resource is used per data connection. The PBX software usually adds the conversion resource into a data connection if it determines that it is necessary for the call. Typical connections that include Modem Pool conversion resources include data calls from Analog Line or Central Office Trunk ports to any digital port or Digital Line or Trunk ports to any analog port. An example of a Data Module to Central Office Trunk connection using a Modem Pool conversion resource is shown in [Figure 10-66](#). When a local data call originates from an analog port normally used for voice service only and terminates on a digital port, a Data Origination access code must be dialed before the extension number for the Modem Pool conversion resource to be included in the connection.

Refer to [Figure 10-66 on page 10-910](#) while reading the following paragraph.

Each Modem Pool conversion resource contains two ports. One of these, an Analog Line Port, is connected (via the PBX network) to the Analog Line or Central Office Trunk Port that is the source of the modem signal. The second port is referred to as the digital port and is connected (again through the PBX network) to the Digital Line or Trunk port associated with the Data Module in the connection. The analog modem signals enter the analog port of the conversion resource in standard Pulse Code Modulation (PCM) format but are converted into Data Communications Protocol (DCP) format before going to the Digital Line or trunk in the connection.

There are two primary types of Modem Pool conversion resources available: an Integrated Pooled Modem and a Combined Modem Pool. The integrated TN758 Pooled Modem circuit pack contains two independent 300 or 1200 baud conversion resources. Each conversion resource contains two interfaces to the

PBX digital network: an analog port and a digital port. The analog port is connected through the PBX network to the analog line or trunk port containing the analog modem signals. The digital port connects through the PBX network to the digital line or trunk port in the call. [Figure 10-66](#) shows a typical end-to-end connection using a conversion resource on the integrated Pooled Modem circuit pack.

**Figure 10-66. Typical Modem Pool Switched Connection with Integrated Pooled Modem**

The Combined Modem Pool conversion resource is the second type available. The function served by the Combined Modem Pool is similar to that of the integrated Pooled Modem circuit pack, but the physical implementation is much

different. It has the advantage of supporting any speed the external modem can support. The integrated Pooled Modem circuit pack can only support 300 or 1200 baud transmission rates. The Combined Modem Pool conversion resource consists of a port on a TN742 or TN746 Analog Line circuit pack, an external modem, a Data Module, and a port on a TN754 Digital Line circuit pack. The tip and ring interface of the Analog Line is connected to the modem, the EIA 232C interface of the modem connects to the Data Module, and the DCP interface on the Data Module is connected to the Digital Line port.

The analog modem signals pass through the Analog Line port to the modem. The modem converts these to EIA 232C signals which are passed on to the Data Module. The Data Module further converts the signals to the DCP protocol for the Digital Line port which passes the signals on to the PBX network. See [Figure 10-67](#).

Certain customer-reported troubles may provide important information for troubleshooting Modem Pool problems. For example, if the customer tries to make a data call requiring a Modem Pool conversion resource, and the Modem Pool and Data Module speeds or other options don't match, they receive a "CHECK OPTIONS" error message on the terminal. If this happens, the Modem Pool administration and customer Data Module option settings should be checked. In addition, if the Modem Pool is a Combined type, option settings should be checked on the external Modem and Data Module making up the Combined Modem Pool. The cabling and connections between the Digital Line port, Data Module, Analog Line port, and Modem should be checked between the Combined Modem Pool components.

There are three types of commands that can be used to test Modem Pool circuits: **test port**, **test modem-pool #**, and **test board**. The **test port** command is generally the first test to run after the Error Log is evaluated and an entry is found for a Modem Pool port. The **test modem-pool #** command runs the same tests as the **test port short** command performed on a Modem Pool port. However, the **test modem-pool #** command can automatically test all ports in the Modem Pool group number specified in #. The **test board** command performs the same tests as **test port** and **test modem-pool #** plus additional tests for circuits common to the entire circuit pack. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for information on additional tests performed with **test board** (#50, #52, and #53).

If the Modem Pool port or group being tested with **test modem-pool #** contains Combined Modem Pools, the ports on the associated TN742 or TN746 Analog Line circuit pack and the TN754 Digital Line circuit pack are tested as a group. Note, however, that Combined Modem Pools are not tested with the tests described in this section and the repair information related to Tests # 96, 97, 98, and 99 is not applicable. The Analog port of the Combined Modem port is tested with Analog port tests (that is, Tests #6, #47, #35, #48 and #36), and the Digital port of the Combined Modem port is tested with TDMODULE/PDMODULE tests (that is, Tests #9, #13, #17 and #175). Therefore, use the repair procedures outlined in the ANL-LINE, ANL-16-L, ANL-NE-L, and TDMODULE/PDMODULE

Maintenance documentation when interpreting the results of the execution of the **test modem-pool #** command on Combined Modem Pools.

**Figure 10-67. Typical Modem Pool Switched Connection with Combined Modem Pool**

Hardware Error Log Entries and Test to Clear Values

| Modem Pool Port Error Log Entries |          |                                     |             |              |                         |
|-----------------------------------|----------|-------------------------------------|-------------|--------------|-------------------------|
| Error Type                        | Aux Data | Associated Test                     | Alarm Level | On/Off Board | Test to Clear Value     |
| 0 <sup>1</sup>                    | 0        | Any                                 | Any         | Any          | test port PCSSpp sh r 1 |
| 18                                | 0        | busyout PCSS                        | WARNING     | OFF          | release port PCSSpp     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

- a. This error type indicates that the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Modem Pool Conference Test*, for example, you may also clear errors generated from other tests in the testing sequence. The tests in this section do not apply to Combined Modem Pool conversion resources. The standard Digital Line and/or Analog Line port tests are run on the ports associated with the Combined Modem Pool. The test descriptions for those maintenance objects (MOs) should be consulted when repairing Combined Modem Pool arrangements.

For example, you may also clear errors generated from other tests in the testing sequence. The tests in this section do not apply to Combined Modem Pool conversion resources. The standard Digital Line and/or Analog Line port tests are run on the ports associated with the Combined Modem Pool. The test

descriptions for those maintenance objects (MOs) should be consulted when repairing Combined Modem Pool arrangements.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|-------------------|
| Modem Pool NPE Crosstalk Test (#96)                   |                     | X                  | D                 |

| Modem Pool Conversion Resource Loop Around Test (#98) | X                   | X                  | ND                |
| Modem Pool Audits Test (#99)                          | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Modem Pool NPE Crosstalk Test (#96)

This test is destructive.

This NPE Crosstalk Test verifies that the NPE is connected only to the desired time slot and is not crosstalking on other time slots. This test operates exactly like Test #6 for other types of port circuits but is performed twice in order to test both NPEs in the Modem Pool Port.

Modem Pool Conference Test (#97)

This test is destructive.

This test checks most of the switching and gain control functions provided by the NPE circuit in the analog section of the conversion resource. This test conferences a 1004-Hz tone through the NPE, looping it back so that it can be verified with a Tone Detector circuit.

Table 10-261. TEST #97 Modem Pool Conference Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Modem Pool Conversion Resource Loop Around Test (#98)**

The Modem Pool Conversion Resource Loop Around Test is set up as follows:

**Figure 10-68. Modem Pool Conversion Resource Loop Around Test Set-up**

Test data patterns are transmitted from the Network Control Channels 1 or 3 over network time slot A through the digital port, looped around through the analog port via time slot C back to the Network Control Channel circuit via time slot B where the patterns are checked for accuracy. Finally, the test forces a disconnect by breaking the connection between the Data Channel and Modem Pool Port (time slot A) and verifying that the Data Channel and Modem Pool Port go on-hook within the proper time.

This test attempts to allocate a Network Control Channel, Modem Pool Port, and other internal resources. If any of these allocation attempts fail, the test cannot be completed and a specific abort error is reported.

Table 10-262. TEST #98 Modem Pool Conversion Resource Loop Around Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5001       | ABORT       | <p>A Network Control Channel could not be allocated for this test. This error is more closely related to the Data Channels (1 or 3 only) on the DATA-CHL circuit pack used for this test than the TN758 Pooled Modem circuit pack itself. Therefore, any hardware testing or replacement activities focus on the DATA-CHL circuit pack. However, the Data Channels on the DATA-CHL circuit pack normally should not be busied out, tested with the <b>test data-module</b> command, or reseated in the carrier to clear this error, since this may drop other data calls that may be active at the time. The administration of Data Channels 1 and 3 should be checked if this error occurs.</p> <ol style="list-style-type: none"><li>1. Wait one minute and attempt the test again.</li><li>2. If the same error persists after five attempts at one-minute intervals, escalate the problem.</li></ol> |
| 5002       | ABORT       | <p>The Network Control Channel allocated for this test could not be set to "maintenance busy" status.</p> <ol style="list-style-type: none"><li>1. Modem Pool Audit Test (#99)

This audit updates the Modem Pool conversion resource status contained in the TN758 Pooled Modem circuit pack's microprocessor. It does not actually test the Pooled Modem circuit pack; therefore, there are no FAIL codes. The audit can only be performed on idle conversion resources. If the conversion resource is in use, the audit aborts.

Table 10-263. TEST #99 Modem Pool Audit Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| NONE       | ABORT       | <p>The system was not able to allocate all the necessary resources to execute this test. An ABORT simply indicates that the conversion resource was in use when the audit was performed. No repair action is necessary unless it was known that the conversion resource was actually idle during the test (yellow in-use LED was off) or was busied out before the test was run. If this is the case, a TN758 failure condition may exist and the following procedure should be used:</p> <ol style="list-style-type: none"><li>1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource.</li><li>2. If the test continues to abort, replace the Pooled Modem circuit pack and retest.</li><li>3. If the circuit pack fails after replacement, escalate the problem.</li></ol> |

# MMI-BD

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO                   |
|------------------------|-------------|-------------------------------------|-----------------------------------|

| MMI-BD                 | MINOR       | test board PCSS l r#                | Multimedia Interface Circuit Pack |
| MMI-BD <sup>2</sup>    | WARNING     | test board PCSS s r#                | Multimedia Interface Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth).
2. Refer to XXX-BD (Common Port Board).

The Multimedia Interface Circuit Pack (TN787D or later) provides a number of H.221 protocol terminations for bit streams received from the TDM bus. The Multimedia Interface demultiplexes the H.221 bit stream (audio, video, data, control, and indication signals) and transmits the bit streams onto the TDM bus so that the appropriate circuit packs can process them.

The Multimedia Interface circuit pack is commonly referred to as the MMI pack for H.221 protocol termination. It is also called the MMCH circuit pack. There are 32 ports (also called resources) on the circuit pack. See MMI-PT for maintenance of these resources.

The MMI circuit pack contains 4 digital signal processors that manage the 32 resources.

 **NOTE:**

Refer to ["Troubleshooting Multimedia Call Handling \(MMCH\)"](#) in [Chapter 5](#) for MMCH troubleshooting information.

| 2049 (j)       | Any          | TSI Loop (#1108)                        | MAJ         | ON           | test board PCSS l r 3  |

1. Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The circuit pack stopped functioning or it was physically removed from the system. The alarm logs approximately 11 minutes after the circuit pack has been removed and/or the SAKI Sanity Test (#53) fails.  
  
If the circuit pack is in the system and the red LED is on, follow the instructions for a red alarm in [“Control and Port Circuit Pack Status LEDs”](#) in [Chapter 7, “LED Interpretation”](#). Also, see “Handling Common Port Circuit Packs.”
- b. This circuit pack has been busied out using the **busyout board PCSS** command.
- c. There are more than four MMI circuit packs in the system. Remove the circuit pack that generated the error in the error log by locating the slot indicated by the error.

- d. Indicates transient communication problems between the switch and this circuit pack. Execute the **test board PCSS** command and refer to the repair procedures for the Control Channel Looparound Test (#52) in the XXX-BD section.
- e. The circuit pack detected an Angel on-board hardware failure. The reported aux data values correspond to the following detected errors:  
  
4352 - External RAM error  
4253 - Internal RAM error  
4355 - ROM Checksum error  
4357 - Instruction set error

Reset the circuit pack by using the **busyout board PCSS**, **reset board PCSS**, and **release board PCSS** commands. When reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one these errors during initialization causes the circuit pack to lock up and appear insane to the system. See the repair procedures in note b for Error Type 1.

- f. This MMI circuit pack reported a loss of MMI synchronization. Refer to Test (#1123) for repair procedures.
- g. A failure of the time slot interchanger has been detected. Reset the circuit pack using the **busyout board PCSS**, **reset board PCSS**, and **release board PCSS** commands. If the reset passes, then the on-board circuitry is healthy. Retire the alarm using the **test board PCSS long clear** command followed by **release board PCSS**.
- h. The circuit pack is hyperactive; that is, it is flooding the switch with messages sent over the control channel. The circuit pack is taken out of service when a threshold number of these errors is reported to the switch. Clear the alarm using the following commands: **busyout board PCSS**, **reset board PCSS**, **test board PCSS long clear**, **release board PCSS**. If the error recurs within 10 minutes, replace the circuit pack.
- i. The TSI Cross Talk Test (#6) failed. See the description of this test and follow the repair procedures.
- j. The TSI Looparound Test (#1108) failed. See the description of this test and follow the repair procedures.

### System Technician-Demanded Tests: Descriptions and Error Code

---

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the TSI Crosstalk Test (#6), for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-265. System Technician-Demanded Tests: MMI-BD

| Order of Investigation                             | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------|---------------------|--------------------|----------------------|-------------------|
| TSI Crosstalk (#6)                                 |                     | X                  |                      | ND                |
| TSI Looparound Test (#1108)                        |                     | X                  |                      | ND                |
| MMI SYNC Status Test (#1123)                       | X                   |                    |                      | ND                |
| MMI SYNC Status Test (#1122)                       |                     | X                  |                      | ND                |
| Control Channel Looparound Test (#52) <sup>2</sup> | X                   | X                  |                      | ND                |
| SAKI Sanity Test (#53) <sup>2</sup>                |                     |                    | X                    | D                 |

- 
1. D = Destructive, ND = Non-destructive

2. Refer to the repair procedure described in XXX-BD (Common Port Circuit Pack) for a description of this test.
- 

TSI Crosstalk Test (#6)

This test is non-destructive.

The Time Slot Interchanger (TSI) chip controls connectivity to the TDM bus. The TSI Cross Talk Test verifies that this TSI talks on the selected TDM bus time slot and never crosses over to time slots reserved for other connections. If the TSI is not working correctly, one-way and noisy connections may occur. If the test passes, then the TSI is able to communicate over the TDM bus. This test is part of the circuit pack’s demand and scheduled long test sequence, and takes approximately 20 to 30 seconds to complete.

Table 10-266. TEST #6 TSI Crosstalk Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                             |

TSI Looparound Test (#1108)

This test is non-destructive.

During this test, the MMI's Time Slot Interchanger (TSI) is listens to a TDM timeslot. A digital count tone loops back in the TSI and onto another TDM timeslot without passing through any resource hardware. A tone detector port verifies the looped data. If the digital count is correct, then the test passes. The test is done for both TDM buses. Failures indicate that the TSI is unreliable.

Table 10-267. TEST #1108 TSI Looparound Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                  |

|            | PASS        | The TSI is correctly using its allocated time slots.                                                                                                                                                                                                                                                                                                                                                                                                        |

MMI Synchronization Status Test (#1122 and 1123)

This test is non-destructive.

To support applications involving multiple MMI circuit packs, the appropriate MMI circuit packs must be synchronized with one another. One such circuit pack is designated as the master sync source, which provides the synchronization signal onto the TDM bus. The other MMI circuit packs in the system listen to this signal.

This test monitors this synchronization state. The test fails if the MMI circuit pack is not in sync. The test passes with auxiliary code 1100 if the MMI circuit pack is in sync and is providing the synchronization signal for the system. The test also passes with an auxiliary code of 1101 if the MMI circuit pack is in sync and listening to the sync signal. MMI circuit packs do not lose the synchronization signal unless an MMI circuit pack is either pulled out of the system or reset by using a technician command.

Test #1122 runs when the **long** option of the **test board** command is entered, initiating the recovery of synchronization. Test #1123 runs when the **short** option of the **test board** command is entered, giving the status of the synchronization. You need not necessarily run the **long** option since synchronization signal recovery should be taking place within software running in the background. Use the **long** option only if synchronization is not established within 5 minutes of investigating the problem.

Table 10-268. TEST #1122/1123 MMI Synchronization Status Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                |

SAKI Sanity Test (#53)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) maintenance documentation as SAKI Sanity Test (#53).

## MMI-LEV (Multimedia Interface Resource Level)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run                                        | Full Name of MO |
|------------------------|-------------|---------------------------------------------------------------|-----------------|
| MMI-LEV                | MAJOR       | See <a href="#">“Resolving MMI-LEV Errors/Alarms”</a> (below) | MMI-LEV         |

The Multimedia Interface Resource Level MO monitors MMI efficiency by tracking the number of MMI ports that are in-service, and then comparing that number with the value entered in the MMIs field on the System-Parameters Maintenance form. This MMIs field is located under the Minimum Maintenance Threshold section. The MMIs field contains the minimum number of MMI ports needed for the Multimedia Call Handling (MMCH) feature to run efficiently and is an administrable field. This field must contain a minimum threshold number for MMI port capacity of between 0-128. The MMCH feature must be enabled on the System-Parameters Customer-Options form before the MMIs field can be changed to a number greater than zero. The algorithm for determining that a low level of MMI resources exists uses the value entered in the MMIs field, and the number of MMI ports that are in-service in the system.

Each MMI circuit pack contains a maximum of 32 ports. If the number of in-service MMI ports falls below the minimum port capacity (value entered on the System Parameters Maintenance form under the Minimum Maintenance Threshold section and in the MMI field), a MMI-LEV error is logged. If this outage continues for 15 minutes, a MAJOR alarm is raised.

### Resolving MMI-LEV Errors/Alarms

MMI ports are a key part of the MMCH feature, and any loss in the number of ports available for use degrades the MMCH customer-defined service level.

If a MMI circuit pack or port is busied out using the **busyout board** or **busyout port** commands, these out-of-service ports are not included in the MMI level calculation, thus allowing a technician to busy out a MMI circuit pack for maintenance reasons without causing a MAJOR alarm to be raised. However, if all of the ports on the MMI circuit pack are not made busy and the circuit pack is removed, an alarm is raised.

**⇒ NOTE:**  
When diagnosing a MMI-LEV problem, begin by resolving any alarms raised against MMI-BD or MMI-PT maintenance objects. Clearing MMI-BD or MMI-PT alarms may clear the MMI-LEV alarm.

The MMI circuit pack is maintained by the software like the Tone Detector circuit pack, which can be removed and reinserted in any port board slot without

administration. Similarly, if a MMI circuit pack is removed from service logically by failing the Archangel sanity scan test or is removed from service physically by removing the circuit pack from the carrier, no error/alarm is raised against either the MMI-BD or the MMI-PT maintenance objects. Therefore, if a MMI-LEV error/alarm exists, yet no alarms have been raised against MMI-BD or MMI-PT maintenance objects, a MMI circuit pack may have been removed from service causing the MMI-LEV error/alarm. To resolve a MMI-LEV MAJOR alarm, restore the number of MMI ports available for service to be equal to or greater than the calculated port capacity.

To determine how many MMI circuit packs are needed for the MMCH feature:

1. Using the **display system-parameters maintenance** command, locate the number listed in the Minimum Maintenance Thresholds (MMIs) field and record this number.
2. Use the **list configuration** command to verify the number of MMI ports.
3. Compare this number with the value listed in the MMI field on the System-Parameters Maintenance form (number listed in step 1 a minimum thresholds number for MMI ports of between 0-128). Each MMI circuit pack contains a maximum of 32 ports. If the number in the MMIs field is less than or equal to 32, one MMI circuit pack is needed. If this number is 64, then two MMI circuit pack are needed.
4. Use the **list configuration** command to verify that the number of MMI circuit packs listed agrees with the required minimum port capacity (from step 1). If the number of MMI circuit packs listed in the step 2 differs from the calculated number, restore the number of MMI circuit packs to the correct value, in order to resolve the MMI-LEV alarm.

Error Log Entries and Test to Clear Values

Table 10-269. MMI-LEV Error Log Entries

| Error Type     | Aux Data | Associated Test | Alarm Level | On/ Off Board | Test to Clear Value |
|----------------|----------|-----------------|-------------|---------------|---------------------|
| 1 <sup>1</sup> | Any      | None            | MAJOR       | OFF           |                     |

1. The number of MMI resources in the system that are in service has fallen below the calculated minimum value. If the number of in-service MMI ports falls below the MMCH port capacity (value entered in the Minimum Maintenance Thresholds for MMIs field) on the System-Parameters Maintenance form, a MMI-LEV error is logged. If this outage continues for 15 minutes, a MAJOR alarm is raised.

To resolve this alarm, correct the out-of-service problem by following these procedures:

1. See “MMI-PT” and “MMI-BD” and resolve any associated alarms.
2. If a MMI-LEV error/alarm exist and none has been raised against MMI-BD or MMI-PT maintenance objects, an MMI circuit pack may have been removed from service causing the MMI-LEV error/alarm. To resolve a MMI-LEV MAJOR alarm,

restore the number of MMI ports available for service to be equal to or more than the calculated port capacity. See the [“Resolving MMI-LEV Errors/Alarms”](#) section above for details.

- 3. If the error continues to alarm, escalate the problem.

**System Technician-Demanded Tests:**  
**Descriptions and Error Code**

---

There are no System Technician-Demanded tests for MMI-LEV.

# MMI-PT

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO           |
|------------------------|-------------|-------------------------------------|---------------------------|
| MMI-PT                 | MAJOR       | test port PCSSpp l r#               | Multimedia Interface Port |
| MMI-PT                 | MINOR       | test port PCSSpp l r#               | Multimedia Interface Port |
| MMI-PT                 | WARNING     | test port PCSSpp l r#               | Multimedia Interface Port |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth).

 **NOTE:**

Refer to [“Troubleshooting Multimedia Call Handling \(MMCH\)”](#) in [Chapter 5](#) for MMCH troubleshooting information.

The Multimedia Interface Circuit Pack provides a number of H.221 protocol terminations for bit streams received from the TDM bus. The Multimedia Interface demultiplexes the H.221 bit stream (audio, video, data, control, and indication signals) and transmits the bit streams onto the TDM bus to be processed by the appropriate circuit packs.

Each Multimedia Interface Circuit Pack contains 32 separately maintained “ports,” more commonly referred to as “resources.” MMI-PT represents one of these 32 resources. At system boot or when the circuit pack is inserted, 32 resources are inserted into the system.

The MMI circuit pack contains 4 Digital Signal Processors (DSPs) which manage the 32 resources. These resources are directly mapped to DSPs:

| Resource | Direct Map |
|----------|------------|
| 1-8      | DSP1       |
| 9-16     | DSP2       |
| 17-24    | DSP3       |
| 25-32    | DSP4       |

All 8 resources that the circuit pack controls may be placed out of service by the failure of one of these DSPs.

**Figure 10-70. TN787 MULTIMEDIA INTERFACE (MMI) CIRCUIT PACK**

Error Log Entries and Test to Clear Values

Table 10-270. MMI-PT Error Log Entries

| Error Type         | Aux Data | Associated Test                | Alarm Level | On/ Off Board | Test to Clear Value     |
|--------------------|----------|--------------------------------|-------------|---------------|-------------------------|
| 0 <sup>1</sup>     | 0        | Any                            | Any         | Any           | test port PCSSpp sh r 1 |

| 513 (e)            | Any      | Resource Loopback Test (#1111) | MIN         | ON            | test port PCSSpp sh r 3 |
| 1025 (f)           | Any      | Uplink error from pack         |             |               |                         |
| 3841 -<br>3844 (g) | Any      | Uplink error from pack         |             |               |                         |

1. Run the short test sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. The customer endpoint connected on a conference sent too many messages to the VSP-MCU in a specified amount of time. Check the “status conference” forms to correlate which customer had the problem. This is a customer endpoint problem and not a VSP-MCU problem.
- b. This port has been busied out by the **busyout port PCSSpp** command.
- c. Indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reseal the circuit pack.
- d. This error occurs if the MMI circuit pack detects a DSP Error. Maintenance software will reset the DSP when this error is received. This error is logged for all 8 resources connected to this particular DSP. If this DSP continues to fail sanity, a Minor alarm is raised. Replace the circuit pack.
- e. This error occurs when the Resource Looparound Test (#1111) fails. Run the Long Test Sequence and note the results of Test #1111.
- f. This error occurs if either the MMI or Voice Conditioner (VC) circuit packs reports a loss of framing on the service channel between these two circuit packs. When a customer endpoint establishes a call to the VSP-MCU, a channel is established between the MMI resource and the VC port. If this channel is detected to go down by either circuit pack, an uplink message is sent. This error is then forwarded to maintenance for both circuit packs.

Run the Long Test Sequence for this MMI resource, and if any of the tests fail, follow the repair procedures for that test. If all tests pass, the cause of the problem might be with the VC pack. See the “VC-DSPPT” repair procedures.

- g. These errors are not related to VSP-MCU. They could be caused by network problems or from the customer endpoints. They are presented here for logging purposes only:

| Code | Description                                                                 |
|------|-----------------------------------------------------------------------------|
| 3841 | CRC4 Error (Frame checksum error)                                           |
| 3842 | Correctable BAS (Control msg single or double bit error, but correctable)   |
| 3843 | Uncorrectable BAS (Control msg bit error -three or more bit, uncorrectable) |
| 3844 | Protocol Error (H.221 Protocol error from endpoint detected)                |

| Resource Looparound Test (#1111) | X                   | X                  | D                 |

1. D = Destructive; ND = Nondestructive

Resource Looparound Test (#1111)

This test is destructive.

This test checks the connectivity of the resource within MMI circuit pack and out to the TDM bus. The object is to test the circuitry that an H.221 bit stream comes in contact with when that stream is demultiplexed, pre-processed, written to the TDM bus and then reread (looped in the TSI), post-processed, multiplexed, and then written back to the TDM bus for verification. The video, audio, and data components of the bit stream are tested separately. If any one of these tests fails, then the resource is taken out of service.

Table 10-271. TEST #1111 Resource Looparound Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

|            | PASS        | The resource is functioning normally.                                                                                                                                                                                                     |

# MMI-SYNC

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO                   |
|------------------------|-------------|-------------------------------------|-----------------------------------|
| MMI-SYNC               | MINOR       | test board PCSS I r#                | Multimedia Interface Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth).

**NOTE:**

Refer to [“Troubleshooting Multimedia Call Handling \(MMCH\)”](#) in [Chapter 5](#) for MMCH troubleshooting information.

Each Port Network (PN) must have a TN787D or later MMI circuit pack assigned as the Multimedia Interface (MMI) master synchronization source for that PN. If one or more MMI circuit pack is administered in a PN, one MMI circuit pack is designated as the master synchronization source for all MMI circuit packs within that PN.

The MMI circuit pack generates a synchronization signal and puts that signal on the TDM bus. Other MMI packs or any other circuit pack within a PN can listen to this signal and “synchronize up” to it. The first MMI circuit pack inserted in a PN is normally designated as the master. As subsequent MMI packs are inserted, they are instructed to listen and synchronize to the time-slot of the master MMI. In the unlikely case of an MMI losing this reference, an uplink message is sent from the MMI circuit pack that lost the signal to maintenance, which also clears the “event” counter on this MMI with a downlink message. This forces the MMI circuit pack to return the current state of the synchronization signal. If the signal is still lost, then the recovery algorithm is entered. Note that during this time, the MMI circuit pack synchronizes to its internal clock, and there should be no service disruption. A loss of synchronization is usually the result of a circuit pack failure. The maintenance strategy is to switch the master source away from the bad pack to another healthy MMI circuit pack within the PN.

A synchronization switch takes place if half or more of the MMI circuit packs in a PN report a loss of synchronization. For example, a PN with two MMIs reporting a loss of sync source switches immediately, three and four MMIs switch if two report the loss, and so forth. A healthy MMI circuit pack becomes the master synchronization source providing the signal on a new timeslot. The other MMI circuit packs within the PN are instructed to listen to this new signal, and the old master stops providing the signal and now listens to the new master MMI. If an MMI is physically removed from the system, then the remaining MMIs report the loss of synchronization. The first MMI with no alarms present becomes the new master of that PN. Once a synchronization switch has occurred, another switch is not allowed for 15 minutes to avoid hyperactive switching. If all the MMIs have alarms, then no switch is made.

If the MMI circuit pack that provides synchronization is craft busied out, it will not affect the PN synchronization. The signal is still provided by the busied-out pack. There is no affect on synchronization if the technician issues a release of the busied-out MMI. Synchronization is not affected by a warm start of the system (reset system 1). For all other restarts (reboot through cold 2), MMI synchronization recovers during board insertion.

Error Log Entries and Test to Clear Values

Table 10-272. MMI-SYNC Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value   |
|------------|----------|-----------------|-------------|--------------|-----------------------|
| 1          | Any      | None            |             |              | See note <sup>1</sup> |
| 257        | Any      | None            | MINOR       | OFF          | See note <sup>2</sup> |

- 
1.

An MMI synchronization switch was successful. Refer to MMI-BD errors for the reason for the switch.
2.

The requested MMI synchronization switch failed. Resolve all MMI-BD alarms.

System Technician-Demanded Tests:  
Descriptions and Error Codes

There are no system technician-demanded tests for MMI-SYNC.

## M/T-ANL (Maintenance/Test Analog Port)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO              |
|------------------------------------|-------------|-------------------------------------------------------|------------------------------|
| M/T-ANL                            | Minor       | test port PCSSpp I                                    | Maintenance/Test Analog Port |
| M/T-ANL                            | Warning     | release port PCSSpp                                   | Maintenance/Test Analog Port |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The Maintenance/Test Analog Port is port number 1 on the TN771 Maintenance/Test circuit pack. This port is used by the Automatic Transmission Measurement System (ATMS) as an Originating Test Line (OTL) or Terminating Test Line (TTL) for test calls over analog trunks. [Figure 10-71](#) shows a typical ATMS configuration.

M/T-ANL maintenance ensures that the analog trunk's testing function is operating correctly. An alarm against M/T-ANL can reduce service, but it will not block it. To accurately measure performance and health of analog trunks, the TN771 should be replaced when a new circuit pack is available.

Figure 10-71. ATMS Tie Trunk Test Call

Hardware Error Log Entries and Test to Clear Values

| M/T-ANL Error Log Entries |          |                                            |             |              |                        |

| 513                       | Any      | Analog Port Sanity Test (#963)             | MINOR       | ON           | test port PCSS01 r 2   |
| 769                       | Any      | Analog Port Digital Loop Around Test (#13) | MINOR       | ON           | test port PCSSpp r 3   |
| 3840(c)                   | Any      | Hook State Inquiry test (#566)             |             |              |                        |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error code appears in the Error Log only if the MTB circuit pack has been removed since the Error Log was last cleared. Verify that the circuit pack has been reinserted.
- b. This error indicates a hardware failure on the Analog Port circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.
- c. This error indicates that call processing records did not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test Analog Port. This error is not service-affecting and no action is required.

System Technician-Demanded Tests:  
Descriptions and Error Codes

---

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Analog Port Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------|---------------------|--------------------|-------------------|
| Analog Port Sanity Test (#963) | X                   | X                  | ND                |
| Digital Loop Around Test (#13) | X                   | X                  | ND                |
| NPE Crosstalk Test (#9)        |                     | X                  | ND                |
| Hook State Inquiry (#566)      | X                   | X                  | ND                |
| Clear Error Counters (#270)    |                     | X                  | ND                |

---

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections.

One or more Network Processing Elements (NPE) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity, gain, and provides conferencing functions on a per port basis. If the NPE is not working correctly, one way and/or noisy connections may be observed. This test is part of a port's long test sequence and takes approximately 10 to 20 seconds to complete

Table 10-273. TEST #9 NPE Cross Talk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

**Analog Port Digital Loop Around Test (#13)**

This test is a modification of the Voice and Control Channel Local Loop Test used by Digital Station (DIG-LINE) maintenance. This test does not perform the control channel and secondary information channel loop around tests as described for DIG-LINE, as these data paths do not exist for the Maintenance/Test Analog Port. The primary information channel is tested by first looping back the data channel onto the TDM Bus, and then sending a digital count from the Tone-Clock circuit pack and receiving the same digital count with a general purpose tone detector. A conference test is done next for the primary information channel. This test is the same as Conference Test (#6).

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests. If either fails or aborts, the sequence is stopped

Clear Error Counters (#270)

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink. Using this method, the message will be sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared. This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel will send a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test Circuit Pack. Therefore, this test should never abort or fail.

Table 10-275. TEST #270 Clear Error Counters

| Error Code | Test Result | Description/ Recommendation                                                                                         |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------|
|            | PASS        | The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent. |

Hook State Inquiry (#566)

This test ensures that the Maintenance/Test Analog Port maintenance software and call processing agree on the on-/off-hook status of the Maintenance/Test Analog Port.

Table 10-276. TEST #566 Hook State Inquiry

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                      |

Analog Port Sanity Test (#963)

This test verifies that the port circuitry involved in the analog trunk testing on the Maintenance/Test Analog Port is functioning properly.

This test will abort if an ATMS Test Call is in progress on the Maintenance/Test Analog Port when the test is requested.

Table 10-277. TEST #963 Analog Port Sanity Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                  |

If the test fails again, replace the circuit pack. |
|            | PASS        | The Maintenance/Test Analog Port analog trunk testing capability is operating correctly.                                                                                                                                                                                                                                                                     |

## M/T-BD (Maintenance/Test Circuit Pack)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO               |
|------------------------------------|-------------|-------------------------------------------------------|-------------------------------|
| M/T-BD                             | MIN         | test board PCSS I                                     | Maintenance Test Circuit Pack |
| M/T-BD                             | WRN         | release board PCSS                                    | Maintenance/Test Circuit Pack |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

 **CAUTION:**  
*In G3iV1.1-286 and G3iV2-386, a TN771D (or later vintage) Maintenance/Test circuit pack must be used.*

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also M/T-DIG (Maintenance/Test Digital Port) and M/T-PKT (Maintenance/Test Packet Bus Port) Maintenance documentation for related digital port and Packet Bus port information, respectively.

M/T-DIG (Maintenance/Test Digital Port) [G3iV1-1.286, G3iV2-386]

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO               |
|------------------------------------|-------------|-------------------------------------------------------|-------------------------------|
| M/T-DIG                            | Minor       | test port PCSSpp l                                    | Maintenance/Test Digital Port |
| M/T-DIG                            | Warning     | release port PCSSpp                                   | Maintenance/Test Digital Port |

1. Where P is the port network number (1 for PPN, 2 or, 3 for EPN-1 and 3 for EPN-2); C is the carrier designation (A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Maintenance/Test Digital Port is a port on the TN771D (or later vintage) Maintenance/Test circuit pack, which is required for G3iV1.1-286 or G3iV2-386. Ports 2 and 3 are Digital Ports. The Maintenance/Test Digital Port provides the ability to perform digital (that is, ISDN-PRI) trunk testing via the TDM Bus. For an ISDN-PRI test call, connections are set up in the system as shown in [Figure 10-72](#).

When the Maintenance/Test Digital Port is participating in an ISDN-PRI test call, the port sends a stream of pseudo-random data along the connected B-channel. The far end loops back this data, and the Maintenance/Test Digital Port compares the data to that which was sent. Errors are recorded on a bit and block basis. Refer to ISDN-TRK (DS1ISDN Trunk) Maintenance documentation for more information on ISDN-PRI test calls.

The Maintenance/Test Digital Port maintenance ensures that the digital trunk testing function is operating correctly. The Maintenance/Test Digital Port is alarmed if maintenance determines that the digital port is operating incorrectly.

 **NOTE:**

An alarm on the Maintenance/Test Digital Port reduces service, but does not block it since the ISDN-TRK has other means to determine the health of the ISDN-PRI trunk facility. However, to accurately measure the error performance and to ensure accuracy of the health of the ISDN-PRI trunk, the Maintenance/Test circuit pack should be replaced when a new circuit pack is available.

Figure 10-72. ISDN-PRI Outgoing Test Call

Hardware Error Log Entries and Test to Clear Values

M/T-DIG Error Log Entries

| Error Type     | Aux Data | Associated Test                     | Alarm Level | On/Off Board | Test to Clear Value    |
|----------------|----------|-------------------------------------|-------------|--------------|------------------------|
| 0 <sup>1</sup> | 0        | Any                                 | Any         | Any          | test port PCSSpp       |
| 1 (a)          | 41018    | none                                | MINOR       | ON           | test port PCSSpp l r 3 |
| 18 (b)         | 0        | busyout port PCSSpp                 | WARNING     | OFF          | release port PCSSpp    |
| 257 (c)        | Any      | NPE Crosstalk Test (#9)             | MINOR       | ON           | test port PCSSpp l r 3 |
| 513 (d)        | Any      | Digital Port Sanity Test (#565)     | MINOR       | ON           | test port PCSS02 r 2   |
| 769 (e)        | Any      | Digital Port Loop Around Test (#13) | MINOR       | ON           | test port PCSSpp r 3   |
| 3840 (f)       | Any      | Hook State Inquiry Test (#566)      |             |              |                        |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates a hardware failure on the Digital Port circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.
- b. The port has been busied out via the **busyout port PCSSpp** command.
- c. This error indicates that Maintenance/Test Digital Port is talking on more than just its assigned time slot. Replace the Maintenance/Test circuit pack.
- d. This error indicates that the Maintenance/Test Digital Port has failed its self-test. Since the Digital Port Sanity Test runs only on Port 2, but tests both Ports 2 and 3, both ports are alarmed when the test fails. Note that the command above indicates to test Port 2, even if the error is logged against Port 3.
- e. This error indicates that the Maintenance/Test Digital Port has been unable to successfully loop data from a tone generator to a tone detector.
- f. This error indicated that call processing records did not agree with on-board records for the hook state (on/off-hook) of the Maintenance/Test Digital Port. This error is not service-affecting and no action is required.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Digital Port Sanity Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation              | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------|---------------------|--------------------|-------------------|

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

This test is a modified version of the Digital Line NPE Crosstalk Test used by DIG-LINE maintenance.

One or more NPE reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity, gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and/or noisy connections may be observed. This test is part of a port's long test sequence and takes approximately 10 to 20 seconds to complete. This test is a modified version of the Digital Line NPE Crosstalk Test used by DIG-LINE maintenance.

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                      |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Any        | FAIL        | The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections.<br><br>1. If the remaining ports are currently not in use (yellow LED is off), try to reset the circuit pack. Then repeat the test.<br><br>2. If the test fails again, replace the circuit pack. |
|            | PASS        | The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.                                                                                                                     |

**Digital Port Loop Around Test (#13)**

This test is a modification of the Voice and Control Channel Local Loop Test used by Digital Station (DIG-LINE) maintenance. This test does not perform the control channel and secondary information channel loop around tests as described for DIG-LINE, as these data paths do not exist for the Maintenance/Test Digital Port. The primary information channel is tested by first looping back the data channel onto the TDM Bus, and then sending a digital count from the Tone-Clock circuit pack and receiving the same digital count with a general purpose tone detector. A conference test is done next for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests. If either fails or aborts, the sequence is stopped.

If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Maintenance/Test Circuit Pack.</li></ol> |
|            | PASS        | <p>The Maintenance/Test Digital Port digital trunk testing capability is operating correctly.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

Clear Error Counters (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink. Using this method, the message is sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared.

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed

port/circuit pack from flooding the SPE with a string of messages). This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel sends a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test Circuit Pack. Therefore, this test should never abort or fail.

**Table 10-280. TEST #270 Clear Error Counters**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                              |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

| Any        | FAIL        | This test should never fail.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to fail, escalate the problem. |
|            | PASS        | The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.                                                      |

**Digital Port Sanity Test (#565)**

This test verifies that the port circuitry involved in the digital trunk testing on the Maintenance/Test Digital Port is functioning properly. This circuitry is common to both Maintenance/Test Digital Ports on the Maintenance/Test circuit pack. Therefore, this test is only run for Port 2. The test aborts when run on Port 3, as described in [Table 10-281](#).

This test operates by connecting the two Maintenance/Test Digital Ports on the TDM Bus so that they talk and listen to each other. Then four self-tests are attempted: (a) sending data from Port 2 to Port 3 in asynchronous mode; (b) sending data from Port 3 to Port 2 in asynchronous mode; (c) sending data from Port 2 to Port 3 in synchronous mode; and (d) sending data from Port 3 to Port 2 in synchronous mode. The test passes if all four of these self-tests are successful. The test stops as soon as any one of these self-tests fails.

This test aborts if an ISDN Test Call is in progress on either Maintenance/Test Digital Port when the test is requested, or if an ISDN Test Call is initiated while the Digital Port Sanity Test is in progress.

**Table 10-281. TEST #161 Loop Around Test**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

If the test fails again, replace the circuit pack. |
|            | PASS        | The Maintenance/Test Digital Port digital trunk testing capability is operating correctly.                                                                                                                                                                                                                                                 |

Hook State Inquiry (#566)

This test ensures that the Maintenance/Test Digital Port maintenance software and call processing agree on the on/off-hook status of the Maintenance/Test Digital Port.

Table 10-282. TEST #161 Loop Around Test

# M/T-PKT (Maintenance/Test Packet Bus Port)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run <sup>1</sup> | Full Name of MO                  |
|------------------------------------|-------------|-------------------------------------------------------|----------------------------------|
| M/T-PKT                            | Minor       | test port PCSSpp I                                    | Maintenance/Test Packet Bus Port |
| M/T-PKT                            | Warning     | release port PCSSpp                                   | Maintenance/Test Packet Bus Port |

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Maintenance/Test Packet Bus Port is a port (always Port #4) on the TN771D (or later vintage) Maintenance/Test circuit pack, which is required for G3iV1.1-286 or G3iV2-386. The Packet Bus port provides the following Packet Bus maintenance functions:

- Packet Bus fault detection - the ability to detect faults (for example, shorts, open leads) on the Packet Bus autonomously (that is, without SPE involvement).
- Packet Bus reconfiguration - the ability to swap faulty leads with spare leads autonomously so that the Packet Bus remains operational. This is accomplished by sending messages to all Packet circuit packs [for example, ISDN-BRI (TN556)] telling them which spare leads to use on the Packet Bus.

Maintenance/Test Packet Bus Port maintenance ensures that these maintenance functions are operating correctly. The Maintenance/Test Packet Bus Port is alarmed if maintenance determines that the port's maintenance functions are operating incorrectly.

When Maintenance/Test Packet Bus Port maintenance determines that the Packet Bus Port is defective, the Packet Bus fault detection and Packet Bus reconfiguration functions provided by the port are turned off.

Maintenance/Test Packet Bus Port maintenance interacts with Packet Bus maintenance. Therefore, there may be alarms on the Packet Bus when there is a fault on the Maintenance/Test Packet Bus Port. Refer to PKT-BUS (Packet Bus) Maintenance documentation for further information.

Hardware Error Log Entries and Test to Clear Values

M/T-PKT Error Log Entries

| Error Type     | Aux Data | Associated Test                            | Alarm Level | On/Off Board | Test to Clear Value    |
|----------------|----------|--------------------------------------------|-------------|--------------|------------------------|
| 0 <sup>1</sup> | 0        | Any                                        | Any         | Any          | test port PCSSpp       |
| 1 (a)          | 41018    | none                                       | MINOR       | ON           | test port PCSSpp l r 3 |
| 18 (b)         | 0        | busyout port PCSSpp                        | WARNING     | OFF          | release port PCSSpp    |
| 257 (c)        | Any      | none                                       | MINOR       | ON           |                        |
| 513 (d)        | Any      | Packet Bus Port Health Inquiry Test (#567) | MINOR       | ON           | test port PCSSpp r 3   |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates a hardware failure with the port circuitry which provides the Packet Bus maintenance functions. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the test command above.
- b. The port has been busied out via the **busyout port PCSSpp** command.
- c. This error indicates that the Maintenance/Test Packet Bus Port has reconfigured the Packet Bus (that is, swapped a bad lead to a spare). Note that this error is sent up whenever the Maintenance/Test Packet Bus Port is initialized (since the Packet Bus Port reconfigures the Packet Bus to whatever state it determines the Packet Bus is in). This occurs if the circuit pack is inserted, if the system is restarted, or if the port is released from a busyout state. Therefore, it is normal for this error to be present in the error log.

If the Maintenance/Test Packet Bus Port reconfigures the Packet Bus 12 times within 15 minutes, a Minor alarm is raised. When the Minor alarm is raised, this is an indication that the Packet Bus maintenance functions are not operating correctly, or that many changes are taking place on the Packet Bus (that is, circuit pack insertion or removal). If the system has been in a stable state for more than 15 minutes, try the following procedures:

- 1. Reset the Maintenance/Test circuit pack from the Manager I terminal, as follows:
  - Enter the **busyout board PCSS** command.

- Enter the **reset board PCSS** command.
  - Enter the **release board PCSS** command.
2. Wait 15 minutes.
  3. If the error recurs, replace the Maintenance/Test circuit pack.

When this alarm is active, the yellow LED is in one of three states:

- If there is no activity on the Maintenance/Test circuit pack, the yellow LED is off. It is OK to replace the Maintenance/Test circuit pack.
  - If there is an indication of an uncorrectable fault on the Packet Bus, the yellow LED will be blinking at a rate of 1 Hz. It is OK to replace the Maintenance/Test circuit pack. Ignore the Packet Bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.
  - If there is other activity on the Maintenance/Test circuit pack (that is, ISDN Test Call), or if there is an indication of a correctable fault on the Packet Bus, the yellow LED will be on steady. If there is an ISDN Test Call in progress, it must be halted via the **clear isdn-testcall grp/member** command prior to replacing the circuit pack. Ignore the Packet Bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.
- d. This error indicates a failure of the Packet Bus Port Health Inquiry Test. Either the Packet Bus Port has reported a self-test failure, or the SPE is able to communicate with the Maintenance/Test Circuit Pack but not with the Maintenance/Test Circuit Pack Packet Bus Port. Refer to the description of the Packet Bus Port Health Inquiry Test, and follow the instructions indicated for the failure code that matches the Aux Data field.

## System Technician-Demanded Tests: Descriptions and Error Codes

---

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Packet Bus Port Health Inquiry Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| Packet Bus Port Health Inquiry Test (#567) | X                   | X                  | ND                |
| Clear Error Counters (#270)                |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Clear Error Counters (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. These counters are used so that CCMS (Control Channel Message Set) messages are not continuously sent uplink. Using this method, the message are sent once, when the counter reaches some preset threshold, and then not sent again until the counter is cleared.

The ports on the Maintenance/Test circuit pack continually run self-tests, whenever the port is idle. The Angel uses a counter so that the Background Maintenance Failure message is only sent uplink once (this keeps a failed port/circuit pack from flooding the SPE with a string of messages). This test is used to clear the counter, so that if the port continues to fail during or after SPE-demanded testing, the Angel sends a message to indicate that fact.

This test is only used to send a message to the Angel on the Maintenance/Test circuit pack. Therefore, this test should never abort or fail.

Table 10-283. TEST #270 Clear Error Counters

| Error Code | Test Result | Description/ Recommendation                                                                                                                                              |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Any        | ABORT       | This test should never abort.                                                                                                                                            |
| Any        | FAIL        | This test should never fail.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to fail, escalate the problem. |
|            | PASS        | The message to clear the Maintenance/Test circuit pack's counter for Background Maintenance Failures has been sent.                                                      |

Packet Bus Port Health Inquiry Test (#567)

This test verifies that the Packet Bus fault detection maintenance function of the Maintenance/Test Packet Bus Port is functioning properly. This is done by having the Maintenance/Test Packet Bus Port perform a self-test. If this self-test passes, then the Packet Bus Port Health Inquiry Test passes. If the self-test fails, or the SPE cannot communicate with the Maintenance/Test Packet Bus Port, then the test fails.

Table 10-284. TEST #567 Packet Bus Port Health Inquiry Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                    |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                                                                                                                                                                                                |
| 2100       | ABORT       | System resources necessary to run this test are not available.                                                                                                                                                                                                                                                                                                                                                                                 |
| 2500       | ABORT       | An internal operation failed; the test could not be completed.<br><br>1. Retry the command at one-minute intervals a maximum of five times.<br><br>2. If the test continues to abort, escalate the problem.                                                                                                                                                                                                                                    |
| 2059       | FAIL        | The Maintenance/Test Packet Bus Port has reported a failure of the on-board self-test.                                                                                                                                                                                                                                                                                                                                                         |
| 2060       | FAIL        | The Maintenance/Test Packet Bus Port has reported an invalid state for the Packet Bus.                                                                                                                                                                                                                                                                                                                                                         |
| 2061       | FAIL        | The SPE cannot communicate with the Maintenance/Test Packet Bus Port, but is able to communicate with the Maintenance/Test Circuit Pack.<br><br>1. Retry the command.<br><br>2. If the test continues to fail, replace the Maintenance/Test circuit pack and retry the command.<br><br>3. If the test continues to fail, refer to PKT-BUS Maintenance documentation to determine if the M/T-PKT failure is being caused by a Packet Bus fault. |
|            | PASS        | The Maintenance/Test Packet Bus Port Packet Bus fault detection capability is operating correctly.                                                                                                                                                                                                                                                                                                                                             |

## OPS-LINE (DS1 OPS Line)

| MO Name As It Appears in Alarm Log | Alarm Level | Initial System Technician Command to Run | Full Name of MO |
|------------------------------------|-------------|------------------------------------------|-----------------|
| OPS-LINE                           | MINOR       | test station <ext> I                     | DS1OPS Line     |
| OPS-LINE                           | WARNING     | test station <ext>                       | DS1OPS Line     |

An analog Off-Premises Station (OPS) can be connected to the system through a DS1 link. A TN767 DS1 Interface circuit pack supports up to 24 DS1OPSs. Since the DS1OPS is an analog telephone set, a channel multiplexer is necessary as the remote DS1 endpoint that converts the digital signal of a DS1 port to the OPS Line and vice versa. See [Figure 10-73](#) for details.

The DS1OPS Line Maintenance provides a strategy to maintain an OPS Line via a port of the DS1 Interface circuit pack. The strategy covers initialization tests, periodic tests, system technician-demanded tests, and alarm resolution and escalation. Two service states are specified in a DS1OPS Line maintenance. They are: *out-of-service* in which the line is in a deactivated state and cannot be used for either incoming or outgoing calls; *in-service* in which the line is in an activated state and can be used for both incoming and outgoing calls. If the DS1 Interface circuit pack is out-of-service, then all lines on the DS1 Interface circuit pack are put into the out-of-service state, and a Warning alarm is raised.

For maintenance of the remote DS1 endpoint (for example, Channel Division Multiplexer, D4 Channel Bank), refer to the maintenance documentation from its vendor for details.

Figure 10-73. DS1 OPS Line Interactions

Hardware Error Log Entries and Test to Clear Values

DS1 OPS Maintenance Error Log Entries

| Error Type     | Aux Data | Associated Test              | Alarm Level | On/Off Board | Test to Clear Value       |
|----------------|----------|------------------------------|-------------|--------------|---------------------------|
| 0 <sup>1</sup> | 0        | Any                          | Any         | Any          | test station <ext> sh r 1 |
| 15 (a)         | Any      | Audit and Update Test (#36)  |             |              |                           |
| 18 (b)         | 0        | busyout station <ext>        | WARNING     | OFF          | release station <ext>     |
| 130 (c)        |          | None                         | WARNING     | ON           | test station <ext>        |
| 1281           |          | Conference Circuit Test (#7) | MINOR       | ON           | test station <ext> I      |
| 1537           |          | NPE Crosstalk Test (#6)      | MINOR       | ON           | test station <ext> I      |
| 1793 (d)       |          |                              |             |              | test circuit pack PCSS I  |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).
- b. The DS1OPS Line has been busied out by a **busyout station <ext>** command. No calls can be made on this line.
- c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- d. Error Type 1793 indicates a problem with the DS1 Interface circuit pack. Since there is no error against the OPS-LINE port, no alarm is raised against the OPS-LINE port. However, there should be errors logged against the DS1 Interface circuit pack. Look for DS1-BD errors in the Hardware Error Log and follow procedures provided in the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)               |                     | X                  | ND                |
| Conference Circuit Test (#7)          |                     | X                  | ND                |
| DS1OPS Switchhook Inquiry Test (#312) | X                   | X                  | ND                |
| Audit and Update Test (#36)           | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-285. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                   |

| Any        | FAIL        | <p>The test failed. This can be due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane.</p> <ol style="list-style-type: none"><li>1. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and to the TONE-PT Maintenance documentation.</li><li>2. Retest when the faults from step 1 are cleared.</li></ol>                                                                                                                                                        |
|            | PASS        | <p>The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol> |

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol> |

Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk as kept in the DS1 Interface circuit pack and in the switch software.

Table 10-287. TEST #36 Audit and Update Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0          | NO BOARD    | <p>The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.</p> <ol style="list-style-type: none"><li>1. Check to ensure that the board translations are correct. Use the <b>list config</b> command, and resolve any problems that are found.</li><li>2. If the board was found to be correctly inserted in step 1, issue the <b>busyout board</b> command.</li><li>3. Issue the <b>reset board</b> command.</li><li>4. Issue the <b>release busy board</b> command.</li><li>5. Issue the <b>test board long</b> command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.</li></ol> |

DS1 OPS Switchhook Inquiry Test (#312)

This test initiates the Switchhook Audit Test. The test queries the switchhook state of the Off-Premises-Station in switch software. If the state in switch software disagrees with the state on the DS1 Interface circuit pack. The state in the switch software is updated to match the state on the DS1 Interface circuit pack.

- 
1.

Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).
2.

The DTDM is considered to be part of the DIG-LINE MO. Refer to the Digital Line testing section for DTDM or linked Data Adapter (DA) failures.
3.

Some of the alarms that are logged due to PDMODULE and TDMODULE test failures may be related to circuit pack problems reported during the Common Port Circuit Pack testing phase. Refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation for information about testing the Digital Line circuit packs.

As illustrated in [Figure 10-74](#), data modules provide an interface between the system TN754, TN784, TN413 [G3iV2-386], or TN754 [G3iV2-386] Digital Line circuit pack and data equipment such as terminals, host computers, and modems. Data modules are used for both dial-up and permanent circuit-switched data calls. DA data modules provide this interface when the system uses a TN2136 [G3iV2-386] Digital Line circuit pack.

**Figure 10-74. Typical Data Module Application**

The MPDM provides an interface for Data Terminal Equipment (terminals), and the MTDM (see Note) provides an interface for Data Communications Equipment (transmission equipment such as modems).

**NOTE:**  
Early versions of these data modules were referred to as PDMs and TDMs, respectively. Later models are designed to provide various customer interfaces through the use of interchangeable interface modules and, therefore, are called modular data modules. Both versions are supported by the tests described in this section.

The PBX loop or digital link between a data module and the Digital Line port supports two logical information channels and one signaling channel. MPDMs and MTDMs use the primary information channel for data communications and the signaling channel for dialing and call supervision. The secondary information channel can be used to support a second data module on a shared digital port.

Data modules are not only used for data calls between terminals, computers, and data communications equipment, but are also used as interfaces to equipment associated with system features such as System Administration, CDR, MCS, ACD, DCS, and AUDIX. Maintenance tests for data modules associated with

those services are covered by tests other than those described here. (See PI-LINK, PMS-PRNT/JNL-PRNT, and PMS-LINK Maintenance documentation.)

Maintenance of MPDMs and MTDMs is closely related to, and interacts with, the Digital Line circuit pack maintenance in some instances and some of the results of testing MPDMs and MTDMs may be affected by the health of the Digital Line circuit pack. This interaction should be kept in mind when investigating the cause of reported data module problems.

Data modules provide a variety of option switches to allow the customer to select data rates, parity, keyboard dialing, local, and remote loop back, etc. An incorrect setting of those switches does not affect error and alarm information or test results described in this section, but it may result in an inoperable condition. Refer to the Installation Manual provided with the data module for more information about those options.

The DA data module provides an AT (Hayes) type interface that allows the customer to select data rates, parity, local, interface mode (**linked** to digital phone or **stand-alone**), and remote loop back, etc. An incorrect selection does not affect error and alarm information or test results described in this section, but it may result in an inoperable condition.

There are instances in this document where the service state of a data module is mentioned. It is helpful to understand what is meant by the different service states that may exist. An explanation of these service states follows:

- **Out-of-Service**—The port, and thus the data module, have been removed from service. A busyout of a port or removal of the associated Digital Line circuit pack causes the data module to be placed in the out-of-service state. Failure of the NPE Crosstalk Test (Test #9) also takes a port out-of-service.
- **Disconnected**—The port is administered but the associated digital link does not respond. An administered port is put in a disconnected state after system booting or circuit pack insertion, until a "link reset pass" message is received from firmware on the associated circuit pack.
- **In-Service**—Once the PBX software has received a "link reset pass" message from the Digital Line port, the port is placed in the in-service state. In case the "link reset pass" message is missed, and an off-hook message is received while the port is in the disconnected state, maintenance software runs an ID request test and the port is put back in service if a correct response is received.

If the link is disconnected, the port returns to the disconnect state. Note that it takes a few minutes (less than five) for the state of a data module port to change from in-service to disconnected after the data module is disconnected from the local PBX loop.

Hardware Error Log Entries and Test to Clear Values

PDMODULE and TDMODULE Error Log Entries

| Error Type       | Aux Data | Associated Test                                                | Alarm Level | On/Off Board | Test to Clear Value     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. G3iV1.1-286 and G3iV2-386 only.

## Notes:

- a. Could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for faulty wiring, check for a defective data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire; see Note). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired automatically within 60 minutes.

The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

### NOTE:

Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111.

- b. This error type and auxiliary data occur when at least 15 off-board problems have been detected with the link to the data module. When an error with the link is detected, an on-board counter is incremented.

The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for faulty wiring, check for a faulty data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire; see the next Note). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired automatically within 60 minutes.

The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

### NOTE:

Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111.

- c. This is an internal type error that occurs when an audit request fails.
- d. This error type is logged when the port in question is busied out by maintenance personnel. Make sure that the port is released from busyout.
- e. There are problems with transmitting to the data module. This is usually an on-board problem and can be ignored if no user complaints are received. Otherwise, check for faulty wiring.

- f. This error indicates that EPF has been turned off due to the overcurrent condition at the data module. Make sure that the data module is connected. Look for faulty wiring or a defective data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire; see Note). If the problem still exists, it may be due to the fact that the PTC is in the "tripped" position due to a short on the power line. This can be corrected by removing the short, unplugging the data module from the wall for about 30 seconds, and plugging it back in. If the problem persists, replace the Digital Line circuit pack. Once the problem has been resolved, the alarm is retired after a predetermined period of time since this counter uses a "leaky bucket" strategy.

The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

**NOTE:**

Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111.

- g. An in-line maintenance error has generated an off-board warning due to some problem with the link to the data module. This can be ignored if no user complaints are received. Otherwise, make sure the data module is connected, check for faulty wiring, check for a defective data module, or reduce the cabling distance between the data module and the PBX (5000 feet for 24-gauge wire and 4000 feet for 26-gauge wire, see Note). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired automatically within 90 minutes.

The DA module is not phantom-powered from the port and hence its range is limited by the Italtel digital phone's limit (0.7 km, 2300 feet, on 26-gauge wire or 1.8 km, 5900 feet, on 22-gauge, 0.6 mm, wire) if in **linked mode**, or by the maximum length of loop allowed from the Digital Line Interface (DLI) component (up to 3.5 km, about 2 miles, with 22-gauge, 0.6 mm, wire) if in **stand-alone mode**.

**NOTE:**

Refer to the *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111.

- h. This indicates that the data equipment went off-hook while the associated link was being initialized (in a disconnected state). Use the **status data-module** command to determine the state of the data module. The off-hook should have changed the service state to in-service. No system technician action is necessary.

- i. This is the resulting code that is generated when the link between the circuit pack and the data module is successfully reset. The link is normally reset when the circuit pack associated with an administered port is first plugged in (assuming that the data module is already in place and connected to the associated port), when a port is first administered (assuming the associated circuit pack is plugged in and that the data module is connected to the associated port), or when a data module is first connected to an administered port. No system technician action is necessary.
- j. This warning off-board alarm occurs only for G3iV1.1-286 or G3iV2-386. The alarm occurs when it appears to the system that a DCP endpoint has been disconnected.
- k. A DCP endpoint may have been disconnected.
- l. This endpoint is part of processor link. Link initialization has failed (or demand test for #183 for PI links has failed) and is indicating the associated PDM as the cause. Check the PDM, the wiring to the PDM and the link to the far end (i.e. AUDIX DCS, etc.) to resolve the problem.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Data Module Internal Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| Data Module Internal Loop Around Test (#175)           |                     | X                  | ND                |
| Network Processing Element Crosstalk Test (#9)         |                     | X                  | ND                |
| Information and Control Channel Loop Around Test (#13) |                     | X                  | ND                |
| Data Module Audits Test (#17)                          | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#9)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. If a secondary data module is assigned, it is tested after the primary data module. If either test fails, both data modules are taken out of service This test usually runs only during the Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-289. TEST #9 NPE Crosstalk Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2500       | ABORT       | Internal System Error.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to fail, escalate the problem.                                                                                                                                                             |
| 1,2        | FAIL        | The NPE of the tested port was found to be transmitting in Error Log. This causes noisy and unreliable connections. Failure Code 1 indicates that the Crosstalk Test failed on the primary channel. Failure Code 2 indicates that the Crosstalk Test failed on the secondary channel.<br><br>1. Replace the circuit pack. |
|            | PASS        | The port is correctly using its allocated time slots.<br><br>1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times and verify that it continues to pass.<br><br>2. If complaints still exist, examine the data module, connections, and wiring.                            |

**Information and Control Channel Local Loop  
Test (#13)**

This is a set of four tests that check the operation of the information and control channels used between the SPE and the Digital Line port circuit.

**➤ NOTE:**

This is an Internal Loop Around test only and does not check building wiring. Use Test #175 for external loop around tests to the data module.

1. The SPE first sends a message to the on-board microprocessor to loop around both the information and control channels for the port. Then, the primary information channel loop back test is run. The test is performed by sending a digital count from the Tone-Clock circuit pack on the primary channel time slot and receiving the same digital count with a GPTD. The digital count looks like transparent data to the on-board microprocessor.

- 2. With the port still in loop around mode, the S channel Loop Around Test is performed next. This test consists of sending four different transparent patterns to the on-board microprocessor, receiving them back, and comparing them.
- 3. The third test is a Loop Around Test for the secondary (alternate) channel. It is not performed for data modules since this channel is not used by MPDMs, MTDMs, and stand-alone DA's [G3iv2-386].
- 4. A Conference Test is done next for the primary channel. This test is the same as the Analog Line Terminal/Port Conference Test (#6).

Only one value (Pass, Fail, or Abort) is generated as a result of four tests run. If any test fails or aborts, the sequence is stopped.

Data Module Audits Test (#17)

This is a series of six tests that are classified as hardware audits. The processor sends messages to the on-board microprocessor to perform the following tests.  
[G1] The audits run only if the station is in-service.

- Switchhook Inquiry — This is an update of the processor's software records based on the on-hook/off-hook status of the data module.
- Bad Scan Inquiry — A message is sent uplink that contains a count generated by certain events relating to the digital loop's (link) conditions. This could be an indication of communication problems between the processor and digital port circuit pack.
- EPF inquiry — The status of the EPF is sent uplink. EPF is not used for data modules.
- ID Request — A request is made to the data module for its status. The data module sends its configuration information and health information back. This information is checked and a pass/fail result is provided.
- Ringer Update — This updates the data module's ringer state according to processor records.
- Translation Update — This is a message normally used with digital stations to refresh the default value that causes the station to send touch-tones only in the primary information channel. This test is not used with data modules.

|            | PASS        | Data Module Audits passed. This digital port circuit pack is functioning properly.<br><br>1. If complaints still exist, investigate by using other port tests, and by examining the data module options, wiring, and connections. |

**Data Module Internal Loop Around Test (#175)**

This test verifies that a data message can be sent from the PBX, through the building wiring, through an internal looparound path in the data module under test, and back to the PBX. [Figure 10-75](#) shows the hardware configuration used for this test.

**Figure 10-75. Internal Loop Around Test**

A signaling message is sent through the digital port circuit pack to the data module under test to request it to enter loop around mode. A test pattern is then sent from the SPE through the Network Control circuit pack (Netcon), over the TDM Bus, through the digital port circuit pack, to the data module where the message is looped around, and sent back through the digital port circuit pack, the TDM Bus, the Network Control circuit pack, and to the SPE where it is checked for consistency.

This test aborts if no terminal or communications equipment is connected to the data module. It also aborts if a number of local PBX resources are not available. These resources include a network control channel from the Network Control circuit pack (there are a maximum of four channels administered as Netcon-type data modules), two TDM time slots (one for each direction of the loop around message), and an idle digital port circuit associated with the data module under test. Failure to allocate any of these resources causes the test to abort with a specific error code for that resource.

A "yes/no" parameter on each data module (MPDM, MTDM, or stand-alone DA only) administration form is required to specify if the Data Module remote Loop Around Test is supported by the data module endpoint. If the parameter is "n" (no), the test does not run.

## PE-BCHL (PRI Endpoint Port)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO   |
|------------------------|-------------|------------------------|-------------------|
| PE-BCHL <sup>1</sup>   | MINOR       | test port PCSSpp l     | PRI Endpoint Port |
| PE-BCHL                | WARNING     | test port PCSSpp sh    | PRI Endpoint Port |

1. For additional repair information, see also UDS1-BD (UDS1 Interface Circuit Pack) maintenance documentation and [“Troubleshooting PRI Endpoint Problems”](#) in [Chapter 5](#).

A PRI Endpoint provides ISDN-PRI (Primary Rate Interface) connections for customers with application equipment or terminal adapters that terminate ISDN-PRI. The equipment or terminal adapters are connected to the switch via the UDS1 interface circuit pack. PRI Endpoint Port (PE-BCHL) maintenance provides a strategy to maintain PRI Endpoint Port hardware circuitry on the UDS1 circuit pack. The maintenance strategy involves logging PRI Endpoint Port hardware errors, running tests for port initialization, periodic and scheduled maintenance, system technician-demanded tests, and alarm escalation and resolution.

## Wideband Switching

The Wideband Switching capability supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. DEFINITY switching capabilities are extended to support wideband calls comprised of multiple DSOs that are switched end-to-end as a single entity.

The Wideband Switching capability is designed for ISDN application equipment (for example, ISDN video codecs), but it retains provisions for non-ISDN application equipment by using PRI terminal adapters. In the same sense that a DEFINITY data module acts as a DCP or BRI terminal adapter between endpoint data (for example, V.35) and dialing (for example, RS-366) interfaces and a DCP interface, a PRI terminal adapter acts as a wideband terminal adapter between endpoint data and dialing interfaces and DEFINITY’s line-side ISDN PRI interface.

The Wideband Switching Capability introduces PRI Endpoints on DEFINITY line-side interfaces. A PRI Endpoint consists of one or more contiguous B-channels on a line-side T1 or E1 ISDN PRI facility, and it has an extension number. Endpoints initiate and receive calls using ISDN SETUP messages that indicate the data rate and specific B-channels to be used, and they communicate all other call status information via standard ISDN messages. Any

DEFINITY ISDN signaling set (for example, AT&T, CCITT, ECMA) may be used for a line-side ISDNPRI facility.

Multiple PRI Endpoints on a one line-side facility are separate and distinct within the facility. Non-overlapping contiguous sets of B-channels are associated with each PRI Endpoint, and the endpoint equipment is expected to initiate calls within these boundaries.

The endpoint application equipment must be able to do the following: use standard ISDN-PRI signaling, adhere to the PRI Endpoint boundaries as administered on DEFINITY when initiating calls, and handle incoming calls appropriately based on the PRI Endpoint.

## Signaling and B-channel States

---

These ports use a separate channel for signaling (for example, for call setup). This mode of operation is known as out-of-band signaling. The separate signaling channel is called a D-channel in ISDN terminology, and it carries all the call control signaling messages for the PRI Endpoint Port B-channels. The D-channel for these B-channels is an ISDN-PRI Signaling Link Port (ISDN-LNK). The signaling protocol used on the ISDN-PRI Signaling Link Port D-channel is defined by one of the four selectable ISDN-PRI Specifications: AT&T, CCITT, ECMA, and ANSI.

The ISDN-PRI Specification defines the possible SERVICE STATES for a B-channel. The service state is negotiated with the far-end terminal adapter, and it changes over time. Also, the service state may have a far-end or near-end component, and it is initialized to the Out-Of-Service/Far-End state. An attempt is made to negotiate the service state to In-Service.

### NOTE:

The service state of a particular PRI Endpoint Port B-channel can be displayed by issuing the **status pri-endpoint <extension>** system technician command.

If a call is present, the ISDN-PRI Specification defines the permissible CALL STATES as well. There are tests in the short and long test sequences for PRI Endpoint Port that are designed to audit these states and to ensure agreement between both ends of the PRI wideband connection.

## Alarming based on Service States:

---

A PRI Endpoint Port B-channel is alarmed with a WARNING if it is placed into a Maintenance/Far-End or Out-Of-Service/Far-End state. While in such a state, the port is unusable for calls to the terminal adapter. However, the user can still use the other remaining ports in the PRI Endpoint to make calls to and from the terminal adapter. When a WARNING alarm is raised, the **status pri-endpoint <extension>** command should be used to determine the exact state of the port.

Other alarms can be diagnosed by using the short and/or long test sequences. Note that a PRI Endpoint Port B-channel can be placed into a Far-End Service State either by direct action of the far-end terminal adapter or by inaction of the far-end terminal adapter. For example, if they do not respond to a Remote Layer 3 Query (see Test #260 for ISDN-PRI Signaling Link Port), the associated PRI Endpoint Port B-channels are placed into the Maintenance/Far-End service state.

A PRI Endpoint Port is a port on a UDS1 interface circuit pack. Therefore, this port depends on the health of the UDS1 interface circuit pack for proper operation (see [Figure 10-76](#)). As noted earlier, a PRI Endpoint Port B-channel also depends on an ISDN-PRI Signaling Link Port D-channel (ISDN-LNK) to carry the signaling traffic. If there is a problem with the ISDN-PRI Signaling Link Port, the PRI Endpoint Port is affected. The ISDN-PRI Signaling Link Port, in turn, depends on the PI-LINK (Processor Interface Link). Processor Interface Link problems affect the ISDN-PRI Signaling Link Port. Keep this hierarchy of dependencies in mind when diagnosing problems.

**Figure 10-76. PRI Endpoint Port Interactions [INTEL]**

**PRI Endpoint Port Service States**

This section defines the possible service states of a PRI Endpoint Port, and it explains the reason for each service state. This section also provides the recommended recovery procedures (when required).

**Service States**

- In-Service (INS)

The B-channel is in its normal operating state.

- Out-of-Service/Far-end (OOS/FE)

A B-channel is initialized to this state when administered. The switch sends messages to the far-end terminal adapter to negotiate the B-channel into service. If the far-end terminal adapter does not respond to the messages within a certain time period, the service state remains out-of-service, and maintenance periodically resends the messages. The port is unusable for calls incoming to the switch and outgoing to the terminal adapter (although other ports in the PRI Endpoint can still be used for incoming and outgoing calls).

- Out-of-Service/Near-end (OOS/NE)

This is the state of the port whenever one of the following is true: a hardware failure exists on the signaling link, the NPE Crosstalk Test fails, or the port is busied out by system technician. In this state, the port is unusable for calls incoming to the switch or outgoing to the terminal adapter (although other ports in the PRI Endpoint can still be used for incoming and outgoing calls). No messages are sent to the far-end terminal adapter until the signaling link comes back into service or until the port is released by system technician.

- Maintenance/Far-end (MTC/FE)

This state is reached when the far-end terminal adapter does not respond to messages sent over the signaling link for a particular port after a certain amount of time. This state is different from OOS/FE inasmuch as the signaling link must be up initially and the B-channels must be in-service. The switch periodically sends messages to the far-end terminal adapter in an attempt to negotiate the port (B-channel) into service. The port is unusable for calls outgoing to the terminal adapter. However, the port services incoming call requests from the far-end (although other ports of the PRI Endpoint can still be used to answer calls incoming to the switch or to place outgoing calls to the terminal adapter). Note that transitions into MTC/FE do not drop stable calls. Therefore, if the service state changes from in-service to MTC/FE, stable calls are unaffected.

- Maintenance/Near-end (MTC/NE)

The port (B-channel) is in this state if the signaling link (PI-LINK) is busied out by system technician. The port (B-channel) is also temporarily in this state if the system technician has issued a **test port PCSSpp I** or a **test pri-endpoint <extension> I** command. Note that transitions into MTC/NE do not drop stable calls. Therefore, a system technician-demanded **busyout link lnk-no** command does not drop stable wideband calls. In this state, the B-channel is not usable either for new calls incoming to the switch or for new calls outgoing to the terminal adapter.

- Pending States (PEND)

If the near-end is expecting a timed response from the far-end for a request to change the service state of a port, the state of the port reflects a Pending state. For example, if the port is out-of-service/far-end and if an

in-service message is sent to the far-end, the service state of the port is OOS/FE-PEND/INS (that is, out-of-service/far-end-Pending/in-service). The far-end has a certain amount of time to respond to the message. The service state reflects this pending state until the timer expires.

The following diagram of the PRI Endpoint Port service states shows the common progression from one service state to another and the event that caused the change of state.

Figure 10-77. Common Progressions in Service States

PRI Endpoint Port Service States

The following table summarizes each of the different PRI Endpoint Port service states that can result when the **status pri-endpoint <extension>** command is issued. From the results of the status command, match the service state to the

corresponding column. Proceed down the column until an "X" is found. The left column indicates possible reasons why the port is in this state, and the right column suggests possible recovery mechanisms. If an alarm against PE-BCHL is present, it is indicated below the "X."

 **NOTE:**  
Refer to "Troubleshooting PRI Endpoint Problems" in [Chapter 5, "Routine Maintenance Procedures"](#) for a layered approach to the processing of PRI Endpoint problems.

Table 10-293. PRI Endpoint Port Service States

| Possible Problem Source               | O/S-NE           | O/S-FE | O/S- FE Pend- ins | maint-NE | maint- FE | maint-FE Pend- ins | INS | Possible Recovery Route                                                                                                                                  |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error type indicates a disagreement between the switch and the terminal adapter at the other end of the connection with regard to the ISDN *call* state of the PRI Endpoint Port. This switch automatically tries to recover by clearing the call (that is, the call is torn down). The **status pri-endpoint <extension>** command can be used to determine the state of the port.

When running the Short Test Sequence of tests, pay close attention to the results of the Call State Audit Test (#257).

- b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate the associated errors (if any).
- c. The PRI Endpoint Port has been busied out by a **busyout pri-endpoint <extension>** command or by a **busyout port <PCSSpp>** command. No wideband calls can be made to this port (although wideband calls can still be made to other ports within this PRI Endpoint if others ports are in service).
- d. The far-end terminal adapter changed its ISDN *service* state to either "out-of-service" or "maintenance." This may be a temporary condition due to the testing of this port by the far-end terminal adapter *or* by a hardware problem with the port. Outgoing calls to the terminal adapter are not allowed over the port (although calls can still be made to other ports that are in service within the same PRI Endpoint). To investigate the status of the port, issue the **status pri-endpoint <extension>** command.
- e. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- f. This error type indicates a disagreement between this switch and the terminal adapter at the other end of the connection with regard to the ISDN service state of the PRI Endpoint Port. This switch tries to recover by performing a service state audit. The **status pri-endpoint <extension>** command can be used to determine the state of the port.

When running the Short Test Sequence, pay close attention to the results of the Service State Audit Test (#256).

- g. This port is not recognized by the far-end terminal adapter. Investigate the PRI Endpoint administration for both the switch and the terminal adapter and make changes as necessary.
- h. The Conference Circuit Test (#7) failed on this port. See Test #7 for the repair procedures.
- i. The NPE Crosstalk Test (#6) failed on this port. See Test #6 for the repair procedures.
- j. This error indicates a failure of the UDS1 Interface circuit pack. When running the Short Test Sequence, the results of the Signaling Link State Check Test (#255) are important.
- k. Two Service State Audit attempts have failed (see Test #256). The port is not usable for any outgoing calls to the terminal adapter (although incoming calls from the terminal adapter are accepted over this port, other ports in the PRI Endpoint can still be used for both incoming and outgoing calls to and from the terminal adapter) until the test passes and the port state is changed to in-service (use the **status pri-endpoint <extension>** command to investigate the port status).

- I. This error type appears when the switch receives an ISDN RESTART message for an ISDN port that is not idle. Usually, calls are not cleared via the RESTART message. Therefore, this error type may be associated with a dropped call report from a user.

The following Aux Data values for Error Type 3585 represent the port's ISDN call state at the time that the unexpected request to restart the channel is received from the remote terminal adapter. This information can be useful if dropped calls (cutoffs) are being reported by users of the PRI Endpoint.

The following list contains important Aux values. Any other such values can be ignored.

- 10
- A call in a stable, talking state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message. This state is called the "active" state.
- 4,  
7,  
8,  
260,  
263
- A call that did not reach the active state but at least reached a ringing state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
- 1,  
3,  
6,  
9,  
265
- A call that has not yet reached a ringing state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.
- 11,  
12,  
19,  
531,  
267,  
268
- A call that was in the process of clearing has been nonetheless cleared by the far-end terminal adapter with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end terminal adapter is attempting to clear ports that it thinks are in a "hung" state. The RESTART message brings the port to an idle condition.

**System Technician-Demanded Tests:**  
**Descriptions and Error Codes**

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-295. System Technician-Demanded Tests: DS1-BD

| Order of Investigation                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------|---------------------|--------------------|-------------------|
| NPE Crosstalk Test (#6)                |                     | X                  | ND                |
| Conference Circuit Test (#7)           |                     | X                  | ND                |
| Audit and Update Test (#36)            | X                   | X                  | ND                |
| Signaling Link State Check Test (#255) | X                   | X                  | ND                |
| Service State Audit Test (#256)        | X                   | X                  | ND                |
| Call State Audit Test (#257)           | X                   | X                  | ND                |

1. D = Destructive, ND = Non-destructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots that are reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's long test sequence, and takes about 20 to 30 seconds to complete.

Table 10-296. TEST #6 NPE Crosstalk Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                               |

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                     |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Any        | FAIL        | The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. The PE-BCHL is moved to the out-of-service/near-end state.<br><br>1. Replace the circuit pack. |
|            | PASS        | The port is able to communicate over the TDM Bus.                                                                                                                                                              |

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464C UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.) The NPE controls port connectivity and gain, and it provides conferencing functions on a per port basis. The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and to conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 10-297. TEST #7 Conference Circuit Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                    |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Could not allocate the necessary system resources to run this test.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                   |
| 1000       | ABORT       | System resources required to run this test are not available. The port may be in use on a valid call. Use the <b>status pri-endpoint &lt;extension&gt;</b> command to determine when the port is available for testing.                                                       |
| 1004       | ABORT       | The port has been seized by a user for a valid call. Use the <b>status pri-endpoint &lt;extension&gt;</b> command to determine when the port is available for testing.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                |
| 1020       | ABORT       | The test did not run due either to an already existing error on the specific port or to a more general circuit pack error.<br><br>1. Examine Error Log for existing errors against this port or against the circuit pack, and attempt to diagnose the already existing error. |

Table 10-297. TEST #7 Conference Circuit Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                  |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2000       | ABORT       | Response to the test request was not received within the allowable time period.                                                                                                                                                                                                             |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                     |
| Any        | FAIL        | The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections.<br>1. Replace the circuit pack. Even though wideband calls do not use the conferencing feature on the NPE, this failure indicates problems with the circuit pack hardware. |
|            | PASS        | The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using the other port tests and by examining the terminal adapter or the external wiring.                                                                              |

Audit and Update Test (#36)

This test sends port level translation data from the switch processor to the UDS1 interface circuit pack to ensure that the port’s translation is correct. The port audit operation verifies the consistency of the current state of the port that is kept in the UDS1 interface circuit pack and in the switch software.

|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | PASS        | <p>The port translation has been updated successfully. The current port states kept in the UDS1 interface circuit pack and in the switch software are consistent. If the port is busied out, the test does not run, but returns PASS. To verify that the port is in-service:</p> <ol style="list-style-type: none"><li>1. Enter <b>status pri-endpoint &lt;extension&gt;</b> to verify that the port is in-service. If the port is in-service, no further action is necessary. If the port is out-of-service, go to Step 2.</li><li>2. Enter the <b>release pri-endpoint &lt;extension&gt;</b> command or the <b>release port &lt;PCSSpp&gt;</b> command to put the port back into in-service.</li><li>3. Retry the test command.</li></ol> |

Signaling Link State Check Test (#255)

As is noted in the general description for a PRI Endpoint Port, the operation of the PRI Endpoint Port depends on the health of the UDS1 interface circuit pack and of the TN765 Processor Interface Link. This test checks the status of those critical elements.

Table 10-299. TEST #255 Signaling Link State Check Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

Further information may also be obtained by consulting the procedures for the ISDN-PRI Signaling Channel (ISDN-LNK). |
| 8          | FAIL        | There is a problem with the UDS1 interface circuit pack.<br><br>1. Consult the procedures for UDS1 interface circuit pack (UDS1-BD).                                                                                                                                                                                                                   |
|            | PASS        | The signaling link hardware is okay.                                                                                                                                                                                                                                                                                                                   |

Service State Audit (#256)

As is noted in the general description for PRI Endpoint Port, these ports may be in one of several service states as defined by the ISDN-PRI Specification. This test performs a service state audit with the far-end terminal adapter to ensure that both sides agree on the service state.

A PASS for this test simply means that an audit message was successfully composed and sent out to the far-end terminal adapter. The ISDN Specification allows up to two minutes for a reply. If no reply is received within that two minute window, this switch automatically tries once again. If that attempt fails, an error is logged (Error Type 3073), and the switch attempts a recovery by automatically retrying approximately every 15 minutes. If the port was initially in the INS (in-service) state, it is now placed into the MTC/FE (maintenance state, far-end problem) state. Until a Service State Audit attempt is successful, no outgoing calls are placed over this port, but incoming calls are be accepted. The service state of this port does not affect the service state of other ports in the PRI Endpoint. If an incoming call that uses this port is presented while in such a state, a Service State Audit attempt is immediately attempted (that is, the switch does not wait for the 15 minute cycle, but instead tries to recover immediately). To investigate the status of this PRI Endpoint Port, issue the **status pri-endpoint <extension>** command.

Table 10-300. TEST #256 Service State Audit Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

|            | PASS        | Wait 4 minutes and then check the Error Log for any new occurrences of Errors Type 3073.<br><br>If there are no occurrences of this error, both sides of the ISDN connection agree on the service state, and the negotiation succeeded. If there is a new occurrence of Error Type 3073, the negotiation failed (that is, the far-end terminal adapter twice failed to respond within the mandatory two minute window). This switch automatically retries approximately every 15 minutes. If the port was initially in the INS (in-service) state, it is now be placed into the MTC/FE (maintenance, far-end problem) state (refer to the "Service States" section, which precedes the PE-BCHL "Hardware Error Log Entries and Test to Clear Values" table). Incoming calls are accepted, but no outgoing calls are originated from this port. If an incoming call is presented, another Service State Audit is immediately performed in an attempt to bring the PRI Endpoint Port to the proper state. |

Call State Audit Test (#257)

If a call is active on the port, the switches on both sides of the connection should agree on the ISDN state of the call as defined in the ISDN Protocol Specification. This test audits internal call state data by querying the far-end terminal adapter

about the ISDN state of the call. It can be helpful when trying to clear a hung call. If the internal call state data on the near-end switch is different than that of the far-end terminal adapter, **the call is torn down**.

As with Test #256 (Service State Audit), a PASS simply means that an appropriate message was composed and sent to the far-end terminal adapter. The ISDN Specification allows up to two minutes for a reply. If a reply is not received within the two minute window, a protocol time-out violation is recorded in the error log against the associated signaling channel (ISDN-PRI Signaling Link Port, which is listed in the Error Log as ISDN-LNK; the Error Type is 1).

Table 10-301. TEST #257 Call State Audit Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

|            | PASS        | This switch sent a call state auditing message to the far-end terminal adapter to verify the state of the call active on this port. If a call state mismatch is found, the call is torn down within two minutes. If no call was active, no message was sent.                                                                                                                                                                                                                                                         |

# PI-BD (Processor Interface Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO                  |
|------------------------|-------------|-------------------------------------|----------------------------------|
| PI-BD                  | MINOR       | test interface PCS sh               | Processor Interface Circuit Pack |
| PI-BD                  | WARNING     | test interface PCS sh               | Processor Interface Circuit Pack |

1. Where P is the port network number (1 for PPN only); C is the carrier designation (for example, A or B for processor complex circuit packs); and S is the address of the slot in the carrier where the circuit pack is located (for example, 1 or 2 for either the first or second Processor Interface circuit packs).

The TN765 Processor Interface (PI) circuit pack provides a front-end processor to the TN777 Processor circuit pack. The PI circuit pack implements the packet layer and link layer of the X.25 protocol (DCS, AUDIX, CMS, OCM links) as well as the link layer of the ISDN-PRI protocol (ISDN links). A system without high or critical reliability supports up to two circuit packs. A high or critical reliability system supports up to four Processor Interface circuit packs, two in each carrier. One pair of the circuit packs on a single carrier can be active at a given time. The other two are in Standby mode. The TN765 is a downloadable circuit pack. This means that at reboot, system power-up, or via system technician command, Processor Interface firmware is downloaded to the circuit pack. For other restarts, a Checksum Test is performed on the firmware. If the Checksum Test fails, then the firmware is downloaded again. The firmware can be automatically downloaded at any time using the **reset interface PCS** system technician command.

On the Active SPE complex or in an unduplicated system, Processor Interface maintenance is used for alarming the circuit pack. If System Communication Interface (PI-SCI) finds an error or alarm condition that can be associated with an on-board problem with the Processor Interface (PI-BD) circuit pack, then it alarms both the System Communication Interface and the Processor Interface circuit pack. Processor Interface circuit pack maintenance is also used to test the common circuit pack functions on the circuit pack. If these tests fail, a circuit pack level alarm is raised on the Processor Interface circuit pack (PI-BD). Port level alarms are raised against PI-PT. See PI-PT (Processor Interface Port) Maintenance documentation for details.

On the Standby SPE complex, the testing of the Processor Interface circuit pack is different. The Standby Processor Interface circuit pack is tested daily via scheduled maintenance or on system technician demand. These tests are to check the Standby PIs hardware and firmware so that if an SPE interchange takes place, the Processor Interface communication links (DCS, ISDN, or AUDIX, for example) recover on the new Active Processor Interface circuit pack in a

short time. If the firmware checksum fails during scheduled maintenance, then the circuit pack can be downloaded again at this time instead of during the SPE interchange. The Processor Interface firmware can be unconditionally downloaded to the Standby SPE circuit pack via the **reset interface PCS** command, where PCS is the carrier/slot of a Standby PI. The command executes the Standby Processor Interface Board Test (#423), but with a download option.

The Active Processor Interface circuit pack is tested in the PI-SCI (System Communication Interface) Maintenance documentation. Refer to that section for details. The test command is **test interface PCS** where PCS is the port network number, carrier, and slot of one of the Standby Processor Interface circuit packs. If the Standby Processor Interface circuit pack is tested, the test sequence for the Standby Processor Interface is followed. If the Active Processor Interface circuit pack's PCS is given, then tests in the Active Processor Interface test sequence are run. On the Active PI, if there are no enabled Processor Interface links on the Communication-Interface Links Form, only the XXX-BD (Common Port Circuit Pack) tests execute.

Error Log Entries and Test to Clear Values

[Table 10-302](#) indicates entries that may be found in the Error Log for Processor Interface circuit packs. Since the Processor Interface circuit pack has common port board functionalities, then cross reference XXX-BD (common port board) maintenance information for more information. Test #423 is the only test described in this section. XXX-BD maintenance describes the other tests mentioned in the following table.

Table 10-302. PI-BD Error Log Entries

| Error Code     | Aux Data | Associated Test                         | Alarm Level | On/Off Board | Test to Clear Value       |
|----------------|----------|-----------------------------------------|-------------|--------------|---------------------------|
| 0 <sup>1</sup> | 0        | Any                                     | Any         | Any          | test interface PCS sh r 1 |
| 1 (a)          | 0        | Circuit pack removed or SAKI Test (#53) | MINOR       | ON           |                           |
| 23 (b)         | 0        | None                                    | WARNI NG    | OFF          |                           |
| 54 (c)         | 0        | None                                    | MAJOR       | ON           | test interface PCS I      |
| 124 (d)        | Any      | None                                    | MAJOR       | ON           | test interface PCS I      |
| 125 (e)        |          | None                                    | MINOR       | ON           |                           |
| 257            | 65535    | Control Channel Test (#52)              | MINOR       | ON           | test interface PCS        |
| 257 (f)        | Any      | None                                    |             |              |                           |
| 513 (g)        | Any      | None                                    |             |              |                           |

Table 10-302. PI-BD Error Log Entries — Continued

| Error Code | Aux Data | Associated Test                     | Alarm Level | On/Off Board | Test to Clear Value   |
|------------|----------|-------------------------------------|-------------|--------------|-----------------------|
| 769 (h)    | 4358     | None                                |             |              |                       |
| 1025 (i)   | 4363     | NPE Audit Test (#50)                |             |              | test interface PCS sh |
| 1538 (j)   | Any      | None                                | MINOR       | ON           |                       |
| 3585 (d)   | Any      | None Test (#423)                    | MAJOR       | ON           | reset interface PCS I |
| 3840 (i)   | Any      | None                                |             |              |                       |
| 3841       | Any      | Standby PI Circuit Pack Test (#423) | MAJOR       | ON           | test interface PCS sh |
| 3999(k)    | Any      | None                                |             |              |                       |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

**WARNING:**

*The "test interface long" command resets the PI-BD and cause all ISDN-PRI and BX.25 links to come down.*

Notes:

- a. Indicates the circuit pack totally stopped functioning or it was physically removed from the system.

**NOTE:**

The alarm is logged about 11 minutes after the circuit pack has been removed and/or SAKI Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, then replace the circuit pack.

**CAUTION:**

*Reseating the circuit pack may cause a system restart if the circuit pack is located on an Active SPE complex.*

If this is a Duplicated Option system, verify that there is an equal number of Processor Interface circuit packs in each SPE complex. If there is not an equal number of Processor Interface circuit packs, this condition could cause alarms on the STBY-SPE, DUPINT, SHDW-CIR, as well as the PI-BD.

- b. The circuit pack has been logically administered but not physically installed. If this alarm remains active for more than 30 minutes, follow normal escalation procedures. **DO NOT PHYSICALLY RESEAT THE CIRCUIT PACK!** The alarm is cleared when the circuit pack is installed and initialization maintenance runs on it. The Standby Processor Interfaces alarm is cleared when Standby maintenance runs on it.
- c. Processor Interface-SCI detected an error while trying to reset the TN765 PI circuit pack. This error indicates a loss of communication with the circuit pack. If this error continues, then replace the TN765 circuit pack. Refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions on how to replace an SPE complex circuit pack. See PI-SCI Maintenance documentation for additional errors.
- d. PI-SCI logged errors that resulted in an error being logged and an alarm being raised against PI-BD. Refer to the PI-SCI Maintenance documentation and resolve all alarms against PI-SCI. If this alarm resulted in an SPE-interchange, issue the **test interface PCS sh** command to try to resolve the PI-BD alarm.
- e. A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to re-administer this slot to match the circuit pack inserted.
- f. This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.
- g. This error, when reported with Aux Data in the range of 4352 to 4358, indicates the circuit pack has reported a hardware failure on the circuit pack. The circuit pack should be replaced. Refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions on how to replace an SPE complex circuit pack.
- h. This error can be ignored, but look for other errors on this circuit pack.
- i. This error is not service-affecting and no action is required.
- j. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
  - 1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with Error Code 2000.
  - 2. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
  - 3. A **list configuration** command shows that the circuit pack and ports are properly installed.

The system tries to restore the circuit pack within 15 minutes. If the error recurs after 15 minutes, replace the circuit pack. (Refer to the "Handling Control Circuit Packs" section in [Chapter 5, "Routine Maintenance Procedures"](#).)

- k. Error type 3999— Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

**System Technician Demanded Tests:  
Descriptions and Error Codes**

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Standby Processor Interface Circuit Pack Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| Standby Processor Interface Circuit Pack Test (#423) | X                   | X                  | ND                |
| Standby Processor Interface Port Test (#404) (a)     | X                   | X                  | ND                |
| Control Channel Loop Test (#52)                      | X                   | X                  | ND                |
| NPE Audit Test (#50)                                 | X                   | ND                 |                   |

1. D = Destructive; ND = Nondestructive

Note:

- a. This test is repeated up to four times since there are four ports on the circuit pack. Cross-reference PI-PT (Processor Interface Port) Maintenance documentation for information about these tests.

**Control Channel Loop Around Test (#52)**

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as Control Channel Loop Around Test (#52).

NPE Audit Test (#50)

Refer to the repair procedure described in the XXX-BD (Common Port Circuit Pack) Maintenance documentation as NPE Audit Test (#50).

Standby Processor Interface Circuit Pack Test (#423)

This test is run only in a High or Critical Reliability system. This test is run on Processor Interface circuit packs that are currently in Standby Mode and thus no active calls are up on these circuit packs. It is very important to periodically test the Standby Processor Interface circuit packs to ensure their health in case of an SPE-interchange. This test is run either by system technician demand (**test interface PCS** or **reset interface PCS**) or during scheduled maintenance. The test resets the circuit pack. The main purpose of this test is to perform a Checksum Test on the downloadable firmware or to download new Processor Interface firmware if the **reset interface PCS** command is used. If the checksum fails, then the firmware is downloaded again from the tape.

Table 10-303. TEST #423 Standby PI Board Test

| Error Code                                                                                                           | Test Result | Description/Recommendation                                                                                                                                                                           |
|----------------------------------------------------------------------------------------------------------------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 9,10                                                                                                                 | ABORT       | Internal system error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                        |
| 1029<br>1030<br>2011<br>2012<br>2013<br>2014<br>2015<br>2016<br>2017<br>2018<br>2020<br>2022<br>2024<br>2025<br>2051 | ABORT       | Refer to "STBY-SPE" for a description of these error codes.                                                                                                                                          |
| 1124                                                                                                                 | ABORT       | There are currently no enabled Processor Interface links in the system.<br><br>1. Wait and run this test when links are enabled and the PI-SCI (System Communication Interface) has been started up. |

Refer to <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a> for instructions on how to replace an SPE complex circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 16<br>80<br>94<br>102 | FAIL        | Internal system error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If problem still exists, redownload firmware using the <b>reset interface</b> command.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 23<br>199             | FAIL        | Download of Processor Interface firmware failed.<br><br>1. Wait 1 minute and retry. A tape access problem could be present. Check that tape is in tape drive.<br><br>2. If the problem persists and Standby TAPE is idle when command is entered, then a problem could exist in either the Standby TAPE or the Processor Interface circuit pack. Replace the tape with a new tape that contains Processor Interface firmware. Retry the command.<br><br>3. If the problem still exists, then refer to the TAPE Maintenance documentation for possible TAPE errors. If there are no TAPE errors, repeat the test command up to five times. If problem still exists, replace the TN765 circuit pack. Refer to <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a> for instructions on how to replace an SPE complex circuit pack.<br><br>4. If problem still exists with new TN765 Processor Interface circuit pack, replace TAPE drive. |
| 9000s                 | FAIL        | Processor Interface Download failed.<br><br>1. Refer to TABLE A, Tape Unit Data Table, and follow the repair recommendations.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|                       | PASS        | TN765 Processor Interface circuit pack initialized correctly. Processor Interface links (X.25 and ISDN) should recover now. See "PI-LINK" for more information if links do not recover.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## PI-LINK (Processor Interface Link)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run | Full Name of MO          |
|------------------------|-------------|------------------------|--------------------------|
| PI-LINK                | MINOR       | test link lnk-no l     | Processor Interface Link |
| PI-LINK                | WARNING     | test link lnk-no l     | Processor Interface Link |

 **NOTE:**  
Reference lnk-no using the **display communication-interface links** command.

The Processor Interface (PI) Communication Link is the physical link that connects DEFINITY to an adjunct such as AUDIX, another node in a DCS network, or an ISDN-PRI connection. These links are either X.25 (DCS, AUDIX, or MIS) or ISDN (ISDN-PRI). The system supports up to four of these links per TN765 Processor Interface circuit pack. PI-LINK maintenance actually monitors several hardware devices: Processor Interface ports, TN754 or TN784 Digital Line ports, PDMS, TDMS, MTDMs, MPDMs, and DS1 facilities. Henceforth, "data module" refers to either PDM, TDM, MPDM, or MTDM. **In much of the following link documentation, the repair procedures described mention various hardware configurations. Choose the procedure appropriate to your configuration.**

The Processor Interface circuit pack provides an EIA connection. This connection can be administered only on Link 1 in a system without High or Critical Reliability. The EIA port is used when an adjunct (AUDIX, for example) is near (less than 25 feet) or further if a modem is used. The EIA port can also be used to connect two PBXs together via DCS. The EIA port cannot be used in a High or Critical Reliability system.

The Processor Interface Link can be in three different states. These states can be seen using the **status link lnk-no** system technician command. If the link is in a *maintenance busy* state, then the system technician had instructed the Processor Interface to be in maintenance busy by entering the **busyout link lnk-no** command or the Processor Interface Link is not established and maintenance is trying to bring it up. This probably means that an error condition is occurring somewhere on the link that keeps the link from being logically connected and carrying data. If the link is busied out, then it can be put back into service by issuing a **release link lnk-no** command. This restarts the link. If the link is for DCS, then it may speed the recovery of the link if **busyout link lnk-no** and **release link lnk-no** are executed on the switch that is establishing the connection (see the Communication-Interface Links form). The link can be in a *disconnected* state if the link cannot be started up. In this case, maintenance tries to establish the link periodically. If the link is up and data is being sent successfully, then the link is in the *in-service* state.

**NOTE:**

When an ISDN-PRI link is busied out via a system technician command, the associated B-channels (ISDN-TRK) are moved to the maintenance and/or far-end state. As a result, stable calls are NOT dropped, but the trunks are removed from the trunk hunt group to prevent them from being selected for outgoing calls. See ISDN-TRK Maintenance documentation.

Up to two Processor Interface circuit packs can be active on the same carrier in the system. Thus, there can be a maximum of eight Processor Interface links in service at any one time. If an error or alarm is detected by PI-LINK that can be associated with a physical port on the Processor Interface circuit pack, then the Processor Interface Port MO is alarmed, which indicates a defective port on the circuit pack. Refer to the PI-PT (Processor Interface Port) Maintenance documentation for details.

It is useful to use the **status processor-channel channel-no** command when troubleshooting the PI-LINK. A processor channel corresponds to a processor application (also called a session) and more than one may be using the same physical link (only for X.25 links). The relevant field of the status screen is the "channel status:" which can be in 1 of 7 different states (see the following table). State 6 is normal state for the processor channel for X.25 links and state 10 is normal state for ISDN links. States 9 and 10 are only applicable to ISDN links.

| States | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1      | Incorrect translations or channel not assigned.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 3      | Attempting to reset the channel but no response from the other end. Getting stuck in this state may be caused by hardware problems, a DS1 synchronization problem or a DCE/DTE conflict in the Communication-Interface Link Form (one end of the link must be DCE and the other must be DTE).                                                                                                                                                                                                                                                                                                                             |
| 4      | The other end acknowledged the channel reset (the two ends are physically connected) but a processor channel connection has not occurred yet. Getting stuck in this state may indicate that translations are incorrect, such as remote processor channel mismatch. To recover from this situation, execute the <b>busyout link lnk-no</b> and <b>release link lnk-no</b> commands. If this is unsuccessful, then use the <b>reset interface</b> command (note that this is a <b>destructive</b> command that tears down all four links). This problem may also be caused by a noisy link or DS1 synchronization problems. |
| 6      | This is the normal state of the channel. The link is in the data transfer state which means that the application is able to send data over the link.                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

| States | Description                                                                                                                                                                                   |
|--------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7      | One or more unexpected messages have arrived; software is attempting to resynchronize the two ends. Usually it takes up to five minutes for the software to recover once it is in this state. |
| 9      | ISDN-PRI link is currently down. It is periodically restarted or can be forced to restart via <b>busyout/release link link-no.</b>                                                            |
| 10     | ISDN-PRI link is up. This is the normal state of the channel. The link is in data transfer state, which means that ISDN data can be sent over the link.                                       |

Figure 10-78 shows the Processor Interface Communications Link (PI-LINK) Interactions.

Table 10-304. PI-LINK (Processor Interface Link) Error Log Entries — Continued

| Error Code | Aux Data | Associated Test | Alarm Level                    | On/Off Board | Test to Clear Value            |
|------------|----------|-----------------|--------------------------------|--------------|--------------------------------|
| 3585 (l)   | Any      | none            | MAJOR/<br>WARNING <sup>2</sup> | OFF          | busyout/release link<br>lnk-no |
| 3841 (m)   | Any      | none            | MINOR/<br>WARNING <sup>2</sup> | OFF          | busyout/release link<br>lnk-no |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.
3. This error type initially raises a warning alarm. If this error type persists, and alarms are not downgraded on this MO due to the values of **set options**, then, after a period of time, a Major alarm is raised.

Notes:

- a. A permanent switched call was dropped. Check the "Link Recovery" section.
- b. The TN765 Processor Interface circuit pack detected an error on a specific link via background maintenance. If the link is down, busyout and then release the link. If this fails, check all connections. If the error reappears consistently, see "Link Recovery" section.
- c. Processor Interface software or firmware detected an error condition on this link. Internal software should initiate the recovery for the link. If the link is still down, see the "Link Recovery" section.

Aux values of concern; any others can be ignored.

- |    |                                                                                                                                       |
|----|---------------------------------------------------------------------------------------------------------------------------------------|
| 0  | Processor Interface circuit pack indicates that the ISDN-PRI link is down.                                                            |
| 1  | An internal software audit indicates that this link has been in overload for at least 20 seconds and is hung.                         |
| 2  | No internal software buffers are available to process a link transition (that is, down to up, or up to down). The transition is lost. |
| 17 | The allocation of a new software write buffer to the Processor Interface circuit pack failed.                                         |
- d. Translation Error—check all administration for the link. Possibly the destination DS1-BD or DIG-BD is not inserted. Busyout and then release the link to restart it. This is not a Processor Interface hardware problem.

Aux values of concern; any others can be ignored.

- 2 Link translation error. If the communication-processor link form indicates this link's destination is a tac+extension, then bring up the dial plan form. If an extension exists with the same first digit as the tac, then this PI link will not establish. To alleviate this problem, either remove the extension on the dial plan form, or change the destination field on the communication-processor link form to use a UDP extension to dial the far-end.
  - 8 Port not administered in software.
- e. This error occurs when the Processor Interface link fails to be established. Check all connections and administration. This could also occur as a result of another error, the failure of Test #182, for example. If the other error on the link can be cleared, then this error may also clear. See the "Link Recovery" section.
- 1, 2 System error.
  - 7 System error. If this error is occurring on all administered links with the same Aux Data and all links are alarmed, then execute the **reset interface** command to restore all the links.
  - 12 One of the two Loop Around Tests failed (#182 or #183). See the "Link Recovery" section.
  - 13 Hardware problem with DS1 facility is affecting ISDN links. Refer to DS1-BD Maintenance documentation.
  - 19 A transient state associated with the D-channel backup protocol. The link is being held in the busy state until call control can be moved to the new active link. No action needs to be taken.

---

*Continued on next page*

- 32771 The remote endpoint indicates that the call is up and the  
32772 local PBX cannot complete the call. Check trunk status (on  
the remote end and local end) if a DS1 trunk is used, or  
check the status of the data module if a data module is  
used in the link. The commands are **status trunk trk-grp/  
member** or **status data-module <ext>**. If the destination is  
in-service/active, then the commands are **busyout trunk  
trk-grp/member** and **release trunk trk-grp/member** (on  
both sides of the link if this is a DCS link). If a data module  
is used in the link, then use a **busyout data-module <ext>**  
command followed by a **release data-module <ext>**  
command. Busy out the Processor Interface Link prior to  
busyout the trunk or data module. Release the Processor  
Interface Link via **release link lnk-no** command and the  
Processor Interface Link re-starts. If this fails, check the  
status of the TN765 port using **status data <ext>** where  
**<ext>** is the extension of the port from the interface  
extension in the Display Communication Link form; if the  
state is "in-service/idle" then manually call the TN765 port  
and transfer the call to appropriate destination, either a  
DS1 Trunk Access Code or the data module extension.  
See "Link Recovery" if error still occurs. See "Link  
Recovery" if error still occurs and link does not establish.
- 32779 Administration problem; check that the Processor Interface  
32782 data module extension exists via the **status data-module  
32801 <ext-no>** command. Verify that the destination extension  
exists and that the correct routing pattern is used. In  
addition, check that the Processor Interface data module  
and the destination extension are administered on the COS  
and/or COR forms.
- 32813 Administration problem; check all administration.
- 32815 The off-premise call timed-out. Check the "Off-Premises  
Tone Detect Timeout Interval" on the Feature-Related  
System Parameters Form. The time-out is administered  
between 6 and 25 seconds. No response was received  
from the remote destination. Check the status of the remote  
destination. This might also indicate possible  
synchronization problems. Network synchronization  
sources should be checked on all networked switches.  
Also see the SYNC Maintenance documentation.
- 32814 Call was answered but not by a remote data module.  
Check the remote destination extension and verify that this  
is a data module.

|       |                                                                                                                                                                                                                                                                                      |
|-------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 32841 | Call went over the trunk and received ring back but did not receive modem answer tone. Check the remote destination for automatic answering.                                                                                                                                         |
| 65528 | Administration problem; check all administration.                                                                                                                                                                                                                                    |
| 65532 | Call setup timed out; retry, and check destination. If the destination is an adjunct (CMS, AUDIX, etc.), then check if the terminal ready light is lighted on the PDM. If not, then the adjunct is down. If the destination is another PBX, then the PBX might be restarting. Retry. |
| 65535 | Link specified is out-of-range (1 through 8).                                                                                                                                                                                                                                        |

---

- f. This error message indicates that the TN765 Processor Interface circuit pack could not transmit the message the software sent to it. See the "Link Recovery" section if the error continues. This is a normal error during "hot start" SPE-interchanges.
- g. Excessive resets on the link. Usually indicates that the remote end is down or the physical connection is broken. A warning alarm is raised initially, followed by a Major alarm if the problem is not cleared. See the "Link Recovery" section.
- h. Excessive I-frame retransmission. Could indicate a noisy link. Recover as in previous note. Aux values indicate the retransmission rate per minute. See the "Link Recovery" section.
- i. If the Aux Data value is 9, then the destination circuit pack (DIG-BD or DS1-BD) is not inserted. Otherwise, DS1 maintenance detected a hardware failure. (DS1 cable disconnected, loss of signal, DS1-BD problems.) Not a Processor Interface Link problem. Check DS1-BD maintenance. Only applicable to ISDN links. Aux value useless. Once the DS1 signal is restored, maintenance automatically restarts the Processor Interface Link. To hasten this process, test the appropriate DS1 Interface circuit pack via **test board PCS** command. When Test #138 (loss of signal) passes, the Processor Interface Link recovers shortly.

In addition to an indication that the link failed to establish the PI-LINK 2561 AUX\_Data, the hardware error log is also updated. This error may indicate two possible conditions:

1. A failure to detect the DTR from the peripheral.

When the DTR is not detected by the data module the AUX\_Data is set to 40. This indicates that the problem is most likely with the peripheral or the connection to the peripheral.

2. A time-out on the EIA interface query request to the data module.

When the data module fails to respond to the EIA interface (query request) the AUX\_Data is set to 41. This may indicate problems with the data module or connection to the data module. Other errors specific to the data module may also be logged if this is the case.

- j. TN765 PI-BD determined that the ISDN link went down. Check connectivity with the other end. Busyout and then release the link to recover. Occurs if DS1 maintenance detected a problem or the remote end is busied out or is down. This also occurs if the ISDN link is unstable or if there is excessive noise on the line. See the "Link Recovery" section.
- k. Excessive LAPD (link-access procedure on the D-channel) invalid frame errors. Could be a noisy line or problems with the TN765 Processor Interface circuit pack. Also check DS1-BD Maintenance documentation. See the "Link Recovery" section.
- l. Occurs 90 seconds after a 2817 Error Code if link does not recover. At this time, all ISDN trunks associated with this link are put into a maintenance far-end state (see ISDN-TRK for details). See the "Link Recovery" section.
- m. The application level process associated with the link has failed to establish a data connection with the far end. This problem prevents data from being processed. The condition may exist even if the link is in a data transfer state. Busyout, and release the link to restart it. This is not a Processor Interface hardware problem.

Aux values of concern; any others can be ignored.

433 OCM application did not start correctly. Reboot the OCM adjunct.

435 Application level process could not connect to session layer process.

- n. Excessive (over threshold) HDLC transmit or receive error rates were reported. Aux Data is the HDLC error rate reported. See the Link Recovery section for troubleshooting this problem

---

## Link Recovery

This section describes the general procedure to take to recover from link errors and alarms. Refer to the "Troubleshooting ISDN-PRI Problems" section in [Chapter 5, "Routine Maintenance Procedures"](#), before proceeding with this "Link Recovery" strategy.

1. Determine the link status using the **status link** command. If the link status is "in-service" and (for X.25 links) all the pairs of processor channels are complete under "LOCAL/REMOTE PROCESSOR CHANNELS" (that is, every "/" is followed by a processor channel number, not a blank), then the link is operating correctly and no further action should be taken. If the link

status is not "in-service," then go to Step 2. If the link status is "in-service" and (for X.25) some of the processor channel pairs are incomplete (remote channel not specified, meaning that the processor channels are not connected), then look at the status of "status processor-channel" for the local processor channels that are not connected.

2. Look for active PI-SCI alarms and follow the procedure for those alarms if there are any. If there are no PI-SCI problems, go on to the next step.
3. If the link is still down, restart the link via the **busyout link lnk-no** system technician command followed by the **release link lnk-no** command. This sequence tears down the call and then tries to bring it back up. If the link is for DCS, it may speed the recovery of the link if **busyout link lnk-no** and **release link lnk-no** commands are executed on the switch that is establishing the connection (see Communication Link form). If the link does not recover, go on to the next step.
4. Check the status of the remote endpoint.
  - a. If the link is busied out, release it.
  - b. Is the switch down or restarting?
5. If link was never brought up:
  - a. Using *DEFINITY Communications System, Generic 1 and System 75 Administration and Measurement Reports*, 555-200-500 and *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Descriptions*, for instructions as needed, verify that the administration is correct as follows:
    - Enter the **display ds1 PCSS** command. Check the compatibility of the DS1 parameters with the far-end and the CSU.
    - Enter **display communication-interface links** command.
    - Enter the **display communication-interface processor-channels** command. Enter the **display communication-interface hop-channels** command (if hop-channels are being used).
    - Enter the **display trunk <grp>/<mbr>** command (if DS1 is being used for DCS).
    - Enter the **status sync** command (if DS1 is being used)—make sure the primary synchronization is administered.
6. If link is an EIA link:
  - Verify via the Communication-Interface Links form that the information for the EIA connection is correct on the local and remote PBXs.

7. Try to isolate the problem in the link if hardware is at fault. Test the link via the **test link lnk-no long** system technician command.
- a. If Test #182 fails three times, replace the TN765 circuit pack. Refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#).

b. If Test #182 passes and Test #183 fails, replace the TN754 or TN784 Digital Line or the TN722 or TN767 DS1 Interface circuit pack, whichever is used in the link. If Test #183 still fails, replace the TN765 PI-BD. Refer to [Chapter 9, "Packet Bus Fault Isolation and Correction"](#).
8. If the preceding tests pass:
- Check the physical transmission link:
- a. Are all the circuit packs physically installed?

b. Are the cables still connected throughout?

c. Check DS1-BD error section for possible connectivity problems if DS1-BD is used in link connection.

d. Check CSU options.
9. Finally, restart the Processor Interface circuit pack via **reset interface PCS**. This resets the circuit pack and restarts ALL the links on it.

System Technician-Demanded Tests:

Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *PI Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence. REMINDER: The command line entry to test the PI-LINK MO is: **test link lnk-no (s or l)**.

| Order of Investigation                                                                   | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| Processor Interface Loop Around Test (#182)                                              |                     | X                  | D                 |
| TDM Loop Around Test (#183)                                                              |                     | X                  | D                 |
| ISDN Hardware Test (#234)                                                                |                     | X                  | ND                |
| Link Quality Test (#233)                                                                 | X                   | X                  | ND                |
| Data Module Internal Loop Around Test (#175) <sup>2</sup>                                |                     | X                  | ND                |
| Digital Line NPE Crosstalk Test (#9) <sup>2</sup>                                        |                     | X                  | ND                |
| Port Circuit Information Channel and Control Channel Loop Around Test (#13) <sup>2</sup> |                     | X                  | ND                |
| Data Module Audits Test (#17) <sup>2</sup>                                               | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive
2. If the PI-LINK under test is BX.25 and if there is an MPDM or an MTDM as part of the link, then the PI-LINK test sequence is expanded to include the tests on the data module. These tests are run via the PDMODULE or TDMODULE maintenance object. Refer to the PDMODULE TDMODULE (Data Module) Maintenance documentation for descriptions and details of these tests.

Processor Interface Loop Around Test (#182)

This test is destructive.

The Processor Interface Loop Around Test is an on-board Loop Around Test. The test requires that the system technician issue a **busyout link lnk-no** command before this test is run. This means that the DCS, AUDIX, or ISDN link, for example, is torn down. It does not access the TDM Bus at all. When the circuit pack is put into local loop around mode, frames are looped internally on the circuit pack. If the test fails, the Processor Interface circuit pack reports the failure. It is a good check of most of the working hardware on the Processor Interface circuit pack.

Table 10-305. TEST #182 Processor Interface Loop Around Test

| Error Code                              | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                   |

Table 10-305. TEST #182 Processor Interface Loop Around Test — Continued

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 12         | FAIL        | PI-BD reported that Loop Around Test failed.<br><br>1. Retry the test.<br><br>2. If it continues to fail, try resetting the circuit pack by the <b>test interface PCS long</b> command. This TEARS down all other links on this circuit pack (DCS, AUDIX, ISDN, etc.).<br><br>3. If the problem still exists, replace the TN765 circuit pack.                                                                                                                                                                                                                                                                                                                                                                                           |
|            | PASS        | The on-board Loop Around Test on the TN765 circuit pack passed. Most of the hardware on the circuit pack was tested except for the TDM Bus buffers. If problem is isolated to TN765 and this test passes, then replace TN765 circuit pack since TDM Bus buffers could be at fault.                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 13         | ABORT       | The TN765 circuit pack has not been reset yet or is currently being reset.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If test continues to abort with error code 13, then check status of all BX.25 and/or ISDN-PRI links on this TN765 via the <b>status link lnk-no</b> command. If all links are not in-service, then reset the TN765 using the <b>test interface PCS long</b> command.<br><br>3. If the TN765 fails to reset, refer to the PI-SCI section of this manual.<br><br>4. Retry the <b>test link lnk-no</b> command.<br><br>5. If the test still aborts with error code 13 or from step 2, and some links are in-service and an error code is still present, escalate the problem. |

TDM Loop Around Test (#183)

This test is destructive.

This test requires that you enter the **busyout link lnk-no** command before running the test. This means that the DCS, AUDIX, or ISDN link, for example, are torn down. This test checks the health of the TN754 or TN784 DIG-LINE or the TN722 or TN767 DS1 Interface circuit pack. This depends on which circuit pack is used on the link. The TN754 or TN784 Digital Line or DS1 Interface circuit pack is put into loop around mode while the PI-BD is instructed to go into remote loop around. If this test fails, and the previous Test #182 passes, then the TN754 or TN784 Digital Line or the DS1 Interface circuit pack should be replaced. It is not run on ports administered as EIA.

|            | PASS        | The loop around from the TN765 PI-BD to the Digital Line or DS1 Interface circuit pack and then back to the PI-BD passed.                                                                                                                                                                                                                                          |

Link Quality Test (#233)

This test queries the TN765 circuit pack for the latest error rates (number/minute) for certain counters that are kept by the TN765. The test passes if all the error rates are below a certain threshold. The counters that are queried are the Level 2 Reset SABM(E) [Set Asynchronous Balanced Mode (Extended)] counter, the Level 2 I-frame Retransmission counter, and the invalid LAPD frame counter.

Table 10-307. TEST #233 Link Quality Test — Continued

| Error Code | Test Result | Description/Recommendation                               |
|------------|-------------|----------------------------------------------------------|
|            | PASS        | PI-LINK currently does not have any of the above errors. |

ISDN Hardware Check Test (#234)

This test checks the status of the ISDN hardware which is the DS1 Interface circuit pack and cabling. Status of the DS1 port is kept by the system. The state of the port can be in-service or out-of-service. This state is updated by DS1 Interface circuit pack maintenance. If DS1 maintenance detects a problem with the physical medium near-end or far-end, the Processor Interface Link maintenance is instructed to restart the link. Therefore, if this test fails, the port is considered out-of-service and the link cannot be brought up until DS1 maintenance changes the state to in-service. This is more of a status inquiry than a test. Thus, the only recovery procedure is to refer to DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation.

Table 10-308. TEST #234 ISDN Hardware Check Test

| Error Code | Test Result | Description/Recommendation                                                                                                                                                                                                                             |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal system error<br>1. Retry the test at 1-minute intervals a maximum of 5 times.                                                                                                                                                                 |
| 1005       | ABORT       | This test only runs for ISDN-PRI links. This link is a BX.25 link and, thus, aborts.                                                                                                                                                                   |
|            | FAIL        | Indicates that there is a physical problem with the DS1 facility link.<br>1. Cross-reference DS1 Interface circuit pack errors for possible reason. Refer to "DS1-BD".<br>2. Retry the test. It continues to fail until the DS1 problem is cleared up. |
|            | PASS        | DS1 facility is functioning correctly.                                                                                                                                                                                                                 |

PI-PT (Processor Interface Port)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO          |
|------------------------|-------------|-------------------------------------|--------------------------|
| PI-PT                  | MAJOR       | test interface PCS sh               | Processor Interface Port |
| PI-PT                  | WARNING     | release data-module <ext>           | Processor Interface Port |

1. Where P is the port network number (1 for PPN only); C is the carrier designation (for example, A or B for processor complex circuit packs); and S is the address of the slot in the carrier where the circuit pack is located (for example, 1 or 2 for either the first or second Processor Interface circuit packs).

PI-PT is the physical port on the TN765 Processor Interface circuit pack. If the Processor Interface Link (PI LINK) MO raises an alarm that can be correlated to an on-board port problem, then PI-PT is alarmed. In a system without High or Critical Reliability, there are no tests that run directly on Processor Interface port. The PI-LINK MO is responsible for the testing of the TN765 ports along with DCS links, AUDIX links, ISDN links, etc. Refer to the PI-LINK (Processor Interface Link) Maintenance documentation for details. In a High or Critical Reliability system, Processor Interface port is used to test the ports on the Standby Processor Interface circuit packs. If the test fails, a Major alarm is raised. More importantly, if a software requested SPE-interchange takes place and an alarm is raised on the Processor Interface port, then the interchange may abort due to alarm severities.

Error Log Entries and Test to Clear Values

Table 10-309. Processor Interface Port PI-PT Error Log Entries

| Error Type     | Aux Data | Associated Test             | Alarm Level | On/Off Board | Test to Clear Value       |
|----------------|----------|-----------------------------|-------------|--------------|---------------------------|

Table 10-309. Processor Interface Port PI-PT Error Log Entries — Continued

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|------------|----------|-----------------|-------------|--------------|---------------------|
| 130 (b)    |          | None            |             |              |                     |
| 257 (a)    | Any      | None            | MAJOR       | ON           | test link lnk-no l  |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. PI-LINK raised this alarm against PI-PT. The Processor Interface Loop Around test failed on one of the ports. Refer to PI-LINK Maintenance documentation for details on resolving this alarm. If this error resulted in an SPE-interchange, then issue the **test interface PCS sh** command on the Standby Processor Interface to try to resolve the alarm.
- b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

System Technician-Demanded Tests:  
Descriptions and Error Codes

PI-PT can be tested by issuing the **test interface PCS** command on the Standby Processor Interface circuit pack. If the Active TN765 Processor Interface circuit pack is tested, then the active test sequence is run (**which is DESTRUCTIVE**). [Refer to PI-SCI (System Communication Interface) Maintenance documentation for details on these tests]. Only the Standby Processor Interface test sequence runs tests directly on PI-PT.

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Standby Processor Interface Port Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-310. System Technician-Demanded Tests: PI-PT Standby Processor Interface

| Order of Investigation                                   | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------------|---------------------|--------------------|-------------------|
| NPE Audit Test (#50) (a)                                 |                     | X                  | ND                |
| Control Channel Loop Around Test (#52) (a)               | X                   | X                  | ND                |
| Standby Processor Interface Circuit Pack Test (#423) (b) | X                   | X                  | ND                |
| Standby Processor Interface Port Test (#404)             | X                   | X                  | ND                |

1. D = Destructive, ND = Non-destructive

Notes:

- a. Refer to “XXX-BD (Common Port Circuit Pack)” for information about these tests.
- b. Refer to “PI-BD” for information about this test.

Table 10-311. System Technician-Demanded Tests: PI-PT Active Processor Interface

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------|---------------------|--------------------|-------------------|
| SCI Start (#176) (a)                       |                     | X                  | D                 |
| SCI Self Test (#231) (a)                   | X                   | X                  | ND                |
| NPE Audit Test (#50) (b)                   |                     | X                  | ND                |
| Control Channel Loop Around Test (#52) (b) | X                   | X                  | ND                |

1. D = Destructive, ND = Non-destructive

Notes:

- a. Refer to the “PI-SCI” for information about these tests.
- b. Refer to “XXX-BD (Common Port Circuit Pack)” for information about these tests.

Standby Processor Interface Port Test (#404)

This test is the same as Test #182 in the Processor Interface Link (PI-LINK) Maintenance documentation. However, this test only runs on the Standby Processor Interface circuit pack. It is an on-board loop around test. This test checks the health of physical port on the circuit pack. If the test fails, then a Major alarm is raised on the circuit pack. When the circuit pack is put into local loop around mode, frames are looped internally on the circuit pack. If the test fails, the Processor Interface circuit pack reports the failure. It is a good check of most of the working hardware on the Processor Interface circuit pack.

Table 10-312. TEST #404 Standby Processor Interface Port Test

| Error Code                                        | Test Result | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                 |
|---------------------------------------------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2<br>9<br>16<br>80<br>84<br>85<br>93<br>94<br>102 | ABORT       | Internal system error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                              |
| 1124                                              | ABORT       | The PI link for this port is currently disabled. This test does not run on disabled PI links.<br><br>1. Retry this test if the PI link is re-enabled. Enter the <b>display communication-interface link</b> command to verify that this link has been disabled.                                                                                                            |
| 1125                                              | ABORT       | The Processor Interface Loop Around Test on this port could not be executed since the Processor Interface circuit pack is not in the correct state.<br><br>1. Check PI-BD for possible errors and resolve them first.<br>2. Rerun the <b>test interface PCS sh</b> command.<br>3. If the test continues to abort while the PI-BD Test (#423) passes, escalate the problem. |

Retry the test. If the test continues to fail, try resetting the circuit pack via the <b>reset interface PCS</b> command.<br><br>2. If test continues to fail, replace the TN765 circuit pack. Refer to <a href="#">Chapter 6, “Reliability Systems: A Maintenance Aid”</a> for instructions on how to replace an SPE complex circuit pack. |
|                                                                                                                                              | PASS        | TN765 Processor Interface Circuit Pack Loop Around Test passed. The hardware associated with this port is functioning properly.                                                                                                                                                                                                                                                                                                   |

# PI-SCI (System Communication Interface)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO                |
|------------------------|-------------|-------------------------------------|--------------------------------|
| PI-SCI <sup>2</sup>    | MAJOR       | test interface PCS                  | System Communication Interface |

- Where P is the port network number (1 for PPN only); C is the carrier designation (for example, A or B for processor complex circuit packs); and S is the address of the slot in the carrier where the circuit pack is located (for example, 1 or 2 for Processor Interface circuit packs 1 or 2).
- For additional repair information, see also PI-BD (Processor Interface Circuit Pack) Maintenance documentation.

**WARNING:**

*The "test interface long" command resets the PI-BD and causes all ISDN-PRI and BX.25 links to come down.*

The PI-SCI (System Communication Interface) MO is used to put the TN765 Processor Interface circuit pack into a state such that BX.25 (DCS, AUDIX, etc.) and ISDN links can be established. The TN765 Processor Interface circuit pack has downloadable firmware. It is the responsibility of PI-SCI to download the firmware to the TN765 circuit pack during initialization. Failures while communicating with the TN765 circuit pack are logged against the PI-SCI MO. There can be up to two SCIs. There is a one-to-one correlation of PI-SCI to Processor Interface circuit packs. In a High or Critical Reliability system, there can be four Processor Interface circuit packs, but only two on the same carrier are active at any one time. If errors against the SCI can be related to the Processor Interface circuit pack, then the circuit pack MO is alarmed (PI-BD). See also PI-LINK (Processor Interface Link) and PI-BD (Processor Interface Circuit Pack) Maintenance documentation.

When investigating BX.25 (DCS, AUDIX, etc.) and ISDN link problems, resolve PI-SCI errors initially, since they might clear up the Processor Interface link problems.

Error Log Entries and Test to Clear Values

Table 10-313. PI-SCI System Communication Interface Error Log Entries

| Error Type     | Aux Data                     | Associated Test       | Alarm Level                    | On/Off Board | Test to Clear Value                               |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. See WARNING below.

WARNING:

The "test interface long" command resets the PI-BD and causes all ISDN-PRI and BX.25 links to come down.

3. Major alarms may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. An error occurred during a hot start processor element interchange that caused the associated Processor Interface links (BX.25 and/or ISDN-PRI) to go down temporarily. If these errors reoccur and there are no other errors against PI-BD or PI-SCI, resolve the other alarm first.

2055     The checksum of the PI memory was not able to be retrieved.

2056     The PI was not able to be put into a stable state such that the switch to the new active PI failed to keep the existing PI links up.

2057     The active PI was unable to copy the image of its memory to the standby PI.

2058     System software error.

- b. This error indicates a possible hardware failure on the TN765 Processor Interface circuit pack. If the error persists, and the SCI is unstable (resets often), type in **test interface PCS long** command. The Processor Interface firmware is redownloaded if the checksum fails. If the problem still exists, automatically redownload the Processor Interface firmware by typing **reset interface PCS**. If this doesn't work, then replace the TN765 Processor Interface circuit pack. These errors also raise alarms against the PI-BD (Processor Interface Circuit Pack).

 **NOTE:**

To replace an SPE complex circuit pack in a Duplication Option System follow the procedures in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#). For a Non-Duplication Option System follow procedures in [Chapter 5, "Routine Maintenance Procedures"](#) for instructions on how to replace the Processor circuit pack (TN786 or TN790).

Use the following steps for G3i-386 and later systems where the Processor Interface firmware resides in the flash ROM memory in the Processor circuit pack (i.e. TN786 or TN790) instead of Tape as in G3i-286. If the firmware can't be successfully downloaded into the Processor Interface circuit pack after entering the "reset interface PCS" command, then use the following steps:

1. Replace the TN765 Processor Interface circuit pack:
2. After the new TN765 Processor Interface circuit pack has been inserted successfully, enter "test interface PCS long" command to verify the results of tests.

If the error still indicates the failure for downloading the firmware into Processor Interface circuit pack, then it's possible that the firmware stored in the Processor circuit pack (TN786 or TN790) is corrupted.

3. Follow the [Chapter 5, "Routine Maintenance Procedures"](#) Software Upgrade procedure to load the system software from the Memory Card with the correct software release number.

After the system software is successfully loaded into Processor circuit pack, boot the system up with the customer translation memory card in slot.

If the failure for downloading the firmware into Processor Interface circuit pack persists after the system reboot, it's possible that the flash ROM chips in Processor circuit pack (TN786 or TN790) may be defective.

4. Replace the Processor circuit pack and repeat the step (3) to load the system software into the Processor circuit pack. Boot the system up again.

If the failure for downloading the firmware into Processor Interface circuit pack persists after the system reboot, it's possible that the M-BUS at the backplane of control carrier may be defective. Replace the control carrier.

- c. Error while communicating with TN765 circuit pack. The software lost handshake with the Processor Interface circuit pack. See Note (b) for recovery.
- d. Error while communicating with TN765 circuit pack. See Note (b) for recovery. This error can also be caused by line problems. Investigate possible transmission errors or noise on the associated line.
- e. An Aux Data value of 23 indicates that the software failed to open the tape in order to download the Processor Interface firmware. Check if the tape is currently in use (that is, if it is spinning or if the yellow LED is on). When the tape is idle, reissue the **test interface PCS long** command. If the test still fails or if the Aux Data value was other than 23, then refer to Test #176 (Sci Start Test) for details on recovery. For all other Aux Data values, reissue the **test interface PCS long** command, and refer to Test #176 (SCI Start Test) for details on recovery.

 **NOTE:**

For G3i-386 and later, see Note (b) for recovery.

- f. Error while communicating with TN765 circuit pack. See Note (b) for recovery. These errors also raise alarms against the PI-BD (Processor Interface Circuit Pack).
- g. Download of Processor Interface firmware failed. If this error persists, then replace the TN765 Processor Interface circuit pack. This error also raises an alarm against PI-BD if the threshold is reached.
- h. An audit of the firmware failed. If BX.25 and ISDN links are still up, no action is needed. If Processor Interface circuit pack is reset continuously, recover as in Note (b).

- i. Error while communicating with TN765 Processor Interface circuit pack. See Note (b) for recovery. System software problem internal to the process that monitors Processor Interface link activity. Escalate the problem if error causes the Processor Interface to be reset (loss of service is noticed).
- j. This error indicates that the TN765 Processor Interface circuit pack did not clear up the overload condition within one minute of logging the initial 2817 error (overload detected). The circuit pack was reset and all Processor Interface links on that circuit pack were also reset.

Short and Long Test Sequences

The SCI and Processor Interface circuit pack are both tested via the same system technician command. The system technician command is **test interface PCS I** or **sh** where PCS is an active Processor Interface circuit pack.

**WARNING:**  
*The "test interface long" command resets the PI-BD and causes all ISDN-PRI and BX.25 links to come down.*

For information about testing the Standby Processor Interface circuit pack, see PI-BD Maintenance documentation. If the Active Processor Interface has no enabled links (see Communication-Interface Links Form in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#), only XXX-BD (Common Port Circuit Pack) tests execute.

System Technician Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *SCI Start Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation              | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------|---------------------|--------------------|-------------------|
| SCI Start Test (#176)               |                     | X                  | D                 |
| SCI Self Test (#231)                | X                   | X                  | ND                |
| Control Channel Loop Test (#52) (a) | X                   | X                  | ND                |
| NPE Audit Test (#50) (a)            |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

- a. For information about these tests, refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation. These tests are run on the PI-BD (Processor Interface Circuit Pack) Maintenance object.

SCI Start Test (#176)

This test is destructive.

This test restarts the System Communication Interface. This implies all BX.25 (DCS, AUDIX, mis, etc.) and ISDN links are restarted. The checksum of the downloadable firmware is tested. If the checksum fails, the firmware is redownloaded from tape. If it passes, SCI Start completes and the associated BX.25 and ISDN Links are started up. If a circuit pack needs to be replaced, refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions on replacing an SPE circuit pack.

The Processor Interface circuit pack firmware is downloaded from the flash ROM memory of Processor circuit pack. If the checksum test fails, then the firmware is re-downloaded again from Processor circuit pack. If it passes, SCI Start completes and the associated BX.25 and ISDN links are started up. If the checksum failure persists, refer the footnote (b) of Hardware Error Table for repair procedure.

In G3i-286 if the problem continues to exist after replacing the tape, then replace the TN765 Processor Interface circuit pack. Refer to <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a> for instructions about replacing an SPE complex circuit pack. Retry the command. |
| 23<br>199<br>9000s | FAIL        | Processor Interface Download failed. Refer to TABLE A Tape Unit Aux Data Table and follow the repair recommendations.<br><br>1. Wait one minute and retry. See note (b) of Hardware Error Table for repair procedure<br><br>2. If problem persists and TAPE is idle when command is entered, then a problem may exist in either the TAPE or the Processor Interface circuit pack. Replace the tape with a new tape that contains Processor Interface firmware. Retry the command.                                                                                                                                                                                            |
|                    | PASS        | TN765 Processor Interface circuit pack initialized correctly. Processor Interface links (BX.25 and ISDN) should recover now. See PI-LINK for more information if links do not recover.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

SCI SELF TEST Test (#231)

This is an on-board test which checks the basic functionality of the TN765 circuit pack. This test runs in the background periodically, or it can be invoked via the **test interface PCS** command. If this test continuously fails, then replace the TN765 Processor Interface circuit pack. Refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for instructions on how to replace an SPE complex circuit pack.

Table 10-315. TEST #231 SCI Self Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 11         | ABORT       | Internal system error<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| 13         | ABORT       | The TN765 PI circuit pack has not been reset yet or is currently being reset.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort with error code 13, then reset the TN765 via "test interface PCS long".<br><br> <b>CAUTION:</b><br><i>Resetting the TN765 will cause all BX.25 (Audix, cms, etc.) and ISDN-PRI links to be briefly torn down.</i><br><br>3. If TN765 fails to be reset, refer to test 176 section description.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 4xxx       | FAIL        | Hardware on the TN765 Processor Interface failed.<br><br>1. 4000 - Assigned data link hardware failure.<br><br>2. 4001 - Unassigned data link hardware failure.<br><br>3. 4002 - CPU function test failed - hardware failure.<br><br>4. 4003 - Local Processor Interface RAM memory test failed - hardware failure.<br><br>5. 4004 - Local EPROM memory test failed - hardware failure.<br><br>6. For all of the above errors, retry the test. If it fails again, the Communication Interface should be restarted. Type in a <b>reset interface</b> command. If the reset is successful, retry the <b>test interface</b> command. If Test #231 still fails with error codes other than 4001, then replace TN765 Processor Interface circuit pack. Refer to <a href="#">Chapter 6, "Reliability Systems: A Maintenance Aid"</a> for instructions on how to replace an SPE complex circuit pack. If test fails with Error Code 4001, then an on-board failure is associated with a non-used port on Processor Interface circuit pack. TN765 circuit pack should be replaced if this port will be used in the future. |
|            | PASS        | TN765 Processor Interface circuit pack passed self-test. On-board hardware is functioning correctly.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## PKT-BUS (Packet Bus)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO |
|------------------------|-------------|-------------------------------------|-----------------|
| PKT-BUS                | MAJOR       | test pkt P l r 2                    | Packet Bus      |
| PKT-BUS                | MINOR       | test pkt P l                        | Packet Bus      |
| PKT-BUS                | WARNING     | test pkt P l                        | Packet Bus      |

- Where P is an appropriate port network number determined from the PORT field on the Alarm or Error Log.

The Packet Bus consists of a single bus, and one such bus appears in each port network. The Packet Bus in each port network is physically independent. Therefore, there is one instance of the Packet Bus maintenance object for each port network.

In DEFINITY, the Packet Bus is used to carry ISDN-BRI and ASAI signaling information. The SPE interface to the Packet Bus is in the TN778 Packet Control circuit pack (PKT-CTRL). Packet Bus maintenance is performed only when the Packet Bus is enabled on the Maintenance-Related System Parameters form. Packet Bus testing is dependent on the Packet Bus port of the TN771 Maintenance/Test circuit pack, the TN778 Packet Control Circuit Pack (PKT-CTRL), the TN570 Expansion Interface circuit pack (EXP-INTF), and on the ISDN-BRI circuit packs (BRI-BD). Packet Bus tests may abort if some of this hardware is not present in the system. Also, these tests may yield inconsistent results if some of this hardware is defective.

The interactions between the Packet Bus and the circuit packs that use the bus are complex. For this reason, the Packet Bus can be alarmed due to a circuit pack failure and, conversely, circuit packs can be alarmed due to a Packet Bus failure. [Chapter 9, "Packet Bus Fault Isolation and Correction"](#) describes Packet Bus maintenance and also the interactions of the bus with the Packet circuit packs. The chapter discusses fault isolation and correction procedures, and it should be referenced for all procedures and required decisions. The "Packet Bus Fault Isolation Flowchart" section of Chapter 9 is the normal starting point in the chapter for experienced technicians. However, technicians who are unfamiliar with the Packet Bus and its use should refer to the introductory material. This section on PKT-BUS is limited to a description of the Error and Alarm Log entries for the Packet Bus maintenance object and to a description of the Packet Bus test sequence.

A failure of one or more circuit packs that use the Packet Bus can cause a Packet Bus alarm. In addition, a Packet Bus failure can cause loss of service to one or more such circuit packs, as well as to the ports and endpoints associated with the ISDN-BRI circuit pack (BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, and

ASAI-ADJ). These interactions are discussed in the "Circuit Packs That Use the Packet Bus" section of [Chapter 9, "Packet Bus Fault Isolation and Correction"](#).

The following list summarizes some of the important points to consider when working with the Packet Bus.

- The Maintenance/Test circuit pack (TN771) is a critical tool for isolating Packet Bus faults. This circuit pack is present in each port network of a high or critical reliability system that is using the Packet Bus. In a standard system, the circuit pack may be included as a customer option. If a TN771 is not present, **one must be taken to the customer site** to allow for proper fault isolation. (A determination as to whether a TN771 circuit pack is in the system is made by entering the **list configuration** command.) Use of the Maintenance/Test Packet Bus port facilities is described under "The Maintenance/Test Circuit Pack (TN771)" in [Chapter 9, "Packet Bus Fault Isolation and Correction"](#). Also, in the same chapter, the section entitled "Special Precaution Concerning the TN771" describes other circumstances when a TN771 must be taken to the customer site.
- Certain catastrophic Packet Bus failures have an effect on Packet circuit pack, port, and endpoint maintenance. The following list summarizes the impact of such failures in this regard.
  - ISDN-BRI circuit pack (BRI-BD) in-line errors indicating possible Packet Bus failures are placed into the error log, but are not acted upon.
  - ISDN-BRI port (BRI-PORT, ABRI-PORT) in-line errors indicating possible Packet Bus failures **are neither placed into the error log nor acted upon**.
  - ISDN-BRI endpoint (BRI-SET, BRI-DAT, ASAI-ADJ) in-line errors **are neither placed into the error log nor acted upon**.
  - Circuit pack and port in-line errors that are not relevant to the Packet Bus or that indicated a circuit pack failure are acted upon in the normal fashion.
  - Normal background maintenance (periodic and scheduled) is not affected.
  - Foreground maintenance (for example, commands executed on the Manager I terminal) are not affected.

The actions in the previous list serve to reduce the system load, which could become excessive if too many maintenance objects are affected by a Packet Bus failure. However, such an excessive load should in no way impede the isolation and the correction of the faults.

When the actions in the list are implemented, Error Type 3329 is logged against PKT-BUS, and a Warning alarm is raised (although other Packet Bus errors in many cases raise more severe alarms, thereby overriding the Warning alarm).

- A Packet Bus failure in the Processor Port Network (PPN) causes Packet traffic (ISDN-BRI, ASAI) in the Expansion Port Networks (EPNs) to fail, even though there is no Packet Bus failure in the EPN. This is true because all Packet traffic requires communication with the Packet Control (PKT-CTRL) circuit pack in the PPN. Due to this requirement, a PPN Packet Bus failure must be investigated first whenever Packet Bus failures occur in multiple port networks.

Error Log Entries and Test to Clear Values

Table 10-316. PKT-BUS Error Log Entries

| Error Type     | Aux Data         | Associated Test                                 | Alarm Level | On/Off Board | Test to Clear Value |
|----------------|------------------|-------------------------------------------------|-------------|--------------|---------------------|
| 0 <sup>1</sup> | 0                | Any                                             | Any         | Any          | test pkt            |
| 1 (a)          | 1-2              | Packet Circuit Pack Audit Test (#570)           | MAJOR       | ON           | test pkt P l r 2    |
| 257 (b)        | Any              | Packet Control Bus Loop Around Test (#571)      | MAJOR       | ON           | test pkt P l r 2    |
| 513 (c)        | 1-24             | Maintenance/Test Circuit Pack Query Test (#572) | MAJOR       | ON           | test pkt P l r 2    |
| 1793 (d)       | Any              | none                                            |             |              |                     |
| 2049 (e)       | 1-3              | Maintenance/Test Circuit Pack Query Test (#572) | MINOR       | ON           | test pkt P l r 2    |
| 2305 (f)       | 1-24             | Maintenance/Test Circuit Pack Query Test (#572) |             |              | test pkt P l        |
| 3329 (g)       | 1-7 or 1000-1007 | none                                            | WARNING     | ON           | test pkt P l        |
| 3585 (h)       | Any              | none                                            | MINOR       | ON           | test pkt P l        |
| 3841 (i)       | Any              | none                                            | MINOR       | OFF          |                     |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

 **NOTE:**  
For PKT-BUS, an ON-BOARD alarm indicates a problem with the Packet Bus itself.

Notes:

- a. Within the last minute, packet circuit packs have reported errors that indicate a possible Packet Bus failure. The Aux Data value is 1 or 2, indicating that only one or more than one Packet circuit pack (respectively) have reported a possible Packet Bus failure.
- b. Packet Bus maintenance has been unable to perform loop around tests from the TN778 Packet Control circuit pack (PKT-CTRL) to itself. This could indicate faults on the Packet Control circuit pack rather than on the Packet Bus. Examine the Error and Alarm Logs for any such errors.
- c. The Maintenance/Test Packet Bus port for this port network has determined that there are more Packet Bus faults than the port can correct. The Aux Data value indicates the number of faulty leads.
- d. Packet circuit packs have detected possible Packet Bus failures via in-line error or background test failure. Examine the Error and Alarm logs for more specific PKT-BUS errors.
- e. The Maintenance/Test Packet Bus port has caused Packet Bus leads to be swapped to spare leads. This error appears only in a High or Critical Reliability system. The Aux Data value indicates the number of faulty leads. If this is the only active error against the Packet Bus, **the Packet Bus is still in service**. Therefore, due to the disruptive nature of the Packet Bus Fault Isolation and Correction procedures, repairs should be deferred until a time when these procedures cause the least interruption in service. This matter is resolved via consultation with the customer. However, be sure not to delay repairs for too long, since the switch is not able to recover from another Packet Bus failure until the existing one is resolved. The procedure described in the section entitled "Special Precaution Concerning the TN771" in [Chapter 9, "Packet Bus Fault Isolation and Correction"](#) is used to ensure that the Maintenance/Test is giving correct information. This procedure may require that a new TN771 be taken to the customer site.
- f. The Maintenance/Test Packet Bus port has detected open leads on the Packet Bus. The Aux Data value indicates the number of open leads.
- g. Packet circuit pack, port, and endpoint maintenance has been disabled due to a Packet Bus failure. The Aux Data value indicates which sources have reported errors that have caused maintenance to be disabled. These sources include the following:
  - In-line errors from Packet circuit packs.
  - Packet Bus Uncorrectable report from the Maintenance/Test Packet Bus port.
  - Packet Bus Interface Failure report from the Packet Control.
  - In an EPN, packet circuit pack, port, and endpoint maintenance will be disabled if a Packet Bus failure occurs in the PPN.

The Aux Data values that indicate these sources are identified in the following table:

| Aux Data | Packet Circuit Pack | Maint/Test Circuit Pack | Packet Control |
|----------|---------------------|-------------------------|----------------|
| 1/1001   | X                   |                         |                |
| 2/1002   |                     | X                       |                |
| 3/1003   | X                   | X                       |                |
| 4/1004   |                     |                         | X              |
| 5/1005   | X                   |                         | X              |
| 6/1006   |                     | X                       | X              |
| 7/1007   | X                   | X                       | X              |

If the Aux Data value is in the range 1000-1007, then Packet circuit pack, port, and endpoint maintenance has been disabled in the EPN due to a PPN Packet Bus failure. If the value is greater than 1000, then there is also a failure of the packet Bus in this EPN and the source of the other information can be determined from the table above.

 **NOTE:**

It is important to remember that problems reported by Packet circuit packs may be caused by **any** circuit pack. However, only Packet circuit packs can detect such problems (inasmuch as TDM-only circuit packs are not affected by these problems).

- h. Include Packet circuit pack, port, and endpoint maintenance has been disabled due to more than one circuit pack reporting in-line errors. If this occurs more than three times in 15 minutes (that is, if maintenance is disabled due to errors and then re-enabled because no more errors are reported), a Minor alarm is raised against the Packet Bus. Note that this error may still be present in the error log even if the "Circuit Pack Audit Test" reports that only one circuit pack has indicated a problem. This occurs if more than one circuit pack reported errors with in any one minute interval since the Packet Bus fault occurred.

 **NOTE:**

Because alarms against a Maintenance Object are not resolved until all alarming has been cleared, an alarm due to a missing Maintenance/Test Packet Bus must be cleared by installing a Maintenance/Test circuit pack before it can be determined if other Packet Bus alarms have been resolved.

- i. The Maintenance/Test Packet Bus port for this port network is not in service. This error appears only in a High or Critical Reliability system, and it can occur in the following cases:

- The Packet Bus port has been busied out (indicated by an Error Type 18), and a Warning alarm is active in the same port network. Release the port by entering the **release port PCSS04** command.
- The Packet Bus port has failed. Resolve any alarms.
- The Maintenance/Test circuit pack was not recognized by the system at the last system restart. Replace the Maintenance/Test circuit pack. There is no Maintenance/Test circuit pack installed in this port network. One must be installed.

System Technician-Demanded Tests:  
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when you are inspecting errors in the system. By clearing error codes associated with the *Packet Circuit Pack Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence.

| Order of Investigation                          | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------|---------------------|--------------------|-------------------|
| Packet Circuit Pack Audit Test (#573)           | X                   | X                  | ND                |
| Maintenance/Test Circuit Pack Query Test (#572) | X                   | X                  | ND                |
| Packet Control Bus Loop Around Test (#571)      | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

Packet Control Bus Loop Around Test (#571)

This test uses circuitry on the Packet Control circuit pack (TN778) to look for faults on the Packet Bus. If the Packet Control circuit pack has detected parity errors on the Packet Bus, or if it is unable to loop back data to itself, the test fails. The test passes if no parity errors are detected and if data is successfully looped back.

This test provides information only for the PPN of a standard system. If the test is run in an EPN or in the PPN of a High or Critical Reliability system, the test aborts.

Table 10-317. Test #571 Packet Control Bus Loop Around Test

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1022       | ABORT       | No Packet Control circuit pack exists in this port network.<br><br>1. This test gives information only for the PPN. Ignore results from this test whenever it is run in other port networks.                                                                                                                                                                                                                                                                          |
| 1024       | ABORT       | The Packet Control circuit pack is in use by Packet Control maintenance at this time. The test cannot be completed until the Packet Control circuit pack becomes available.<br><br>1. Wait for Packet Control maintenance to finish using the Packet Control circuit pack. (The green LED goes out.)<br><br>2. Re-enter the command.                                                                                                                                  |
| 1141       | ABORT       | The Packet Control circuit pack is out-of-service.<br><br>1. Determine if the Packet Control circuit pack is busied out (this is indicated by an Error Type 18 logged against PKT-CTRL). If the pack is busied out, release the pack by entering the <b>release packet-control</b> command. Then re-enter the command.<br><br>2. If the Packet Control circuit pack is NOT busied out, refer to PKT-CTRL Maintenance documentation for recommended repair procedures. |
| 1143       | ABORT       | This test is run only in high or critical reliability systems.<br><br>1. Ignore results from this test when it is run in a high or critical reliability system.                                                                                                                                                                                                                                                                                                       |
| 2000       | ABORT       | The test timed-out while waiting for the packet to be returned from the loop around.<br><br>1. Re-enter the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, check for problems with the Packet Control (look for PKT-CTRL errors in the Error and Alarm Logs).                                                                                                                                                          |
| 2076       | ABORT       | The parity error check circuitry on the Packet Control circuit pack is not functioning correctly.<br><br>1. Run the test again.<br><br>2. If the same abort occurs again, refer to PKT-CTRL to attempt to correct the fault.                                                                                                                                                                                                                                          |
| 2060       | ABORT       | The link on the Packet Bus that is being used to perform the test has failed.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times.<br><br>2. If the test continues to abort, check for problems with the Packet Control (look for PKT-CTRL error in the Error and Alarm Logs).                                                                                                                                                                     |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2100       | ABORT       | Maintenance could not allocate all of the necessary system resources to perform this test.                                                                                                                                                                            |
| 2500       | ABORT       | An internal operation failed; the test could not be completed.<br>1. Retry the command at 1-minute intervals a maximum of 5 times.                                                                                                                                    |
| 1          | FAIL        | The Packet Control Bus Loop Around Test failed (parity errors were detected from the test packet).                                                                                                                                                                    |
| 2          | FAIL        | The Packet Control Bus Loop Around Test failed (the Packet Control circuit pack could not bring up a loop around link on the Packet Bus).<br>1. Refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9 to determine the cause of the test failures. |
|            | PASS        | No faults have been detected on the Packet Bus by the Packet Control circuit pack. This indicates that the Packet Bus is operating correctly.                                                                                                                         |

Maintenance/Test Circuit Pack Query Test (#572)

This test queries the Maintenance/Test Packet Bus port about the state of health of the Packet Bus. If the Maintenance/Test circuit pack indicates that the Packet Bus has faults, the test fails. The corresponding failure code describes the severity, type, and number of faults. The test passes if the Packet Bus is fault-free.

 **NOTE:**  
A Maintenance/Test circuit pack is usually not present in a Standard system unless the customer has purchased this circuit pack to use for ISDN-PRI test calls, or to enhance the system's ability to quickly recognize a Packet Bus failure.

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1xxx       |             | The Maintenance/Test Packet Bus port has reconfigured the Packet Bus around the faulty leads. This occurs only in high or critical reliability systems.                                                                                                               |
| 2xxx       |             | The Maintenance/Test Packet Bus port is unable to correct all of the Packet Bus faults it has detected.                                                                                                                                                               |
| x0xx       |             | None of the Packet Bus faults are open faults.                                                                                                                                                                                                                        |
| x1xx       |             | At least some of the Packet Bus faults are open faults. Look for Error Type 2305 in the Error Log. The Aux Data value indicates the number of open leads.                                                                                                             |
| xxZZ       |             | The last 2 digits of the error code indicate the total number of faulty Packet Bus leads detected by the Maintenance/Test Packet Bus port.<br><br>1. Refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9 to determine the cause of the failures. |
|            | PASS        | No faults have been detected on the Packet Bus by the Maintenance/Test circuit pack. This indicates that the Packet Bus is operating correctly.                                                                                                                       |

Packet Circuit Pack Audit Test (#573)

This test determines whether Packet circuit packs have reported Packet Bus-related in-line errors within the last minute. If so, the failure code indicates whether one or more circuit packs have reported failures within the last minute.

Due to the one minute time constraint included as part of this test, the test is designed to delay 15 seconds before returning a result in cases where the test has failed within the last five minutes. This procedure helps ensure that a repeated sequence of the test does not always yield the same result. If no failure has occurred in the last five minutes, a PASS is returned immediately.

Table 10-319. Test #573 Packet Circuit Pack Audit Test

| Error Code | Test Result | Description/ Recommendation                                                                                                            |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------|
| 2500       | ABORT       | An internal operation failed; the test could not be completed.<br><br>1. Retry the command at 1-minute intervals a maximum of 5 times. |

Table 10-319. Test #573 Packet Circuit Pack Audit Test — Continued

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | FAIL        | One Packet circuit pack has reported Packet Bus-related in-line errors within the last minute.                                                                                                                                                                                                                                                                                                                                                                                                      |
| 2          | FAIL        | More than one Packet circuit pack has reported Packet Bus-related in-line errors within that last minute.<br><br>1. Refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9 to determine the cause of the error reports.                                                                                                                                                                                                                                                           |
|            | PASS        | No Packet circuit packs have reported Packet Bus-related in-line errors within the last minute. This indicates that the Packet Bus is healthy, or that a Packet Bus fault is transient or is being caused by a faulty Packet circuit pack. If this test passes while there are other signs of a Packet Bus failure (as indicated, for example, in the Error/Alarm Logs or by other test failures), refer to the "Packet Bus Fault Isolation Flowchart" section in Chapter 9 to isolate the problem. |

# PKT-CTRL (Packet Control Circuit Pack)

| MO Name (in Alarm Log) | Alarm Level | Initial Command to Run              | Full Name of MO             |
|------------------------|-------------|-------------------------------------|-----------------------------|
| PKT-CTRL               | MAJOR       | reset packet-control C <sup>1</sup> | Packet Control Circuit Pack |
| PKT-CTRL               | MINOR       | test packet-control C <sup>2</sup>  | Packet Control Circuit Pack |
| PKT-CTRL               | WARNING     | release packet-control C            | Packet Control Circuit Pack |

1. If the specified Packet Control circuit pack is in the active SPE, it must first be busied-out via the **busyout packet-control C** command. After testing has completed, the Packet Control circuit pack should be released from the busyout state via the **release packet-control C** command.
2. Where C is the carrier designation (A or B) and should be specified only in a High or Critical Reliability system.

 **CAUTION:**

A detailed flowchart for isolating and resolving Packet Bus faults is included in [Chapter 9, "Packet Bus Fault Isolation and Correction"](#). This flowchart, along with the other information presented in the chapter, can help in resolving problems that are not isolated to the Packet Control. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9 in addition to the MO documentation for Packet Bus.

The TN778 Packet Control circuit pack is the hardware component that serves as the interface between the SPE and the Packet Bus. It terminates the Link Access Procedure D (LAPD) protocol and provides support for thousands of signaling links. As shown in [Figure 10-79](#), a Packet Control link generally terminates on the Packet Control circuit pack and a packet endpoint which is connected to a Packet circuit pack. An ASAI adjunct is an example of a packet endpoint, and a TN556 is an example of a Packet circuit pack. In G3iV1.1-286 or G3iV2-386, the following Packet circuit packs (packs that can connect to the Packet Bus) are available:

- TN556 ISDN-BRI Line Circuit Pack
- TN570 Expansion Interface Circuit Pack
- TN771 Maintenance/Test Circuit Pack
- TN778 Packet Control Circuit Pack

**Figure 10-79. Hardware Configuration**

The Packet Control circuit pack is not administered in the normal manner; there is no **add** or **remove** command associated with it. However the "Packet Bus Activated?" field on the Maintenance-Related System Parameters Form indicates if the Packet Control circuit pack is "administered." If the "Packet Bus Activated?" field is set to "yes," a Packet Control circuit pack should be installed in the system, since the Packet Control circuit pack is required in systems which use the Packet Bus. If a Packet Control circuit pack is not installed, and the "Packet Bus Activated?" field is set to "yes," a major on-board alarm is raised against the PKT-CTRL MO. This alarm indicates that the Packet Control circuit pack is "missing." Refer to the "Maintenance-Related System Parameters Form" section in [Chapter 5, "Routine Maintenance Procedures"](#) for more information on the "Packet Bus Activated?" field.

Note that the Packet Control circuit pack is listed by the **list configuration all** or **list configuration control** commands only if the Packet Control circuit pack is physically inserted into its slot and the Packet Bus is activated by setting the "Packet Bus Activated?" field to "yes" on the Maintenance-Related System Parameters Form. If the Packet Control circuit pack is physically inserted into its slot but the Packet Bus is not activated, then the Packet Control circuit pack will not appear in the output of the **list configuration all** or **list configuration control** commands.

The **status packet-control C** command provides useful information about the Packet Control circuit pack. This command displays the service state of the circuit pack and various link-related information. The service state "out" indicates that service is not being provided and users are being disrupted. Maintenance takes the Packet Control circuit pack out-of-service due to certain faults, or as a result of the **busyout packet-control C** command being run. Refer to the "Status Commands" section in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#) for more information on the **status packet-control** command.

Error Log Entries and Test to Clear Values

Table 10-320. Packet Control Error Log Entries

| Error Type | Aux Data | Associated Test              | Alarm Level | On/Off Board | Test to Clear Value        |
|------------|----------|------------------------------|-------------|--------------|----------------------------|
| 1(a)       | Any      | None                         | MAJOR       | ON           | reset packet-control C (k) |
| 18         | 0        | busyout packet-control C     | WARNING     | OFF          | release packet-control C   |
| 257 (b)    | Any      | None                         | MAJOR       | ON           | reset packet-control C (k) |
| 513 (c)    | 0        | None                         |             |              |                            |
| 769 (d)    | Any      | Loop Around Test (#585)      |             |              |                            |
| 1025 (e)   | 1        | Parity Circuitry Test (#584) | MINOR       | ON           | test packet-control C I    |
| 1281 (f)   | 0        | None                         |             |              |                            |
| 1537 (g)   | 0        | None                         |             |              |                            |
| 1793 (h)   | 0        | None                         |             |              |                            |
| 2049 (i)   | 0        | None                         |             |              |                            |
