Notice

Every effort was made to ensure that the information in this book was complete and accurate at the time of printing. However, information is subject to change.

Your Responsibility for Your System’s Security

Toll fraud is the unauthorized use of your telecommunications system by an unauthorized party, for example, persons other than your company’s employees, agents, subcontractors, or persons working on your company’s behalf. Note that there may be a risk of toll fraud associated with your telecommunications system and, if toll fraud occurs, it can result in substantial additional charges for your telecommunications services.

You and your system manager are responsible for the security of your system, such as programming and configuring your equipment to prevent unauthorized use. The system manager is also responsible for reading all installation, instruction, and system administration documents provided with this product in order to fully understand the features that can introduce risk of toll fraud and the steps that can be taken to reduce that risk. Lucent Technologies does not warrant that this product is immune from or will prevent unauthorized use of common-carrier telecommunication services or facilities accessed through or connected to it. Lucent Technologies will not be responsible for any charges that result from such unauthorized use.

Lucent Technologies Fraud Intervention

If you suspect that you are being victimized by toll fraud and you need technical support or assistance, call Technical Service Center Toll Fraud Intervention Hotline at 1 800 643-2353.

Federal Communications Commission Statement

Part 15: Class B Statement. This equipment has been tested and found to comply with the limits for a Class B digital device, pursuant to Part 15 of the FCC Rules. These limits are designed to provide reasonable protection against harmful interference in a residential installation. This equipment generates, uses, and can radiate radio-frequency energy and, if not installed and used in accordance with the instructions, may cause harmful interference to radio communications. However, there is no guarantee that interference will not occur in a particular installation. If this equipment does cause harmful interference to radio or television reception, which can be determined by turning the equipment off and on, the user is encouraged to try to correct the interference by one or more of the following measures:

- Reorient the receiving television or radio antenna where this may be done safely.
- To the extent possible, relocate the receiver with respect to the telephone equipment.
- Where the telephone equipment requires ac power, plug the telephone into a different ac outlet so that the telephone equipment and receiver are on different branch circuits.

Part 68: Network Registration Number. This equipment is registered with the FCC in accordance with Part 68 of the FCC Rules. It is identified by FCC registration number AS593M-11185-MF-E.

Part 68: Answer-Supervision Signaling. Allowing this equipment to be operated in a manner that does not provide proper answer-supervision signaling is in violation of Part 68 rules. This equipment returns answer-supervision signals to the public switched network when:

- Answered by the called station
- Answered by the attendant
- Routed to a recorded announcement that can be administered by the CPE user

This equipment returns answer-supervision signals on all DID calls forwarded back to the public switched telephone network. Permissible exceptions are:

- A call is unanswered
- A busy tone is received
- A reorder tone is received

Trademarks

DEFINITY is a registered trademark of Lucent Technologies in the U.S. and throughout the world.

AUDIX is a registered trademark of Lucent Technologies.

Ordering Information

Call: Lucent Technologies Publications Center
Voice 1 800 457-1235 International Voice 317 361-5353
Fax 1 800 457-1764 International Fax 317 361-5355

Write: Lucent Technologies Publications Center
P.O. Box 4100
Crawfordsville, IN 47933

Order: Document No. 555-230-127
Comcode 108041948
Issue 1, August 1997

For additional documents, refer to the section entitled, “Related Documents” in “About This Book.”

You can be placed on a Standing Order list for this and other documents you may need. Standing Order will enable you to automatically receive updated versions of individual documents or document sets, billed to account information that you provide. For more information on Standing Orders, or to be put on a list to receive future issues of this document, please contact the Lucent Technologies Publications Center.

Warranty

Lucent Technologies provides a limited warranty on this product. Refer to the “Limited use Software License Agreement” card provided with your package.

European Union Declaration of Conformity

Lucent Technologies Business Communications Systems declares that XXX equipment specified in this document conforms to the referenced European Union (EU) Directives and Harmonized Standards listed below:

EMC Directive	89/336/EEC
Low Voltage Directive	73/23/EEC

The “CE” mark affixed to the equipment means that it conforms to the above Directives.

Disclaimer

Intellectual property related to this product and registered to AT&T Corporation has been transferred to Lucent Technologies Incorporated.

Any references within this text to American Telephone and Telegraph Corporation or AT&T should be interpreted as references to Lucent Technologies Incorporated. The exception is cross references to books published prior to December 31, 1996, which retain their original AT&T titles.

Heritage

Lucent Technologies - formed as a result of AT&T’s planned restructuring - designs, builds, and delivers a wide range of public and private networks, communication systems and software, consumer and business telephone systems, and microelectronics components. The world-renowned Bell Laboratories is the research and development arm for the company.

Acknowledgment

About This Book

General

This book has the information needed to monitor, test, and maintain DEFINITY® Enterprise Communications Server Release 6 Systems and covers many of the faults and troubles that can occur in the system. Most maintenance requirements are simple procedures due to the modular, self-testing nature of the system.

This document covers information related to DEFINITY ECS Release 6.1, including all incremental releases.

Simple, traditional troubleshooting methods are sometimes sufficient to locate and clear faults. The traditional methods include terminal substitution, visual inspections, continuity checks, and clarification of operating procedures with users.

The information in this book is intended for use by:

- A maintenance technician dispatched to a DEFINITY System site in response to a trouble alarm or a user trouble report,
- A maintenance technician located at a remote maintenance facility, or
- The user's assigned maintenance technician. The technician is expected to have a knowledge of telecommunications fundamentals and of the DEFINITY Enterprise Communications Server Release 5 Systems to the extent that the procedures in this book can be performed, in most cases, without assistance.

Each DEFINITY System has a user-designated System Manager who is responsible for administration of the system. The maintenance technician should work closely with the user's System Manager.

This book is not intended to solve all levels of troubles. It is limited to troubles that can be solved by using the Alarm Log, Error Log, trouble-clearing procedures, maintenance tests, and traditional troubleshooting methods. If the trouble still has not been resolved, it the responsibility of the maintenance technician to escalate the problem to a higher level of technical support. Escalation should conform to the procedures in the *Technical and Administration Escalation Plan*.

When features, screen displays, equipment, or operations differ between system types, for example, Generic 3 V4, Release 5si, or Release 5si + memory, these differences are clearly identified by use of the following indicators: "[G3V4]", "[R5si]", or "[R5 si + memory]."

Conventions Used in This Document

The following conventions are used in this document:

- DEFINITY Systems are called G3V4, Release 5; Release 5vs, Release 5si, Release 5si + memory, and Release 6.
- All occurrences of G3siV4, G3siV4+m, Release 5si, and Release 5 si + memory are called Release 5si unless a specific configuration is required to differentiate among product offerings.
- All occurrences of R5 without a suffix following the "5" refer to Release 5si, and Release 5si + memory.
- A component of a DEFINITY System, such as a circuit pack, occurring without a reference to any specific system, is part of G3V4 or Release 5.
- The term "ASAI" is synonymous with the newer CallVisor ASAI.
- All physical dimensions in this book are in English (Foot Pound Second) (FPS) followed by the metric Centimeter Grams Second (CGS) in parenthesis. Wire gauge measurements are in AWG followed by the diameter in millimeters in parenthesis.
- Admonishments used in this book are as follows:

CAUTION:

This sign is used to indicate possible harm to software, possible loss of data, or possible service interruptions.

WARNING:

This sign is used where there is possible harm to hardware or equipment.

DANGER:

This sign is used to indicate possible harm or injury to people.

Organization

This book is organized into two volumes: volume 1 contains Chapters 1 through 9, and volume 2 contains Chapter 10.

- [Chapter 1, “Maintenance Architecture”](#) describes the system’s design and maintenance strategy.
- [Chapter 2, “Circuit Packs and Power”](#) describes DEFINITY circuit packs. It also explains how power is supplied to the system.
- [Chapter 3, “Management Terminals”](#) describes the various management terminals that can be used on the system and how to set up the terminals.
- [Chapter 4, “Initialization and Recovery”](#) describes the various reset and reboot processes, and discusses how these processes are used to perform maintenance and to recover systems or subsystems that are out of service.
- [Chapter 5, “Routine Maintenance Procedures”](#) discusses common maintenance tasks, including: removing and installing circuit packs, removing and restoring power, performing system backups, upgrading software, and various testing and troubleshooting procedures.
- [Chapter 6, “Reliability Systems: A Maintenance Aid”](#) provides detailed hardware and functional descriptions as well as additional repair strategy (in addition to the procedures provided in this document) for Standard, High, and Critical Reliability systems.
- [Chapter 7, “LED Interpretation”](#) is a quick reference to interpreting circuit pack LEDs.
- [Chapter 8, “Maintenance Commands and Trouble-Clearing Aids”](#) has the maintenance commands, and explains how to use these commands using the management terminal. Specific command syntax plus typical forms and display output are also given in the chapter.
- [Chapter 9, “Packet Bus Fault Isolation and Correction”](#) describes Pack Bus maintenance and the interactions of the bus with Packet circuit packs. The chapter also discusses how Packet Bus faults are isolated and corrected.
- [Chapter 10, “Maintenance Object Repair Procedures”](#) has specific troubleshooting and repair instructions for every component in the system. The chapter contains repair procedures for system-alarmed and user-reported troubles. For each MO, a table lists the alarm level, hardware error associated with the MO, and the associated test that caused the error. The test sequences and the specific command line entry required to

run the tests are given and a brief description of each test. Explanations of error codes associated with each test are given, as are specific maintenance procedures to be used to resolve each problem.

Each MO is described in a separate section of [Chapter 10, "Maintenance Object Repair Procedures"](#). The individual sections are labeled with the name of the MO exactly as the name appears in the Alarm Log; for example, MAINT (for Maintenance circuit pack). The only exception is the MO name for Common Port Circuit Pack maintenance which is XXX-BD. The XXX-BD section contains a set of common tests used by certain circuit packs listed in the section. The common portion of these circuit packs is the generic hardware that interfaces with the Time Division Multiplex (TDM) Bus.

Lucent Technologies listens carefully to its readers. The organization of this book is a direct result of user feedback. Your feedback is important. Use the feedback form at the back of this book to send your comments to Lucent Technologies.

Safety Precautions

When performing maintenance or translation procedures on the system, users must observe certain precautions. Observe all caution, warning, and danger statements to prevent loss of service, possible equipment damage, and possible personal injury. In addition, the following precautions regarding electromagnetic interference (EMI) and static electricity must be observed:

Electromagnetic Interference

This equipment generates, uses, and can radiate radio frequency energy. Electromagnetic fields radiating from the switch may cause noise in the customer's equipment. If the equipment is not installed and used in accordance with the instruction book, radio interference may result.

WARNING:

To maintain the EMI integrity of the system, maintenance personnel must ensure that all cabinet panels, covers, and so forth, are firmly secured before leaving the customer's premises.

Static Electricity

To prevent or reduce electrostatic discharge (ESD), always attach wrist grounding straps before working on switch components or handling circuit packs.

CAUTION:

Electrostatic discharge can damage or destroy circuit packs containing integrated circuits (ICs).

The ESD wrist strap, cable assembly, and spare fuses are packed in a plastic bag and placed in the top of the system cabinet. Use the ESD wrist strap when troubleshooting, performing maintenance, or handling any circuit packs associated with the system.

Class 1 Laser Device

The DEFINITY ECS contains a Class 1 Laser device if single-mode fiber optic cable is connected to a remote Expansion Port Network (EPN). The LASER device operates within the following parameters:

Power Output: -5 dBm

Wavelength: 1310 nm

Mode Field Diameter: 8.8 microns

DANGER:

Use of controls or adjustments or performance of procedures other than those specified herein may result in hazardous radiation exposure.

Contact your Lucent Technologies representative for more information.

Security Issues

A number of matters concerning maintenance are affected by security issues. For details, be sure to consult the *GBCS Products Security Handbook, Release 6*, 555-025-600.

CAUTION:

Login security is an attribute of the DEFINITY® Enterprise Communications Server (ECS) Release 5 software.

Standards Compliance

The equipment presented in this document complies with the following (as appropriate):

- ITU-T (Formerly CCITT)
- ECMA
- ETSI
- IPNS
- DPNSS
- National ISDN-1
- National ISDN-2

- ISO-9000
- ANSI
- FCC Part 15 and Part 68
- EN55022
- EN50081
- EN50082
- CISPR22
- Australia AS3548 (AS/NZ3548)
- Australia AS3260
- IEC 825
- IEC950
- UL 1459
- UL1950
- CSA C222 Number 225
- TS001

Electromagnetic Compatibility Standards

This product complies with and conforms to the following:

- Limits and Methods of Measurements of Radio Interference Characteristics of Information Technology Equipment, EN55022 (CISPR22), 1993
- EN50082-1, European Generic Immunity Standard
- FCC Parts 15 and 68
- Australia AS3548

NOTE:

The system conforms to Class A (industrial) equipment. Voice terminals meet Class B requirements.

- Electrostatic Discharge (ESD) IEC 1000-4-2
- Radiated radio frequency field IEC 1000-4-3
- Electrical Fast Transient IEC 1000-4-4
- Lightning effects IEC 1000-4-5
- Conducted radio frequency IEC 1000-4-6
- Mains frequency magnetic field IEC 1000-4-8

- Low frequency mains disturbance

The system conforms to the following:

- Electromagnetic compatibility General Immunity Standard, part 1; residential, commercial, light industry, EN50082-1, CENELEC, 1991
- Issue 1 (1984) and Issue 2 (1992), Electrostatic discharge immunity requirements (EN55024, Part 2) IEC 1000-4-2
- Radiated radio frequency field immunity requirements IEC 1000-4-3
- Electrical fast transient/burst immunity requirements IEC 1000-4-4

European Union Standards

Lucent Technologies Business Communications Systems declares that the DEFINITY equipment specified in this document bearing the “CE” mark conforms to the European Union Electromagnetic Compatibility Directives.

The “CE” (Conformité Européenne) mark indicates conformance to the European Union Electromagnetic Compatibility Directive (89/336/EEC) Low Voltage Directive (73/23/EEC) and Telecommunication Terminal Equipment (TTE) Directive (91/263/EEC) and with i-CTR3 Basic Rate Interface (BRI) and i-CTR4 Primary Rate Interface (PRI) as applicable.

The “CE” mark is applied to the following Release 5 products:

- Global AC powered Multi-Carrier Cabinet (MCC)
- DC powered Multi-Carrier Cabinet (MCC) with 25-Hz ring generator
- AC powered Single-Carrier Cabinet (SCC) with 25-Hz ring generator
- AC powered Compact Single-Carrier Cabinet (CSCC) with 25-Hz ring generator
- Enhanced DC Power System

Related Documents

The following books are useful for system-related information:

DEFINITY ECS Release 6.1.0 — Change Description, Issue 1, 555-230-474

Gives a high-level overview of what is new in DEFINITY ECS Release 6. Describes the hardware and software enhancements and lists the problem corrections for this release.

DEFINITY ECS Release 6 — System Description Pocket Reference, Issue 1, 555-230-211

Provides hardware descriptions, system parameters, listing of hardware required to use features, system configurations, and environmental requirements. This compact reference combines and replaces Release 6 *System Description and Specifications* and Release 6 *Pocket Reference*.

DEFINITY ECS Release 6 — Administration and Feature Description, Issue 2, 555-230-522

Provides descriptions of system features. Also provides step-by-step procedures for preparing the screens that are required to implement the features, functions, and services of the system. Includes the applications and benefits, feature interactions, administration requirements, hardware requirements, and procedures for voice terminal, data module, and trunk group administration.

DEFINITY ECS Release 5 — System Monitoring and Reporting, Issue 4, 555-230-511

Provides detailed descriptions of the measurement, status, security, and recent change history reports available in the system and is intended for administrators who validate traffic reports and evaluate system performance. Includes corrective actions for potential problems. Issue 2 of this document was titled *Traffic Reports*. The Release 5 version of this document applies to Release 6 as well.

DEFINITY Communications System Generic 3 Planning and Configuration, Issue 2, 555-230-601

This document was written for Generic 3 Version 2 software, but still contains relevant information for the ECS.

Provides step-by-step procedures for the account team in determining the customer's equipment and hardware requirements to configure a system according to the customer specifications. Includes detailed requirements and block diagrams.

DEFINITY ECS Release 5 — Installation and Test for Single-Carrier Cabinets, Issue 3, 555-230-894

Provides procedures and information for hardware installation and initial testing of single-carrier cabinets. The Release 5 version of this document applies to Release 6 as well.

This document is available in the following languages: English, German (DE), Dutch (NL), Brazilian Portuguese (PTB), European French (FR), Castilian Spanish (SP), Italian (IT), Russian (RU), and Japanese (JA). To order, append the language suffix to the document number; for example, 555-230-894DE for German. No suffix is needed for the English version.

DEFINITY ECS Release 5 — Installation and Upgrades for R5vs, Issue 1, 555-230-124

Provides procedures and information for hardware installation, upgrades, and initial testing of compact single-carrier cabinets. The Release 5 version of this document applies to Release 6 as well.

DEFINITY ECS Release 6 — Installation and Test for Multi-Carrier Cabinets, Issue 3, 555-230-112

Provides procedures and information for hardware installation and initial testing of multi-carrier cabinets.

DEFINITY ECS Release 6 — Installation for Adjuncts and Peripherals, Issue 2, 555-230-125

Provides procedures and information for hardware installation and initial testing of ECS adjunct and peripheral systems and equipment.

DEFINITY Communications System Generic 3vs/si — Upgrades and Additions, Issue 1, 555-230-108

Provides procedures for an installation technician to convert an existing DEFINITY Communications System earlier than Generic 3 Version 4 to Generic 3vs/si Version 4.

DEFINITY ECS Release 6 — Upgrades and Additions for R6vs/si, Issue 3, 555-230-120

Provides procedures for an installation technician to convert an existing DEFINITY Communications System Generic 3 Version 4 to DEFINITY ECS and from DEFINITY ECS Release 5 to DEFINITY ECS Release 6.

Included are upgrade considerations, lists of required hardware, and step-by-step upgrade procedures. Also included are procedures to add control carriers, switch node carriers, port carriers, circuit packs, auxiliary cabinets, and other equipment.

DEFINITY ECS Release 6 — Maintenance for R6r, Issue 1, 555-230-126

Provides detailed descriptions of the procedures for monitoring, testing, troubleshooting, and maintaining the R6r ECS. Included are maintenance commands, step-by-step trouble-clearing procedures, the procedures for using all tests, and explanations of the system's error codes.

BCS Products Security Handbook, Issue 6, 555-025-600

Provides information about the risks of telecommunications fraud and measures for addressing those risks and preventing unauthorized use of BCS products. This document is intended for telecommunications managers, console operators, and security organizations within companies.

DEFINITY ECS Release 5 — Terminals and Adjuncts Reference, Issue 8, 555-015-201

Provides descriptions of the peripheral equipment that can be used with System 75, System 85, DEFINITY Communications System, and DEFINITY ECS. This document is intended for customers and Lucent Technologies account teams for selecting the correct peripherals to accompany an ECS. The Release 5 version of this document applies to Release 6 as well.

AT&T Network and Data Connectivity Reference, 555-025-201

Federal Communications Commission Statement

Part 68: Statement

Part 68: Answer-Supervision Signaling. Allowing this equipment to be operated in a manner that does not provide proper answer-supervision signaling is in violation of Part 68 rules. This equipment returns answer-supervision signals to the public switched network when:

- Answered by the called station
- Answered by the attendant
- Routed to a recorded announcement that can be administered by the CPE user

This equipment returns answer-supervision signals on all DID calls forwarded back to the public switched telephone network. Permissible exceptions are:

- A call is unanswered
- A busy tone is received
- A reorder tone is received

This equipment is capable of providing users access to interstate providers of operator services through the use of access codes. Modification of this equipment by call aggregators to block access dialing codes is a violation of the Telephone Operator Consumers Act of 1990.

This equipment complies with Part 68 of the FCC Rules. On the rear of this equipment is a label that contains, among other information, the FCC registration number and ringer equivalence number (REN) for this equipment. If requested, this information must be provided to the telephone company.

The REN is used to determine the quantity of devices which may be connected to the telephone line. Excessive RENs on the telephone line may result in devices not ringing in response to an incoming call. In most, but not all areas, the sum of RENs should not exceed 5.0. To be certain of the number of devices that may be connected to a line, as determined by the total RENs, contact the local telephone company.

NOTE:

REN is not required for some types of analog or digital facilities.

Means of Connection

Connection of this equipment to the telephone network is shown in the following table.

Manufacturer's Port Identifier	FIC Code	SOC/REN/ A.S. Code	Network Jacks
Off/On Premises Station	OL13C	9.0F	RJ2GX, RJ21X, RJ11C
DID Trunk	02RV2-T	0.0B	RJ2GX, RJ21X
CO Trunk	02GS2	0.3A	RJ21X
CO Trunk	02LS2	0.3A	RJ21X
Tie Trunk	TL31M	9.0F	RJ2GX
1.544 Digital Interface	04DU9-B,C	6.0P	RJ48C, RJ48M
1.544 Digital Interface	04DU9-BN,KN	6.0P	RJ48C, RJ48M
120A2 Channel Service Unit	04DU9-DN	6.0P	RJ48C

If the terminal equipment (DEFINITY® System) causes harm to the telephone network, the telephone company will notify you in advance that temporary discontinuance of service may be required. But if advance notice is not practical, the telephone company will notify the customer as soon as possible. Also, you will be advised of your right to file a complaint with the FCC if you believe it is necessary.

The telephone company may make changes in its facilities, equipment, operations or procedures that could affect the operation of the equipment. If this happens, the telephone company will provide advance notice in order for you to make necessary modifications to maintain uninterrupted service.

If trouble is experienced with this equipment, for repair or warranty information, please contact the Technical Service Center at 1-800-248-1234. If the equipment is causing harm to the telephone network, the telephone company may request that you disconnect the equipment until the problem is resolved.

It is recommended that repairs be performed by Lucent Technologies certified technicians.

The equipment cannot be used on public coin phone service provided by the telephone company. Connection to party line service is subject to state tariffs. Contact the state public utility commission, public service commission or corporation commission for information.

This equipment, if it uses a telephone receiver, is hearing aid compatible.

Maintenance Architecture

1

The maintenance subsystem is a part of the software that initializes and maintains the system. The software continuously monitors system health, and keeps a record of errors detected in the system. The maintenance subsystem also provides a user interface for on-demand testing.

This chapter provides a brief description of the Release 5 maintenance strategy and the background information on the system's overall functions. For detailed descriptions of components and subsystems, refer to related topics in [Chapter 10, "Maintenance Object Repair Procedures"](#).

Maintenance Objects

The system is partitioned into separate entities called Maintenance Objects (MOs). Each MO is referred to by an upper-case, mnemonic-like name that serves as an abbreviation for the MO. For example, "CO-TRK" stands for "Central Office TRUnK". Each MO is monitored by the system and has its own maintenance strategy. Most MOs are individual circuit packs. Some MOs are hardware components that reside on part of a circuit pack. For example, the TDM bus Clock circuits reside on the Tone/Clock circuit pack. Other MOs, such as cabinet environmental sensors, represent larger subsystems or sets of monitors. Finally, some MOs, such as SYNChronization, represent processes or a combination of processes and hardware.

"Maintenance names" are recorded in the error and alarm logs. Individual copies of an MO are assigned an address that defines the MO's physical location in the system. These locations display as the "PORT" field in the alarm and error logs and as output of various commands such as **test board**, **busy tdm-bus**, and so forth.

Alarm and Error Reporting

During normal operations, software or firmware may detect error conditions relevant to specific MOs. The system attempts to fix or circumvent these problems automatically. However, if a hardware component incurs too many errors, an alarm is raised. Errors are detected in two ways:

- For “in-line” errors, firmware on the component detects the occurrence of an error during ongoing operations.
- For other types of errors, a “periodic test” or a “scheduled test” started by the software detects the error. The technician can run these tests on demand by using the maintenance commands described in [Chapter 8, “busyout journal-printer”](#), and [Chapter 10, “Maintenance Object Repair Procedures”](#).

Software puts the error in the error log, and increments the error counter for that error. When an error counter is “active,” (greater than zero), there is a maintenance record for the MO.

Alarms are classified as MAJOR, MINOR, or WARNING, depending on the effect on system operation. They are also classified as ON-BOARD or OFF-BOARD.

- MAJOR alarms identify failures that cause a critical degradation of service. These alarms require immediate attention.
- MINOR alarms identify failures that cause some service degradation but that do not render a crucial portion of the system inoperable. MINOR alarms require attention. However, typically a MINOR alarm affects only a few trunks or stations or a single feature.
- WARNING alarms identify failures that cause no significant degradation of service or equipment failures external to the switch. These failures are not reported to INADS or to the attendant console.
- ON-BOARD problems originate in the circuitry on the alarmed circuit pack.
- OFF-BOARD problems originate in a process or component that is external to the circuit pack.

Alarms are discussed further in [Chapter 10, “Maintenance Object Repair Procedures”](#).

Maintenance Testing

Most troubles are reduced to the circuit pack level and can be identified by LEDs on the circuit packs and software reports generated by the system. The maintenance tests in the system are divided into three groups:

- Periodic

Background tests are performed by software maintenance, usually on an hourly basis. These tests are nondestructive and can be run during high traffic periods without interfering with calls.

- **Scheduled**
Background tests performed by software maintenance, usually on a daily basis, are generally more thorough than periodic testing. The tests are considered destructive and are run only during off-hours so as not to interfere with calls.
- **Fixed interval**
Background tests performed by software maintenance at regular time intervals (these intervals cannot be administered). These tests run concurrently with periodic maintenance. The following table lists the MOs that run fixed interval testing.

Maintenance Object	Interval (minutes)
POWER	60
SPE-SELEC	60
STBY-SPE	120
TDM-BUS	10
TONE-PT	10

Demand tests are also run by the system when it detects a need or by maintenance personnel in trouble-clearing activities. Demand tests include periodic tests plus other tests required only when trouble occurs. Some nonperiodic demand tests may disrupt system operation. In this book, destructive (service-disrupting) tests are identified in boldface type.

Maintenance personnel can use the management terminal to initiate the same tests that the system initiates. The terminal screen displays the test results.

Protocols

This section describes the protocols handled by the system and the points where these protocols change. [Figure 1-1](#) is a pictorial guide through data-transmission state changes. [Figure 1-1](#) illustrates the flow of data from DTE equipment, like a terminal or host, through DCE equipment, like a modem or data module, into a communications port on the system. The data flow is shown by solid lines. Below these lines are the protocols used at particular points in the data stream.

Not shown in the [Figure 1-1](#) is the treatment of D-channels in ISDN-PRI and ISDN-BRI transmissions. PRI and BRI D-channels transport information elements

that contain call-signaling and caller information. These elements conform to ISDN level-3 protocol. In the case of BRI, the elements are created by the terminal or data module; for the PRI, the elements are created by the system, which inserts them into the D-channel at the DS1 port.

For ISDN transmissions, therefore, BRI terminals and data modules, and DS1 ports insert, interpret, and strip both layer-2 DCE information and layer-3 elements. Also, the DS1 port passes layer-3 elements to the system for processing.

Layers

The Open System Interconnect (OSI) model for data communications contains seven layers, each with a specific function. Communications to and through the system concern themselves only with layers 1 and 2 of the model.

Layer 1, or the *physical layer*, covers the physical interface between devices and the rules by which bits are passed. Among the physical layer protocols are RS-232, RS-449, X.21, DCP, DS1, and others.

Layer 2, or the *data-link layer*, refers to code created and interpreted by the DCE. The originating equipment can send blocks of data with the necessary codes for synchronization, error control, or flow control. With these codes, the destination equipment checks the physical-link reliability, corrects any transmission errors, and maintains the link. When a transmission reaches the destination equipment, it strips any layer-2 information the originating equipment may have inserted. The destination equipment only passes to the destination DTE equipment the information sent by the originating DTE equipment. The originating DTE equipment can also add layer-2 code to be analyzed by the destination DTE equipment. The DCE equipment treats this layer as data and passes it along to the destination DTE equipment as it would any other binary bits.

Layers 3 to 7 (and the DTE-created layer 2) are embedded in the transmission stream and are meaningful only at the destination DTE equipment. Therefore, they are shown in the figure as "user-defined," with no state changes until the transmission stream reaches its destination.

Figure 1-1. Data Transmission States

Usage

The following is a list of the protocols when data is transmitted to and through the system. The list is organized by protocol layers. Refer to [Figure 1-1](#).

Layer-1 Protocols

Layer-1 protocols are used between the terminal or host DTE and the DCE, used between the DCE equipment and the system port, and used inside the system.

The following layer-1 protocols are used between the DTE equipment and the DCE equipment. DCE equipment can be data modules, modems, or Data Service Units (DSUs). A DSU is a device that transmits digital data to a particular digital endpoint over the public network without processing the data through any intervening private network switches.

- *RS-232* — A common physical interface used to connect DTE to DCE. This protocol is typically used for communicating up to 19.2 kbps
- *RS-449* — Designed to overcome the RS-232 distance and speed restrictions and lack of modem control
- *V.35* — A physical interface used to connect DTE to a DCE. This protocol is typically used for transmissions at 56 or 64 kbps

The following protocols are used at layer 1 to govern communication between the DCE equipment and the port. These protocols consist of codes inserted at the originating DCE and stripped at the port. The DS1 protocol can be inserted at the originating, outgoing trunk port and stripped at the destination port.

- *Digital Communications Protocol (DCP)* — A standard for a 3-channel link. This protocol sends digitized voice and digital data in frames at 160 kbps. The channel structure consists of two information (I) channels and one signaling (S) channel. Each I-channel provides 64 kbps of voice and/or data communication and the S-channel provides 8 kbps of signaling communication between the system and DTE equipment. DCP is similar to ISDN-BRI
- *Basic Rate Interface (BRI)* — An ISDN standard for a 3-channel link, consisting of two 64-kbps bearer (B) channels and one 16-kbps signaling (D) channel. For the implementation of this standard, see *DEFINITY Communications System and System 75 and System 85 ISDN BRI Reference*, 555-025-103
- *Primary Rate Interface (PRI)* — An ISDN standard that sends digitized voice and digital data in T1 frames at 1.544-Mbps or, for countries outside the United States, in E1 frames at 2.048-Mbps. Layer 1 (physical), layer 2 (link), and layer 3 (network) ISDN PRI protocols are defined in *AT&T System 75 and 85 — DS1/DMI/ISDN-PRI — Reference Manual*, 555-025-101. At 1.544 Mbps, each frame consists of 24 64-kbps channels plus 8 kbps for framing. This represents 23 B-channels plus 1 D-channel.

The maximum user rate is 64 kbps for voice and data. The maximum distances are based on T1 limitations. At 2.048 Mbps, each E1 frame consists of 32 64-kbps channels

- *Analog* — A modulated voice-frequency carrier signal
- *ADU Proprietary* — A signal generated by an ADU. The signal is for communication over limited distances and can be understood only by a destination ADU or destination system port with a built-in ADU
- *Digital Signal Level 1 (DS1)* — A protocol defining the line coding, signaling, and framing used on a 24-channel line. Many types of trunk protocols (for example, PRI and 24th-channel signaling) use DS1 protocol at layer 1
- *European Conference of Postal and Telecommunications rate 1 (CEPT)* — A protocol defining the line coding, signaling, and framing used on a 32-channel line. Countries outside the United States use CEPT1 protocol

Inside the system, data transmission appears in one of two forms:

1. Raw digital data, where the physical layer protocols, like DCP, are stripped at the incoming port and reinserted at the outgoing port.
2. Pulse Code Modulation (PCM)-encoded analog signals (analog transmission by a modem), the signal having been digitized by an analog-to-digital coder/decoder (CODEC) at the incoming port.

Layer-2 Protocols

Layer-2 protocols are given below:

- *8-bit character code* — Between the DTE equipment and the DCE equipment. Depending on the type of equipment used, the code can be any proprietary code set.
- *Digital multiplexed interface* proprietary — Family of protocols between the originating DCE and the destination DCE for digital transmission. See *DEFINITY Communications System and System 75 and System 85 DS1/DMI/ISDN PRI Reference*, 555-025-101; and *Digital Multiplexed Interface [DMI] Technical Specification*, 555-025-204
- *Voice-grade data* — Between the originating DCE and the destination DCE for analog transmission

Protocol States

[Table 1-1](#) summarizes the protocols used at various points in the data transmission stream. See [Figure 1-1](#).

Table 1-1. Protocol States for Data Communication

Transmiss- ion Type	Incoming DTE to DCE	OSI Layer	Protocols DTE to DCE	DCE to System Port	Inside System
Analog	Modem	1	RS-232, RS-449, or V.35	analog	PCM
		2	8- or 10-bit code	voice-grade data	voice-grade data
	ADU	1	RS-232	ADU proprietary	raw bits
		2	asynchronous 8-bit code	asynchronous 8-bit code	DMI
Digital	Data Module	1	RS-232, RS-449, or V.35	DCP or BRI	raw bits
		2	8-bit code	DMI	DMI
	Digital Signal Level 1 (DS1)	1	any	DS1	PCM or raw bits
		2	8-bit code	DMI or voice- grade data	DMI or voice- grade data

 **NOTE:**
OSI means Open Systems Interconnect
PCM means Pulse Code Modulated
DMI means Digital Multiplexed Interface

Both the physical-layer protocol and the Digital Multiplexed Interface (DMI) mode used in the connection are dependent upon the type of 8-bit code used at layer 2 between the DTE equipment and DCE equipment, as listed in [Table 1-2](#) and [Table 1-3](#).

Table 1-2. Physical-Layer Protocol Versus Character Code

Protocol	Code
RS-232	Asynchronous 8-bit ASCII, and synchronous
RS-449	Asynchronous 8-bit ASCII, and synchronous
V.35	Synchronous

Table 1-3. Digital Multiplexed Interface (DMI) Mode Versus Character Code

DMI Mode	Code
0	Synchronous (64 kbps)
1	Synchronous (56 kbps)
2	Asynchronous 8-bit ASCII (up to 19.2 kbps), and synchronous
3	Asynchronous 8-bit ASCII, and private proprietary

Connectivity Rules

[Figure 1-1](#) implies the following connectivity rules:

- Only the DS1 port and the analog trunk port are trunking facilities (all other ports are line ports). For communication over these facilities, the destination DCE equipment can be a hemisphere away from the system, and the signal can traverse any number of intervening switching systems before reaching the destination equipment.
- Data originating at any type of digital device, whether DCP or BRI, can exit the system at any type of digital port — BRI, digital-line, PRI, DS1, and others; as long as the call destination is equipped with a data module using the same DMI mode used at the call origin. This is because once the data enters the system through a digital port, its representation is uniform (raw bits at layer 1, and DMI at level 2), regardless of where it originated.
- Although data entering the system through an EIA port has not been processed through a data module, the port itself has a built-in data module. Inside the system, port data is identical to digital line data. Data entering the system at a DCP line port can exit at an EIA port. Conversely, data entering the system at an EIA port can exit at any DCP line port. The destination data module must be set for Mode-2 DMI communication.
- Voice-grade data can be carried over a DS1 facility as long as the destination equipment is a modem compatible with the originating modem
- If a mismatch exists between the types of signals used by the endpoints in a connection (for example, the equipment at one end is an analog modem, and the equipment at the other end is a digital data module), a modem-pool member must be inserted in the circuit. When the endpoints are on different switches, it is recommended that the modem-pool member be put on the origination or destination system. A modem-pool

member is always inserted automatically for calls to off-premises sites via analog or voice-grade trunking. For internal calls, however, the systems are capable of automatically inserting a modem-pool member.

- Data cannot be carried over analog facilities unless inside the system it is represented as a Pulse Code Modulation (PCM)-encoded analog signal. To do this for data originating at a digital terminal, the signal enters the system at a digital port and exits the system at a digital port. The signal then reenters the system through a modem-pool connection (data-module to modem to analog-port) and exits the system again at an analog port.
- Although DS1 is commonly called a trunk speed, here it names the protocol used at layer 1 for digital trunks. Some trunks use different signaling methods but use DS1 protocol at layer 1 (for example, PRI and 24th-channel signaling trunks).

Disconnect Supervision

Disconnect supervision means the CO has the ability to release a trunk when the party at the CO disconnects, and the system is able to recognize the release signal. In general, a CO in the United States provides disconnect supervision for incoming calls but not for outgoing calls. Many other countries do not provide disconnect supervision on either incoming or outgoing calls.

The system must provide the assurance that at least one party on the call can control the dropping of the call. This avoids locking up circuits on a call where no party is able to send a disconnect signal to the system. Internal operations must check to be sure one party can provide disconnect supervision. An incoming trunk that does not provide disconnect supervision is not allowed to terminate to an outgoing trunk that does not provide disconnect supervision.

In a DCS environment, an incoming trunk without disconnect supervision can terminate to an outgoing DCS trunk connecting two nodes. The incoming trunk is restricted from being transferred to a party without disconnect supervision on the terminating node.

This is because, through messaging, the terminating node knows the originating node cannot provide disconnect supervision. This messaging is not possible with non-DCS tie trunks, and the direct call is denied.

Some two-wire loop start trunks outside the United States provide busy tone disconnect in place of line signals. For these trunks, an adjunct can be attached to the trunk to listen for busy or other disconnect tone. When a tone is detected, the adjunct sends line signals for disconnect to the system.

Administration is provided for each trunk group to indicate whether it provides disconnect supervision for incoming calls and for outgoing calls.

Transfer on Ringing

A station or attendant may conference in a ringing station or transfer a party to a ringing station. When a station conferences in a ringing station and then drops the call, the ringing station is treated like a party without disconnect supervision. However, when a station transfers a party to a ringing station, the ringing station party is treated like a party with disconnect supervision. Two timers (Attendant Return Call Timer and Wait Answer Supervision Timer) are provided to ensure the call is not locked to a ringing station.

Conference, Transfer, and Call-Forwarding Denial

If a station or attendant attempts to connect parties without disconnect supervision together, the following is possible:

- *Digital Station or Local Attendant Transfer:* if a digital station attempts to transfer the two parties together, the call appearance lamp flutters, indicating a denial. If transferring to a DCS trunk, the denial may drop the call since the transfer is allowed and the other system is queried for disconnect supervision.
- *Analog Station Transfer:* if an analog station attempts to transfer two parties together by going on-hook, the analog station is no longer on the call and the transfer cannot be denied.
- *Centralized Attendant Service (CAS) Attendant Transfer:* if a CAS attempts to transfer two parties together by pressing the release key, the release link trunk is released and the branch attempts a transfer by going on-hook
- *Station Conference/Dropout:* if a station conferences all parties, the conference is allowed since the station has disconnect supervision. When the station is dropped from the call, the call is dropped since the other parties do not have disconnect supervision.
- *Station Call Forwarding:* if a station is call forwarded off-premise to a trunk without disconnect supervision, the calling party without disconnect supervision is routed to the attendant

[Table 1-4](#) lists the various protocols, with applications and maximum limitations.

Table 1-4. Protocols Used in DEFINITY

Protocol	Applications	Maximum Data Rate	Maximum Distance
DCP	Digital switch to data endpoints	64 kbps	5000 feet (1524 m) for data 3000 feet (915 m) for voice
RS-232	System to administration terminal. Data module to host computer	19.2 kbps	50 feet (15.2 m)
	Data module to printer	64 kbps	17 feet (5.9 m)
	Data module for downloading and high-speed data transfer	64 kbps	17 feet (5.9 m)
	EIA interface (Data line to ADU)	19.2 kbps	2000 feet (610 m)
		9.6 kbps	5000 feet (1524 m)
		4.8 kbps	7000 feet (2130 m)
		2.4 kbps	12,000 feet (3654 m)
		1.2 kbps	20,000 feet (6100 m)
		0.3 kbps	40,000 feet (12200 m)
RS-449	Processor Interface to Processor Interface	19.2 kbps	200 feet (61 m)
		9.6 kbps	400 feet (122 m)
		4.8 kbps	800 feet (244 m)
		2.4 kbps	1600 feet (488 m)
SSI	715 BCS-2 to Processor Interface 500 series printers to Processor Interface	56 kbps	5000 feet (1524 m)
BISYNC	Processor Interface line controller to host computer for terminal emulation (9.6 kbps)	2.4 kbps 4.8 kbps 9.6 kbps	
BX.25	Communication interface to MSA, DCS, ISDN, or AUDIX	9.6 kbps	
SDCPI	Data module to Processor Interface	64 kbps	17 feet (5.9 m)
RS-366	Host computer to ACU		50 feet (15.2 m)
	Data module to ACU	64 kbps	17 feet (5.9 m)
V.35	Data module to data endpoints	56 kbps	50 feet (15.2 m)

Continued on next page

Table 1-4. Protocols Used in DEFINITY — Continued

Protocol	Applications	Maximum Data Rate	Maximum Distance
Category A	Data modules to terminals or cluster controller	64 kbps	500 feet (152 m)
	Data module in ASCII emulation mode	9.6 kbps	
ISDN-BRI	Communication interface to ISDN-BRI S/T	64 kbps	655 feet (199.3 m) to network interface or repeater 1310 feet (399.3 m) system to system
	ISDN-BRI U	160 kbps	18,000 feet (5486.4 m) from system to network interface, and then ~2000 feet to phone
ISDN-PRI	Communication interface to ISDN-PRI	64 kbps	655 feet (199.3 m) to network interface or repeater 1310 feet (399.3 m) system to system

 **NOTE:**
ADU means Asynchronous Data Unit
BCS means Business Communications System
MSA means Message Servicing Adjunct
ACU means Automatic Call Unit

Transmission Characteristics

The system transmission characteristics comply with the American National Standards Institute/Electronic Industries Association (ANSI/EIA) standard RS-464A (SP-1378A). The following tables list some general switch transmission characteristics.

Frequency Response

Table 1-5 lists the analog-to-analog frequency response for station-to-station or station-to-CO trunk, relative to loss at 1 kHz for the United States.

Table 1-5. Analog-to-Analog Frequency Response

Frequency (Hz)	Maximum Loss (dB)	Minimum Loss (dB)
60	—	20
200	5	0
300 to 3000	1	-0.5
3200	1.5	-0.5
3400	3	0

Table 1-6 lists the analog-to-digital frequency response of the system for station or CO-trunk-to-digital interface (DS0), relative to loss at 1 kHz for the United States.

Table 1-6. Analog-to-Digital Frequency Response

Frequency (Hz)	Maximum Loss (dB)	Minimum Loss (dB)
60	—	20
200	3	0
300 to 3000	0.5	-0.25
3200	0.75	-0.25
3400	1.5	0

Insertion Loss for Port-to-Port; Analog or Digital

[Table 1-7](#) lists the insertion loss in the system for different connection types for the United States. [Table 1-8](#) shows the overload and cross-talk characteristics.

Table 1-7. Insertion Loss for the United States

Typical Connections	Nominal Loss (dB) at 1 kHz
On-premises to on-premises station	6
On-premises to off-premises station	3
Off-premises to off-premises station	0
On-premises station to 4-wire trunk	3
Off-premises station to 4-wire trunk	2
Station-to-trunk	0
Trunk-to-trunk	0

Table 1-8. Overload and Crosstalk

Overload level	+3 dBm0
Crosstalk loss	>70 dB

Intermodulation Distortion

[Table 1-9](#) lists the intermodulation distortion in the system for analog-to-analog and analog-to-digital, up to 9.6 kbps data

Table 1-9. Intermodulation Distortion

Four-Tone Method	Distortion
Second-order tone products	>46 dB
Third-order tone products	>56 dB

Quantization Distortion Loss

[Table 1-10](#) lists the quantization distortion loss in the system for analog port to analog port.

Table 1-10. Quantization Distortion Loss

Analog Port-to-Analog Port	
Signal Level	Distortion Loss
0 to -30 dBm0	>33 dB
-40 dBm0	>27 dB
-45 dBm0	>22 dB

[Table 1-11](#) lists the quantization distortion loss in the system for analog port to digital port and digital port to analog port.

Table 1-11. Quantization Distortion Loss

Analog Port-to-Digital Port or Digital Port-to-Analog Port	
Signal Level	Distortion Loss
0 to -30 dBm0	>35 dB
-40 dBm0	>29 dB
-45 dBm0	>25 dB

Terminating Impedance: 600 Ohms nominal
Trunk balance impedance (selectable): 600 Ohms nominal or complex Z [350 Ohms + (1 k Ohms in parallel with 0.215uF)]

Impulse Noise

On 95% or more of all connections, the impulse noise is 0 count (hits) in five minutes at +55 dBmC (decibels above reference noise with C-filter) during the busy hour.

ERL and SFRL Talking State

Echo-Return Loss (ERL) and Single-Frequency Return Loss (SFRL) performance is usually dominated by termination and/or loop input impedances. The system provides an acceptable level of echo performance if the ERL and SFRL are met.

Station-to-station	ERL should meet or exceed 18 dB SFRL should meet or exceed 12 dB
Station to 4-wire trunk connection	ERL should meet or exceed 24 dB SFRL should meet or exceed 14 dB
Station to 2-wire trunk connection	ERL should meet or exceed 18 dB SFRL should meet or exceed 12 dB
4-wire to 4-wire trunk connection	ERL should meet or exceed 27 dB SFRL should meet or exceed 20 dB

Peak Noise Level

Analog to analog — 20 dBrnC (decibels above reference noise with C-filter)

Analog to digital — 19 dBrnC

Digital to analog — 13 dBrnC

Echo Path Delay

Analog port to analog port — ≤ 3 ms

Digital interface port to digital interface port — ≤ 2 ms

Service Codes

Service codes (for the United States only) are issued by the Federal Communications Commission (FCC) to equipment manufacturers and registrants. These codes denote the type of registered terminal equipment and the protective characteristics of the premises wiring of the terminal equipment ports.

Private line service codes are as follows:

- 7.0Y — Totally protected private communications (microwave) systems
- 7.0Z — Partially protected private communications (microwave) systems
- 8.0X — Port for ancillary equipment
- 9.0F — Fully protected terminal equipment

- 9.0P — Partially protected terminal equipment
- 9.0N — Unprotected terminal equipment
- 9.0Y — Totally protected terminal equipment

The product line service code is 9.0F indicating it is terminal equipment with fully protected premises wire at the private line ports.

Facility Interface Codes

A Facility Interface Code (FIC) is a five-character code (United States only) that provides the technical information needed to order a specific port circuit pack for analog private lines, digital lines, MTS lines, and WATS lines.

Table 1-12 through Table 1-14 list the FICs. Included are service order codes, Ringer Equivalency Numbers (RENS), and types of network jacks that connect a line to a rear panel connector on a carrier.

Table 1-12. Analog Private Line and Trunk Port Circuit Packs

Circuit Pack	FIC	Service Order Code	Network Jack
TN742 and TN747B Off-Premises Station Port, and TN746B Off-Premises Station Port or On-Premises Station port	0L13C	9.0F	RJ21X
TN760/B/C/D Tie Trunk	TL31M	9.0F	RJ2GX

Table 1-13. Digital Trunk Port Circuit Packs

Circuit Pack	FIC	Service Order Code	Network Jack
TN1654 and TN574 DS1 Converter; TN722B DS1 Tie trunk; and TN767 and TN464 DS1 Interface	04DU9B,C	6.0P	RJ48C and RJ48M

Table 1-14. MTS and WATS Port Circuit Packs

Circuit Pack	FIC	Ringer Equivalency Number (REN)	Network Jack
TN742 and TN746B Analog Line	02LS2	None	RJ21 and RJ11C
TN747B Central Office Trunk	02GS2	1.0A	RJ21X
TN753 DID Trunk	02RV2-T	0,0B	RJ21X
TN790 Processor	02LS2	1.0A	RJ21X
TN1648 System Access and Maintenance	02LS2	0.5A	RJ21X

Multimedia Interface (MMI)

The Multimedia Interface handles the following protocols:

- International Telecommunications Union (ITU) H.221 — Includes H.230, H.242, H.231, and H.243 protocol
- American National Standards Institute (ANSI) H.221 — Includes H.230, H.242, H.231, and H.243 protocol
- BONDING (Bandwidth On Demand INoperability Group) Mode 1
- ESM HLP HDLC Rate Adaptation

The Vistium Personal Conferencing System is supported either through the 8510T BRI terminal or directly through the Vistium TMBRI PC board.

Using the World Class Core (WCC) BRI interface, most desktop multimedia applications are supported through the Personal Computer's BRI interface.

Circuit Packs and Power

2

This chapter discusses the hardware configurations contained within and supported by the DEFINITY Systems. Where appropriate, detailed information down to the circuit pack level is provided. This chapter also discusses the power sources required to enable the various components within the system.

Circuit Packs

The following table list all circuit packs supported by DEFINITY Release 5 systems. For information concerning vintages and current versions, see *Reference Guide for Circuit Pack Vintages and Change Notices* which is published periodically as a special edition of the *AT&T Technical Monthly*.

For more information concerning which circuit packs are needed for different environments and locales, see the Application Notes section of *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*.

[Table 2-1](#) lists circuit packs by Apparatus Code, Name, and Type. See the *Reference Guide for Circuit Pack Vintages and Change Notices* for circuit packs that pertain to your system.

Table 2-1. Circuit packs and modules supported by DEFINITY

Apparatus Code	Name	Type
631DA1	AC Power Unit	Power
631DB1	AC Power Unit	Power
644A1	DC Power Unit	Power
645B1	DC Power Unit	Power
649A	DC Power Unit	Power
676B	DC Power Supply	Power

Power

There are two basic powering options available with the Release 5si systems. These options include AC and DC. The cabinets and their associated power supplies can be powered by 120/208 volts AC either directly or from a Universal Power Supply (UPS) system. Alternatively, the cabinets and their power supplies may be powered by -48 volts DC from a battery power plant.

The Release 5vs system requires between 80 and 264 or between 90 and 132 volts AC. The system can be powered directly or from the WP-90510 power supply. The DC power option is not available with this system.

Except for the Release 5vs system, each control cabinet in an AC-powered system has an internal battery that provides a short term holdover to protect the system against short power interruptions. This method is known as the Nominal Power Holdover Strategy. The battery is connected so that it automatically provides power if the AC service fails. The time and extent of the holdover varies according to the type of cabinet and to whether or not the system has a duplicated control complex.

[Table 2-2](#) summarizes the response to the interruption of power service in systems without an internal holdover battery.

Table 2-2. Response to Power Service Interruption (without Internal Holdover Battery)

Cabinet Power Interruption	Less Than Power Supply Decay	Greater Than Power Supply Decay
-48 volt DC external power or multicarrier cabinet with UPS, no internal battery.	None on system, some impact on 48-volt powered circuits.	All calls dropped, system reloads.

The next two tables indicate various responses to the interruption of power service in DEFINITY Systems equipped with an internal holdover battery.

[Table 2-3](#) provides a summary of holdover times. [Table 2-4](#) indicates the types of cabinet power interruption based on power holdover durations.

Table 2-3. Response to Power Service Interruption with an Internal Holdover Battery

System and Configuration	Cabinet	Holdover for Entire Cabinet (in seconds)	Holdover for Entire Control Carrier (in minutes)
Standard	PPNMCC	10	10
High, Critical	PPNMCC	10	5
Standard/High, Critical	PPN SCC/ESCC	1/4	2
Standard/High, Critical ¹	EPN MCC	15	none
Standard/High, Critical	EPN SCC/ESCC	1/4	none

1. The holdover times listed are in effect if the EPN contains a TN775 maintenance circuit pack. However, if the EPN contains a TN775B maintenance circuit pack, the holdover time for the entire cabinet is 10 seconds, and the holdover time for the control carrier is 10 minutes.

Table 2-4. Types of Cabinet Power Interruption

System and Cabinet	Shorter Holdover Than Entire Cabinet	Longer Holdover than Entire Cabinet, Shorter Holdover than Control Carrier	Longer Holdover Than Control Carrier
PPN SCC	No calls dropped	All calls dropped	System reloads
EPN SCC	No calls dropped	All calls dropped	System reloads

NOTE:
When EPN power is interrupted for greater than the cabinet holdover but less than the control carrier holdover, calls in the control carrier are held for the duration of the interruption but are dropped when power is restored.

Single-Carrier Cabinets

In single-carrier cabinets, there is no internal AC wiring or distribution and no software interaction with the power system. The power supplies themselves take about 250 milliseconds for the voltages to drop below limits.

The control cabinet that houses the Switch Processing Element (SPE) is the only cabinet that has an internal battery reserve. All other control cabinets and port cabinets have the 250 millisecond power supply decay delay, after which all connections and links associated with the cabinets are dropped.

The SPE control cabinet has a battery that furnishes power to the processor memory complex for a minimum of two minutes if the battery is fully charged. This battery is recharged after power is restored, but the charging process is not monitored by the system. The cabinet is not able to detect AC power loss, and it notices only a DC power output failure as the power supply output decays.

The memory contents are preserved, and the processor continues operating during the two minute period. However, the tone-clock circuit pack is not held over, and as a result, no connections are possible. The battery does not supply all the voltages necessary for the internal modem circuit on the processor circuit pack. As a result, no call is originated to INADS, and the switch cannot answer any calls. Thus, the switch cannot report any internal or external alarms during this period. After two minutes (depending on the condition of the battery), the processor and memory are lost, and the system is totally inactive.

If power is restored in less than 250 milliseconds, no calls are dropped. If power is restored between 250 milliseconds and two minutes, all calls are dropped, and memory is maintained. However, since the tone-clock was lost, the system undergoes a reset once the AC restoral process clears all calls and the alarm log (in which errors are retained). The switch keeps a record of the restart in the error log, but it might not detect a power error if the outage is between 1/4 of a second and one minute, during which time only a loss of clock and not a loss of the power failure that caused the loss of clock is logged. After one minute, a power error is logged. If the outage exceeds the battery holdover interval, the error logs and alarm logs are lost (since they cannot be saved to tape). Depending on the size of the system, it can take up to one minute to restore service to the ports. After a power outage of two minutes following the restoral of AC power, the system re-initializes from the tape. It takes about 10 minutes to restore service. Again, if the customer has frequent power outages or critical service needs, an external UPS or DC power system should be considered.

 NOTE:

For more power control information, refer to AC-POWER, DC-POWER, and POWER maintenance objects.

Management Terminals

3

General

Maintenance personnel can use the management terminal to initiate the same tests that the system initiates. Test results display on the terminal screen. This chapter illustrates these terminals, explains how to use them, and identifies the typical maintenance tasks that can be performed from them.

Management Terminals

The maintenance interface for the system technician is the management terminal. These terminals may be referred to as an *administration terminal*.

The following terminals are supported as administration terminals:

- 715 BCS
- 2900/715 BCS
- 715 BCS-2

In a standard reliability system, the terminal connects to the Processor circuit pack. In the PPN of a high or critical reliability system, the administration terminal connects to the Duplication Interface circuit pack in the PPN. In the EPN of a standard reliability system or of a high or critical reliability system, the administration terminal connects to the Maintenance circuit pack in the EPN.

Duplication Interface circuit pack A controls and monitors the same environment leads as the Maintenance/Tape Processor in a PPN system without high or critical reliability. Duplication Interface circuit pack A also supports the serial channel to the terminal in a PPN for a high or critical reliability system. The terminal connects to Duplication Interface circuit pack A via a connector, labeled

DOT (Duplication Option Terminal), on the back of cabinet A. At any time, the terminal may be disconnected from the Duplication Interface circuit pack A and connected directly to the active processor circuit pack by attaching the terminal to the connector labeled **TERM**. This connection should be made only if the terminal fails to function, since a problem with the Duplication Interface circuit pack A may be present.

Typical tasks that can be performed at the terminal are shown below.

- Display Error and Alarm logs
- Test circuit packs
- Test system functions
- Busyout and release system equipment
- Reset the system
- Monitor the system
- Check status of maintenance objects
- Check system translations

Most maintenance functions performed at the local administration terminal can also be done remotely at the INADS (Initialization and Administration System).

Terminal Keyboard

The keyboard is equipped with cursor keys, editing keys, and transaction keys. The three types of keys are described here.

Cursor Keys: Cursor keys are used to move the cursor between fields and pages on a screen form. The cursor must be positioned on a field before the user can add or change information in that field.

Editing Keys: Two editing keys, BACKSPACE and Clear, are provided. BACKSPACE is used to erase the character at the current cursor position. The cursor moves one position to the left each time the key is pressed. If the cursor is at the first position of the data entry field, it erases the character at the first position. Clear when pressed simultaneously with the Shift is used to clear all data in a field on a screen form. The cursor must be positioned at the field the user wants to clear before Clear is pressed.

Transaction Keys: Three transaction keys, Cancel, Enter, and Help, are provided. CANCEL is used to erase a form or command. Once the key is pressed, the system returns the user to the command (tasks request) level and asks for a new command. Enter is used to store the data entered on a screen form in the system's memory. Help displays information on the type of data that can be entered into the field associated with the current cursor position. The system displays all the permissible entries the user can input for that field. This key can be pressed at the "enter command" level to obtain a list of all commands.

System Login Procedure

Forced Password Aging and Administrable Logins

Release 5 and later releases provide enhanced login/password security by adding a security feature that allows users to define their own logins/passwords and to specify a set of commands for each login. The system allows up to 11 customer logins. Each login name can be customized and must be made up of from 3 to 6 alphabetic/numeric characters, or a combination of both. A password must be from 4 to 11 characters in length and contain at least 1 alphabetic and 1 numeric symbol. Password aging is an optional feature that the super-user administering the logins can activate.

NOTE:

If several users are logging in and out at the same time, a user may see the message "Transient command conflict detected; please try later". After the "users" have completed logging in or out, the terminal is available for use.

The password for each login can be aged starting with the date the password was created, or changed, and continuing for a specified number of days (1 to 99). The user is notified at the login prompt, 7 days before the password expiration date, that the password is about to expire. When the password expires the user is required to enter a new password into the system before logging in. If a login is added or removed, the "Security Measurement" reports are not updated until the next hourly poll, or a **clear measurements security-violations** command is entered. Once a non-super-user has changed the password, the user must wait 24 hours to change the password again.

Security is enhanced by providing a logoff notification screen to a system administrator at log off while either the facility test call or remote access features are still administered. The administrator can be required to acknowledge the notification before completing the logoff process. Logoff notification is administered on the Login Administration screen.

Release 5 and later releases are delivered to the customer with one customer "super-user" login/password defined. The customer is required to administer additional login/passwords as needed. The super-user login has full customer permissions and can customize any login created.

Login permissions for a specified login can be set by the super-user to block any object that may compromise switch security. Up to 40 administration or maintenance objects commands can be blocked for a specified login in.

Release 5 and later releases commands are grouped into three command categories. Each of the three command categories has a group of command subcategories listed under them, and each command subcategory has a list of command objects that the commands acts on. A super-user can set a users

permissions to restrict or block access to any command in these categories. The three main categories are:

- Common Commands
 - Display Admin. and Maint. Data
 - System Measurements
- Administration Commands
 - Administer Stations
 - Administer Trunks
 - Additional Restrictions
 - Administer Features
 - Administer Permissions
- Maintenance Commands
 - Maintain Stations
 - Maintain Trunks
 - Maintain Systems
 - Maintain Switch Circuit Packs
 - Maintain Process Circuit Packs

These categories are displayed on the Command Permissions Categories form.

To Log In

1. Enter your login name and password on the login and password screen.
If your password has expired, you see the message:
Your password has expired, enter a new one.
Reenter current password:

Login: telmgr

Password:

Your Password has expired, enter a new one.

Reenter Current Password:

New Password:

Reenter New Password:

Figure 3-1. Password Expiration Screen

The Password Expiration screen displays when you log in. See [Figure 3-1](#). If your password is expired, you are prompted to enter a new password. If your password is within 7 days of the expiration date, you see:

WARNING: Your password will expire in X days

To Logoff

To logoff, enter “logoff” at the command prompt. You will receive a logoff screen if any of the following is true. If either a or b (see below) is true and an acknowledgment is required, or if any of c, d, or e is true, you need to respond to the “Proceed with Logoff?” prompt on the logoff screen. See [Figure 3-2](#). The response is defaulted to “n”; you will need to enter “y” to override the default.

- a. If Facility Test Call Notification has been enabled for your login (see Adding Customer Logins and Assigning Initial Passwords).
- b. If Remote Access Notification has been enabled for your login (see Adding Customer Logins and Assigning Initial Passwords).
- c. If Alarm Origination is disabled.
- d. If any active major or minor alarm is active.
- e. If any resource is busied out.

CAUTION:

To leave the Facility Test Call administered after you logoff poses a significant security risk.

CAUTION:

To leave the Remote Access feature administered after logging off poses a significant security risk if you are using the feature in conjunction with the Facility Test Call feature.

CAUTION:

No alarms report through the INADS interface if Alarm Origination is disabled.

CAUTION:

A busied out resource is one that is out of service. Be sure to verify if a busied resource needs to be released or if the resource should remain busied out.

```
Facility Test Call Administered
Remote Access Administered
Alarm Origination is currently disabled.
Active major or minor alarm detected; be sure to resolve it.
*** Busied out resource detected; verify if release is needed! ****

Proceed With Logoff: [n]
```

Figure 3-2. Logoff Screen

To Display a Login

1. Enter the command **display login [login name]** and press Enter.

The system displays the requested login's:

- Name
- Login type
- Service level
- Disable following a security violation value
- Access to Inads Port value
- Password aging cycle length

- Facility test call notification and acknowledgment
- Remote access notification and acknowledgment

To List Logins

1. Enter the command **list logins**.

The system displays the following information for all current logins:

- Name
- Service level
- Status (active, inactive, disabled, svn-disabled, void)
- Password aging cycle length

The system displays only those logins with the same, or lower, service level as the requestor.

To Remove a Login

1. Enter the command **remove login [login name]**.

The system displays the Login Administration form.

2. Press the ENTER key to remove the login, or press Cancel to exit the remove login procedure without making a change.

To Test a Login

1. Enter your login name at the login prompt.
2. After the user enters the correct login name and password and the login is administered correctly, the system displays the command line interface.

Administering Customer Logins and Forced Password Aging

Adding Customer Logins and Assigning Initial Password

To add a customer login you must be a super-user, have administrative permissions, and:

1. Enter the **add login [name]** command to access the Login Administration form.
2. Enter your super-user password in the Password of Login Making Change field on the Login Administration form.

The 3- to 6-character login name (characters 0-9, a-z, A-Z) entered with the **add login [name]** command is displayed in the Login's Name field.

3. Enter "customer" in the Login Type field. The system default for the Login Type field is "customer." The maximum number of customer logins of all types is 11.
4. Enter super-user or non-super-user in the Service Level field. Default is none-super-user.
 - "super-user" gives access to the **add, change, display, list, and remove** commands for all customer logins and passwords. The super-user can administer any mix of super-user/non-super-user logins up to a total of ten additional system logins.
 - "non-super-user" permissions are limited by restrictions specified by the super-user when administering the non-super-user login. A non-super-user can change his/her password with permission set by the super-user, however once a password has been changed the non-super-user must wait 24 hours before changing the password again. A non-super-user cannot change other user passwords, login characteristics, or permissions.
5. Enter "y" in the Disable Following a Security Violation field to disable a login following a login security threshold violation,. This field is a dynamic field and only appears on the Login Administration form when the SVN Login Violation Notification feature is enabled. The system default for the Disable Following a Security Violation field is "y."
6. Enter "y" in the Access to INADS Port? field to allow access to the remote administration port,. This field only displays if Acct. has first enabled customer super-user access to the INADS Remote Administration Port. Default is "n".
7. Enter a password for the new login in the Login's Password field. A password must be from 4 to 11 characters in length and contain at least 1 alphabetic and 1 numeric symbol. Valid characters include numbers, and !&*?;'^(),.- (the system will not echo the password to the screen as you type).
8. Re-enter the password in the Login's Password field. The system will not echo the password to the screen as you type.
9. Enter the number of days (1 to 99) from the current day, that you want the password to expire, in the Password Aging Cycle Length field. If a you enter a blank in this field, password aging does not apply to the login.
10. Decide whether or not to leave the default of yes ("y") in the Facility Test Call Notification? field. If "y" is selected, the user receives notification at logoff that the facility test call feature access code is administered. If you do not want the notification to appear, set the field to "n".

**CAUTION:**

Leaving The facility Test Call administered after logging off poses a significant security risk.

- 11. Decide whether or not to leave the default of yes (“y”) in the Facility Test Call Notification Acknowledgment Required field. If “y” is selected, the user is required to acknowledge that they wish to logoff while Facility Test Call is still administered. If you do not want to force the user to acknowledge, set the field to “n”. This field appears only if the Facility Test Call Notification field is set to 'y’
- 12. Decide whether or not to leave the default of yes (“y”) in the Remote Access Notification? field. If “y” is selected, the user receives notification at logoff that remote access is still administered. If you do not want the notification to appear, set the field to “n”.

 **CAUTION:**
To Leave Remote Access feature administered after logging off poses a significant security risk if you are using the feature in conjunction with the Facility Test Call feature.

- 13. Decide whether or not to leave the default of yes (“y”) in the Remote Access Acknowledgment Required? field. If “y” is selected, the user is required to acknowledge that they wish to logoff while remote access is still administered. If you do not want to force the user to acknowledge, set the field to “n”. This field appears only if the Facility Test Call Notification field is set to 'y’.

Screen 3-1. Login Administration

Changing a Login's Attributes

To change a customer login's attributes you must be a super-user, have administrative permissions (specifically, the Administration Permission field must be set to "y" for the super-user), and:

1. Enter the **change login [name]** command to access the Login Administration form.
2. Enter your super-user password in the Password of Login Making Change field on the Login Administration form. The 3- to 6-character login name (characters 0-9, a-z, A-Z) entered with the **change login [name]** command is displayed in the Login's Name field.
3. Enter "customer" in the Login Type field.
4. Enter "super-user" or "non-super-user" in the Service Level field.

NOTE:

You cannot change your own service level.

5. To disable a login following a login security threshold violation, enter "y" in the Disable Following a Security Violation field. This field is a dynamic field and only appears on the Login Administration form when the SVN Login Violation Notification feature is enabled.
6. To allow access to the remote administration port, enter "y" in the Access to INADS Port? field. This field will only display if Lucent Technologies has first enabled customer super-user access to the INADS Remote Administration Port.
7. Enter a password for the new login in the Login's Password field. A password must be from 4 to 11 characters in length and contain at least 1 alphabetic and 1 numeric symbol. Valid characters include numbers, and !&*?;'^(),.- (the system will not echo the password to the screen as you type).
8. Re-enter the password in the Login's Password field. The system will not echo the password to the screen as you type.
9. Enter the number of days (1 to 99) from the current day, when you wish the password to expire, in the Password Aging Cycle Length field. If a blank is entered in this field, password aging does not apply to the login.

Administering Login Command Permissions

Users with super-user permissions can set the permissions of the logins they create. The Command Permissions Categories form displays fields to which a user with super-user permissions can give or limit access. These commands are divided into three categories:

- Common Command
- Administration Commands
- Optional Maintenance Commands

Each of the three main categories have subcategories listed under them that when set to a "y" give permission to use the command sets associated with that category. When the Command Permissions Categories form is displayed for a login, the subcategories fields appear with the fields set to give the login full permissions for that login type. The super-user administering login permissions can set any of these field to deny access to a command category for the specified login. If the super-user making the assignments has full super-user permissions and would like to limit permissions for a category, the super-user can do so by entering "y" in the Additional Restrictions field located under the Administration Category section of the Command Permissions Categories form.

Refer to the Command Permissions Form Entries Tables at the end of this section for a list of command Objects and Actions by:

- Display Administration and Maintenance
- Administer Features
- Administer Permissions
- Administer Stations
- Administer Trunks

The information in the tables will help you to establish command permissions for user logins.

To administer command permissions, log in as super-user and:

1. Access the Command Permissions Categories form by entering **change permissions login [login name]**. When the form is displayed for a login, the default permissions for that "login type" are shown. The super-user administering the login can change a "y" to "n" for each subcategory field.
2. Select a category for the login and enter "y" in each field where permission to perform an administrative or maintenance action is needed. The command object you select must be within the permissions for the login type you are administering.

If the Maintenance option is set to "y" on the Customer Options form, the super-user can enter "y" in the Maintain Switch Circuit Packs? or Maintain Process Circuit Packs fields.

3. A super-user with full super-user permissions (super-user administering the login cannot have the Additional Restrictions field set to “y” for his/her own login) can restrict additional administrative or maintenance actions for a specified login by entering “y” in the Additional Restrictions field on the Command Permission Categories form. Enter the additional restrictions for a login in the Restricted object list fields on the Command Permission Categories Restricted Object List form. You can enter up to 40 command names (object names) to block actions associated with a command category for a specified login.

Testing a Login

- 1. Enter your login name at the login prompt.

Login: telmgr

Password:

Screen 3-5. Login Prompt Form

After the user enters the correct login name and password and the login is administered correctly, the system displays the command line interface.

To log into the system, do the following:

1. Turn on the administration terminal. Verify that the screen displays:
login:
2. Enter your login name, then press Enter. Verify that the screen displays:
password:
3. Enter your password, then press Enter.

For security reasons, the password is not displayed as you type it. The system verifies that a valid login and password name were entered. If an invalid login or password name was entered, the screen displays:

login incorrect:, and you must repeat the procedure.

If the system recognizes the login and password name, verify that the screen displays the software version.

4. For your terminal type, complete one of the following:

Terminal Type (Enter 513, 715, VT220, 4410, or 4425): [513]

- a. If the terminal is a 513 BCT, press Enter. The 513 in brackets [513] is the system default terminal.
 - b. If the terminal is a 610 BCT or a 615 MT that has a 513 emulation cartridge, press Enter.
 - c. If the terminal is a 610 BCT or a 615 MT that does not have a 513 emulation cartridge, enter 4410 and press Enter.
 - d. If the terminal is any other of the types listed, enter the terminal type and press Enter.
5. You can deactivate INADS alarm origination whenever you log in as craft. After you supply the terminal type information requested, the system displays the following if alarm origination is activated on the Maintenance System-Parameters screen:

 NOTE:

Unless you are in a special situation, please reduce unnecessary trouble tickets by always answering "y" to the following prompt to suppress Alarm Origination.

Suppress Alarm Origination: [y]

The default answer is yes. If you do NOT wish to suppress alarm origination, enter no. Any other entry defaults to yes. The **test inads-link** command works regardless of whether you have overridden INADS alarm origination.

6. Verify that the screen displays: *enter command:*

You may enter the desired command, such as **display station xxxx** or press Help to obtain the list of permissible commands.

Command Line Details

After a successful login, the administration terminal displays `enter` command : and waits for entry of a command.

A command is made up of multiple words that are typed on the keyboard and that instruct the system to perform a particular task. The system's command structure follows the format: Action, Object, and Qualifier.

The first word entered is the *Action*. It specifies the operation to be done (for example, test, display, or reset).

The second word entered is the *Object*. It specifies the object to receive the action (for example, station, trunk group, or hunt group).

The third word(s) entered is/are the *Qualifier*. The Qualifier is one or more words or digits used to further identify or complete the Object. Depending on the Object used, a Qualifier may or may not be used.

An example of a command line used to do a short test twice on a station with the extension number 1212 is: *test station 1212 short r 2*. In this example, *test* is the Action, *station* is the Object, and *1212 short r 2* is the Qualifier.

Spaces separate the Action, Object, and Qualifier on the command line.

NOTE:

Command line words do not have to be completely spelled out. All that is required is to type enough letters to make the word unique.

Screen Forms

After the user completes a command line, the terminal displays the appropriate screen form(s). Screen forms are system-generated forms that are formatted to allow easy entry of translation data.

Screen forms enable the user to change the translations of the system by typing parameters on the keyboard. Screen forms also allow system technician to display errors and alarms. Each screen form consists of a title, page number, body area, and a help and error message line. Specific screen forms exist for each type of administrable function.

DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description contains detailed information and examples of the screen forms generated by the system.

Switch-Based Bulletin Board

This feature will allow a user to leave messages in the system in order to communicate with other system users.

NOTE:

This feature is not intended as a substitute for the existing procedures for escalating problems, but only as an aid to the existing process.

Description

The bulletin board service provides an easy interface for the customer and Lucent Technologies to leave messages on the system.

The bulletin board feature makes it easy for the customer to communicate with Lucent Technologies (and vice-versa). For example, when a new load is installed on a switch in the customer's system, Lucent Technologies can leave the customer messages which describe new functionality. This feature also allows Lucent Technologies to keep the customer informed on the progress of trouble items. In addition, the feature can be used by the customer to provide additional information concerning problems that have already been escalated.

Accessing the Bulletin Board

Any user with the appropriate permissions can log into the system and have access to the bulletin board. User's who have "Maintain System" or "Administer Features" permissions can enter, change, display, print, or schedule to print a message. Users who have "Display Admen" and "Maintain Data" permission can display the bulletin board. Any user who has "Display" permission can display, print, and schedule to print the contents of the bulletin board.

When logging onto the system, users will be notified of any messages on the bulletin board. The notification message will indicate the last time the bulletin board was updated, if any "High-Priority" message exists, and if the bulletin board is 80% or more full. If a "High-Priority" message exists, the command prompt will change to the following message:

- High-Priority Bulletin Board Messages Entered:

After the next command is entered, the default command prompt returns to the screen.

User Considerations

- Only one user at a time may edit a message on the bulletin board.
- The user must have the proper permissions to access the bulletin board.

- The user must maintain the information stored on the bulletin board. It is the user's responsibility to delete old messages. If the bulletin board is full, any new messages overwrite old messages.

System Considerations

The Bulletin Board feature provides up to 3 pages of text for each message. Each page is limited to 20 lines of text, and each line of text is limited to 40 characters per line. The first 10 lines of text on page 1 is reserved for Lucent Technologies Service's High-Priority messages.

System Bulletin Board Commands

The system commands "**change bulletin board**," "**display bulletin board**," and existing commands in the user interface are provided for use in the Switch Based Bulletin Board.

Editing a Bulletin Board Message

1. Log into the system with "Maintain System" or "Administer Features" permissions.
2. Enter the command "**change bulletin-board**."
3. Follow system prompts.

To display messages on the Switch Based Bulletin Board the user must:

1. Log into the system with "Maintain System", "Display Admin", or "Maint Data" permissions.
2. Enter the command "**display bulletin board**."
3. Follow system prompts.

Editing a Switch-Based Bulletin Board Message

A message may contain up to three pages of information. Message lines 1 through 10 on page 1 are reserved for Lucent Technologies Services *High-Priority* messages (the "init" and "inads" logins can edit the first 10 lines on page one). Pages 2 and 3 will allow up to 20 lines of text, and each line of text may be up to 40 characters per line. Each line of text has an associated date field that is populated automatically by the system each time the line is modified.

The control keys used to edit existing feature forms must be used to edit a message in the Switch Based Bulletin Board. The following characters are allowed for use in the text field:

- Uppercase/Lowercase letters, spaces, numerals, and !@#\$%^&*()_-+=[\];'"/<>./?.

NOTE:
Tab characters are not allowed. The existing command line interface will cause the cursor to move to the next field if a Tab character is entered.

If a user changes any lines that cause two or more consecutive blank lines, then the bulletin board will be automatically reorganized (upon submittal). Two or more blank lines will be consolidated into a single blank line. If a blank line is at the top of a form, it will also be deleted. This function will help prevent holes in the bulletin board screens as old entries are deleted.

To save a message entered into the bulletin board text field, the user must execute the **save translation** command.

G3V3 software is required for the bulletin board feature. The bulletin board feature, as described in this document is available in G3V4. The G3V3/G3V4 feature on the systems-parameters customers-options form need not be enabled.

The following screen is an example of bulletin board messages between Lucent Technologies and a customer who is having trouble with trunk group translations:

```
display bulletin-board           Page 1 of 3

      Messages (* indicates high-priority)      Date

* AT&T is in the process of                    02/02/95
* investigating your trunk lockup problem.      02/02/95
* The Bulletin Board will be updated as         02/02/95
* information is found.                        02/02/95
* We have identified the problem.               02/02/95
* The trunk you added does not provide          02/02/95
* disconnect supervision, however your trunk    02/02/95
* group was administered as such.              02/02/95
* Please call for details.                     02/02/95
*
We recently added a new trunk group (14)        02/03/95
and have had trunk group members locking up.  02/03/95
We see the error - Thanks for checking.        02/03/95
```

System Logoff Procedure

The system logoff procedure should be done any time the terminal is not being used. This assures that system translations are not accidentally corrupted. The **monitor system** command, when canceled, automatically causes a terminal user to be logged off and, thus, prevents unauthorized use of the terminal. Use the following procedure to log off the system:

1. Verify that the screen displays: enter command:
2. Enter **logoff** and press Enter. The screen displays: *login*:

If after either logging on as system technician or issuing a system technician command no additional command is issued for 30 minutes, an automatic time-out and logoff occurs. At that time, any alarms in the system previously unreported to INADS are reported. If you are logged in at two separate administration terminals, the system waits until the second terminal times out or until you log off before reporting such alarms to INADS.

Logoff Notification alerts system administrators if features that present a significant security risk are enabled. A message displays on the system administration/maintenance interface. Additionally, the user can be required to acknowledge the notification before the logoff is completed.

DEC VT220 Terminal

The system supports use of the DEC VT220 connected to the system and used in the same way as the other terminals. When logging in, at the terminal-type prompt the user should enter "VT220" to initialize the correct parameters. Keyboard definitions shown in [Table 3-5](#) are in effect:

Table 3-5. Keyboard Definitions for the DEC VT220 Terminal

Initialization and Recovery

4

When the system is powered up, or when it experiences a catastrophic fault that interrupts its basic functions, the system undergoes a reboot. Besides “reboot,” there are several less severe resets available to the system that allow it to recover from disrupting errors. The user can initiate these resets by using the reset system commands. These commands are used to manually restart the system at various levels, depending on the required test activity. The reset system commands are discussed in [Chapter 8, “Maintenance Commands and Trouble-Clearing Aids”](#).

A system is reset due to a loss of power, or via one of the following:

- Reset commands at the administration terminal.
- Maintenance software, from which the system can reset itself. (This process starts when certain software and hardware errors are detected by the software.)
- “Interchange,” which is a type of reset that can be scheduled as part of daily maintenance in High or Critical Reliability systems.

WARNING:

When the system is rebooted or reset at level 2, 3, 4, or 5, all voice terminal and attendant console features are adversely affected. Users should be advised of services that are lost and that, as a result, must be reactivated. See “Removing Power” in [Chapter 5, “Routine Maintenance Procedures”](#).

The administration terminal display and circuit pack LEDs indicate the progress of the recovery process. LEDs are discussed in [Chapter 7, “LED Interpretation”](#).

The sections that follow discuss successful system resets. For each level of reset, a typical administration terminal display is provided. Note that any

4 Initialization and Recovery

Reset System 1 (System Warm Start)

Page 4-2

hexadecimal numbers shown in parentheses, such as "(=8B89)," are only examples and are subject to change. Subsequent sections discuss the recovery process following an SPE-Down Mode and for "duplication interface-processing element communication down."

NOTE:

If any of the diagnostic tests fail, the system may or may not function properly, and the LMM may or may not proceed with the restart. If the LMM does not proceed with the restart, the system goes into SPE-Down Mode. In failure cases, the appropriate part (for example, the Processor circuit pack) should be replaced.

NOTE:

Use and check the results of the **set/get vector** command found in the "Set Commands" section in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#), to determine how much time should be added for the recovery levels. Also, if an update file is applied on a system reset, add from 30 seconds to one minute to the recovery time for that reset.

Reset System 1 (System Warm Start)

This recovery takes about 30 seconds. All stable phone calls remain up. In-progress calls are dropped. No new calls can be made during this time.

In this restart, all software (Oryx/Pecos, drivers, maintenance, and so forth.) is reset.

Typical Display

```
RESET 1 (WARM) PERFORMED
```

Reset System 2 (System Cold Start Without Translations Loading)

All Port circuit packs are reset. All telephone sessions are dropped. Telephones begin to reconnect to the switch within 30 seconds. In a large system, reconnection of all telephones may take up to five minutes.

In this restart, all software (Oryx/Pecos, drivers, maintenance, and so forth) is reset. In addition, the TDM Bus and all port circuit packs are reset. Typical displays in a Release 5vs/si system follow:

Typical Display Release 5vs/si and Later Systems

INTERNAL REGISTER TEST	PASSED
LOCAL BUS TEST	PASSED
ROM CHECKSUM TEST	PASSED
CONTROL STATUS TEST	PASSED
DCACHE TEST	PASSED
ICACHE TEST	PASSED
WRITE BUFFER TEST	PASSED
BTO TEST	PASSED
TIMER TEST	PASSED
RESET 2 (COLD_2) PERFORMED	

Reset System 3 (System Cold Start With Translations Loading)

Emergency Transfer is invoked. Translations reload from translation card. Depending on the translations, the reloading process could take from five to 30 seconds. Thereafter, all port circuit packs are reset, and all telephone sessions drop. Telephones begin to reconnect to the switch within 30 seconds. In a large system, reconnection of all telephones may take up to five minutes.

In this restart, all software (Oryx/Pecos, drivers, maintenance, and so forth) is reset. After the software is reset, all translations load from translation card. In addition, the TDM Bus and all port circuit packs are reset. Typical displays in a Release 5 vs/si system follow:

Typical Display (TN790 Release 5vs/si and Later Systems)

INTERNAL REGISTER TEST	PASSED
LOCAL BUS TEST	PASSED
ROM CHECKSUM TEST	PASSED
CONTROL STATUS TEST	PASSED
DCACHE TEST	PASSED
ICACHE TEST	PASSED
WRITE BUFFER TEST	PASSED
BTO TEST	PASSED
TIMER TEST	PASSED
RESET 3 (COLD_1) PERFORMED	

Reset System 4 (System Reboot)

Emergency Transfer is invoked. The boot image is already in the flash ROM memory. The system reboots immediately after the LMM performs a series of diagnostics on the processor and memory. Translations reload from the translation card. Depending on the translation, the reloading process takes from five to 30 seconds.

Thereafter, all port circuit packs are reset, and all telephone sessions drop. Telephones begin to reconnect to the switch within 30 seconds. In a large system, reconnection of all telephones may take up to five minutes. Typical displays in a Release 5 system follow:

Typical Display (TN790 Release 5 and Later)

Reset System 5 (System Reboot and Run All 24-Hour Tests)

Emergency Transfer is invoked. The LMM performs a series of diagnostics on the processor, on memory, and on memory card. Some diagnostics perform twice. This takes less than three minutes.

The boot image is already in the flash ROM memory. The system reboots immediately after the LMM performs a series of diagnostics on the processor and memory. Translations reload from the translation card. Depending on the translation, the reloading process takes from five to 30 seconds. Thereafter, all port circuit packs are reset, and all telephone sessions drop. Telephones begin to reconnect to the switch within 30 seconds. In a large system, reconnection of all telephones may take up to five minutes. Finally, scheduled maintenance is initiated. Typical displays in a Release 5vs/si system follow:

Reset System Interchange (High or Critical Reliability Systems Only)

SPE-interchange (system hot start) is denoted by an "i" in the initcauses log. This restart is used to transfer control from the Active SPE to the Standby SPE in the least disruptive manner. Interchange (i) is the most transparent of all levels of restart and causes no disruption of service to telephone users. This restart takes fewer than two seconds.

⇒ NOTE:
The administration terminal is logged off. No diagnostics are performed, and only the login prompt displays.

An interchange (i) can be performed in one of the following three ways:

- a. System Technician-Demanded: using the **reset system interchange** command
- b. Scheduled Maintenance
- c. Software-Requested: The software requests the interchange when it determines that the Standby SPE is healthier than the current Active SPE

⇒ NOTE:
For most SPE alarms, interchange to the standby SPE is achieved using the hot restart (i). However, there may be other alarms for which another restart level (1 through 4) must be used to achieve a transition to the Standby SPE. See [Table 6-1, "Software-Requested Interchanges Caused by Alarm Conditions"](#) in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#), for a complete list of alarms and restart levels.

Procedure for SPE-Down Mode

Due to fatal hardware and software problems, it is possible for a system to go into SPE-Down Mode. In this mode, the system invokes emergency transfer and does not provide any other service. Moreover, while in this mode, the software does not (or cannot) run at all. In a high or critical reliability system the system goes into SPE-Down mode **only when both SPEs go into SPE-Down mode**.

There is an interface to the system by maintenance. The Processor circuit pack, is responsible for maintenance in a standard reliability system. In a high or critical reliability system, the maintenance is provided by the A-carrier Duplication Interface (DUPINT-A) TN772 circuit pack with help from the processor.

The administration terminal, which connects directly to the processor in a standard reliability system and to DUPINT-A in a high or critical reliability system, provides a very limited interface to the system. Technicians can display alarms or restart the system. Only a subset of control complex alarms displays.

The following are sample displays for SPE-Down mode and the alarms displayed.

Display for SPE-Down in a Standard Reliability system:

```
*****SPE DOWN MODE*****  
You can display alarms and reset system(4).  
SPE_DOWN->
```

[Screen 4-1](#) and [Screen 4-2](#) show all possible SPE-Down alarms in a standard reliability system and in a high or critical reliability system, respectively.

DISPLAY ALARMS:						
Physical Name	Logical Name	On Board?	Alternate Name	Alarm Type	Date Alarmed	Date Resolved
-----	PROC_BD	y	-----	MAJOR	-----	-----
-----	MEM_BD_0	y	-----	MAJOR	-----	-----
-----	M_BUS	y	-----	MAJOR	-----	-----
-----	MAINT*	y	-----	MAJOR	-----	-----
-----	NETCON_BD	y	-----	MAJOR	-----	-----
-----	TAPE_UNIT	-----	-----	MAJOR	-----	-----
-----	NO_TAPE	-----	-----	MAJOR	-----	-----

Screen 4-1. Display Alarms Command

* The “MAINT” designation is used for PR-MAINT.

Display for SPE-Down in a High or Critical Reliability System:

*****SPE DOWN MODE*****
You can display alarms [a|b] and reset system(4) [a|b].
SPE_DOWN->

[Screen 4-2](#) shows only one SPE-Down alarm in a high or critical reliability system after entering the **display b** command:

DISPLAY ALARMS B:						
Physical Name	Logical Name	On Board?	Alternate Name	Alarm Type	Date Alarmed	Date Resolved
-----	PROC_BD	y	-----	MAJOR	-----	-----

Screen 4-2. Display Alarms (one SPE-Down)

 **NOTE:**
A standard reliability system tries to restart itself every 20 minutes. A high or critical system tries to restart itself every 10 minutes.

The first step is to determine the location of the problem. It is possible for two or more circuit packs to have failed. It is also possible for a fatal problem with one circuit pack to affect another circuit pack. This is especially true for the Processor and Memory circuit packs, where a failure in one affects the other. All three of the following methods should be employed to determine where the fatal fault lies.

1. Use **display alarms** command:

Issuing the **display alarms [a | b]** command at the administration terminal shows where maintenance thinks the problem lies. The alarms are a good indication of why the system went down. They should be used with the following two methods.
2. Observe red LEDs:

Observe the red LEDs on the circuit pack to determine where software or processor firmware (LMM) had a problem.
3. Use the **reset** command:

In 286 system, issuing the **reset** command (Standard Reliability system) or the **reset [a | b]** command (High or Critical Reliability system) causes the system to attempt a **reset system 4**. Observe all the diagnostics on the screen, and note if the LMM has a problem with any of the diagnostics, as this information should give a good indication of where the problem lies.

The procedure to get a system out of SPE-Down mode follows.

 NOTE:

This is important! If you cannot complete the first step or have problems with the maintenance interface, then the first step should be to replace the Processor circuit pack. In a high or critical reliability system the DUPINT-A circuit pack can also cause SPE-Down.

1. If the alarms indicate a tape failure, replace the tape or tape drive and go to Step 3. Otherwise, verify that there is a good tape in the tape drive. If a tape is not present or if either the tape or tape drive is defective, then restarting the system using the **reset** command causes the system to go down again.
2. In a High or Critical Reliability system, select a carrier to repair first.

When it is possible to accurately determine the location of the problem, use the **display alarms [a | b]** command to display alarms for both SPEs and check the red LEDs on the processor complex circuit packs. Select the carrier where the red LEDs indicate the circuit pack alarmed. Bring up the system on that carrier and then refer to Standby SPE Maintenance documentation to repair the Standby SPE.

In a Standard Reliability system or after a carrier is chosen in a High or Critical Reliability system, determine which circuit pack is defective by displaying alarms and observing the red LEDs (as discussed previously). Depending on the alarms, use [Table 4-1](#) to replace the circuit packs indicated, one by one, in the order shown.

Table 4-1. Order of Circuit Pack Replacement

Alarm	Suggested Circuit Packs To Replace
PROC_BD	1) Processor 2) Network Control
MEM_BUS	1) Processor 2) Network Control
PROC_MEM	1) Processor
OFFBD_MEM	1) Processor 2) Network Control
INVALID_ERR	1) Processor 2) Network Control
MAINT_BD	1) Processor 2) Network Control
NETCON_ABSENT	1) Network Control 2) Processor
NO_CARTRIDGE	1) Memory Card 2) Network Control 3) Processor

Procedure for Duplication Interface —
Processing Element Communication
Down

In a High or Critical Reliability system, it is possible for both SPEs to stop communicating with the A-carrier TN772 Duplication Interface (DUPINT-A) circuit pack. Thus, the DUPINT-A, which is in charge of maintenance, prints the following message on the administration terminal:

Duplication Interface-Processing Element Communication down

The system may continue to function on one of the SPEs. However, the system is not able to provide any interface to the administration terminal.

If the system is still providing service, connect the administration terminal to the Active SPE (check the amber LED on the Processor circuit pack). Then, if

4 Initialization and Recovery

Procedure for Duplication Interface — Processing Element Communication Down

Page 4-12

software provides a login on the administration terminal, you can determine the problems via the **display alarms** command.

If the system is not providing service, there is a problem with the Processor circuit packs and/or DUPINT-A. Replace these circuit packs, one by one, until the system starts functioning normally.

Routine Maintenance Procedures

5

The following general purpose maintenance procedures may be used with other repair strategies to clear system-alarmed and user-reported troubles.

Suppress Alarm Origination [y]

When logged in as “craft”, no alarms are reported to INADS. After logging off, INADS automatically reactivates, and any unresolved alarms are reported to INADS.

Also, when logged in as “craft,” an automatic logoff of the terminal occurs after 30 minutes of non-use. At that time, any unresolved alarms are reported to INADS. If you are logged in as “craft” at 2 different terminals, the logoff occurs when the second terminal remains unused for 30 minutes.

NOTE:

The **test inads-link** command functions even if INADS Alarm Origination is overridden.

Handling Control Circuit Packs

PPN Control Circuit Packs

WARNING:

It is NOT recommended that you reseal circuit packs unless the documentation specifically instructs you to do so. If it is required to reseal a

circuit pack, follow the instructions below which explain how to unseat, reseal, and replace circuit packs.

The procedures for unseating, reseating, and replacing control circuit packs vary depending on the system configuration. Therefore, before performing these maintenance activities, refer to the appropriate procedure below.

Procedure for a Standard Reliability Cabinet

To unseat a control circuit pack:

1. Remove power from the PPN using the procedure provided in [“Removing Power”](#).
2. Slide the latch pin upward to unlock the locking lever.
3. Pull down on the locking lever until the circuit pack disconnects from its socket.
4. Pull the circuit pack just enough to break contact with the backplane connector, but do not remove it from the cabinet.

To reseal a circuit pack:

1. Push the unseated circuit pack back into the backplane connector.
2. Lift the locking lever until the pin engages.
3. Restore power to the PPN using the procedure provided in [“Restoring Power”](#)

To replace Control circuit packs:

1. Remove power from the PPN using the procedure in the [“Removing Power”](#)
1. Unseat the circuit pack.
2. Slide the circuit pack out of the slot.
3. Replace the circuit pack as per the following procedure:

NOTE:

If a new circuit pack does not correct the problem, install the original circuit pack.

NOTE:

If you are replacing a TN790 circuit pack, refer to [“TN790 Processor Circuit Pack \(Memory\)”](#) in this chapter.

To install a new circuit pack or return the original one to service:

1. Carefully insert the circuit pack and push it all the way into its mounting slot.

2. Lift the locking lever until the latch pin engages.
3. Restore power to the PPN using the procedure in ["Restoring Power"](#).
4. Verify that the circuit pack LED indications are correct.
5. Test the replaced control circuit pack by issuing the system technician commands after power has been restored.

Network Control Circuit Pack

WARNING:

When a TN777B Network Control circuit pack is reseated or replaced, the correct date and time setting must be manually entered and verified.

The TN777B Network Control Pack holds a translation card. Before this circuit pack is handled, remove the translation card.

1. Check that the "card in use" LED is not lighted. Otherwise, removing the memory card may damage the data recorded on it.
2. Carefully pull the translation card from the card slot.

To insert the card into the slot:

1. Take the translation card and hold it in front of you so that the card's label is facing to your left.
2. With the card in this position, insert the shorter edge of the card into the mounting slot. Then, gently push the card forward until you feel some resistance at the opposite edge of the card. Once you feel this resistance, the card is inserted. About 3/4 of an inch of a fully inserted card should appear outside of the card slot.

WARNING:

Remember, assuming you are directly facing the circuit pack, the card label should be facing to your left. If this is not the case, remove the card and start again.

3. Test the inserted card by issuing the **test card-mem** system technician command.

EPN Control Circuit Packs

Control circuit packs are unseated, reseated, replaced, and tested in the same way as Port circuit packs. Refer to the ["Handling Control Circuit Packs"](#) section in this chapter. Note the special precautions required when handling the TN776 and TN570 Expansion Interface (EXP-INTF) circuit packs and the EPN TN768 and TN780 Tone-Clock circuit packs.

EPN Expansion Interface Circuit Packs

If the system has high or critical reliability, verify that the Expansion Interface to be unseated or replaced is NOT a part of the Active Expansion Interface Link. Issue the **status system** command. If the Expansion Interface circuit pack is shown to be a part of the Active Expansion Interface Link, use the **set expansion-link PCSS** command to make the current Standby link the Active one.

EPN Tone-Clock Circuit Packs

If the EPN has redundant Tone-Clock circuit packs, make sure the Tone-Clock to be unseated or replaced is the Standby circuit pack. Issue the **status system** command. If the Tone-Clock is shown as Active, use the **set tone-clock PC** command to make the current Standby Tone-Clock the Active one.

TN790 Processor Circuit Pack (Memory)

Unless upgrading memory, the TN790 must have the same number of SIMMs as the replaced circuit pack.

CAUTION:

Be sure to use a Lucent Technologies-provided SIMM. Other brands may have incompatible edge connectors and could produce unpredictable results.

Removing Power

When power is removed, the following features deactivate:

- Attendant Trunk Group Control
- Automatic Callback
- Call Park
- Make Busy for Direct Department Calling (DDC) and Uniform Call Distribution (UCD)

The procedures for removing power vary depending on the system configuration. Before performing these activities, refer to the following appropriate procedure.

WARNING:

Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the [“DEFINITY AUDIX System Power Procedures”](#) below, on the circuit pack, and in DEFINITY AUDIX documentation.

DEFINITY AUDIX System Power Procedures

Manually Power Down AUDIX System

A yellow caution sticker on the system's power unit notifies technicians to shut down the DEFINITY AUDIX System prior to powering down the system.

1. Using a pointed object, such as a paper clip or pen (do not use a pencil), press the Boot/shutdown button. The button is located at the top right portion of the front panel.
2. Hold the boot/Shutdown button in until the LCD display flashes the message MSHUT .
3. Release the Boot/Shutdown button.

NOTE:

The DEFINITY AUDIX System takes about five minutes to shut down. The "heartbeat" indication on the display continues to flash.

Procedure for a Single-Carrier Cabinet PPN

This procedure applies to a single-carrier cabinet PPN with or with high or critical reliability, where the cabinet is powered by either an AC or a DC power source.

WARNING:

If a translation card alarm is present, or if a translation card problem is suspected, do not save translations of the translation card that is provided with the system.

CAUTION:

Check that the *translation card is present in the system or check that the translation card is in the TN777B Network Control circuit pack.*

4. At the administration terminal, enter the **save translation** command.
5. In a standard reliability system on the Processor circuit pack in the PPN, and on the Maintenance circuit pack in the EPN, set the Emergency Transfer switch to "ON."

CAUTION:

*When removing power, Error Log information is lost. If the data is to be retained, enter the **reset system 4** command. This command restarts the system and may take several minutes. Wait for the login prompt before proceeding.*

6. To remove power from the cabinet:

- In an AC-Powered system, turn off the power in each cabinet individually. The ON/OFF switch is located at the rear of the carrier behind the WP-91153 Power Unit.
- In a DC-Powered system, turn off the power in each cabinet individually. The ON/OFF switch is located at the rear of the cabinet, behind the 676B Power Unit.

Procedure for a Single-Carrier Cabinet EPN

This procedure applies to a single-carrier EPN with or without high or critical reliability, where the cabinet is powered by either an AC or a DC power source.

Power may be removed from the EPN without affecting the PPN.

⇒ NOTE:

In a high or critical reliability system, if power is to be removed from an individual cabinet only, make sure that the affected cabinet does not contain an Expansion Interface circuit pack that is part of the Active Expansion Link or an Active Tone-Clock. To determine which Expansion Interface Link and Tone-Clock are active, issue the **status system** command. To determine the synchronization reference, use the **display synchronization** command.

1. To remove power from the cabinet:

- In an AC-Powered system, turn off the power in each cabinet individually. The ON/OFF switch is located at the rear of the cabinet behind the WP-91153 Power Unit.
- In a DC-Powered system, turn off the power in each cabinet individually. The ON/OFF switch is located at the rear of the cabinet behind the 676B Power Unit.

Restoring Power

The procedures you need to restore power depend on the system configuration. Before performing these activities, refer to the following appropriate procedure.

⇒ NOTE:

If the AUDIX unit has been powered down, refer to [“Power Up the AUDIX System” on page 5-8](#).

Procedure for Single Carrier Cabinet PPN

This procedure applies to single-carrier cabinet PPNs with or without high or critical reliability, where the cabinet is powered by either AC or DC power.

⇒ NOTE:

In a high or critical reliability system, if power is to be removed from an individual cabinet only, make sure that the affected cabinet does not contain an Expansion Interface circuit pack that is part of the Active Expansion Link or an Active Tone-Clock. To determine which Expansion Interface Link and Tone-Clock are active, issue the **status system** command. To determine the synchronization reference, use the **display synchronization** command.

1. Restore power as follows:

⇒ NOTE:

If the cabinet is powered by a 676B Power Unit, the 676B must have been powered off for at least 10 seconds before being powered on. If not, the 676B Power Unit does not restart.

- In an AC-Powered system, turn on the power in each cabinet individually. The ON/OFF switch is located at the back of the cabinet behind the WP-91153 Power Unit.
 - In a DC-Powered system, turn on the power in each cabinet individually. The ON/OFF switch is located at the back of the cabinet behind the 676B Power Unit.
2. Make sure that the translation card is properly inserted into the slot.
 3. The system now goes through the rebooting process. The translations are loaded from the translation card, and rebooting takes about three minutes.
 4. When system power is restored, the appropriate display is shown on the administration terminal.

The display is the same as a **reset system 4** that is described in [“Reset System 4 \(System Reboot\)”](#) in [Chapter 4, “Initialization and Recovery”](#).
 5. After the system reboot is finished and all trouble is cleared, return the EMER XFER (Emergency Transfer) switch(es) to AUTO. This restores the system to the normal operating mode.
 6. Reset the time using the **set time** command. Use **display time** command to verify.

Procedure for Single-Carrier Cabinet EPN

Power may be restored to the EPN without affecting the PPN.

This procedure applies to single-carrier cabinet EPNs with or without high or critical reliability, where the cabinet is powered by either AC or DC power.

⇒ NOTE:

In a high or critical reliability system, if power is to be removed from an individual cabinet only, make sure that the affected cabinet does not

contain an Expansion Interface circuit pack that is part of the Active Expansion Link or an Active Tone-Clock. To determine which Expansion Interface Link and Tone-Clock are active, issue the **status system** command. To determine the synchronization reference, use the **display synchronization** command.

1. To restore power to the cabinet:

 NOTE:

If the cabinet is powered by a 676B Power Unit, the 676B must have been powered off for at least 10 seconds before being powered on. If not, the 676B Power Unit does not restart.

- In an AC-Powered single-carrier cabinet system, turn on the power in each cabinet individually. The ON/OFF switch is located at the back of the cabinet behind the WP-91153 Power Unit.
 - In a DC-Powered single-carrier cabinet system, turn on the power in each cabinet individually. The ON/OFF switch is located at the back of the cabinet behind the 676B Power Unit.
2. The EPN circuit packs is inserted and the EPN is available for call processing.
 3. After the system reboot is finished and all trouble is cleared, return the Emergency Transfer switch to AUTO. This restores the system to the normal operating mode.

Power Up the AUDIX System

1. Using a pointed object such as a paper clip or a pen (do not use a pencil), press the Boot/Shutdown button.
2. Hold the boot/Shutdown button in until the display indicates the message, BTEST, steady on.
3. Release the Boot/Shutdown button. the DEFINITY AUDIX system takes approximately 5 minutes to power up.
 - The display has the following sequence of steady on messages:
 - OSINIT
 - OS
 - AINIT
 - ADX
 - The DEFINITY AUDIX System is now powered up. When the system is in the active state, the display indicates ADX, and the red LED is off.

 NOTE:

When powering up, the DEFINITY ADUXI System automatically reboots. This sequence may show an MD or MJ ADX alarm in the display until the system has powered up. When the system has completed its power up sequence, the display reads: ADX.

Troubleshooting Control Cabinet Power Units

1. Check that the translation card is in the TN777B circuit pack and enter the **save translation** command.
2. On the Processor circuit pack in the PPN, set the EMER XFER (Emergency Transfer) switch to ON. This locks the system in the Transfer Mode until the trouble is cleared.

 WARNING:

Electrostatic discharge can destroy or severely damage integrated circuits or circuit packs. Always wear the electrostatic discharge (ESD) wrist grounding strap when handling circuit packs. Connect the wrist strap to one of the metal tabs located on the lower left or right side of one of the carriers.

3. Unlatch the locking lever and unseat the power unit.
4. Unseat all the *control* circuit packs.
5. Reseat the power unit. If the yellow LED on the suspect power unit lights immediately, the control circuit packs can be presumed to be healthy. If the yellow LED on the suspect power unit does **not** light immediately, continue with the next step.
6. Reseat the circuit packs one at a time while observing the LED on the power unit.
 - a. If the yellow LED on the power unit lights when a specific circuit pack is reseated, unseat and reseat the same circuit pack again to rule out a transient problem. If the yellow LED lights again, the problem is with the circuit pack, and the power unit is functioning properly. Replace the defective circuit pack.
 - b. If the yellow LED on the suspect power unit does **not** light during the reseating of the control circuit packs, continue with the next step.
7. Unseat all *port* circuit packs.
8. Reseat the port circuit packs one at a time following the same steps outlined above for control circuit packs.
9. If none of the control or port circuit packs appears to be defective, replace the power unit.

10. When the system reboot has completed, return the EMER XFER (Emergency Transfer) switch to AUTO. This restores the system to the normal operating mode.

Replacing Components (Release 5vs or Later)

Components within the Release 5vs can be replaced while the unit is attached to the wall. Also, if the wires and cables at the back of the cabinet are neatly bundled, these wires and cables need not be disconnected.

[Figure 5-1](#) and [Figure 5-2](#) provide views of the power supply sub-assembly. [Figure 5-3](#) provides a view of the fan sub-assembly. The sections following the figures discuss how to disassemble the unit and then replace the power supply or fans within the unit.

CAUTION:

When replacing either the power supply or the fans within a Release 5vs unit that is already attached to the wall, you should disconnect the entire fan panel from the unit. Otherwise, if the fan panel is left to dangle, the cable assemblies leading out from the fans (which are connected to the fan panel) and into the backplane might become damaged or disconnected from the backplane.

Figure 5-1. Power Supply Sub-Assembly (Outside View)

Power Supply

1. Remove the four screws on the top of the cabinet.
2. Remove the four screws from the fan panel at the rear of the unit. Then remove the fan panel.
3. If the unit is attached to the wall, disconnect the entire fan panel.
4. Extending out from the power supply is a cord consisting of numerous individual wires. This cord plugs into the backplane. A Burndy connector is at the end of the cord. Squeeze the sides of the connector to release the latch. Then pull the connector off of the backplane.
5. Remove the power supply from the unit. Once the power supply is removed, disconnect the AC power cord.
6. Reconnect the AC power cord, insert the new power supply, reconnect the Burndy connector and the cord, reinsert (if removed) the reconnected fan panel, screw the fan panel back onto the unit, and reinsert the screws on the top of the unit.

Figure 5-2. Power Supply Sub-Assembly (Inside View)

Figure 5-3. Fan Sub-Assembly

Fans

1. At the back of the unit, remove the four screws from the fan panel. Then remove the panel.
2. If the unit is attached to the wall, disconnect the entire fan panel.

CAUTION:

The power cord for each fan extends from a plug on the backplane. Do not tug on any of these cords. Otherwise, the corresponding plug on the backplane might come off.

3. Each fan has a power cord. At the end of each power cord is a plug and receptacle. Disconnect the plug for each fan that is to be replaced. Then remove the appropriate fan(s).
4. Install the new fan(s), reconnect the fan plug(s), reconnect the fan panel (if disconnected), and screw the fan panel back onto the back of the unit.

System Backup

System translations can be restored by using the data on the system or on the backup translation card if the length of power failure is appropriate for the corresponding system. [Table 5-1](#) lists the requirements:

Table 5-1. Requirements for System Backup

Minimum Length of Power Failure (in Minutes)	System
2	Single-Carrier Cabinet Standard System
2	Single-Carrier Cabinet High or Critical Reliability System

Save Translation

To ensure that the translation card contains the most recent copy of the translation data, the system can automatically save the translation data onto the translation card every 24 hours. Automatic daily backup of the system translation data is controlled by an entry in the system parameters that defaults to "daily".

If many translation data changes are made, it is recommended that you save the translation data using the **save translation** command. This action saves the new changes to the translation card without having to wait for the next automatic daily translation backup.

 **NOTE:**
The **save translation** command blocks all maintenance commands except some **list**, **display**, **monitor**, and **status** commands.

The system blocks the execution of any commands that change translations or trigger a maintenance action (for example, **test board**, **busyout port**, and so forth). The **status card-mem** command is blocked during the save translation operation.

In a high or critical reliability system, if the **save translation** command is entered without a qualifier, an attempt is made to save the translations on *both* the Active and Standby SPE. If the command is qualified with either "spe-active" or "spe-standby," the translations are saved only on the specified SPE. For example, if, when the **save translation** command was issued, the translations were successfully saved on the active SPE's translation card, but were not successfully saved on the standby SPE's translation card, issue the **save translation spe-standby** command to save the translations on the standby SPE as well.

The system blocks the execution of any commands that change the translation, access a translation card, or trigger a maintenance action.

CAUTION:

It is recommended that "save translation" be performed after business hours so that dial tone delays are not encountered.

CAUTION:

Do not issue the "save translation" command when alarm conditions are present.

Save Recorded Announcements

In a high or critical reliability system, if the **save announcements** command is entered without a qualifier, an attempt is made to save the integrated announcements on *both* the Active and Standby SPE. If the command is qualified with either "spe-active" or "spe-standby," the integrated announcements are saved only on the specified SPE. For example, if, when the **save announcements** command was issued, the integrated announcements were successfully saved on the Active SPE's translation card, but were not successfully saved on the Standby SPE's translation card, then you would issue the **save announcements spe-standby** command to save the announcements on the Standby SPE as well.

WARNING:

The "save announcements" commands should only be used after business hours or when the system is operating during a low usage period. The system takes about 45 minutes to one hour to transfer the recorded announcements from the Announcement circuit pack to the system tape. During this interval, use of the administration terminal is blocked for other activities until the command completes.

Translation Card Backup

In case of a power failure, the system translations can be restored using the translation card. Translation data can be saved during the daily scheduled maintenance. However, if the translation data changes frequently, translations should be saved frequently to ensure that the most up-to-date information is kept.

Note that only one translation card is provided with the system. It is recommended that the customer purchase additional translation cards to serve as backup or replacement. Translation cards should be alternated periodically.

It is also recommended that backup copies of the translation data be made weekly, or after many changes have been made to the translation data. This minimizes the loss of recent translation data changes if the translation card in the system becomes damaged.

Enter the **save announcements** command to save the recorded announcements in the system on the translation card.

NOTE:
A 10 MByte or larger translation card is required to save and restore announcements.

The system takes about 10 minutes to complete this task. Because the terminal is unavailable during this time, it is recommended that this command be used after business hours. During this time period, the terminal cannot be used to administer the system until the transfer is complete; however, all other terminals (if provided) are allowed to perform administration procedures.

Enter the **restore announcements** command to restore the recorded announcements from the translation card back into system memory. The system takes about 22 minutes to complete this task. After completing the task, the system performs an audit to make sure that the announcements on the announcement circuit pack match the announcements administered in the system.

The working copy of the announcements is stored on the announcement circuit pack. A backup copy should be made on a 10 Mb or larger translation card. The following procedure is used to make a backup Memory Card:

1. Remove the translation card from the Netcon circuit pack.
2. Insert the backup translation card into the Netcon circuit pack.
3. Enter the **save translation** command and press Enter. This instructs the system to take all translation information in memory and transfer it into the translation card. The following display appears:

```
save translation                                     SPE A

                                     SAVE TRANSLATION

Processor                Command Completion Status      Error Code
SPE_A                    Success                        0

Command successfully completely

enter command:
```

Screen 5-1. Save Translation — SPEA

4. Verify that the command successfully completes. If not, an error message appears. In such a case, refer to the “Translation Card Errors” section.

5. If the system is equipped with a TN750 Announcement circuit pack, the recorded announcements can be saved using the **save announcement** commands. Enter the command and press Enter. The following display appears:

```
save announcements

                                SAVE ANNOUNCEMENTS

Processor                        Command Completion Status      Error Code
SPE_A                           Success                        0

Command successfully completely

enter command:
```

Screen 5-2. Save Announcements Screen — SPEA

6. Verify that the command successfully completes. If not, an error message appears. In such a case, refer to the “Translation Card Errors” section.
7. Remove the backup translation card and insert the original translation card.
8. Label the backup translation card with the date and time it was updated. A special notation on the card clearly distinguishes it from other cards.
9. Store the backup translation card in a secure place.

Translation Card Errors

Translation card-related failures may occur for two reasons: the card is at fault, or the Netcon circuit pack is at fault. The following is a list of the error messages and recommended responses to each.

1. Cannot access file storage area—Implies that the wrong translation card may be installed.
- Response:* Check to see which translation card is installed. If the correct one is installed, test it.
2. Cannot turn on 12 volt power supply—Implies that something may be wrong with the Netcon circuit pack, which contains the power supply.
- Response:* Test the 12-volt power supply by entering the **test card-mem** command from the terminal. Executing this command causes the system to run Test 701 (12 Volt Power Supply Test). If the power supply test fails, replace the Netcon circuit pack. Then repeat whichever command failed.

3. Invalid directory on Card-Mem — The translation card needs refreshing. Run **test card-mem** and be sure all tests pass.
4. Card-Mem is unusable — Something is wrong with the translation card. Replace the translation card.
5. Could not write to Card-Mem — Something is wrong with the translation card. Test the translation card.
6. Cannot access mass storage system now; try again later — The storage system is in use. Try again later.
7. Request is incompatible with currently running operations — The storage system is in use. Try again later.
8. Card-Mem is not inserted in the system — Insert the translation card.
9. Cannot access file; wrong type of Card-Mem is inserted — The correct translation card for the desired operation has not been inserted. Load the appropriate translation card.
10. File size exceeded — There is no more file space. Call your Lucent Technologies representative.
11. Upgrade Memory Card inserted — The system upgrade translation card may have been inserted instead of the translations card. Insert the translation card.
12. Card-Mem is write-protected — The switch on the top side of the translation card is incorrectly set. Move the switch to the down position.
13. Transmission problem; please try later — There is a problem communicating with the announcement circuit pack. Check to see that the announcement circuit pack has been correctly administered. Use the **change data <extension_number>** command. Verify that the announcement circuit pack is in the correct slot in the processor. If so, wait and retry.
14. Command has been aborted; please try later — The command was pre-empted. Try again later.
15. Saved copy of translations is unusable — The copy of the translations on your translation card is faulty. Re-enter the **save translation** command.

Software Upgrade

The software upgrade feature permits a DEFINITY System to upgrade its software to include new features and to fix software problems. Performing an upgrade on a system without high or critical reliability requires a **reset system 4** (reboot) and thus causes a service disruption. Performing an upgrade on a system equipped with high or critical reliability requires only a **reset system 2** (Cold-2) restart that is less disruptive.

WARNING:

No administration changes should be entered during the following software upgrade procedure. There can be substantial time gaps between steps and, since the system cannot prevent administration changes, it is up to the system technician to make sure that none are attempted during the entire software upgrade process.

NOTE:

This section does not apply to processor hardware upgrades such as upgrading a 386 system to a Release 5vs/si or later system. See "Upgrades and Additions/Software Upgrades".

Procedure on a System using Translation Cards

The software in a Release 5vs/si or later system can be upgraded to include new features and to fix software problems. Performing an upgrade on a standard reliability system requires a Reset System 4 (reboot) and thus causes a service disruption. Performing an upgrade on a high or critical reliability system requires only a Reset System 2 (Cold-2) restart, which is less disruptive.

CAUTION:

Do not enter any administration changes during the following software upgrade procedure. There can be substantial time gaps between steps and, since the system cannot prevent administration changes, it is up to the system technician to make sure that none are attempted during the entire software upgrade process. This includes making sure that no one (including the customer) is making administration changes through connections other than through the local administration terminal.

Standard Reliability (Simplex) Systems

The software upgrade for a standard reliability system can take up to 130 minutes, during which time service is interrupted for about 15 minutes. Upgrade software cannot be done remotely, and it must be performed at the local terminal. Ensure that the following items are available before proceeding:

- Generic program card with the software release running currently in the system
- Generic program card containing the new software to which the upgrade is to be done
- Translation card on which the system translations are to be saved (the card should already be in the system)
- Software patch (if it exists) that is currently applied to the system (this patch is downloaded if a software backout is required)

- Software release label to be applied to the processor circuit pack after a successful upgrade.

The following table indicates the processes and their corresponding time allotment for the upgrade procedure.

Process	Time (minutes)
save translation	10
save announcement	45
upgrade software	10
save translation	10
save announcements	45
miscellaneous	10
Total Time	130

[Figure 5-4](#) illustrates the output that appears on the terminal during the upgrade procedure.

Figure 5-4. Typical Start-up Messages (TN790)

Save Current Translations to Original Translation Card

1. Set the write switch on the original translation card down to record. Insert the card into the slot on the TN777B faceplate.
2. Enter **save translation** and press **Enter** to get translations onto the translation card. This takes about 10 minutes. The yellow LED on the TN777B is on. If the translations were corrupted, the following error message displays when logging in:

**WARNING:**
Translation corruption detected; call Lucent Technologies distributor immediately.

NOTE:

The **save translation** command cannot function if the translation corruption message appears.

Disable TTI

Enter **change system-parameters features** and press Enter. Use Page 2 of the form to disable Terminal Translation Initialization (TTI) by changing the value to **n**.

List Configuration Software Version

Issue the **list configuration software-versions** command to determine if any patches have been applied.

NOTE:

If the system must be restored to the old software, download the correct patches.

Disable Scheduled Maintenance

Enter **change system-parameters maintenance**, and press Enter. Use this form to prevent scheduled daily maintenance from interfering with the update or upgrade.

NOTE:

If scheduled maintenance has begun, set the value of the "Stop Time" field to 1 minute after the current time. If scheduled maintenance has not yet begun, change the value of the "Start Time" field to a time after the upgrade is finished.

Disable Alarm Origination to INADS

1. Enter **change system-parameters maintenance** and press Enter.
2. Enter **n** in the *Alarm Origination* field and press Enter.
3. For some releases of system software, disable *Cleared Alarm Notification* and *Restart Notification* before submitting the form.

CAUTION:

Disabling alarm origination prevents the system from generating alarms, thus preventing unnecessary trouble tickets.

Save Announcements

1. If the system is equipped with a TN750/B Announcement circuit pack, enter **display announcements**, and press Enter. If administered recorded announcements are listed, enter **save announcements** [from PCSS] and

press Enter. Where P is the port network number (1 for PPN, and 2-4 for EPN), C is the carrier designation (A, B, C, or D), and SS is the number of the slot in which the circuit pack resides (01 to 21).

 NOTE:

If multiple TN750/B circuit packs are present, you *must* specify the slot location for the save announcements command. If there is only one announcement circuit pack, the system defaults to the proper location.

 NOTE:

The TN750C Announcement circuit pack has on-board non-volatile storage and does not need to be saved to the translation card.

Shut Down DEFINITY LAN Gateway System

If a DEFINITY LAN Gateway system resides in the control cabinet to be upgraded, prepare to shut down the DEFINITY LAN Gateway assembly and allow the disk to completely spin down.

CAUTION:

Save the system parameters if you plan to reuse the current system.

CAUTION:

Neglecting to shut down a DEFINITY LAN Gateway assembly before powering down the system cabinet where it resides can damage the LAN Gateway disk.

1. Log onto the DEFINITY LAN Gateway. *See the DEFINITY Communications System Generic 3 Installation, Administration and Maintenance of CallVisor ASAI over the DEFINITY LAN Gateway, 555-230-223, for the procedure to log on.*
2. When the main menu appears, select *Maintenance*.
3. Select *Reset System* from the *Maintenance* menu.
4. Select *Shutdown* from the *Reset System* menu.
5. Unseat the LAN Gateway assembly from its backplane connectors.

Shut Down DEFINITY AUDIX System

1. If a DEFINITY AUDIX System resides in the control cabinet to be upgraded, shut down the AUDIX assembly and allow the disk to completely spin down.

WARNING:

Neglecting to shut down AUDIX before powering down the system cabinet where it resides can damage the AUDIX disk.

2. Unseat the AUDIX assembly from its backplane connectors in the carrier.

Power Down Basic Control Cabinet

CAUTION:

Powering down the PPN cabinet causes important system data, such as BCMS data, records of queued ACD calls, Automatic Wakeup request, and Do Not Disturb requests to be lost. Refer to DEFINITY Enterprise Communications Server Release 5.4 Maintenance for R5vs/si for information about preparing the system for a power down.

1. Set the basic control cabinet power supply circuit breaker to OFF.

Replace Circuit Packs

1. At the basic control cabinet, remove the combined TN786B/CPP1 Processor/Memory circuit pack.
2. Install the TN790 Processor circuit pack into the control cabinet slot labeled "PROCR."

Reseat DEFINITY LAN Gateway System

Reseat the LAN Gateway assembly into its backplane connectors.

Reseat DEFINITY AUDIX System

Reseat the AUDIX assembly into its backplane connectors.

Reboot the System

1. Set the basic control cabinet power supply circuit breaker to ON.
2. The system performs the reset level 4 rebooting process by loading translations from the translation card. This takes 8 to 11 minutes.
3. Peel the paper backing from the TN790 Processor circuit pack position label (designation strip) and affix it to the front of the control cabinet.
4. Install a circuit pack blank into the slot previously occupied by the CPP1.
5. Log in as "craft" at the login: prompt on the terminal.
6. Enter **set time**, and press Enter to set the time and ensure that the system is booted properly.

7. Enter **list configuration software-version**, and press Enter to compare the version number of the Release 5.4 software program (displayed on the terminal) with the TN790 version number (written on a label on the TN790's faceplate). If the version numbers are not the same, change the version number on the TN790 label so that they agree.
8. Perform a sanity check on the system running the new software by executing the following commands in this order:
 - a. **status system 1** (to check out unusual status in the system)
 - b. **list station** (to ensure that the translation is read in properly)
 - c. **display alarm** (to ensure no alarm is raised in the system)
 - d. **list trunk-group** (to ensure the translation is read in properly)
 - e. **list hunt-group** (to ensure the translation is read in properly)

This ensures there is no translation corruption and the translations can be saved with the new software.

 NOTE:

If the new load must be returned to the previous software load, re-install the TN786B/CPP1 circuit packs and reboot with the previous version's translation card.

9. Get the DOSS order number of the upgrade, and call the regional CSA to request an "init" login. Once logged in as "init," the CSA should assign the Release 5.4 option, which automatically sets the 24-hour password aging for the upgraded system's customer logins.

 NOTE:

Certain forms have changed for DEFINITY ECS R5. Upgraded translations may appear on a different form, fields may shift within a form, and the name assignments to particular fields may change.

10. Notify the switch administrator that any previous login names and passwords still exist, but that the passwords expire in 24 hours. The new login names and passwords must conform to the requirements below.

 NOTE:

A password must have from 4 to 11 alphanumeric characters including at least 1 alphabetic character and 1 numeric character. A login name must have from 3 to 6 alphanumeric characters.

11. Since an R1V3.0 G3-MA cannot notify users about expiring passwords, disable password aging for any login name used with an R1V3.0 G3-MA.

Restart DEFINITY LAN Gateway System

1. Log onto the DEFINITY LAN Gateway.
2. When the main menu appears, select *Maintenance*.

3. Select *Reset System* from the *Maintenance* menu.
4. Select *Restart System* from the *Reset System* menu.

Save Upgraded Translations onto New Translation Card

1. Enter **status system 1**, and press Enter to verify the system is in "active" mode.
2. If the system contains a TN750/B Announcement circuit pack, check for completion of an automatic restore of announcements before removing the original translation card. If the system has been running for at least 45 minutes since power on, this operation should be complete. Check the yellow LED on the TN750/B which is lit during the download. If the restore did not start within 15 minutes of power on, enter **restore announcements**, and press Enter.
3. At this point, all telephones should be working properly.
4. Insert the new Release 5.4 translation card. Verify the write switch is down.
5. The original translation card can be reformatted and reused. Enter **format card-mem announcements** and press Enter. This formats the original translation card into Release 5.4 format (even if no announcement circuit packs are installed).
6. Enter **save translation**, and press Enter. This instructs the system to write all translation information from memory onto the translation card.
7. If the system is equipped with a TN750/B Announcement circuit pack and announcements were restored in the above step, enter **save announcements ['from' cabinet(1-X). carrier (A-D), slot (0-20)]** and press Enter. Where cabinet/carrier/slot is the location of the TN750/B.

NOTE:

If multiple TN750/B circuit packs are present, you *must* specify the slot location for the save announcements command. If there is only one announcement circuit pack, the system defaults to the proper location.

Enable TTI

If TTI was optioned prior to the software upgrade:

1. Enter **change system-parameters features** and press Enter.
2. Use page 2 of the form to change the TTI field back to y.

Enable Scheduled Maintenance

Enter **change system-parameters maintenance**, and press Enter. Enable the scheduled daily maintenance.

Enable Customer Options

1. Enter **change system-parameters customer-options**.
2. Use these forms to verify the customer options are properly set.

NOTE:

In the Basic Call Setup field, if ISDN-PRI? was set to y before the upgrade, be sure to set the field back to y.

Resolve Alarms

Examine the alarm log. Resolve any alarms that may exist using *DEFINITY Enterprise Communications Server Release 5.4 Maintenance for R5vs/si*.

Verify Alarm Origination to INADS

Be sure the system is part of the existing INADS database by calling the INADS Database Administrator at the Technical Service Center (TSC). Verify that INADS can dial into the system and that the system can dial out to INADS. As part of the system registration process, the INADS Database Administrator enables Alarm Origination.

Return Equipment

Return the replaced equipment (including the old Translation Card) to Lucent Technologies according to the requirements outlined in the following documents:

*BCS/Material Logistics, MSL/Attended Stocking Locations
Methods and Procedures for Basic Material Returns*

High and Critical Reliability (Duplex) Systems

The upgrade procedure for high and critical reliability systems takes up to two hours. Service is interrupted for about five minutes. The procedure cannot be done remotely, and it must be performed at the PPN (local) terminal.

Ensure that the following items are available before proceeding:

1. Generic software card with the software release currently running in the system
2. Generic software card containing the new software to which upgrades are to be made
3. Translation cards on which to save system translations (these cards should already be in the system)
4. Software patch (if it exists) that is currently applied to the system (this patch is downloaded if a software backout is required)

5. Software release label to be applied to the processor circuit pack after a successful upgrade

The following table indicates the processes and their corresponding time allotment for the upgrade procedure.

Process	Time (minutes)
save translation	9
save announcement	45
upgrade software	15
save translation	9
miscellaneous	11
Total Time	90

[Figure 5-5](#) presents output that appears on the terminal during this procedure.

Figure 5-5. Terminal Display for a Duplex System Software Upgrade

Save Current Translations to Original Translation Card

1. Set the write switch on the original translation card down to record. Insert the card into the slot on the TN777B faceplate.
2. Enter **save translation** and press **Enter** to get translations onto the translation card. This takes about 5 minutes. The yellow LED on the TN777B is on. If the translations were corrupted, the following error message displays when logging in:

WARNING:

Translation corruption detected; call Lucent Technologies distributor immediately.

NOTE:

The **save translation** command cannot function if the translation corruption message appears.

Disable TTI

Enter **change system-parameters features** and press **Enter**. Use Page 2 of the form to disable Terminal Translation Initialization (TTI) by changing the value to n.

List Configuration Software Version

Issue the **list configuration software-versions** command to determine whether any patches have been applied.

NOTE:

If the system must be restored to the old software, download the correct patches back onto the system.

Disable Scheduled Maintenance

1. Enter **change system-parameters maintenance**, and press **Enter**. Use this form to prevent scheduled daily maintenance from interfering with the update or upgrade.

NOTE:

If scheduled maintenance has begun, set the value of the "Stop Time" field to one minute after the current time. If scheduled maintenance has not yet begun, change the value of the "Start Time" field to a time after the upgrade is finished.

Disable Alarm Origination to INADS

1. Enter **change system-parameters maintenance** and press **Enter**.

2. Enter **n** in the *Alarm Origination* field and press Enter.
3. For some releases of system software, disable *Cleared Alarm Notification* and *Restart Notification* before submitting the form.

CAUTION:

Disabling alarm origination prevents the system from generating alarms, thus preventing unnecessary trouble tickets.

Save Announcements

1. If the system is equipped with a TN750/B Announcement circuit pack, enter **display announcements**, and press Enter. If administered recorded announcements are listed, enter **save announcements** [from PCSS] and press Enter. Where P is the port network number (1 for PPN, and 2-4 for EPN), C is the carrier designation (A, B, C, or D), and SS is the number of the slot in which the circuit pack resides (01 to 21).

NOTE:

If multiple TN750/B circuit packs are present, you *must* specify the slot location for the save announcements command. If there is only one announcement circuit pack, the system defaults to the proper location.

NOTE:

The TN750C Announcement circuit pack contains on-board non-volatile memory. It is not necessary to back up a TN750C.

Shut Down DEFINITY LAN Gateway System

If a DEFINITY LAN Gateway system resides in the control cabinet to be upgraded, prepare to shut down the DEFINITY LAN Gateway assembly and allow the disk to completely spin down.

CAUTION:

Save the system parameters if you plan to reuse the current system.

WARNING:

Neglecting to shut down a DEFINITY LAN Gateway assembly before powering down the system cabinet where it resides can damage the LAN Gateway disk.

1. Log onto the DEFINITY LAN Gateway. *See the DEFINITY Communications System Generic 3 Installation, Administration and Maintenance of CallVisor ASAI over the DEFINITY LAN Gateway, 555-230-223, for the procedure to log on.*
2. When the main menu appears, select *Maintenance*.

3. Select *Reset System* from the *Maintenance* menu.
4. Select *Shutdown* from the *Reset System* menu.
5. Unseat the LAN Gateway assembly from its backplane connectors.

Shut Down DEFINITY AUDIX System

1. If a DEFINITY AUDIX System resides in the control cabinet to be upgraded, shut down the AUDIX assembly and allow the disk to completely spin down.

WARNING:

Neglecting to shut down AUDIX before powering down the system cabinet where it resides can damage the AUDIX disk.

2. Manually Power Down AUDIX System

A yellow caution sticker on the system's power unit notifies technicians to shut down the DEFINITY AUDIX System prior to powering down the system.

- a. Using a pointed object, such as a paper clip or pen (do not use a pencil), press the Boot/shutdown button. The button is located at the top right portion of the front panel.
- b. Hold the boot/Shutdown button in until the LCD display flashes the message MSHUT .
- c. Release the Boot/Shutdown button.

NOTE:

The DEFINITY AUDIX System takes about five minutes to shut down. The "heartbeat" indication on the display continues to flash.

3. Unseat the AUDIX assembly from its backplane connectors in the carrier.

Power Down Basic Control Cabinet

CAUTION:

Do not power down the entire system. This defeats the purpose of high or critical reliability configurations.

CAUTION:

Powering down the control cabinet causes important system data, such as BCMS data, records of queued ACD calls, Automatic Wakeup request, and Do Not Disturb requests to be lost. Refer to DEFINITY Enterprise Communications Server Release 5.4 Maintenance for R5vs/si for information about preparing the system for a power down.

Set the basic control cabinet power supply circuit breaker to OFF.

Replace Circuit Packs

1. Remove the combined TN786B/CPP1 Processor/Memory circuit pack from the basic control cabinet.
2. Install the TN790 Processor circuit pack into the control cabinet slot labeled "PROCR."

Reboot the System

1. Set the basic control cabinet power supply circuit breaker to ON.
2. The system performs the reset level 4 rebooting process by loading translations from the translation card. This takes 10 to 15 minutes.
3. Peel the paper backing from the new circuit pack position label (designation strip) and affix it to the front of the basic control cabinet.
4. Install a circuit pack blank into the slot previously occupied by the CPP1.

Power Down Duplicated Control Cabinet

CAUTION:

Do not power down the entire system. This defeats the purpose of high or critical reliability configurations.

Set the duplicated control cabinet power supply circuit breaker to OFF.

Replace Circuit Packs

1. Remove the combined TN786B/CPP1 Processor/Memory circuit pack from the duplicated control cabinet.
2. Install the TN790 Processor circuit pack into the control cabinet slot labeled "PROCR."

Reseat DEFINITY LAN Gateway System

Reseat the LAN Gateway assembly into its backplane connectors in the carrier.

Reseat DEFINITY AUDIX System

Reseat the AUDIX assembly into its backplane connectors.

Reboot the System

1. Set the duplicated control cabinet power supply circuit breaker to ON.

2. The system performs the reset level 4 rebooting process by loading translations from the translation card. This takes 10 to 15 minutes.
3. Peel the paper backing from the new circuit pack position label (designation strip) and affix it to the front of the duplicated control cabinet.
4. Install a circuit pack blank into the slot previously occupied by the CPP1.
5. Log in as "craft" at the login: prompt on the management terminal.
6. Enter **set time**, and press Enter to set the time and ensure that the system is booted properly.
7. Enter **list configuration software-version**, and press Enter to compare the version number of the Release 5.4 software program (displayed on the terminal) with the TN790 version number (written on a label on the TN790's faceplate). If the version numbers are not the same, change the version number on the TN790 label so that they agree.
8. Perform a sanity check on the system running the new software by executing the following commands in this order:
 - a. **status system 1** (to check out unusual status in the system)
 - b. **list station** (to ensure that the translation is read in properly)
 - c. **display alarm** (to ensure no alarm is raised in the system)
 - d. **list trunk-group** (to ensure the translation is read in properly)
 - e. **list hunt-group** (to ensure the translation is read in properly)

This ensures there is no translation corruption and the translations can be saved with the new software.

 NOTE:

If the new load must be returned to the previous software load, re-install the TN786B/CPP1 circuit packs and reboot with the previous version's translation card.

9. Get the DOSS order number of the upgrade, and call the regional CSA to request an "init" login. Once logged in as "init," the CSA should assign the DEFINITY ECS R5 option, which automatically sets the 24-hour password aging for the upgraded system's customer logins.

 NOTE:

Certain forms have changed for DEFINITY ECS R5. Upgraded translations may appear on a different form, fields may shift within a form, and the name assignments to particular fields may change.

10. Notify the switch administrator that any previous login names and passwords still exist, but that the passwords expire in 24 hours. The new login names and passwords must conform to the requirements below.

 NOTE:

A password must have from 4 to 11 alphanumeric characters including at least 1 alphabetic character and 1 numeric character. A login name must have from 3 to 6 alphanumeric characters.

11. Since an R1V3.0 G3-MA cannot notify users about expiring passwords, disable password aging for any login name used with an R1V3.0 G3-MA.

Restart DEFINITY LAN Gateway System

1. Log onto the DEFINITY LAN Gateway.
2. When the main menu appears, select *Maintenance*.
3. Select *Reset System* from the *Maintenance* menu.
4. Select *Restart System* from the *Reset System* menu.

Save Upgraded Translations onto New Translation Card

1. Enter **status system 1**, and press Enter to verify that the system is in the "active/standby" mode.

 NOTE:

At this point, all telephones should be working properly.

2. Insert the new Release 5.4 translation card. Verify the write switch is down.
3. The original translation card can be reformatted and reused. Enter **format card-mem announcements** and press Enter. This formats the original translation card into Release 5.4 format (even if no announcement circuit packs are installed).
4. Enter **save translation**, and press Enter. This instructs the system to write all translation information from memory onto both translation cards.
5. If the system is equipped with a TN750/B Announcement circuit pack and announcements were saved above, enter **restore announcements**, and press Enter. Once the administered recorded announcements are restored, enter **save announcements** [from PCSS] and press Enter. Where P is the port network number (1 for PPN, and 2-4 for EPN), C is the carrier designation (A, B, C, or D), and SS is the number of the slot in which the circuit pack resides (01 to 21).

 NOTE:

If multiple TN750/B circuit packs are present, you *must* specify the slot location for the save announcements command. If there is only one announcement circuit pack, the system defaults to the proper location.

NOTE:

The TN750C Announcement circuit pack has on-board non-volatile storage and does not need to be saved to the translation card.

Enable TTI

If TTI was enabled prior to the software upgrade:

1. Enter **change system-parameters features** and press Enter.
2. Use page 2 of the form to change the TTI field back to y (if necessary).

Enable Scheduled Maintenance

Enter **change system-parameters maintenance**, and press Enter. Use this form to enable scheduled daily maintenance.

Enable Customer Options

1. Enter **change system-parameters customer-options** and press Enter.
2. Use these forms to verify the customer options are properly set.

NOTE:

In the Basic Call Setup field, if ISDN-PRI? was set to y before the upgrade, be sure to set the field back to y.

Resolve Alarms

Examine the alarm log. Resolve any alarms that may exist using *DEFINITY Enterprise Communications Server Release 5.4 Maintenance for R5vs/si*.

Verify Alarm Origination to INADS

Be sure the system is part of the existing INADS database by calling the INADS Database Administrator at the Technical Service Center (TSC). Verify that INADS can dial into the system and that the system can dial out to INADS.

As part of the system registration process, the INADS Database Administrator enables Alarm Origination.

Return Equipment

Return the replaced equipment (including the old Translation Card) to Lucent Technologies according to the requirements outlined in the following documents:

BCS/Material Logistics, MSL/Attended Stocking Locations

Methods and Procedures for Basic Material Returns

Preventive Maintenance Procedures

The following preventive maintenance procedures should be followed when you are visiting customer sites:

Air Filters

Air filters should be inspected annually. If a filter is dirty or clogged, first tap it on the ground. If the filter is still dirty or clogged, then wash it with warm water and a mild detergent. A vacuum cleaner can be used if one is available. If there is no facility for washing or vacuuming the air filter, then replace the filter. Refer to "CABINET" maintenance object for more information on air filters and fans.

Tape Head/Capstan

The tape drive head (also called the tape head) should be cleaned at least once a year. Moreover, it should be cleaned as part of the preventive maintenance strategy. It is recommended that you inspect the tape head during each maintenance visit and that you clean the tape head several times a year. In addition, a dated label should be placed on the tape drive unit after the tape head is cleaned. New tapes leave more abrasive particles on the tape head.

The tape head can be accessed for cleaning from the front of the drive by opening the tape access door with your finger. Refer to TAPE Maintenance documentation for more details on cleaning the tape head.

Batteries

The batteries should be replaced every four years or whenever a POWER alarm occurs in the system.

Preventive Maintenance Log

[Figure 5-6](#) shows a sample of the AT&T Preventive Maintenance Log. Whenever you complete any of the preventive maintenance procedures described in this section, be sure to fill in the requested information on the log form before you leave the customer's premises.

[illegible]

- Analog Tie Trunk Back-to-Back Testing
- Terminating Trunk Transmission Testing
- Troubleshooting ISDN-PRI Problems
- Troubleshooting PRI Endpoint Problems
- Troubleshooting ISDN-PRI Test Calls

Complete descriptions of each feature are provided in the *DEFINITY Enterprise Communications Server Release 5.4 Administration and Feature Description*.

Refer to *DEFINITY Communications System Generic 1 and Generic 3 — Console Operations*, 555-230-700, and *DEFINITY Communications System Generic 1 and Generic 3 Voice Terminal Operations* as required for detailed operating procedures (does not include Facility Test Calls, Analog Tie Trunk Back-to-Back Testing, Terminating Trunk Transmission Testing, Troubleshooting ISDN-PRI Problems, Troubleshooting ISDN-PRI Test Calls, or Troubleshooting ISDN-BRI Problems described in this chapter.)

Automatic Circuit Assurance

Requires the use of a display-equipped voice terminal (may be nondisplay type if the Voice Message Retrieval feature is provided) or an attendant console. An "ACA activate/deactivate" button (one per system) is required on the voice terminal or attendant console.

Automatic Circuit Assurance (ACA) assists users in identifying possible trunk malfunctions. The system maintains a record of the performance of individual trunks relative to short and long holding time calls. The system automatically initiates a referral call to an attendant console or display-equipped voice terminal when a possible failure is detected.

Holding time is the elapsed time from when a trunk is accessed to the time a trunk is released. When ACA is enabled via administration, the system measures the holding time of each call.

A short holding time limit and a long holding time limit are preset by the System Manager for each trunk group. The short holding time limit can be from 0 to 160 seconds. The long holding time limit can be from 0 to 10 hours. The measured holding time for each call is compared to the preset limits for the trunk group being used.

Measurements are not made on personal CO lines, out-of-service trunks, or trunks undergoing maintenance testing.

Busy Verification of Terminals and Trunks

Requires the use of a multi-appearance voice terminal or attendant console equipped with a "verify" button.

Busy Verification of Terminals and Trunks allows a user at a voice terminal or attendant console to make test calls to trunks, voice terminals, and hunt groups (DDC/UCD). These test calls check the status of an apparently busy resource. This provides an easy method to distinguish between a voice terminal or resource that is truly busy and one that only appears busy because of a trouble condition.

Trunk Group Busy/Warning Indicators to Attendant

Requires the use of an attendant console.

Trunk Group Busy/Warning Indicators to Attendant provides the console user with a visual indication of the trunk group status for each trunk group associated with the 12 Trunk Group Select buttons located on the console. Trunk groups with busy indications during nonbusy periods should be checked to ensure that the trunks are busy and not out-of-service. Use the Busy Verification of Terminals and Trunks feature to test the suspected faulty trunks.

Trunk Identification by Attendant

Requires the use of a display-equipped voice terminal or an attendant console equipped with a "trunk id" button.

Trunk Identification by Attendant allows a voice terminal or attendant console user to identify a specific trunk being used on a call. This is useful when a user experiences noise or poor transmission on a trunk call. The trunk identification (access code and group number) is displayed when the "trunk id" button is pressed while on a trunk call. Use of this feature is denied if there are more than two trunks on a call. If the call is trunk-to-trunk, the identification displayed is of the last trunk added to the call.

Facility Test Calls

The Facility Test Calls feature provides a voice terminal user the capability of placing test calls to access specific trunks, touch-tone (DTMF) receivers, time slots, and system tones. The test call can be made by a local voice terminal user by dialing an access code.

NOTE:

For the ISDN-PRI Test Call feature, see "[Troubleshooting ISDN-PRI Test Call Problems](#)" later in this chapter.

NOTE:

The following test call descriptions are for voice terminal users:

Trunk Test Call

The trunk test call accesses specific Tie or CO trunks. DID trunks cannot be accessed.

To place a call:

1. Dial the Facility Test Call Feature Access Code (for example, 197, see Note), and listen for dial tone.

NOTE:

The Facility Test Call Access Code (FAC) is administered on the Feature Access Codes Form. The 197 FAC code used here is an example. For more information on FAC, refer to *DEFINITY Communications System Generic 3 Implementation*, 555-230-653.

2. Dial the 6-digit port number "PCSSpp"

P = Port network number (1 for PPN or 2 or 3 for EPN)
C = Carrier number (A=1, B=2, C=3, D=4, E=5)
SS = Slot number (01—20)
pp = Port number

The channels on a DS1 trunk are addressed by using the channel number for the port number.

3. Listen for one of the following tones:
 - Dial Tone or Silence—trunk is connected. Go to Step 4. If you hear a dial tone, it is coming from the far end. If the far end has been disabled, you do not hear dial tone. However, depending on far-end administration, you may still be able to dial digits. All digits dialed after the port number are transmitted using end-to-end DTMF signaling; therefore, if the trunk being tested is a rotary trunk, it is not possible to break dial tone.
 - Reorder Tone—trunk is busy or maintenance busy.
 - Intercept Tone— a trunk or touch-tone (DTMF) receiver has not been accessed.
4. Place a call. Even if you do not hear a dial tone, you may still be able to dial digits, depending on the administration of the far-end switch.

All digits dialed after the port number are transmitted using end-to-end DTMF signaling; therefore, if the trunk being tested is a rotary trunk, it will not be possible to break dial tone.

If the call does not go through (that is, no ringing), determine if the trunk circuit pack has been removed.

Touch-tone (DTMF) Receiver Test Call

The touch-tone (DTMF) receiver call accesses and tests the four touch-tone (DTMF) receivers located on the Tone Detector circuit pack. **To place the call:**

1. Dial the Facility Test Call Feature Access Code (for example, 197, see Note), and listen for dial tone.

NOTE:

The Feature Access Code (FAC) is administered on the Feature Access Codes Form. The 197 FAC code used here is an example.

2. Dial the 6-digit port number "PCSSpp":

P = Part network number (1 for PPN or 2 or 3 for EPN)

C = Carrier number (A=1, B=2, C=3, D=4, E=5)

SS = Slot number (01—20)

pp = Touch-tone (DTMF) Receiver Port number (01, 02, 05, or 06))

3. Listen for one of the following tones:

- Confirmation Tone—touch-tone (DTMF) receiver is connected. Go to Step 4.
- Reorder Tone—touch-tone (DTMF) receiver is busy.
- Intercept Tone—a touch-tone (DTMF) receiver or trunk has not been accessed.

4. Dial **1234567890*#** and listen for Confirmation tone (test passed) or intercept tone (test failed). The test fails if the touch-tone (DTMF) receiver does not recognize all the touch-tone (DTMF) signals.
5. To test another touch-tone (DTMF) receiver, repeat Steps 2 through 4.
6. To terminate the test call, hang up the station set used for testing.

Time Slot Test Call

The time slot test call connects the voice terminal user to a specific time slot located on the TDM Buses (A or B) or out-of-service time slots. **Specific Time Slots To place the call:**

1. Dial the Facility Test Call Feature Access Code (for example, 197, see Note), and listen for dial tone.

NOTE:

The Feature Access Code (FAC) is administered on the Feature Access Codes Form. The 197 FAC code used here is an example.

2. Dial port network number (1 for PPN or 2 or 3 for EPN), then press # and the 3-digit time slot number "xxx," where:

xxx = Time slot number (000 through 255 on Bus A and 256 through 511 on Bus B)

3. Listen for one of the following tones:
 - Confirmation Tone—time slot is idle or maintenance busy
 - Reorder Tone—time slot is busy
 - Dedicated Tone—One of the following tones is heard (see [Table 5-2](#))

Table 5-2. TDM Bus Time Slot Numbers

TDM Bus A time slot	TDM Bus B time slot	Tone Heard
000	256	Reorder
001	257	Reorder
002	258	Reorder
003	259	Reorder
004	260	Reorder
005	261	Touch Tone 1 - 697Hz
006	262	Touch Tone 2 - 770 Hz
007	263	Touch Tone 3 - 852Hz
008	264	Touch Tone 4 - 941 Hz
009	265	Touch Tone 5 - 1209 Hz
010	266	Touch Tone 6 - 1336Hz
011	267	Touch Tone 7 - 1447 Hz
012	268	Touch Tone 8 - 1633 Hz
013	269	Dial Tone
014	270	Reorder Tone
015	271	Alert Tone
016	272	Busy Tone
017	273	Ringback Tone
018	274	Special Ringback Tone
019	275	2225 Hz Tone
020	276	Music
021	277	Tone on Hold
022-253	278-509	Confirmation (used for calls)
254	510	Reorder
255	511	Confirmation

Out-of-Service Time Slots To place the call:

1. Dial the Facility Test Call Feature Access Code (for instance, 197, see Note), and listen for dial tone.

⇒ NOTE:
The Feature Access Code (FAC) is administered on the Feature Access Codes Form. The 197 FAC code used here is an example.

2. Dial port network number (1 for PPN or 2 or 3 for EPN), then dial ** and listen for the following tones:
 - Confirmation Tone—Connection is made. Go to Step 3.
 - Reorder Tone—No time slots are out-of-service.
3. Repeat from Step 1 to alternate between out-of-service time slots on TDM Bus A and B.

System Tone Test Call

The system tone test call connects the voice terminal user to a specific system tone. **To place the call:**

1. Dial the Facility Test Call Feature Access Code (for instance, 197, see Note), and listen for dial tone.

⇒ NOTE:
The Facility Test Call Access Code (FAC) is administered on the Feature Access Codes Form. The 197 FAC code used here is an example.

2. Dial port network number (1 for PPN or 2 or 3 for EPN), then dial * followed by the two-digit tone identification number listed in [Table 5-3](#).
3. Listen for the tone that was specified.

⇒ NOTE:
For a definition of Call Progress Tones see *DEFINITY Enterprise Communications Server Release 5.4 System Descriptions and Specifications*.

Analog Tie Trunk Back-to-Back Testing

The TN760B circuit pack can be configured for back-to-back testing (also known as connectivity testing) by making translation and cross-connect changes. This testing configuration allows for the connection of Tie Trunks back-to-back in the same switch to verify the operation of Tie Trunk ports. The tests can be performed in either the E & M or simplex modes.

E & M Mode Test Procedure

The procedures to perform the Analog Tie Trunk port test in the E & M mode are as follows:

1. At the administration terminal, enter **list configuration trunks** command to determine which ports are assigned on the Tie Trunk circuit pack.
2. Enter **display dialplan** command to determine the Trunk Access Code (TAC) format.
3. Enter **display port xx** command for all ports defined in Step 1. This action displays the trunk groups to which the ports belong (that is, of which the ports are members).

NOTE:
See the [“Handling Control Circuit Packs”](#) section in this chapter for details on how to remove and replace port circuit packs.

4. Insert the circuit pack back into the slot.

5. Enter **display trunk xx p** command for each trunk group identified in Step 3. This command displays the specified trunk group on the administration terminal screen and prints a hard copy on the printer. Save this data for later use.
6. Remove all members defined by these ports from the trunk group(s) using the **ch trunk xx** command.
7. Remove the Tie Trunk circuit pack from the carrier slot.
8. Set the dip (option) switches for each of the two ports to be tested on the Tie Trunk circuit pack to "E & M mode" and "unprotected."
9. Enter **add trunk n** command to add a new (test) trunk group. Then enter the following information:

■ Group Type — tie

■ TAC — (use trunk access code obtained from dial plan)

■ Trunk Type (in/out) — wink/wink

■ Port — assign two of the ports from the tie trunk

■ Mode — E & M

■ Type — specify one port as t1 standard and other port as t1 compatible

Examples of the Trunk Group forms are shown in [Screen 5-3](#) and [Screen 5-4](#)..

Screen 5-4. Trunk Group Form — E & M Mode (Page 2 of 2)

- 10. Locate the Tie Trunk port terminal connections at the cross-connect field. See [Table 5-4](#).
- 11. At the cross-connect field, disconnect outside trunk facilities from the Tie Trunk ports and mark the disconnected wires for later reconnecting the Tie Trunk ports back to normal operation. The D Impact Tool (AT-8762) is required to perform this step.
- 12. Use jumper wires (DT 24M-Y/BL/R/G and DT 24P-W/BRN) and the D Impact Tool to connect wiring between the two ports assigned in Step 9 at the cross-connect field. For example, if the two ports on the Analog Tie Trunk circuit pack are port 1 and 2, connect the wirings as shown below:

13. Check all wirings to verify good connections between the two test ports.
14. Place a call from one voice terminal to another voice terminal using the Tie Trunk ports assigned. Dial TAC and extension. For example, if TAC of Tie Trunk group is 110 and station number is 5012, then dial 110 5012. If the call cannot be made, either one of these ports could be defective. There are four ports on TN760B (port 1, 2, 3, and 4), try different combinations to determine defective ports.
15. If there is a defective port on the circuit pack, try to switch to an unused port. However, if all ports are normally used, then replace the circuit pack.
16. Disconnect the jumpers between two ports. Then use administration terminal and trunk printouts to restore all trunk group changes to normal values.

Simplex Mode Test Procedure

The procedures to perform the Analog Tie Trunk Port Test in the simplex mode are as follows:

1. Repeat Steps 1 through 7 of the E & M Mode Test Procedure.
2. Set the dip (option) switches for each of the two ports to be tested on the Tie Trunk circuit pack to simplex mode.
3. Enter **add trunk n** command to add a new (test) trunk group. Then enter the following information:
 - Group Type — tie
 - TAC — (use trunk access code obtained from dial plan)
 - Trunk Type (in/out) — wink/wink
 - Port — assign two of the ports from the tie trunk
 - Mode — simplex
 - Type — type 5

An example of the Trunk Group Form Page 2 is shown in [Screen 5-5](#).

- 4. Locate the Tie Trunk port terminal connections at the cross-connect field. See [Table 5-4](#).
- 5. At the cross-connect field, disconnect outside trunk facilities from the Analog Tie Trunk ports and mark the disconnected wires for later when the Tie Trunk ports are placed back into normal operation. The D Impact Tool (AT-8762) is required to perform this step.
- 6. Use jumper wires (DT 24M-Y/BL/R/G) and the D Impact Tool to connect wiring between the two ports assigned in Step 4 at the cross-connect field. For example, if the two ports on the Analog Tie Trunk circuit pack are ports 1 and 2, connect the wirings as shown below:

- 7. Repeat Steps 13 through 16 of the E & M Mode Test Procedure.

Terminating Trunk Transmission Testing

The Terminating Trunk Transmission (TTT) (noninteractive) feature provides for extension number access to three tone sequences that can be used for trunk transmission testing from the far end of the trunks.

The three test types should have extension numbers assigned on the Maintenance-Related System Parameters Form.

Test Type 100:_____ Test Type 102:_____ Test Type 105:_____

Test Type 100 provides:

1. 5.5 seconds of 1004 Hz tone at 0dB
2. Quiet until disconnect; disconnect is forced after one minute

Test Type 102 provides:

1. 9 seconds of 1004 Hz tone at 0dB
2. 1 second of quiet
3. This cycle is repeated until disconnect; disconnect is forced after 24 hours.

Test Type 105 provides:

1. nine seconds of 1004 Hz at -16dB
2. one second of quiet
3. nine seconds of 404 Hz at -16dB
4. one second of quiet
5. nine seconds of 2804 Hz at -16dB
6. 30 seconds of quiet
7. one half second of Test Progress Tone (2225 Hz)
8. approximately five seconds of quiet
9. forced disconnect

Troubleshooting ISDN-PRI Problems

The following flowchart, [Figure 5-7](#) and [Figure 5-8](#), defines a layered approach when troubleshooting ISDN-PRI problems. Since a problem at a lower layer affects upper layers, layers are investigated from low to high. In the flowchart, the DS1 facility is layer 1, the TN765 Processor Interface is layer 2, and the ISDN trunks are layer 3. Transient problems are diagnosed on Page 2 of the flowchart, [Figure 5-8](#).

Figure 5-7. Processing of ISDN-PRI Problems (Page 1 of 2)

Figure 5-8. Processing of ISDN-PRI Problems (Page 2 of 2)

Troubleshooting PRI Endpoint Problems

The following flowchart, [Figure 5-9](#) and [Figure 5-10](#), defines a layered approach when troubleshooting PRI endpoint problems. Since a problem at a lower layer affects upper layers, layers are investigated from low to high. In the flowchart, the DS1 facility is layer 1, the TN765 Processor Interface is layer 2, and the ISDN trunks are layer 3.

The troubleshooting procedure described here diagnoses faults between the switch and the line-side PRI terminal adapter/ISDN-PRI endpoint equipment. Problems encountered on the network-side of a wideband connection or problems with end-to-end equipment compatibility are out of the scope of this section.

Figure 5-9. Processing of PRI Endpoint Problems (Page 1 of 2)

Figure 5-10. Processing of PRI Endpoint Problems (Page 2 of 2)

Troubleshooting ISDN-PRI Test Call Problems

An ISDN-PRI test call is a call of a diagnostic nature that is placed across an ISDN-PRI user-network interface to a previously designated number. An ISDN-PRI test call is also a maintenance procedure concerned with the identification and verification ISDN-PRI user-network interface problems. The ISDN-PRI test call can access ISDN-PRI trunks only.

Placing an Outgoing ISDN-PRI Test Call

NOTE:
An ISDN-PRI test call can be placed only if the circuit translates to an ISDN-PRI trunk.

An ISDN-PRI test call can be originated via either the *synchronous* or the *asynchronous* method. Each method is described below.

Synchronous Method

One command is used in this method to start, stop and query an ISDN-PRI test call. In the synchronous method, an outgoing ISDN-PRI test call may be part of a system technician-demanded long test sequence to test a circuit pack, port, or trunk. Therefore, the command line entry can be any of the following:

test trunk <grp>/<mbr> long [repeat #]

test port PCSSpp long [repeat #]

test board PCSS long [repeat #]

The "long" qualifier must be entered in the above commands in order for the ISDN test call to run. The repeat number (#) can be any number from 1 through 99 (default = 1).

The following information is displayed in response to the above commands:

- **Port:** The port address (PCSSpp) is the port network number, carrier designation, slot, and circuit of the maintenance object under test.
- **Maintenance Name:** The type of maintenance object tested.
- **Test Number:** The actual test that was run.
- **Test Results:** Indicates whether the test passes, fails, or aborts.
- **Error Code:** Additional information about the results of the test. (See the ISDN Trunk Maintenance documentation for details.)

Asynchronous Method

⇒ NOTE:

The asynchronous method requires a Maintenance/Test circuit pack to be physically present in the system.

In this method, four commands are used to start, stop, query, and list an outgoing ISDN-PRI test call. These commands are as follows:

clear isdn-testcall <grp>/<mbr> (stop)

list isdn-testcall (list)

status isdn-testcall <grp>/<mbr> (query)

test isdn-testcall <grp>/<mbr> [minutes] (start)

⇒ NOTE:

Before placing an outgoing ISDN-PRI test call, verify that the FAC on the System Features Form has been administered as well as the Far End Test Line No and TestCall Bearer Capability Class (BCC) on the Trunk Group Administration Form. Furthermore, if the ISDN-PRI trunk is of the "cbc" (call

by call) service type, then the Testcall Service field on Trunk Group Administration Form must have been administered also.

To initiate an outgoing ISDN-PRI test call in the asynchronous method, issue the following command:

test isdn-testcall <grp>/<mbr> [minutes]

This command enables you to specify a specific the trunk on which to originate the ISDN-PRI test call.

 **NOTE:**
The optional qualifier can also be used that specifies in minutes the duration of the test call. If no duration is specified, the default duration is used which is 8.4 or 9.6 seconds. The qualifier "minutes" accepts the numeric values one through 120 (that is, two hours = 120 minutes).

[Screen 5-6](#) shows a typical response to the **test isdn-testcall** command:

```
test isdn-testcall
```

Port	Maintenance Name	Test Number	Test Result	Error Code
1B1501	ISDN-TRK	258	PASS	

Screen 5-6. Typical Response to Test ISDN-Testcall Command

The meaning of the information displayed in response to the above command is described in the following list.

- **Port:** The port address (PCSSpp) is the port network number, carrier designation, slot, and circuit of the maintenance object under test.
- **Maintenance Name:** The type of maintenance object tested.
- **Test Number:** The actual test that was run.
- **Test Results:** Indicates whether the test passes, fails, or aborts.
- **Error Code:** Additional information about the results of the test. (See the ISDN Trunk Maintenance documentation for details.)

The functions of the **clear**, **list**, and **status** commands associated with the ISDN Testcall are summarized in the following list. For more detailed information, refer to the appropriate sections as directed.

- **Clear isdn-testcall <grp>/<mbr>** enables you to cancel an in-progress ISDN-PRI test call and allow another test call to start. For details on this command, refer to the **clear isdn-testcall** command description in the "Clear Commands" section of [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).
- **List isdn-testcall <grp>/<mbr>** enables you to list all the ISDN-PRI trunks in use for an ISDN-PRI test call in the system. For details on this command, refer to the **list isdn-testcall** command description in the "List Commands" section of [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).
- **Status isdn-testcall <grp>/<mbr no> [minutes]** enables you to check on the progress of an outgoing test call. When an outgoing ISDN-PRI test call completes in a specific port network, another ISDN-PRI trunk from the same port network is available for testing (regardless of whether the **status** information has been displayed). For details on this command, refer to the **status isdn-testcall** command description in the "Status Commands" section of [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

Troubleshooting the Outgoing ISDN-Testcall Command

If the TestCall BCC field appears on the Trunk Group Administration Form, make sure the TestCall BCC field indicates the correct BCC for the service provisioned on the ISDN-PRI trunk. The TestCall BCC values are defined as follows:

- 0—Voice
- 1—Digital Communications Protocol Mode 1
- 2—Mode 2 Asynchronous
- 3—Mode 3 Circuit
- 4—Digital Communications Protocol Mode 0 (which is usually the default).

⇒ NOTE:

If the ISDN-PRI trunk is of type "cbc," make sure the TestCall Service field on the Trunk Group Administration Form indicates the correct service so that a network facility message can be sent across the ISDN-PRI network

If the outgoing ISDN-PRI test call keeps aborting, please make sure that the far-end device can handle DCP Mode 0 or DCP Mode 1.

⇒ NOTE:

Before attempting to make an ISDN-PRI test call to the public network (that is, the network is the far-end), make sure that test call service is provisioned by the network. The user must subscribe to Test Type 108 service and have the correct far-end test call number administered on the trunk group form for the call to be allowed.

Troubleshooting Backplane Voltage Problems

The TN2036 Voltage Range circuit pack is a test tool that allows easy access to the backplane pins that provide various voltages to control and port slots. Probes from a voltmeter can be plugged into the access point for the desired voltage and a ground access point to measure the voltage. This circuit pack itself has instructions for use printed on the side as well as a listing of the voltage tolerance range for each voltage on the front panel. The voltages and tolerances are as follows:

ringing voltage: 75 -> 115 VAC

+12 VDC: 11.4 -> 12.6 VDC

+5 VDC: 4.95 -> 5.35 VDC

-5 VDC: -4.95 -> -5.35 VDC

-48 VDC: -43 -> -53 VDC

neon message waiting voltage: -80 VDC -> -165 VDC

The type of cabinet determines where the circuit is placed to measure the voltages. For single-carrier cabinets, all voltages except +12 VDC and +5 VDC can be measured from any port slot. However, the neon message waiting voltage requires that the system have a TN752 or TN755 Power Unit circuit pack. The Tape Drive slot is used to measure +12 VDC.

NOTE:

All control circuit packs should be removed from the backplane before this measurement is made.

The +5 VDC measurement must be made in two separate cabinet locations since the power unit has two independent +5 VDC outputs [+5 VDC and +5(B) VDC]. Each output supplies a different section of the cabinet with power. For the control cabinet, make one measurement in the processor slot and another in any port slot. For an EPN control cabinet, make one measurement in any port slot from 1 to 4 and another in any port slot from 5 to 16. For a port cabinet, make 1 measurement in any port slot from 1 to 6 and another in any port slot from 7 to 18.

Troubleshooting Multimedia Call Handling (MMCH)

Before troubleshooting any problems associated with the DEFINITY MMCH, always be sure that the endpoint is operating correctly (audio, video, and data) by making point-to-point test calls. If possible, make the test calls over the

network to test the connectivity and routing of network calls from the endpoint. This eliminates problems such as disconnected audio or video cables and network troubles.

64 Kbps Calls Terminate but Far End Receives 56 Kbps Indication

Description

Some 2x64 Kbps conferences on the DEFINITY MMCH do not establish because of framing, audio, or video problems.

For calls that are routed in the network through a Lucent Technologies/LEC interface, the originating equipment may launch a 64 Kbps call attempt, and the far end receives either a 56 Kbps or 64 Kbps indication. If the far end receives a 64 Kbps indication, the call may have used 56 Kbps facilities. If so, the call may exhibit any of the following conditions:

- No handshaking in one direction or both (call disconnects after timeouts)
- Call connects, but audio or video is corrupted (audio noise or no video)
- Call succeeds without disruption (this is the least likely since one endpoint must be aware that the call is really 56 Kbps to connect)

If any of the above conditions occur, then 64 Kbps calls from the site are blocked.

Solution

Administer the conference for connection at 56 Kbps.

Calls Terminate with No Audio

Description

To support endpoints that do not support Multipoint Command Conference (MCC), the DEFINITY MMCH changes its capability set and initiates a capability set exchange with the endpoint when the Selected Communications Mode (SCM) changes. If the endpoint does not follow the SCM audio mode, the MCU may include the endpoint as a secondary (audio only) endpoint. If the endpoint sends an unknown or unsupported audio mode, then the TN788B decoder port mutes the endpoint from the conference. The user may hear the conference but may not be heard by other parties in the conference.

Solution

1. Use the Status Conference x form and check the Audio Mode field for the current operating mode of the conference.

2. Another indication of the audio modes is in the "Incoming Mode Commands from Endpoint and Outgoing Commands from MMI" on page 3 of the Status Conference x Endpoint y form. Check the Audio fields under the Mode Commands/Communication Modes section of the form.

Some Parties Cannot Be Heard by Others (Audio Subsetting)

Description

Problems where varying subsets of the conference hear different things may have problems with the various summing resources/groups that are in use. Traditionally these faults are caused by the SPE not cleaning up the connections properly. Isolation and diagnosis should focus on the VC resources in use by that conference.

Solution

1. Use the **status conference** command to list the VC resources in use by this conference. Try a hot replacement of any VC boards in use, which refreshes the VC translations and move all of the audio connections to different VC ports.
2. If the problem still exists, try dropping the conference and then bringing the conference back up again. Not only does this refresh VC translations, but uses different timeslots as well.
3. If the problem still exists, suspect a hardware problem. If practical, wait for the DEFINITY MMCH to be idle (no active conferences), and then check the circuit packs for active (yellow) LEDs. If any of these are unexpected, such as on a VC board, try replacing the board and then bringing the conference up again.

Calls Terminate with No Video

Description

Generally, loss of video can be divided into 2 types. The first occurs when the DEFINITY MMCH switches to the endpoint, but nobody sees them. The receivers see either "black" video or a frozen image of the previous speaker depending on the codec of the manufacturer. The type occurs when the DEFINITY MMCH does not switch to an endpoint.

Solution

In the first type described above, wiring problems, power to the camera, or video encoder circuit pack problems in the codec are typical causes.

In the second type, no video from an endpoint typically occurs because it is not a valid video source. This can be checked by looking at page 1 of the Status

Conference x Endpoint y Vid form under the Capability section. In this section, a “y” or “c” suggests that the endpoint has video. An “e” means ept has not declared any video capability in cap set, “n” is audio only, and “blank” means audio add-on.

Also check page 1 of the Status Conference x Endpoint y Vs form for indication of the video state for the endpoint values.

Calls Terminate Correctly but Are Unstable

Description

A number of conditions will lead to some or all endpoints having stability problems during the course of a conference. A lack of stability from an endpoint is noticeable by a lack of a video switching while the party is the only talker or excessive disconnects from that endpoint.

Synchronization

Generally, the most common problem is a mismatch in synchronization sources between the endpoint and the DEFINITY MMCH. This typically causes low-level (Px64) handshake problems that can trigger the endpoint/MMCH to disconnect the call. The MCCH's timers are set to sufficiently high values so that, normally, the endpoint will timeout and disconnect first. If installed in a customer network, it is a good idea to perform an audit of the path synchronization is being supplied. If there are different clock sources between endpoints and the DEFINITY MMCH, some problems are sure to occur. The severity of these problems can range from a handshake failure every few seconds to one per day. Depending on the type of endpoint, this can cause the endpoint to disconnect or just freeze video until the main problem is resolved.

Specifically, PictureTel System 4000 endpoints seem to be the most sensitive to instability. The Lucent Technologies Vistium also disconnects fairly infrequently. Last, the CLI Rembrandt II VP freezes video and waits for framing to be recovered.

Network Configuration Concerns with Synchronization

When auditing a network for synchronization, avoid unnecessary hops. Thus, a switch providing star-configuration synchronization is preferred over a daisy-chain configuration. Additionally, if there are DEFINITY PBXs that have EPNs, synchronization should be provided to sub nodes from the same port network through which the PBX receives its synchronization. Passing synchronization through the PBX Expansion Interface adds an unnecessary hop to the path and creates another potential point of failure.

Expansion Interface Duplication

If a customer's network uses PBX EPNs with duplicated Expansion Interfaces, scheduled switching of the Expansion Interface links should be disabled on the PBX via **change system-parameters maintenance**. When scheduled maintenance runs and switches the links, there is a brief corruption of the data path. If endpoints have active calls when the switch occurs, this corruption of the data path causes Px64 handshake problems, which lead to the endpoints losing video source status, and sometimes disconnecting as described above. Disabling the EI switching is in the customer's best interest to prevent the disruption of the Px64 data stream. The customer will get the same level of alarm indications and maintenance on the EI links, regardless of the status of scheduled switching.

PRI D-Channel Backup

A somewhat unlikely source of call stability problems occur where the translations for PRI D-channel Backup between two non-MCU switches were incorrect. As an example, on switch A, DS1 1A10 was designated as the primary source, and on switch B, the corresponding DS1 was designated as the secondary source. When scheduled maintenance was run on the switch that had an active standby D-channel, an audit disconnected some calls using the link. The problem was corrected when the the D-channel primary/secondary assignments matched.

Processor Duplication on the PBX

Do not enable the PI link switch on scheduled maintenance. This can cause link stability problems on the Accunet Bandwidth Controller (ABC).

Voice-Activated Switching Problems

Voice-activated switching on the DEFINITY MMCH does not follow the loudest talker. The MMCH queues all speaking parties and selects a new video broadcaster (the second-oldest speaking party) when the oldest speaking party has stopped talking. The new broadcaster will see the last speaker as its video. The system can also "learn" about the noise coming from an endpoint to help prevent false switches, adapting both to noise level and repetitive sounds such as a fan. This adaptation occurs over approximately 10 seconds.

No Switching, Full Motion Video

If a room is excessively noisy, the DEFINITY MMCH may receive sufficient audio signal to conclude that there is a speaker present. Use the Status Conference x form to determine if the MMCH thinks an endpoint is talking. The MMCH sets the Ts field to t for each endpoint if there is voice energy detected. This endpoint may have to mute when nobody at the site is speaking to allow the conference to proceed normally. Remind the customer that it may be necessary to mute if a side conversation is going on in the background, just as one would do in an

audio conference. If the system does not switch broadcasters even after the current broadcaster has muted, check the conference administration using the **display conference X** command to ensure that the conference is in voice-activated mode. Also verify that parties who were speaking are valid video sources as described in the "[Calls Terminate with No Video](#)" section above.

The See-Me feature (MCV) can also cause VAS to "lock-up." An endpoint can activate MCV to force their site to become the broadcaster. If they do not disable the feature when finished, the system remains in this mode indefinitely. Beginning with Release 3.0, the **status conference X** command shows that MCV is in effect by displaying av in the Video Status (Vs) column. Page 3 of the Status Conference X Endpoint Y form also has a Broadcaster field that indicates MCV is in effect with (SEE-ME) as the broadcaster. The same scenario can occur in a CHAIR or UCC-controlled conference with a designated broadcaster. In this situation the CHAIR/UCC has not released the designated broadcaster and returned to VAS mode. If there is a UCC-designated broadcaster, **status conference X** indicates a Video Status of u. Also, for UCC rollcall the return video may appear to be stuck. Check the Video Status for an "R," indicating rollcall.

If none of the examples above appears to be the cause, and if the room was quiet, all speakers are valid video sources, the conference is voice-activated, and the speaker can be heard, then escalate the problem.

Video Never Switches to a Particular Party

Description

Verify that the endpoint is a valid video source as described in the "[Calls Terminate with No Video](#)" section above. If it is, then the audio from the endpoint may not have sufficient voice signal for the hardware to determine the parties at the endpoint are speaking. Check the Talk field on page three of the Status Conference X Endpoint Y form to see if the talking bit is y. Next, check the audio by standing adjacent to the microphone and speaking at a normal level.

Solution

If the audio is not muffled:

1. Use the **status conference** command to determine which port on the TN788B (VC board) is connected to this endpoint.
2. Check the VC (TN788B) board using the **test board xxyy long** command.
3. Drop the call.
4. Find another available port, then:
 - a. Busayout the port to which the endpoint was connected.

- b. Make another call to the same conference. If the problem corrects itself, then the previous port may be bad. If there are other VC boards with sufficient available ports to replace calls on the current VC, then pull the board that has the bad endpoint on it (the **status conference** command displays the encoder port associated with the call). The system will automatically reestablish the VC connections without dropping the call. If this fixes the problem, then replace the board, as it has at least one bad port. Reseating the board may temporarily fix the problem due to the hard reset done to the board.

Audio Echo

Echo in conference calls, particularly those with large delay characteristics, is totally disruptive. When Voice Activated Switching is taken into account, the effects are disastrous. Various arrangements of the microphone(s) and room speaker(s) may be needed.

For some Lucent Technologies Vistium endpoints, if an external speaker is attached or was attached when the system was last rebooted, this endpoint will cause audio echo throughout the conference. First, isolate the offending endpoint by asking each endpoint to mute, one at a time, until the echo disappears.

If the input from an endpoint is located too close to the speakers of an endpoint, then acoustic echo is created. The microphone must be moved away from the speakers.

Normally, if any microphone in the room is moved relative to the speakers, that site will cause echo until the echo canceller in the codec retrains itself, some will require a manual reset. If a PictureTel keypad is configured with external microphones connected to the keypad, then the internal microphone and external microphone(s) "sing" to each other if the "ext mic" bat switch is set to "int mic" on the back of the keypad. In this configuration, VAS locked on that site, and the acoustic "singing" was inaudible.

Rate Adaptation

Because of a lack of a clear explanation in standards, sometimes endpoints do not work well with each other and the DEFINITY MMCH. The MMCH will only allow a conference to downgrade from 64kbps to 56 kbps operation on conferences that have the Rate Adaptation flag set to y.

When a downgrade does occur, information on the Status Conference form indicates the success or failure of the 64kbps-endpoints that are participants to properly rate adapt to 56kbps. As a general indication that the conference has rate adapted, the Conference Transfer Rate and Effective Transfer Rate fields show initial and current transfer rates, respectively. For each 64-kbps

endpoint the column that indicates Rate Adapt shows an n if the endpoint did not follow the procedures as specified by the H.221. If an endpoint shows y, it did successfully rate adapt. If an endpoint shows c, it joined the conference at 56kbps.

Once the conference rate adapts, the endpoints that do not properly follow suit, will become audio-only endpoints. A conference will not rate adapt from 56 kbps back to 64 kbps until all endpoints disconnect from the conference and it idles.

The PictureTel 1000 Release 1.1C, PictureTel 6.01 software, and the Vistium 2.0 software successfully rate adapt with the MCU. External rate adaptation techniques used by VTEL and CLI are known to cause problems with the endpoint when used with this feature.

Endpoint or I-MUX in Loopback Mode

Some endpoints have a loopback enable feature. This makes DEFINITY MMCH data loopback at the MMCH when a connection is in progress. The loopback can be enabled prior to or during a connection.

The MMCH does not detect the loop and continues to VAS. In most scenarios, the switch occurs, but within a few seconds, the broadcaster's return video becomes its own image. Once the broadcaster stops speaking, the system "false" switches to an apparently random port that was not speaking.

Install DS1 CPE Loopback Jack (T1 Only)

Using the DS1 CPE Loopback Jack (apparatus code 700A, comcode 107988867), a technician can test the DS1 span between the system and the network interface point. The loopback jack is required when DC power appears at the interface to the ICSU. *The loopback jack isolates the ICSU from the DC power and properly loops the DC span power.*

NOTE:

The loopback jack operates with any vintage of TN767E (or later) or TN464F (or later) DS1 circuit packs and with G3V3 EDI release 3 (or later) software. The loopback jack operates with the 120A2 (or later) Integrated Channel Service Unit (ICSU) only; *not* the 31xx series of Channel Service Units or other external CSUs or earlier ICSUs.

Loopback Jack Installation

Configurations Using a Smart Jack

The preferred location of the loopback jack is at the interface to the Smart Jack. This provides maximum coverage of CPE wiring when remote tests are run using the loopback jack. If the Smart Jack is not accessible, install the loopback jack at the extended demarcation point.

1. If there is no extended demarcation point, install the loopback jack directly at the network interface point as shown in [Figure 5-11](#).
2. If there is an extended demarcation point and the Smart Jack is not accessible, install the loopback jack as shown in [Figure 5-12](#).
3. If there is an extended demarcation point, but the Smart Jack is accessible, install the loopback jack as shown in [Figure 5-13](#).

Configurations Without a Smart Jack

1. Install the loopback jack at the point where the cabling from the ICSU plugs into the “dumb” block. If there is more than one “dumb” block, choose the one that is closest to the Interface Termination feed or the fiber MUX. This provides maximum coverage for loopback jack tests. Refer to [Figure 5-14](#) and [Figure 5-15](#).

Installation

1. To install the loopback jack, simply disconnect the RJ-48 (8-wide) connector (typically an H600-383 cable) at the appropriate interface point and connect the loopback jack in series with the DS1 span. See [Figure 5-11](#) through [Figure 5-15](#).
2. Plug the H600-383 cable from the ICSU into the female connector on the loopback jack.
3. Plug the male connector on the loopback jack cable into the network interface point.

NOTE:

Do not remove the loopback jack after installation. This is not a test tool and should always be available to remotely test a DS1 span.

Administration

1. At the management terminal, enter **change ds1 <location>**. The “location” is the DS1 interface circuit pack for which the loopback jack was installed.
2. Be sure the “near-end CSU type” is set to integrated.

3. On page 2 of the form, change the supply CPE loopback jack power field to y.

NOTE:

Setting this field to y informs the technician that a loopback jack is present on the facility. This allows a technician to determine that the facility is available for remote testing.

4. Enter **save translation** to save the new information.

DS1 Span Test

This test should only be performed after the DS1 circuit pack and the 120A2 (or later) ICSU have been successfully tested using appropriate maintenance procedures. The DS1 span test consists of 2 sequential parts. Each part provides a result indicating if there is a problem in the CPE wiring. CPE wiring may be considered problem-free only if the results of both parts are successful.

The first part of the span test powers-up the loopback jack and attempts to send a simple code from the DS1 board, through the wiring and loopback jack, and back to the DS1 board. Maintenance software waits about 10 seconds for the loopback jack to loop, sends the indication of the test results to the management terminal, and proceeds to the second part of the test.

The second part of the test sends the standard DS1 3-in-24 stress testing pattern from the DS1 board, through the loopback jack, and back to a bit error detector and counter on the DS1 board. The bit error rate counter may be examined at will via the management terminal, and provides the results of the second part of the test. The test remains in this state until it is terminated so that the CPE wiring may be bit error rate tested for as long as desired.

1. Busy out the DS1 circuit pack by entering **busyout board UUCCSS** (where UUCCSS is the cabinet, carrier, and slot number of the DS1 board).
2. At the management terminal, enter **change ds1 <location>** and verify the near-end csu type is set to integrated.
3. Change to page 2 of the DS1 administration form and confirm that the TX LBO field is 0dB. If not, record the current value and change it to 0dB for testing. Press Enter to implement the changes or press Cancel to change nothing.
4. Enter **test ds1-loop <location> cpe-loopback-jack**. This turns on simplex power to the loopback jack and waits about 20 seconds for any active DS1 facility alarms to clear. A "PASS" or "FAIL" displays on the terminal. This is the first of the 2 results. A "FAIL" indicates a fault is present in the wiring between the ICSU and the loopback jack. The loopback jack may also be faulty. A "PASS" only indicates that the loopback jack looped successfully, not that the test data contains no errors. If a "PASS" is obtained, continue with the following steps.

NOTE:

The loss of signal (LOS) alarm (demand test #138) is not processed during this test while the 3-in-24 pattern is active.

- 5. Enter **clear meas ds1 loop <location>** to clear the bit error count.
- 6. Enter **clear meas ds1 log <location>** to clear the performance measurement counts.
- 7. Enter **clear meas ds1 esf <location>** to clear the ESF error count.
- 8. Enter **list meas ds1 sum <location>** to display the bit error count. Refer to [Table 5-5](#) for troubleshooting information.

Table 5-5. DS1 Span Troubleshooting

Displayed Field	Function	Indication
Test: cpe-loopback-jack	Pattern 3-in-24	The loopback jack test is active.
Synchronized	Y or N	If "y" displays, the DS1 circuit pack has synchronized to the looped 3-in-24 pattern and is accumulating a count of the bit errors detected in the pattern until the test has ended. If "n" displays, retry the test 5 times by ending the test per Step 11 and re-starting the test per Step 4. If the circuit pack never synchronizes, substantial bit errors in the 3-in-24 pattern are likely. This could be intermittent connections or a broken wire in a receive or transmit pair in the CPE wiring.
Bit Error Count	Cumulative count of detected errors	If there are no wiring problems, the counter remains at 0. A count that pegs at 65535 or continues to increment by several hundred to several thousand on each list meas command execution indicates intermittent or corroded connections, severe crosstalk, or impedance imbalances between the two conductors of the receive pair or the transmit pair. Wiring may need replacement. Note that "ESF error events" counter and the ESF performance counter summaries ("errored seconds", "bursty errored seconds", and so forth) will also increment. These counters are not used with the loopback jack tests. However, they will increment if errors are occurring. Counters should be cleared following the test.

9. Repeat Steps 5 through 8 as desired to observe bit error rate characteristics. Also, wait 1 to 10 minutes between Steps 5 through 7. One minute without errors translates to better than a 1 in 10 to the eighth error rate. Ten minutes without errors translates to better than a 1 in 10 to the ninth error rate.
10. If the test runs for 1 minute with an error count of 0, confirm that the 3-in-24 pattern error detector is operating properly by entering **test ds1-loop <location> inject-single-bit-error**. This causes the 3-in-24 pattern generator on the DS1 circuit pack to inject a single-bit error into the transmit pattern. A subsequent **list meas ds1 summary <location>** command displays the bit error count. If a count greater than 1 is displayed, replace the ICSU and retest. If the problem continues, replace the DS1 circuit pack.
11. Terminate the test by entering **test ds1-loop <location> end cpe-loopback-jack-test**. Wait about 30 seconds for the DS1 to re-frame on the incoming signal and clear DS1 facility alarms.

Loopback termination fails under the following conditions:

- a. The span is still looped somewhere. This could be at the loopback jack, at the ICSU, or somewhere in the network. This state is indicated by a fail code of 1313. If the red LED on the loopback jack is on, replace the ICSU. Re-run the test and verify that the loopback test terminates properly. If not, replace the DS1 circuit pack and repeat the test.
 - b. The DS1 cannot frame on the incoming span's signal after the loopback jack is powered down. This means that there is something wrong with the receive signal into the loopback jack from the "dumb" block or the Smart Jack. If the service provider successfully looped and tested the span, up to the Smart Jack, this condition isolates the problem to the wiring between the loopback jack and the Smart Jack. Refer to "Loopback Jack Fault Isolation Procedures" for information on how to proceed in this case. The test cannot be successfully terminated until a good signal is received. To properly terminate the test before a good receive signal is available, enter **reset board <location>**.
12. Restore the "TX LBO" field to the original value recorded in Step 2.
 13. Release the DS1 circuit pack using the **release board UUCSSpp** command.
 14. Leave the loopback jack connected to the DS1 span.

Loopback Jack Fault Isolation Procedures

This section describes the possible DS1 configurations in which the loopback jack may be used. These configurations are: when the DS1 provider includes a Smart Jack, when no Smart Jack is provided at all, and when sites use fiber multiplexers. These configurations are separated into "Configurations Using a Smart Jack" and "Configurations Without a Smart Jack."

Configurations Using a Smart Jack

The addition of the loopback jack and the presence of a Smart Jack divides the DS1 span into 3 separate sections for fault isolation. These sections are shown in [Figure 5-11](#) through [Figure 5-13](#) for the different span configurations. They are:

- Section 1: Between the 120A2 (or later) ICSU and the loopback jack.
- Section 2: Between the loopback jack and the Smart Jack (network interface point).
- Section 3: From the Smart Jack to the CO. It is necessary to contact the DS1 provider to run this test.

A problem can exist in 1 or more of the 3 sections. The field technician is responsible for finding and correcting problems in the first 2 sections. The DS1 service provider is responsible for finding and correcting problems in the third section. Testing is divided into 3 steps.

- Test customer premises wiring (section 1 in the following 3 figures) from the ICSU to the loopback jack as described in "DS1 Span Test."
- Test the CO-to-network interface wiring (section 3 in [Figure 5-11](#)) using the Smart Jack loopback (CO responsibility). Coordinate this test with the DS1 provider.
- Test the short length of customer premises wiring (section 2 in the following 3 figures) between the loopback jack and the Smart Jack. This can be done using a loopback that "overlaps" section 2 of the cable. Any of the following loopbacks can do this:
 - a. The local ICSUs line loopback, which is typically activated, tested, and then deactivated by the DS1 service provider at the CO end.
 - b. The local DS1 interface's payload loopback, activated and tested by the DS1 service provider at the CO end.
 - c. The far-end ICSU's line loopback. This test is activated at the management terminal by entering **test ds1-loop <location> far-csu-loopback-test-begin**. The test is terminated by entering **test ds1-loop <location> end-loopback/span-test**. Bit error counts are examined as described in "DS1 Span Test." This test method is the least preferable because it covers wiring that is not in the local portion of the span. This test only isolates problems to

section 2 wiring if there are no problems in the wiring between the far-end CO and the far-end ICSU. Coordinate this test with the DS1 service provider.

If any of the above tests (a, b, or c) fail, a problem is indicated in section 2 as long as the tests for section 1 and section 3 pass. Since section 2 includes the network interface point, it is necessary to work with the service provider to isolate the fault to the loopback jack cable, the “dumb” block, or the Smart Jack.

	9. Central Office

Figure 5-15. Network Interface at "Dumb" Block with Repeater Line to Fiber MUX

Section 2 includes the short cable from the loopback jack to the "dumb" block demarcation point (part of the loopback jack). This is the only portion of section 2 that is part of customer premises wiring but is not covered in the loopback jack's loopback path.

A problem can exist in 1 or both of the 2 sections. The field technician is responsible for finding and correcting problems in section 1 and the loopback cable portion of section 2. The DS1 service provider is responsible for finding and correcting problems in the majority of section 2. Testing is divided into 2 steps.

1. Test customer premises wiring (section 1 in [Figure 5-14](#)) from the ICSU to the loopback jack as described in the “DS1 Span Test” section.
2. Test the loopback jack-to-“dumb” block and “dumb” block-to-CO wiring (section 2 in [Figure 5-14](#)). This can be done using a loopback that “overlaps” the section of the span. Any of the following loopbacks can do this:
 - a. The local ICSUs line loopback, which is typically activated, tested, and then deactivated by the DS1 service provider at the CO end.
 - b. The local DS1 interface’s payload loopback, activated and tested by the DS1 service provider at the CO end.
 - c. The far-end ICSU’s line loopback. This test is activated at the management terminal by entering **test ds1-loop <location> far-csu-loopback-test-begin**. The test is terminated by entering **test ds1-loop <location> end-loopback/span-test**. Bit error counts are examined as described in the “DS1 Span Test” section. This test only isolates problems to section 2 wiring if there are no problems in the wiring between the far-end CO and the far-end ICSU. Coordinate this test with the DS1 service provider.

If any of the above tests (a, b, or c) fail, a problem is indicated in section 2. This could mean bad loopback jack -to-“dumb” block cabling, but is more likely to indicate a problem somewhere between the “dumb” block and the CO. This is the responsibility of the DS1 service provider. If the DS1 Span Test confirms that there are no problems in section 1, the technician should proceed as follows to avoid unnecessary dispatch.

- Identify and contact the DS1 service provider
- Inform the DS1 provider that loopback tests of the CPE wiring to the “dumb” block (section 1) showed no problems
- If the far-end ICSU line loopback test failed, inform the DS1 provider
- Request that the DS1 provider perform a loopback test of their portion of the section 2 wiring by sending someone out to loop section 2 back to the CO at the “dumb” block.

If this test fails, the problem is in the service provider’s wiring.

If the test passes, the problem is in the cable between the loopback jack and the “dumb” block. Replace the loopback jack.

Configurations Using Fiber Multiplexers

Use the loopback jack when customer premises DS1 wiring connects to an on-site fiber multiplexer (MUX) and allows wiring to the network interface point on the MUX to be remotely tested. This requires that ICSUs be used on DS1 wiring to the MUX.

Fiber MUXes can take the place of Interface termination feeds as shown in [Figure 5-11](#) , [Figure 5-12](#), [Figure 5-13](#), and [Figure 5-14](#). Test these spans using the same procedures as metallic spans. Note the following points:

1. Fiber MUXes may have loopback capabilities that can be activated by the service provider from the CO end. These may loop the signal back to the CO or back to the DS1 board. If the MUX provides the equivalent of a line loopback on the "problem" DS1 facility, this may be activated following a successful loopback jack test and used to isolate problems to the wiring between the loopback jack and the MUX.
2. Be aware that there are installations that use repeatered metallic lines between the MUX and the "dumb" block. Theses lines require DC power for the repeaters and this DC power is present at the "dumb" block interface to the CPE equipment. *A loopback jack is required in this configuration to properly isolate and terminate the DC power.*

To check for the presence of DC, make the following 4 measurements at the network interface jack:

1. From Transmit Tip (T, Pin 5) to Receive Tip (T1, Pin 2)
2. From Transmit Ring (R, Pin 4) to Receive Ring (R1, Pin 4)
3. From Transmit Tip (T, Pin 5) to Transmit Ring (R, Pin 4)
4. From Receive Tip (T1, Pin 2) to Receive Ring (R1, Pin 4)

All measurements should read 0 (zero) volts DC. For pin numbers and pin designations, refer to *Integrated Channel Service Unit (ICSU) Installation and Operation*, 555-230-193.

Operating Charasteristics

If a TN464F or TN767E and a 120A2 were installed in a system running pre-G3V3 software and the software is later upgraded to G3V3 Release 3 or later, reseal the DS1 circuit pack so that the ICSU administration fields will appear on the DS1 administration form.

Reliability Systems: A Maintenance Aid

6

General

A high or critical reliability system provides highly-available call processing because single points-of-failure in the system that result in loss of call processing are minimized. Such a system uses the existing duplicated TDM buses, provides the SPE, translation card, and Tone-Clock circuit pack duplication, and it uses packet bus redundancy. These components are each single points of failure in a standard reliability system.

The SPE is fully duplicated. The two SPEs are mounted in separate carriers and powered by different carrier power supplies. As a result, a high or critical reliability system has two control carriers: the A control cabinet and the B control cabinet.

Since the circuit packs in the two SPEs are the same, the SPEs have identical capabilities. Either SPE can act as the active SPE. However, only one of the SPEs can be the active SPE at any given time. The active SPE performs the same operations that the single SPE performs in a standard system; that is, all call processing, administration, and maintenance activities being performed by the switch. All memory writes performed on the active SPE are copied to the other SPE. The other SPE is known as the standby SPE. Its role is to take over as the active SPE if the current active SPE fails. If the active SPE (or a component of the active SPE) fails, the system automatically switches to the standby SPE.

Under normal conditions, the system operates using both TDM Buses. If the system detects transmission problems on one of the buses, it takes that bus out-of-service and operates with only one bus. This action results in a reduction in capacity. However, if the system detects a problem with one of the Tone-Clock circuit packs, it is able to take that circuit pack out-of-service without any impact on system capacity or performance.

The Packet Bus is NOT duplicated in the same way that the TDM Bus is duplicated (that is, there is one Packet Bus, while there are two TDM Buses). However, there are several spare leads on the Packet Bus itself that are not normally used. In a High or Critical Reliability system, the TN771 Maintenance/Test circuit pack is provided. This circuit pack has ability to detect faulty Packet Bus leads and to instruct all Packet circuit packs (for example ISDN-BRI, Packet Control, TN570 Expansion Interface circuit packs) to use up to three spare leads in place of defective ones.

The rest of this chapter provides a detailed description of the High and Critical Reliability systems that are available in as well as of the Standard system that is available across the board. The chapter explains the duplicated hardware and includes a description of the TN772 Duplication Interface circuit pack. It provides a look at the following concepts relevant to high and critical reliability systems: memory shadowing, SPE modes, and SPE-interchanges.

In addition, this chapter contains technical descriptions important to the general maintenance of High and Critical Reliability systems, such as a list of the appropriate system technician commands, SPE circuit pack LED strategies, installation and replacement procedures for SPE Control Carrier circuit packs, and for the Inter-Carrier Cable (ICC).

This chapter uses the term "Standard Reliability system" or "Standard system" to denote a system without duplication.

Reliability Options

The Release 5 systems are available in three different reliability options: standard, high and critical reliability. An increased level of reliability is implemented by duplicating various components so that standby components can take over (interchange) when a failure occurs on an active component. Most interchanges take place with no disruption of current service, and they allow for repairs to be made without disruption. Furthermore, duplication allows for the upgrading and maintenance of duplicated components and software without service disruption. The following sections describe which components are duplicated with each option.

Standard Reliability

On standard reliability systems, the 512-time-slot TDM bus is divided into two duplicate 256-time-slot buses, A and B. Call traffic is shared between the two buses. The first five time slots on each bus are reserved for the control channel, which is active on only one of the two buses at a time. Likewise, the next 17 time slots are reserved for carrying system tones. The tone time slots are not necessarily on the same bus (A or B) as the control channel. If any failure that affects the ability of the active control channel or the tone time slots to function takes place, the other bus becomes active for those time slots. For more

information, see TDM-BUS Maintenance section in [Chapter 10, "Maintenance Object Repair Procedures"](#), and the **set tdm** command in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

High Reliability

High reliability systems duplicate components that are critical to the viability of the system as a whole to prevent a single failure from dropping all service. These components include the following:

- PPN control carrier and carrier power units (OLSSs)
- All SPE circuit packs, including the Processor, Memory, Network Controller, Processor Interface, Packet Controller, and Duplication Interface circuit packs
- PPN Tone Clock circuit pack (EPN Tone-Clocks are not duplicated)
- TDM buses (described in the previous section)

The duplicated SPEs operate in active/standby fashion. Operation of this duplication is described in the STBY-SPE and DUPINT MO sections in [Chapter 10, "Maintenance Object Repair Procedures"](#). Interchanges of the SPE and of PPN Tone-Clocks operate independently unless induced by use of the SPE-select switches.

Critical Reliability

Critical reliability systems include all of the features of the High Reliability option described in the previous section. Additionally, these systems duplicate components of Port Network Connectivity (PNC) and of other components that are critical to the viability of each EPN. These components include the following:

- PPN and EPN Tone-Clock circuit packs
- PPN and EPN Expansion Interface circuit packs
- Inter-PN cabling

The entire direct-connected fiber connectivity is duplicated between each pair of port networks. Each duplicated fiber pair operates in an active/standby manner with all inter-PN calls set up on both fibers so that the active SPE can assume control without disruption of service. Each fiber pair between a pair of port networks operates independently of the other fiber pairs with respect to the active/standby operation (that is, the A-carrier fiber can be active between the PPN and EPN 1, and the B-carrier fiber can be active between the PPN and EPN 2).

The Tone-Clocks in each EPN operate in an active/standby manner independently from other duplication strategies.

Duplicated Hardware

A description of the hardware components used in a high or critical reliability system follows.

SPE Duplication

Each SPE in a high or critical reliability system consists of the following circuit packs:

- Processor Circuit Pack (TN790)
- Network Control Circuit Pack (TN777B)
- Packet Control Circuit Pack (TN778)

NOTE:

There may be zero or one Packet Control circuit pack. However, both SPEs must have an equal number of circuit packs.

- Processor Interface Circuit Pack(s) (TN765)

NOTE:

There may be zero, one, or two Processor Interface circuit pack. However, both SPEs must have an equal number of Processor Interface circuit packs.

- Duplication Interface Circuit Pack (TN772)

Duplication Interface Circuit Pack

The Duplication Interface circuit pack is required to support SPE duplication. Duplication Interface A is part of the SPE in the A control carrier, and Duplication Interface B is part of the SPE in the B control carrier.

The Duplication Interface circuit packs provide a broad range of functionality. Alone, Duplication Interface A provides control of the following components: the duplicated Processor circuit packs, the duplicated Tone-Clock circuit packs, the environmental maintenance monitoring and control, and G3MT terminal connection. Together, Duplication Interface A and Duplication Interface B provide memory shadowing from Active SPE Memory to Standby SPE Memory and communication between software on the Active SPE and the Standby SPE.

Duplication Interface A controls a lead that indicates to the duplicated Processor and Network Control circuit packs, respectively, which SPE is currently the Active SPE. This lead is known as the SPE Select lead. Duplication Interface A controls another set of leads that indicate to the duplicated TN768 and TN780 8

Tone-Clock circuit packs which of the two is currently the active one. These leads are known as the Tone-Clock Select leads. System software can request that the SPE Select lead and/or the Tone-Clock Select leads be changed. Duplication Interface A controls and monitors in the PPN of a High or Critical Reliability system the same set of environmental leads that the EPN TN775 or TN775B Maintenance circuit pack controls and monitors in an EPN.

The Duplication Interface circuit packs communicate with one another over the Inter-Carrier Cable (ICC). In a multicarrier cabinet, the ICC physically consists of two 25-pin connector cables known as ICC-A and ICC-B. In a single-carrier cabinet, the ICC physically consists of three 25-pin connector cables known as ICC-A, ICC-B, and ICC-C. The ICC connects the Duplication Interface circuit packs via pin fields on the backplane. The pin fields where ICC-A and ICC-B (and ICC-C in a single-carrier cabinet) are connected are labeled on the backplane near the pin fields for the Duplication Interface circuit packs. The ICC carries leads related to maintaining a High or Critical Reliability system. Furthermore, without the ICC properly attached, the system cannot function as either a High or Critical Reliability system or as a Standard system.

The Duplication Interface circuit packs support serial links that provide for G3 MT connection, memory shadowing from Active SPE Memory to Standby SPE Memory, and communication between software on the Active SPE and the Standby SPE. Four serial links are supported:

1. The serial link from Duplication Interface A to the G3 MT.
2. The serial link from Duplication Interface A to the Maintenance/Tape Processor in carrier A.
3. The serial link from Duplication Interface A to the Maintenance/Tape Processor in carrier B.
4. The serial link from Duplication Interface A to Duplication Interface B.

 NOTE:

The Duplication Interface B circuit pack does not communicate directly with either Maintenance/Tape Processor or with the G3MT.

Duplication Interface A supports the serial channel to the G3MT that is connected to the Duplication Interface A circuit pack by a connector on the back of carrier A labeled "DOT" (Duplication Option Terminal). If the Duplication Interface A circuit pack becomes defective, and the B carrier becomes the Active SPE, the terminal can be connected to the Maintenance/Tape Processor in carrier B by connecting the terminal to the connector labeled "TERM" on the back of carrier B. If the Duplication Interface A circuit pack becomes defective and carrier A becomes the Active SPE, the terminal can be connected to the Maintenance/Tape Processor in carrier A by connecting the terminal to the connector labeled "TERM" on the back of carrier A.

Communication between software on the Active SPE and the Standby SPE is conducted via a message flow between the two Processors. The flow of messages from the Processor in carrier A to the Processor in carrier B is as

follows: Processor A to Maintenance/Tape Processor A over the serial link to Duplication Interface A over the serial link to Maintenance/Tape Processor B to Processor B. The flow in the reverse direction is exactly opposite.

The serial link between Duplication Interface A and Duplication Interface B is involved only in memory shadowing from the Active SPE to the Standby SPE as described in the ["Memory Shadowing"](#) section.

SPE Select Switches

The SPE-SELEC (SPE Select) switches are located on the TN772 Duplication Interface circuit packs and are used to hard-select the Active SPE in a high or critical reliability system. "Hard-select" means that the SPE Select switches can be moved from the AUTO position to force the current Active SPE to remain the Active SPE or to force the current Standby SPE to become the Active SPE. Hard selection of the Active SPE using the SPE Select switches overrides any attempts by the system software to switch to the Standby SPE to make it become the Active SPE.

Each switch has three positions:

- SPE-A (the left position)
- AUTO (the middle position)
- SPE-B (the right position)

To hard-select SPE A as the Active SPE, *both* SPE Select switches must be moved **one at a time** to the SPE-A position. To hard-select SPE-B as the Active SPE, *both* SPE Select switches must be moved to the SPE-B position. Any other combination of SPE Select switches leave control of the Active SPE to the system software.

Inter-Cabinet Cable

As described previously, the ICC connects the two TN772 Duplication Interface circuit packs and is a basis of support for the Duplication Interface circuit pack functionality described previously.

The ICC carries leads related to maintaining a High or Critical Reliability system. The SPE Select lead indicates which SPE is the Active SPE. The Tone-Clock Select leads indicate which Tone-Clock circuit pack is active. SPE Select switch state leads indicate the position of the SPE Select switches. Emergency Transfer leads indicate whether Emergency Transfer is on or off in the PPN cabinet. Other leads "combine" the INADS, CDR, and the Customer-Provided Alarming device channels from the two Maintenance/Tape Processors.

The ICC also carries an indication of whether memory shadowing is enabled or disabled. Information to be shadowed is sent over the serial link between

Duplication Interface B and Duplication Interface A; this serial link is carried over the ICC.

Communication between software on the Active SPE and the Standby SPE is sent over the serial link between Duplication Interface A and the Maintenance/Tape Processor in carrier B. This serial link is also carried over the ICC.

The presence of the ICC also causes ID pins on the backplane to indicate that the system is a high or critical reliability system rather than a standard reliability system.

The ICC is difficult to connect, and its proper connection is critical to the operation of the system. Refer to the [“Procedure for Installing/Replacing the Inter-Cabinet Cable”](#) section for details on how to properly connect the ICC.

Tone-Clock Circuit Pack Duplication

For more information about the Tone-Clock circuit packs see TONE-BD Maintenance Object in [Chapter 10, “Maintenance Object Repair Procedures”](#).

The TONE-BD (Tone-Clock) MO functionality is made up of the TONE-PT (Tone Generator) and the TDM-CLK (TDM Bus Clock). The Tone Generator provides all tones required by the system; the TDM Bus Clock provides synchronization for the TDM Bus and aids in monitoring and selection of SYNC (Synchronization) references.

Each High or Critical Reliability system provides two Tone-Clock circuit packs. In this configuration, a failed Tone-Clock circuit pack is switched off-line and an operational circuit pack is put on-line. Duplication Interface A selects the Active Tone-Clock circuit pack by driving the Tone-Clock Select lead. The selection of the Active Tone-Clock circuit pack is independent of the selection of the Active SPE.

Time Division Multiplexing Bus Duplication

The TDM Bus is composed of two separate, independent buses called bus A and bus B. The first five time slots of both buses are reserved for communication between the SPE and port circuit packs. These time slots are known as the control channel. The control channel is a vital component and must be operational for the system to provide meaningful customer voice and data services. In addition to the control channel time slots, several other time slots are reserved for system use. These additional time slots are for the standard tones. The standard tones include the dial tone and the touch tones.

The ability to move the control channel and tones from a defective TDM Bus to an operational TDM Bus is a key component of a highly-available system. The system can detect transmission errors on the control channel, errors can be diagnosed, and corrective actions can be taken when necessary. If a bus is found to be defective, it is taken out-of-service. All existing calls on the

out-of-service bus are maintained, but no new calls are assigned to the out-of-service bus.

In addition to the system software's ability to detect a defective bus and perform a TDM Bus switch, the user also has the ability to specify if and when a scheduled control channel switch is to be performed.

Packet Bus Redundancy

The Packet Bus is used to provide ISDN-BRI signaling via the TN778 Packet Control circuit pack. The Packet Bus is not physically duplicated in the same way that the TDM Bus is duplicated. However, there are several spare leads on the Packet Bus itself that are not normally used. In a High or Critical Reliability system that is using the Packet Bus, a TN771 Maintenance/Test circuit pack is provided for each port network. The Maintenance/Test circuit pack has the ability to test the Packet Bus and discover shorted or open leads on the Packet Bus. When such a fault is discovered, the Maintenance/Test circuit pack sends a message to each circuit pack that uses the Packet Bus, instructing that circuit pack to use one of the spare leads in place of the defective lead.

The Maintenance/Test circuit pack can recover up to three Packet Bus lead failures by this mechanism. This provides high availability by decreasing the chance of a blocking Packet Bus fault by two orders of magnitude.

The Maintenance/Test circuit pack has other capabilities, primarily with respect to ISDN-PRI Test Call features. Because of these other capabilities, the Maintenance/Test circuit pack is available as an option in Standard Reliability systems or in High and Critical Reliability systems that are not using the Packet Bus. In such systems, the Packet Bus redundancy capabilities of the Maintenance/Test circuit pack are NOT enabled.

Duplication Concepts

High and critical reliability systems employ several concepts of duplication. These are described in the following sections.

Memory Shadowing

Most of the time the Standby SPE is in a mode known as Standby Mode (see ["SPE Modes"](#) section) in which it is ready to assume the role of the Active SPE. To be ready to assume the role of the Active SPE, PR-MEM Release 5vs/si and later must be an up-to-date reflection of Active SPE Memory. This is accomplished by the memory shadowing mechanism.

The SHDW-CIR (Common Shadow Circuitry) on the Active SPE TN772 DUPINT (Duplication Interface) detects all memory writes that the Active SPE PROCR (Processor) makes to Active SPE Memory. The Active SPE Common Shadow

Circuitry sends this information to the Common Shadow Circuitry on the Standby SPE Duplication Interface via the ICC. The Common Shadow Circuitry on the Standby SPE Duplication Interface then writes the data to Standby SPE Memory. This logical connection between Active SPE Memory and Standby SPE Memory is known as the SHDW-LNK (Memory Shadowing Link).

Although most of the components making up the Memory Shadowing Link (that is, Active SPE Memory, both sets of Common Shadow Circuitry, and Standby SPE Memory) are tested and maintained individually, the integrity of the entire logical connection is also tested and maintained to make sure that the shadowing mechanism is functional and that Standby SPE Memory is the same as Active SPE Memory. Therefore, this testing is done under the guise of the Memory Shadowing Link.

SPE Modes

As described earlier, the Active SPE is the SPE that is currently responsible for all call processing, administration, and maintenance activities being performed by the switch. The Active SPE is always in Active Mode.

The role of the Standby SPE is to be ready to take over as the Active SPE in the event that the current Active SPE fails. The Standby SPE does not perform Call Processing or Administration activities. It does perform Maintenance activity, but this is carried out completely under the direction of the Active SPE in order to monitor and maintain the health of the Standby SPE.

The Standby SPE is always in one of three modes: Standby, Maintenance, Busout, or Down. Usually the Standby SPE is in Standby Mode. In this mode, the SW-CTL (Switch Control) on the Standby SPE Network Control circuit pack is isolated from the TDM Bus so that it does not attempt to control the bus and interfere with the Switch Control on the Active SPE Network Control circuit pack. Similarly, the Standby SPE Packet Control circuit pack is isolated from the Packet Bus so that it does not attempt to control the Packet bus, and thus interfere with the Active SPE Packet Control circuit pack. The Standby SPE PROCR (Processor) is held in a reset state so that it does not run software. Finally, Standby SPE is being shadowed into from Active SPE Memory—meaning that Standby SPE Memory is updated to reflect every change in Active SPE Memory (for example, calls and administration changes). In Standby Mode, the Standby SPE is available to assume the role of the Active SPE.

In certain circumstances, the Standby SPE is put into Maintenance Mode by the Active SPE. In this mode, the Standby SPE is still isolated from the TDM and Packet Buses, but is no longer having its Memory shadowed into; its Processor is no longer held in a reset state. In Maintenance Mode, the Standby SPE accepts maintenance activity requests from the Active SPE to perform testing on Standby SPE components. For many of the requested activities, system software on the Standby SPE is brought up to conduct the activity. Translation saves and announcement saves may be performed on the Standby SPE when it is in Maintenance Mode. While in Maintenance Mode, the Standby SPE is not as

readily available to assume the role of the Active SPE, but may do so depending on the severity of the Active SPE fault(s).

In Busyout Mode, the Standby SPE is busied out by the *busyout SPE-standby* command. Only system technician-requested activities are carried out on the Standby SPE until a *release SPE-standby* command is executed. Refer to the **status system** command in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#) for information concerning Standby Modes. Whenever the Standby SPE is returned to Standby Mode from Maintenance Mode, its Memory is refreshed.

 NOTE:

Verify that the Standby SPE is functional (no duplication alarms exist and the SPE has returned to the Standby Mode) by running the **status system 1** command. If the standby SPE is in the maint/idle mode with no standby alarms, use the **standby refresh** command to put the standby SPE into the standby mode. Verify the results by using the **status system 1** command. For more information about the **status system** command see [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

 NOTE:

The system software automatically returns the Standby SPE from Maintenance Mode to Standby Mode at the completion of any maintenance activity. However, it is also possible to force the Standby SPE to return to Standby Mode by issuing the **refresh spe-standby** command from the G3MT terminal. The **refresh spe-standby** command preempts Standby SPE Maintenance Mode except that of entering maintenance mode. See the ["System Technician Commands for High and Critical Reliability Systems"](#) section for a description of the **refresh spe-standby** command.

This means that all of Active SPE DRAM Memory is shadowed over into Standby SPE Memory. The refresh is necessary because, while in Maintenance Mode, memory shadowing to the Standby SPE is disabled, and Standby SPE Memory is not updated to reflect changes in Active SPE Memory. After the refresh, Standby SPE Memory is again an up-to-date reflection of Active SPE Memory.

The Standby SPE goes into Down Mode when certain error conditions are detected. These error conditions are described in detail in the "Hardware Error Log Entries and Test to Clear Values" section of STBY-SPE (Standby SPE) Maintenance documentation in [Chapter 10, "Maintenance Object Repair Procedures"](#). Once the error condition(s) that caused the Standby SPE to go into Down Mode is (are) corrected, the Standby SPE is first put into Maintenance Mode to conduct testing on Standby SPE components and is then returned to Standby Mode.

The current mode of the Standby SPE can be determined by issuing the **status system** command.

SPE-Interchanges

The process by which the Standby SPE takes over for the Active SPE is referred to as an SPE-interchange. There are six conditions under which an SPE-interchange is initiated:

- Upgrade Software

Issuing the **upgrade software** command to upgrade the software on a High or Critical Reliability system reboots the Standby SPE from the standby translation card and then invokes an SPE-interchange so that the system is now running on the new software.

- System Technician Command

Issuing the **reset system interchange** command on the G3MT terminal causes an SPE-interchange to be initiated.

- Alarm Condition

If a Major or Minor alarm is activated on any circuit pack, an SPE-interchange is initiated, provided the health of the Standby SPE is better than that of the Active SPE. [Table 6-1](#) lists the MOs, the alarm levels, the level of SPE-interchange initiated, and the severity given to the alarm for all MOs that can cause software requested SPE-interchanges. The health of an SPE is based upon the single most severe alarm active within that SPE. The higher the severity level, the more severe the problem. The restart level of the interchange also depends on the single most severe alarm within the active SPE. Hot Restarts occur only when the Standby SPE is in standby mode. For example, the active SPE has a MAJOR SHDW-CIR and a MINOR DATA-BD alarm, and the standby SPE has a MAJOR TAPE alarm. In this case, the severity level of the active is 60, the severity level of the standby is 65, and no SPE-interchange would occur.

- SPE Select Switches

An SPE-interchange can be initiated by moving both SPE Select Switches, **one at a time**, to the position that selects the Standby SPE for Active Mode. The SPE Select Switches were described earlier in this chapter.

- Scheduled Maintenance

An SPE-interchange can be requested as a part of scheduled maintenance. This mechanism is used to exercise both SPEs. An SPE-interchange can be requested as part of scheduled maintenance by issuing the **change system-parameters maintenance** command and updating the form.

- Processor Insanity

Duplication Interface A (DUPINT, TN772) periodically audits the sanity of each of the Processor circuit packs. If the Active SPE does not respond to the sanity audit, Duplication Interface A initiates an SPE-interchange.

Table 6-1. Software-Requested Interchanges Caused by Alarm Conditions

Maintenance Object	Alarm Level	On/Off Board	Fault Severity Level	Restart Level
STBY-SPE	WARNING	OFF	120	None
MEM-BD	MAJOR or MINOR	ON	110	Hot or Warm ¹
MEMORY	MAJOR or MINOR	ON	110	Hot or Warm ¹
STBY-SPE	MAJOR	ON	100	None
PROCR	MAJOR	ON	70	Hot or Warm ¹
SW-CTL	MAJOR	ON	65	Cold 2
MEM-CARD	MAJOR	OFF	65	Cold 1
12V-PWR	MINOR	ON	65	Hot
DUPINT	MAJOR	ON	61	Hot
CARR-POW	MAJOR	ON	61	Cold 2
SHDW-CIR	MAJOR	ON or OFF	60	Warm
SHDW-LINK	MAJOR	ON	60	Warm
SW-CTL	MINOR	ON	40	Hot
PR-MAINT	MINOR	ON	30	Hot
PI-BD	MAJOR or MINOR	ON	20	Hot
PKT-CTRL	MAJOR	ON or OFF	20	Hot
PKT-CTRL	MINOR	ON or OFF	15	Hot
PI-PT	MAJOR	ON	15	Hot
DATA-CHL	MINOR	ON	15	Hot
DATA-CON	MINOR	ON	15	Hot
DATA-BD	MINOR	ON	15	Hot
CARD-MEM	MINOR	ON or OFF	10	Hot
PR-MAINT	MINOR	OFF	8	Hot

1. If the Standby SPE is in Standby mode when the alarm occurs, a Hot SPE-Interchange occurs. If the Standby is in Maintenance mode when the alarm occurs, however, a Warm SPE-Interchange rather than a Hot SPE-Interchange occurs.

Regardless of the condition that initiates an SPE-interchange, the G3MT is always logged off as a result of the SPE-interchange. The G3MT is available to log into after the SPE-interchange is complete and the “login” prompt is displayed.

System Technician Commands for High and Critical Reliability Systems

The following system technician commands support high and critical reliability systems. Complete descriptions of these commands are found in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

Commands for SPE Duplication

- The **busyout SPE-standby** command stops all background maintenance activities on the Standby SPE, and it doubles memory shadowing.
- The **release SPE-standby** command refreshes the Standby SPE, and it allows all background standby maintenance activities to continue.
- The **status system** command displays the status of the Active SPE and the Standby SPE (among other information).

➤ NOTE:

Verify that the Standby SPE is functional (no duplication alarms exist and the SPE has returned to the Standby Mode) by running the **status system 1** command. If the standby SPE is in the maint/idle mode with no standby alarms, use the **standby refresh** command to put the standby SPE into the standby mode. Verify the results by using the **status system 1** command. For more information about the **status system** command see [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

- The **status mem-card [1] a|b** command displays the status of the Active SPE Memory Card or the status of the Standby SPE Memory Card.
- The **test processor [1] a | b [short | long]** command tests the specified Processor circuit pack.
- The **test memory [1] a | b [short | long]** command tests the specified on-circuit pack memory with an optional Memory Expansion circuit pack.
- The **test card-mem [1] a | b [short | long]** command tests either the Active SPE Memory Card or the Standby SPE Memory Card.
- The **test network-control [1] a | b [short | long]** command tests the specified TN777B Network Control circuit pack and the Memory Card.
- The **test packet-control [1] a | b [short | long]** command tests the specified TN778 Packet Control circuit pack.
- The **test interface [1] a1 | b1 [short | long]** command tests the specified first TN765 Processor Interface circuit pack.
- The **test interface [1] a2 | b2 [short | long]** command tests the specified second TN765 Processor Interface circuit pack.

- The **test duplication-interface [1] a | b [short | long]** command tests the specified TN772 Duplication Interface circuit pack.
- The **test shadow-link** command tests the SHDW-LINK (Memory Shadowing Link). Refer to “MEM-BD” in [Chapter 10, “Maintenance Object Repair Procedures”](#) for a detailed description of this command.
- The **set vector <level> [spe-active | spe-standby | spe-maint]** command requests that a core dump be taken when a system restart of level <level> occurs.
- The **reset system interchange** command requests an SPE-interchange.
- The **test spe-standby [short | long]** command tests the Processor, Memory, Network Control, Processor Interface, Duplication Interface, and translation card circuit packs in the control carrier containing the Standby SPE. Refer to “STBY-SPE” in [Chapter 10, “Maintenance Object Repair Procedures”](#) for a detailed description of this command.
- The **refresh spe-standby** puts the Standby SPE into Standby mode.

**CAUTION:**

Because of the power of the “refresh spe-standby” command, its full impact is described here so that it is clearly understood.

The **refresh spe-standby** command is used to immediately put the Standby SPE into Standby Mode. The command conducts the same activities regardless of whether the Standby SPE is already in Standby Mode or whether it is in Maintenance Mode. When this command is issued, most Standby SPE maintenance activity that is currently in progress is preempted, the Standby SPE Processor is held reset, and the Standby SPE Memory is refreshed (that is, all of Active SPE DRAM Memory is shadowed to Standby SPE Memory). Recall that the refresh is necessary because, while the Standby SPE is in Maintenance Mode, memory shadowing is disabled. When the Standby SPE is returned to Standby Mode, its Memory must be brought up-to-date with Active SPE Memory. If the system was trying to enter Maintenance Mode, the **refresh spe-standby** command aborts with the message, “Cannot interrupt Standby SPE while entering maintenance mode; please try later.”

**WARNING:**

Because of its power to preempt Standby SPE maintenance activities, the “refresh spe-standby” command should be used judiciously. If the Standby SPE is in Maintenance Mode when the “refresh spe-standby” command is issued, the maintenance activity that is being conducted by the Standby SPE is immediately terminated.

The following side-effects may occur:

- Testing of the Standby SPE components that are the target of the maintenance activity may not have completed. Depending on the maintenance activity and the point at which it is terminated, tests that

detect faults and/or lack of faults on those Standby SPE components may not have had the opportunity to run. Accordingly, alarms are not raised or retired on the components.

- If the maintenance activity is scheduled maintenance, and if the **refresh spe-standby** command is issued before a scheduled translation save is performed, the translation save is not done, and the translation data on both the Active SPE and Standby SPE tapes or memory cards do not reflect changes made since the last translation save.

In general, after a **refresh spe-standby** command has been used and the user has finished working with the system, the **test spe-standby long** command should be issued if the **refresh spe-standby** command preempted a Standby SPE maintenance activity.

Additionally, if the **refresh spe-standby** command was used in the time frame in which scheduled maintenance with a translation save was to have been conducted, the **save translation** command should be issued to ensure that the current translation data has been written to the Active SPE and Standby SPE tapes or Memory Cards. When using the **refresh spe-standby** command to preempt Standby SPE maintenance activities, it may be necessary to issue the **refresh spe-standby** command multiple times to preempt all Standby SPE maintenance activity. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled “standby” on the status system form, wait 20 minutes. This does not include cases where the command completes with the G3MT terminal message “Refresh not successful; use ‘display errors’ to check for STBY-SPE errors” or “Cannot interrupt Standby SPE while entering maintenance mode; please try later.” Issue the **refresh spe-standby** command once more.

Commands for TDM Bus Duplication

- The **status system** command displays the bus on which the control channel and tones currently reside (among other information).
- The **test tdm port-network [1 | 2 | 3] [short | long]** command tests both TDM Buses.
- The **set tdm port-network [1 | 2 | 3] a | b [override]** command moves the control channel and dedicated tones to the specified TDM Bus.
- The **busyout tdm port-network [1 | 2 | 3] bus a | b** command places the specified bus in a maintenance busy state.
- The **release tdm port-network [1 | 2 | 3] bus a | b** command places a busied-out bus back in service.

Commands for Packet Bus Redundancy

- The **status system** command displays the status of the Packet Bus, and the number of faulty and open leads that the Maintenance/Test circuit pack has found.
- The **test pkt port-network [1 | 2 | 3]** command tests the Packet Bus.

Commands for Tone-Clock Circuit Pack Duplication

- The **status system** command displays the Tone-Clock circuit pack that is currently supplying tones and clocks (among other information).
- The **test tone-clock [1 | 2 | 3] a | b [short | long]** command tests the specified TN768 Tone-Clock circuit pack.
- The **set tone-clock [1 | 2 | 3] a | b [override]** command makes the specified Tone-Clock circuit pack active.
- The **busyout tone-clock [1 | 2 | 3] a | b** command places the specified Tone-Clock circuit pack in the maintenance busy state.

 **NOTE:**
This cannot be the one that is currently active.

- The **release tone-clock [1 | 2 | 3] a | b** command removes the specified Tone-Clock circuit pack from the maintenance busy state.

Processor Complex Circuit Pack LED Strategies

The LEDs on the circuit packs in the two SPEs have the following meanings:

- Processor Circuit Pack

Yellow	Green	Red	Meaning
On	Off	-	Active mode
On	On	-	Active mode: Maintenance running
Off	On	-	Maintenance mode; Memory not refreshed
Off	Off	-	Maintenance mode; Memory refreshed
-	-	On	Fault on Processor circuit pack

NOTE:

In addition to the standard LEDs, the Processor circuit pack has the red major and minor alarm LEDs, an amber warning LED, a green ack LED, and a red Emergency Transfer LED.

- Duplication Interface Circuit Pack (PICP)(B carrier) (TN772)::

Yellow	Green	Red	Meaning
On	-	-	SPC in active mode
	On	-	Maintenance running on PICP
-	-	On	Fault on PICP

- Duplication Interface Circuit Pack (DICP)(A carrier) (TN772):

Yellow	Green	Red	Meaning
On	-	-	SPC in active mode, or A carrier Tone-Clock circuit pack active
	On	-	Maintenance running on DICP
-	-	On	Fault on DICP

Each Duplication Interface circuit pack has another red LED associated with the SPE Select Switch. The purpose of the red switch LED is to serve as a reminder that an SPE is being forced to be the Active SPE and, therefore, the system is not duplicated. Both SPE Select Switch LEDs (one on each Duplication Interface circuit pack) are on when an SPE is being forced to be the Active SPE by the consistent positions of the two SPE Select Switches. Both LEDs are extinguished when the SPE Select Switch positions are inconsistent or when both SPE Select Switches are in the position. In the latter two cases, the Active SPE is automatically selected by the system software.

- Processor Interface Circuit Pack (TN765):

Yellow	Green	Red	Meaning
On	-	-	Link terminated at PICP
	On	-	Maintenance running on PICP
-	-	On	Fault on PICP

- Network Control Circuit Pack (TN777B):

Yellow	Green	Red	Meaning
On	-	-	Link terminated at NCCP
	On	-	Maintenance running on NCCP
-	-	On	Fault on NCCP

There is also an yellow LED (below Memory Card slot). When ON, the Memory Card is in use.

- Packet Control Circuit Pack(PCCP)(TN778)

Yellow	Green	Red	Meaning
On	-	-	Link terminated at PCCP
	On	-	Maintenance running on PCCP
-	-	On	Fault on PCCP

- Tone-Clock Circuit Pack:

NOTE:

For information on the standard amber/green/red LEDs see TONE-BD Maintenance Object in [Chapter 10, "Maintenance Object Repair Procedures"](#).

Repair Procedures for High and Critical Reliability

This section describes the procedure for installing or replacing Standby SPE circuit packs. These circuit packs are:

- Processor Circuit Pack (TN790)
- Memory Expansion Board (CPP1)
- Network Control Circuit Pack (TN777[B])
- Packet Control circuit pack (TN778)
- Processor Interface circuit pack(s) (TN765)
- Duplication Interface circuit pack (TN772).

This procedure does **not apply** to the TN768 or TN780 Tone-Clock circuit pack. Refer to 'TONE-BD", "TONE-PT", or "TDM-CLK" in [Chapter 10, "Maintenance](#)

[Object Repair Procedures](#)" for the procedure to replace the Tone-Clock circuit pack.

CAUTION:

When circuit packs in the Active SPE are to be replaced, this section provides procedures for performing an SPE-interchange to place the circuit packs in the Standby SPE mode. SPE circuit packs should never be replaced while they are located in the Active SPE.

Use this section when:

1. Defective (that is, alarmed) Active or Standby SPE circuit packs are to be replaced. The procedure begins at the ["Replacing Defective SPE Circuit Packs"](#) section. Ignore the ["Upgrading SPE Circuit Packs"](#) section, as it does **not apply** to replacing defective Standby SPE circuit packs.
2. Healthy Standby SPE circuit packs are to be upgraded. The procedure begins at the ["Upgrading SPE Circuit Packs"](#) section. Ignore the ["Replacing Defective SPE Circuit Packs"](#) as it does **not apply** to upgrading Standby SPE circuit packs.

The ["Circuit Pack Replacement Procedure"](#) and ["Additional Tests for Replaced DATA-CHL, PKT-CTRL, and PROCR Circuit Packs"](#) sections apply to both situations but should be referred to only **after** reading the appropriate sections as instructed previously.

Replacing Defective SPE Circuit Packs

Determine that software is running by looking at the G3MT and verifying that it does not have either the "SPE DOWN MODE" or the "Duplication Interface - Processing Element Communication Down" message displayed.

Software Not Running

If system software is not running or if it stops running at any point during this procedure, the suggested order of Processor Complex circuit packs to replace in an attempt to fix the SPE down problem is:

- Processor Circuit Pack (TN790)
- Network Control Circuit Pack (TN777[B])
- Packet Control circuit pack (TN778)
- Duplication Interface circuit pack (TN772)
- Processor Interface circuit pack (TN765)

Software Running

If system software is running, determine which SPE is the Standby SPE by issuing the **status system** command from the G3MT terminal. Look at the SPE and MODE fields in the upper left corner of the form to determine which SPE (A or B) is the Active SPE; it is labeled as "active." The other SPE is the Standby SPE and is labeled as either "standby," "maint," or "down."

Follow the "Circuit Pack Replacement Procedure" described later for each Standby SPE circuit pack to be replaced. Continue with this procedure as follows.

1. If alarms are against the Active SHDW-CIR, Active DUPINT, or SHDW-LNK, replace the Duplication Interface circuit pack. Proceed to the ["Handling SHDW-CIR and SHDW-LNK Alarms in the Active SPE"](#) or ["Handling DUPINT Alarms in the Active SPE"](#) sections as applicable.
2. If these sections do not need to be referenced, proceed to the ["Circuit Pack Replacement Procedure"](#) section.

The rest of this section describes how the system behaves when there are faulty circuit packs in the SPEs and is meant to be informative rather than part of the general procedure of replacing SPE circuit packs.

NOTE:

When circuit packs **other than the Duplication Interface circuit pack in the Active SPE** are defective, the SPE containing the more severely defective circuit packs is usually in the Standby SPE.

Handling SHDW-CIR and SHDW-LNK Alarms in the Active SPE

Check for the existence of SHDW-CIR alarms against the Active SPE Duplication Interface circuit pack or SHDW-LNK alarms. If there are Active SPE SHDW-CIR or SHDW-LNK alarms, inform the customer that a COLD 2 restart of the system is needed and determine a time at which to restart may be. At that time, complete the following steps:

1. Make sure that the tape (memory card) in the Active SPE tape unit (memory card slot) has the most current translations. If it does not, issue the **save translations spe-active** command to put the most current translations on it.
2. Exchange the tapes (memory cards) in the Active SPE and Standby SPE so that the Standby SPE tape unit (memory card slot) contains the tape (memory card) from the previous step.
3. For a 386 system, if the Standby SPE is not in standby mode, issue the **refresh spe-standby** command to put it into standby mode if possible (see the previous Note). If the Standby SPE was successfully put into standby mode, then issue the **reset system interchange** command to

cause a PEI. If the refresh or system interchange are unsuccessful, then use the SPE select switches to hard select the Standby SPE (this will result in a COLD 2 restart of the system).

4. If the **upgrade software (reset system interchange)** command is successful, an SPE-interchange results in the new Active SPE performing a COLD 2 (HOT) restart. Follow the "Circuit Pack Replacement Procedure" described later. If the **upgrade software** command failed, determine why the failure occurred, resolve the problem, and repeat this entire procedure.

Handling DUPINT Alarms in the Active SPE

Check for the existence of DUPINT alarms against the Active SPE Duplication Interface circuit pack. If there are Active SPE DUPINT alarms, inform the customer that a reboot of the system may be required and determine a time at which a reboot may be done. At that time, complete the following steps:

1. Make sure that the translation card in the Active SPE has the most current translations. If it does not, issue **save translations spe-active** to put the most current translations on it.
2. Exchange the translation cards in the Active SPE and Standby SPE so that the Standby SPE contains the card with the most current translations.
3. Throw the SPE Select Switches on the TN772 Duplication Interface circuit packs to force an SPE-interchange so that the current Standby SPE becomes the new Active SPE. If SPE B is currently the Standby SPE, throw both SPE Select Switches to the right. If SPE A is currently the Standby SPE, throw both SPE Select Switches to the left.

If the Duplication Interface circuit pack actually severed the Memory Shadowing Link resulting in corruption of Standby SPE Memory, the SPE-interchange results in the new Active SPE performing a Reboot. However, if the defect in the Duplication Interface circuit pack did not sever the Memory Shadowing Link, the SPE-interchange results in the new Active SPE performing a Warm Start instead.

4. After the SPE-interchange is complete, log into the terminal. Follow the "Circuit Pack Replacement Procedure" described later **for each circuit pack to be replaced in the new Standby SPE.**

Upgrading SPE Circuit Packs

Determine which SPE is the Standby SPE by issuing the **status system** command. Look at the SPE and MODE fields in the upper left corner of the form. The Active SPE; it is labeled as "active." The other SPE is the Standby SPE and is labeled as either "standby," "maint," or "down."

Follow the "[Circuit Pack Replacement Procedure](#)" described later *for each Standby SPE circuit pack to be upgraded.*

When all Standby SPE circuit packs have been upgraded, force the Active SPE to become the Standby SPE as follows:

1. Issue the **status system** command from the terminal. Look at the SPE and MODE fields in the upper left corner of the form to determine the status of the Standby SPE. Recall that the Standby SPE is labeled as either “standby,” “maint,” or “down.”
2. If the Standby SPE is labeled as “maint,” continue issuing the **refresh spe-standby** command followed by the **status system** command until the Standby SPE is labeled “standby.”

⇒ NOTE:

It may be necessary to issue the **refresh spe-standby** command multiple times to preempt all Standby SPE maintenance activity. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled “standby” on the status system form, wait 20 minutes. Issue the **refresh spe-standby** command once more.

3. If the Standby SPE is labeled “standby,” issue the **reset system interchange** command from the G3MT. After the SPE-interchange is complete, log into the terminal, issue the **status system** command, and verify that the SPEs have reversed roles.
4. Then, follow the “Circuit Pack Replacement Procedure” **for each circuit pack to be upgraded in the new Standby SPE.**

Circuit Pack Replacement Procedure

This procedure **does not** apply to the TN768 Tone-Clock circuit pack. Please refer to “TONE-BD”, “TONE-PT”, or “TDM-CLK” in [Chapter 10, “Maintenance Object Repair Procedures”](#) for the procedure to replace the Tone-Clock circuit pack.

⇒ NOTE:

See the flowchart of the procedure for installing or replacing Standby SPE Circuit Packs In Duplication Option Systems at the end of this section, for use as a circuit pack replacement maintenance aid.

The following procedure involves throwing the SPE Select Switches to hard-select the current Active SPE. After completing the circuit pack replacement procedure, verify that the SPE Select Switches have been returned to the AUTO position both by noting their position and by noting that the SPE Select Switch LEDs on the TN772 Duplication Interface circuit packs are not on.

1. Throw the SPE Select Switches, **one at a time**, to force selection of the current Active SPE. If SPE B is currently the Active SPE, throw both SPE Select Switches, **one at a time**, to the right. If SPE A is currently the Active SPE, throw both SPE Select Switches, **one at a time**, to the left. Throwing the SPE Select Switches automatically disables shadowing.

⇒ **NOTE:**

Do not remove power before proceeding with step 2. All PPN Control Carriers used in High or Critical Reliability Systems (A slot for the Duplication Interface circuit pack identifies these carriers.) have staggered pins to support the hot plug-in of circuit packs.

2. Unseat the Standby SPE Processor circuit pack. (It is not necessary to entirely remove the Standby SPE Processor circuit pack from its slot.)
3. If the circuit pack to be replaced is the TN772 Duplication Interface in the A carrier, continue with this step. Otherwise, proceed to Step 4.

Issue the **status system** command from the terminal, and check the status of the Tone-Clock in the 1B carrier:

- a. If the SERVICE STATE field indicates that the 1B carrier Tone-Clock is "in" (that is, in service) and the SYSTEM CLOCK and SYSTEM TONES fields indicate that it is "active," proceed to Step 4.
- b. If the SERVICE STATE field indicates that the 1B carrier Tone-Clock is "in" (that is, in service) but the SYSTEM CLOCK and SYSTEM TONES fields indicate that it is "standby," then check the Error Log for an active Error Type 3329 against the 1B TONE-BD by issuing the **display error** command. If this error exists, proceed to Step 4.

⇒ **NOTE:**

Error Type 3329 implies that the Tone-Clock circuit pack probably cannot provide system clocks and an attempt to set the system clocks to this circuit pack would result in a **reset system 2** of the system. When the 1A Duplication Interface circuit pack is replaced, however, the system experiences a loss of clock, and a **reset system 2** occurs.

If an active Error Type 3329 is not logged against the 1B TONE-BD, issue the **set tone-clock 1B** command from the G3MT terminal to make the 1B carrier Tone-Clock active. Verify that the switch occurs by issuing the **status system** command and checking that the SERVICE STATE, SYSTEM CLOCK and SYSTEM TONES fields are now "in" and "active." Proceed to Step 4.

⇒ **NOTE:**

If the 1B Tone-Clock circuit pack is defective the switch may have failed and a **reset system 2** may have occurred. In this case, proceed to Step 4. However, the system experiences a loss of clock and another **reset system 2** when the 1A Duplication Interface circuit pack is replaced.

- c. If the SERVICE STATE field indicates that the 1B carrier Tone-Clock is "out" (that is, out-of-service), refer to the TONE-BD (Tone-Clock circuit pack), TONE-PT (Tone Generator), and TDM-CLK (TDM Bus Clock) Maintenance documentation in [Chapter 10, "Maintenance](#)

[Object Repair Procedures](#)", to restore it to service. Proceed to Step 4 regardless of whether or not the attempt to restore the 1B Tone-Clock to service was successful.

 NOTE:

If the 1B Tone-Clock was not successfully restored to service, the system experiences a loss of clock, and a **reset system 2** when the 1A Duplication Interface circuit pack is replaced.

4. If the circuit pack to be replaced is the TN772 Duplication Interface, throw the SPE Select Switch of the replacement Duplication Interface circuit pack to the same position as the SPE Select Switch on the Duplication Interface circuit pack that was removed.

If the Standby Processor is not being replaced Install the replacement circuit pack and reinsert the Standby SPE Processor circuit pack.

- a. If the circuit pack that was replaced was the TN772 Duplication Interface in the A carrier, the G3MT terminal is logged off. Log in to the Manager I terminal and proceed to Step 7.
5. If the circuit pack to be replaced is a TN790 Standby SPE Processor circuit pack loaded with the same software as loaded in the Active Processor or is a TN770 Standby SPE Processor circuit pack, install the circuit pack and proceed to Step 7.
6. If the circuit pack to be replaced is a TN790 Standby SPE Processor circuit pack and the software is being loaded from the generic program card, continue with the following steps:

 NOTE:

The TN790 must have the same number of SIMMs as the replaced circuit pack.

- a. Insert the generic program card into the Active SPE. Issue the **list configuration software-versions** command. If the software matches and the UPDATE FILE Identifier displays **none**, continue with this procedure. *Replace the translation card in the Active SPE.*
- b. Insert the generic program card into the Standby SPE.
- c. Install the TN790 Standby Processor circuit pack. When the Standby Processor starts to initialize and detects the program card, it does a software upgrade and displays the progress of this upgrade on the terminal.
- d. When prompted, replace the program card in the Standby SPE with the translation card. The Standby SPE boots up with the translation.

 NOTE:

Perform this operation within two minutes. Otherwise the Standby SPE will boot up without translations. However, it will

recover the translations when the Active SPE enables memory shadowing to the Standby SPE.

- e. At the prompt **REPLACE TRANSLATION MEM-CARD ON <ACTIVE SPE> WITH SOFTWARE MEM-CARD**, wait 3 minutes for the Standby SPE to initialize before proceeding to next step.
 - f. Issue the **list configuration software-versions long** command to ensure that both SPEs are running identical software. Use the next step if the this command does not display the software versions, otherwise skip the next step.
 - g. Issue the **busyout spe-standby** command followed by the **release spe-standby** command to force the Standby SPE into a mode to accept the **list configuration software-versions long** command. Wait 5 minutes for the Standby SPE to initialize and issue the **status system 1st-cabinet** command. The Standby SPE failed to initialize if the Standby SPE Mode is **down**. If the Standby SPE Mode is **maint/init** or **maint/entering**, execute the **busyout spe-standby** and **release spe-standby** command up to 2 more times. If this step does not succeed, try this procedure again.
7. Issue the **status system 1st-cabinet** command. The status system form indicates the presence of MAJOR and MINOR alarms on both SPEs. If SPE alarm counts are displayed, run component tests to resolve these alarms. Allowed tests include **test spe-standby**, **test duplication-interface**, and **test shadow-link**. Use the next step if the allowed test commands are not accepted, otherwise skip the next step.

CAUTION:

If the Duplication Interface circuit pack is being tested, Test #278 fails because the SPE Select Switches are thrown.

8. Issue the **busyout spe-standby** command followed by the **release spe-standby** command to force the Standby SPE into a mode to accept the **test commands** attempted in the previous step. Wait 5 minutes for the Standby SPE to initialize and issue the **status system 1st-cabinet** command. If the Standby SPE failed to initialize if the Standby SPE Mode is **down**. If the Standby SPE Mode is **maint/init** or **maint/entering**, execute the **busyout spe-standby** and **release spe-standby** command up to 2 more times. If this step does not succeed, try this procedure again.
9. If other Standby SPE circuit packs are to be replaced, return to Step 2.
10. Move each SPE Select Switch back to the AUTO position. If any of the TN777B Network Control or the Processor circuit packs were replaced, please refer to the ["Additional Tests for Replaced DATA-CHL, PKT-CTRL, and PROCUR Circuit Packs"](#) section.

**WARNING:**

Move only one SPE Select Switch at a time. DO NOT move both switches at the same time.

**WARNING:**

If the Active SPE has alarms in it, an SPE-interchange may occur after moving each SPE Select Switch back to the AUTO position.

Maintenance activity is performed automatically on the Standby SPE after the SPE Select Switches are returned to their AUTO positions in Step 10. This can be verified by issuing the **status system** command and noting that the Standby SPE is labeled as "maint." It may take up to 5 minutes for this activity to begin. The maintenance activity itself takes from 10 to 30 minutes to complete.

**NOTE:**

The time required for the maintenance activity to finish depends on the number of TN765 Processor Interface circuit packs, the number of administered ports on the Processor Interface circuit packs, the number of administered data channels on the TN777B Network Control circuit pack, and the current load on the system.

Verify the completion of the maintenance activity by issuing the **status system 1** command and noting whether the Standby SPE is labeled as "standby."

Although not recommended at this stage of the procedure, the maintenance activity on the Standby SPE can be preempted using the **refresh spe-standby** command. To preempt the maintenance activity, continue issuing the **refresh spe-standby** command followed by **status system 1** command until the status system form shows that the Standby SPE is labeled "standby."

It may be necessary to issue the **refresh spe-standby** command multiple times to preempt all Standby SPE maintenance activity. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. Issue the **refresh spe-standby** command once more.

If the **status system 1** command continues to show SPE alarms, issue the appropriate command(s) from the G3MT terminal to test these alarmed MOs.

After Step 10, if the Active SPE contains more severely defective circuit packs than the Standby SPE, an SPE-interchange may occur. The presence of alarms in the Active and Standby SPE can be verified by issuing the **status system** command. The status system form indicates the presence of MAJOR and MINOR alarms on both SPEs. If the Active SPE has alarms in it, an SPE-interchange may occur. The occurrence of the SPE-interchange can be verified by issuing the **status system** command to determine which SPE is now the Active SPE.

Additional Tests for Replaced DATA-CHL, PKT-CTRL, and PROCR Circuit Packs

After **all** affected circuit packs have been replaced, if the replaced circuit packs include the TN777B Network Control circuit pack(s), the TN778 Packet Control circuit pack(s), or the Processor circuit pack(s), additional testing is required to ensure that the new circuit packs are healthy. This testing must be done on these circuit packs when they are located in the Active SPE. Issue the **status system** command to determine which SPE is currently the Active SPE and determine the SPE, Active or Standby, in which each replaced Network Control, Packet Control, and/or Processor circuit pack resides.

If any of the replaced circuit packs are located in the Active SPE, test it by issuing the **test network-control [a | b]**, **test packet-control [a | b]**, or **test processor [a | b]** command, as appropriate. If any tests fail or abort, refer to the SW-CTL (Switch Control), DATA-CHL (Network Control Data Channel), PKT-CTRL (Packet Control Circuit Pack, DATA-BD (Network Control Circuit Pack), or PROCR, and PR-MAINT (Maintenance/Tape Processor) Maintenance documentation in [Chapter 10, "Maintenance Object Repair Procedures"](#), as appropriate.

If any of these circuit packs are located in the Standby SPE, force the Standby SPE to become the Active SPE as described in "Upgrading SPE Circuit Packs." However, before the Standby SPE is made to become the Active SPE, the replaced circuit pack should first be tested while on the Standby SPE. Then, test these circuit packs (that are now located in the Active SPE) by issuing the **test network-control [a | b]**, **test packet-control [a | b]**, or **test processor [a | b]** command, as appropriate. If any tests fail or abort, refer to the SW-CTL (Switch Control), DATA-CHL (Network Control Data Channel), DATA-BD (Network Control Circuit Pack), PKT-CTRL (Packet Control Circuit Pack), or PROCR, and PR-MAINT (Maintenance/Tape Processor) Maintenance documentation in [Chapter 10, "Maintenance Object Repair Procedures"](#), as appropriate.

WARNING:

Before leaving the system, verify that the SPE Select Switches have been returned to their proper position. The switches should be in the AUTO position and the SPE Select Switch LEDs should be off on both the TN772 Duplication Interface circuit packs.

See the following flowchart, [Figure 6-1](#), [Figure 6-2](#) and [Figure 6-3](#), for the procedure for installing or replacing Standby SPE Circuit Packs in Duplication Option System.

Figure 6-1. Page 1 Procedure for Replacing Standby SPE Circuit Packs

Figure 6-2. Page 2 Procedure for Replacing Standby SPE Circuit Packs

Figure 6-3. Page 3 Procedure for Replacing Standby SPE Circuit Packs

Procedure for Installing/Replacing the Inter-Cabinet Cable

The Inter-Cabinet Cables (ICCs) are physically located on the back of the cabinet behind the panels and between the A control cabinet and the B control cabinet. The panels must first be opened to see the ICCs.

WARNING:

Damage can be done to the Inter-Cabinet Cables during removal or installation. Follow the guidelines listed below to minimize the possibility of damage to the cables and later need of replacement.

To remove ICC-A, ICC-B, or ICC-C:

1. Remove power from the system. Refer to the [“Removing Power”](#) section in [Chapter 5, “Routine Maintenance Procedures”](#).
2. Grasp the cable connector, not the cable itself. Attempting to remove a cable by pulling on the cable itself can damage the cable-to-connector interface.
3. Pull the cable straight out. Pulling the connector from the backplane at an angle can bend the backplane pins.
4. Push the ICC connector onto the insulated sleeves.

CAUTION:

The pins should not show through the back of this connector. If they do, they ICC may be shorted out.

The only way to check the connector-cable-connector integrity is with a continuity test.

To re-install ICC-A, ICC-B, or ICC-C:

1. Verify that the backplane pins are not bent. If any are bent, they must be straightened or replaced before continuing.
2. Align the ICC connector with the backplane pins and push partially into place.
3. Use a dental mirror and light to view the back sides of the connector. Determine that all 50 backplane pins are seated correctly in the ICC connector.
4. Push the ICC connectors fully onto the insulated sleeves. The pins should not show through the back of the connectors. If the pins show through, the ICC may be shorted out.

Blocking Standby SPE Maintenance Activities for System Testing

Sometimes it is necessary to block Standby SPE maintenance activities so that system technician commands that test Standby SPE components can be conducted without being blocked with the G3MT terminal message line "Standby SPE busy with another task; for information use 'status system'." To block Standby SPE maintenance activities, perform the steps listed below.

WARNING:

The following procedure involves throwing the SPE Select Switches to hard-select the current Active SPE. After completing the circuit pack replacement procedure, verify that the SPE Select Switches have been returned to the AUTO position both by noting their position and by noting that the SPE Select Switch LEDs on the TN772 Duplication Interface circuit packs are not on.

1. Throw the SPE Select Switches (on the TN772 Duplication Interface circuit packs) to force selection of the current Active SPE. If SPE-B is currently the Active SPE, throw both SPE Select Switches to the right. If SPE-A is currently the Active SPE, throw both SPE Select Switches to the left.
2. Issue the **status system 1st-cabinet** command from the G3MT terminal. The status system form indicates the presence of MAJOR and MINOR alarms on both SPEs. If SPE alarm counts are displayed, run component tests to resolve these alarms. Allowed tests include test spe-standby, test duplication-interface, and test shadow-link. Use the next step if the allowed test commands are not accepted, otherwise skip the next step.

CAUTION:

If the Duplication Interface circuit pack is being tested, Test #278 fails because the SPE Select Switches are thrown.

3. Issue the busyout spe-standby command followed by the release spe-standby command to force the Standby SPE into a mode to accept the **test commands** attempted in the previous step. Wait 5 minutes for the Standby SPE to initialize and issue the status system 1st-cabinet command. If the Standby SPE failed to initialize if the Standby SPE Mode is down. If the Standby SPE Mode is **maint/init** or maint/entering, execute the busyout spe-standby and release spe-standby command up to 2 more times. If this step does not succeed, try this procedure again.
4. Move each SPE Select Switch back to the AUTO position.

WARNING:

Move only one SPE Select Switch at a time. DO NOT move both switches at the same time.

Maintenance activity is performed automatically on the Standby SPE after the SPE Select Switches are returned to their AUTO positions in Step 4. This can be verified by issuing the **status system** command and noting that the Standby SPE is labeled as "maint." The maintenance activity takes from 10 to 30 minutes to complete. (The time required for the maintenance activity to complete depends upon the number of TN765 Processor Interface circuit packs, the number of administered ports on the Processor Interface circuit packs, the number of administered data channels on the TN777B Network Control circuit pack, and the current load on the system.) The completion of the maintenance activity can be verified by issuing the **status system** command and noting whether the Standby SPE is labeled as "standby."

Although not recommended at this stage of the procedure, the maintenance activity on the Standby SPE can be preempted using the **refresh spe-standby** command. To preempt the maintenance activity, continue issuing the **refresh spe-standby** command followed by **status system** command until the status system form shows that the Standby SPE is labeled "standby."

It **may** be necessary to issue the **refresh spe-standby** command multiple times to preempt all Standby SPE maintenance activity. If the **refresh spe-standby** command successfully completes five times without the Standby SPE becoming labeled "standby" on the status system form, wait 20 minutes. This **does not include** cases where the command completes with the G3MT terminal message line errors "Refresh not successful; use 'display errors' to check for STBY-SPE errors" or "Cannot interrupt Standby SPE while entering maintenance mode; please try later."

Issue the **refresh spe-standby** command once more.

6	Reliability Systems: A Maintenance Aid	
	<i>Blocking Standby SPE Maintenance Activities for System Testing</i>	

Page 6-34

LED Interpretation

7

General

The lighting and unlighting of LEDs indicates to the system user the status of various maintenance components in the system. LEDs are located on the attendant console, on all circuit packs in the switch cabinets and, optionally, on customer-designated voice terminals. The following LEDs are included in the system:

- Processor circuit pack and maintenance circuit pack LEDs
- Duplication interface circuit pack LEDs
- Attendant console LEDs
- Carrier power unit LEDs
- Power distribution unit LEDs
- Control and port circuit pack status LEDs

Processor and Maintenance Circuit Pack LEDs

The front panels of the Processor circuit pack and the Maintenance circuit pack are identical. Each has two groups of LEDs. One group indicates the status of the pack, and the other group (which includes the Major, Minor, and Warning alarms described previously) reflects maintenance conditions in the entire system (that is, the PPN and EPN cabinets). See [Figure 7-1](#).

- Red (alarm)—the system has detected a fault in this circuit pack.

⇒ NOTE:

Alarms on the PROCR, PR-MAINT, MEMORY, and PR-MEM MOs are indicated by the red LED on the Processor circuit pack.

- Green (test)—the system is running tests on this circuit pack.

⇒ NOTE:

On the Standby Processor circuit pack, green means that the Standby Switch Processing Element (SPE) is not refreshed (that is, it is in Maintenance or Down Mode).

⇒ NOTE:

On the Maintenance circuit pack, the green LED may blink very faintly once per second. This is the normal operating state of the Maintenance circuit pack. The faint blink is due to a once-per-second self-test executed by the Maintenance circuit pack.

- Yellow (busy)—this circuit pack is in use. In a high or critical reliability system, the yellow LED is always off for the Standby Processor and Memory circuit packs even when in Maint mode.
- MAJOR ALARMS (red)
- MINOR ALARMS (red)
- WRNG (warning) ALARMS (yellow)
- ACK (acknowledgment) (green)—indicates Major or Minor alarms have been reported to INADS
- EMERGENCY TRANSFER (red)—indicates emergency transfer has been invoked

⇒ NOTE:

If the AC power cord is unplugged from the control cabinet, the emergency transfer feature invokes, however the EMERGENCY TRANSFER LED (red) is not lit due to loss of AC power.

Figure 7-1. Indicators on Maintenance and Processor Circuit Packs

Duplication Interface Circuit Pack LEDs

In a High or Critical Reliability system, there are two Duplication Interface circuit packs. One is located in carrier A and one in carrier B of the PPN. Each circuit pack has two groups of LEDs. The top three have the traditional function of indicating the status of the pack. The LED located at the bottom of the faceplate directly beneath the SPE AUTO switch is labeled OVERRIDE. Under normal operating conditions, the SPE AUTO switch is in the AUTO (center) position (see [Figure 7-2](#)). This means that the system controls which SPE is active. However, there will be times (during maintenance activity, for example) when you, the technician, may choose to manually override the SPE selection function. To override system selection of the Active processor, move the SPE Select switches one at a time on *both* Duplication Interface circuit packs from the AUTO position

to either the "A" position or the "B" position. Thus, when both SPE Select switches have been moved to either "A" or "B," the OVERRIDE LED turns red and lights steadily.

NOTE:
Failure to move both SPE Select switches to the same position causes the system to retain control of processor selection.

To return control of the SPE selection to the system, return the SPE Select switches on both Duplication Interface circuit packs to the AUTO position (one at a time to avoid accidentally selecting the other SPE). The OVERRIDE LED goes dark.

Figure 7-2. Duplication Interface Circuit Pack Indicators

Attendant Console LEDs

The console has two red LEDs, labeled ALM and ACK, on the left side of the dial. The left LED lights steadily when there is a Major or Minor alarm at the switch cabinet. The right LED lights steadily if the alarm has been successfully reported to INADS. If the system is unable to report the alarm to INADS, the LED flashes; signaling the attendant to call INADS and report the alarm.

Cabinet Power Unit LEDs

For a description of Cabinet Power Unit LEDs, refer to “AC-POWER” for AC-Powered Systems and “DC-POWER” for DC-Powered Systems in [Chapter 10, “Maintenance Object Repair Procedures”](#).

Power Distribution Unit LEDs

For a description of Power Distribution LEDs, refer to “AC-POWER” for AC-Powered Systems and “DC-POWER” for DC-Powered Systems in [Chapter 10, “Maintenance Object Repair Procedures”](#).

Control and Port Circuit Pack Status LEDs

Each circuit pack has three LEDs on the front panel visible at the front of the carrier. On all circuit packs, except the TN736 Power Unit, the LEDs indicate:

1. Red (alarm) — If the circuit pack is communicating with the system, the system has detected a fault in this circuit pack. An on-board alarm for this circuit pack is displayed in the Alarm Log.

The circuit pack also lights this LED when either the circuit pack has not yet initialized communication with the system or when the circuit pack loses contact with the system and stops functioning (circuit pack is said to be “in reset”). In these cases, there may not be an alarm in the Alarm Log. To determine if the red LED is lit because the circuit pack is not in contact with the system, issue the **list configuration board PCSS** command, where PCSS refers to the slot containing this circuit pack. If the system does not detect the circuit pack, this command returns “Identifier not assigned” or “no board.”

If the circuit pack has just been inserted, the system may still be initializing the circuit pack. If, after 5 minutes, the circuit pack still has not initialized communications with the system, check the MO for any special instructions (for example, EPN Maintenance circuit pack can stop EXP-INTF circuit pack from initializing). If the MO does not provide the needed information, perform the following steps:

- Check the Error Log for TONE-BD and TDM-BUS errors. Enter **test tdm P** where P is the port network containing the relevant slot. Refer to "Restarting Nonfunctioning Port Circuit Packs" in [Chapter 10, "Maintenance Object Repair Procedures"](#) in the general description of the "TDM-BUS". Enter **test tone-clock PC**, where P is the network containing the relevant slot, and C is the carrier containing the relevant slot. Follow appropriate sections for any "TONE-BD" and "TDM-BUS" errors.
- Reseat the suspect circuit pack.

WARNING:

Reseating some circuit packs may be very destructive (for example, Control Carrier circuit packs.)

Wait 5 minutes. Then issue the **list configuration board PCSS** command. If the result indicates that the system still has not registered the circuit pack, go to next step.

- Try to insert the circuit pack into a different slot and try to insert a different circuit pack into the suspect slot (provided the maintenance documentation for this circuit pack does not warn against either of these actions).
 - If the system seems to be functioning correctly, but the circuit pack does not start communicating with the system, replace the circuit pack.
2. Green (test)—the system is running tests on this circuit pack.
 3. Yellow (busy)—indicates that the circuit pack is in use.

NOTE:

A port circuit pack also lights its red LED when it performs initialization tests (for example, when the circuit pack is initially inserted into the system). If all initialization tests pass, the red LED is turned off. If any initialization tests fail, the red LED remains lighted and the circuit pack is not placed into service.

Packet circuit packs such as the TN556 ISDN BRI-Line and TN570 Expansion Interface perform extensive initialization tests and light both the red and green LEDs during that testing.

During the various states of operation (start-up testing, normal operation, circuit failure, and so forth) circuit pack status LED indications appear as shown in [Table 7-1](#).

Table 7-1. Circuit Pack Status LEDs

Equipment Type	LED	Description
Port Circuit Packs	Red	On briefly during power up, circuit pack reseating, resetting, and system reset. Steadily on if circuit pack fails start-up test or fails while in use. Off during normal operation.
	Green	Briefly on during circuit pack testing following power up, circuit pack reseating, and system reset. On during periodic, scheduled, and system technician demanded testing. Off during normal operation.
	Yellow	On when any port in the circuit pack is in use, otherwise, off. The yellow LED on the TN771 Maintenance/Test circuit pack may blink. This has special meaning for systems using Packet Bus. Refer to "Packet Bus" for more information.
Control Circuit Packs	Red	On briefly during power up and system reset. Steadily on if circuit pack fails start-up test or fails while in use. Off during normal operation.
Control Circuit Packs <i>(continued)</i>	Green	On briefly during board testing following power up and system reset. Also on during periodic, scheduled, and system technician-demanded testing. Off during normal operation.

Continued on next page

Table 7-1. Circuit Pack Status LEDs — *Continued*

Equipment Type	LED	Description
	Yellow	Network Control ■ Lit when one of the data channels is in use ■ On the TN777B Network Control circuit pack, a fourth yellow LED with the label “Card in use” is lit when the translation card is in use. Processor ■ Lit during processor initialization. Lit steady on the Active SPE and off during normal operation on the Standby SPE. Memory. ■ Lit during system initialization (stays lit until Emergency Transfer is turned off). Lit steady on the Active SPE and off during normal operation on the Standby SPE. Packet Control ■ Lit when at least one Packet Control is in use. Packet Control LEDs do not light up (not even for the test led command) if the packet feature is not enabled on the Systems-Parameters Maintenance screen. Tone Detector/Generator ■ Slow blinking when clock is in use. Otherwise, off. Processor Interface ■ Lit when one (or more) channels (links) is in use. Otherwise, off. Duplication Interface ■ Lit steady on the Active SPE and dark during normal operation on the Standby SPE. Exception: Duplication Interface Circuit Pack A has the yellow LED lit steady if Tone/Clock Circuit Pack 1B is active, regardless of which SPE is active and which is standby.

Maintenance Commands and
Trouble-Clearing Aids

8

For Maintenance Objects and Maintenance Commands for the DEFINITY Wireless Business System (DWBS), refer to the appropriate maintenance documentation that accompanies the DWBS.

This chapter provides additional trouble-clearing information for resolving both system-alarmed and user-reported troubles. This chapter supplements the information found in [Chapter 10, "Maintenance Object Repair Procedures"](#). The information consists of using the maintenance commands as trouble-clearing aids. The maintenance commands are used to control, test, and obtain information associated with maintenance objects (MOs). The commands require the use of the administration terminal or remote Initialization and Administration System (INADS) interface (a valid login and password to perform maintenance are required).

In this chapter, the commands are first identified and organized into categories. Thereafter, each command is described individually.

busyout access-endpoint

This command is destructive.

This command busyouts a specified access endpoint.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout access- endpoint	extension	Extension number of access endpoint (per dial-plan) Examples: busyout access-endpoint 25012 busyout access-endpoint 77868	init inads craft nms	none	See below

Feature Interactions

- If there is an active call on the specified access endpoint, this command causes the call to drop.

Output

The following example shows the output for the **busyout access-endpoint 22502** command and assumes that access endpoint ports for extension 22502 are in cabinet 1, carrier C, slot 11, circuit 1 to 6. The responses display on a test-by-test basis with one line of data for each test result.

```
busyout access-endpoint 22502                                SPE A

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result  Error Code
01C1101   WAE-PORT              22502     PASS
01C1102   WAE-PORT              22502     PASS
01C1103   WAE-PORT              22502     PASS
01C1104   WAE-PORT              22502     PASS
01C1105   WAE-PORT              22502     PASS
01C1106   WAE-PORT              22502     PASS

Command Successfully Completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	Name of maintenance object (wideband access endpoint = WAE-PORT; single port access endpoint = TIE-DS1)
Alt. Name	The alternate way of identifying the maintenance object. This field contains the extension number of the access endpoint.
Result	Test result: Pass, Fail, Abort
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout board

This command puts all the ports associated with the specified access endpoint in a maintenance busy (craft busy) state. No periodic or scheduled tests are performed on the busied out access endpoint ports until they are released. When the access endpoint ports are maintenance busy, the access endpoint is removed from active service on the switch, meaning that no call processing activity can include the busied objects because terminals on the administered

ports do not receive dial-tone. Warning alarms are generated on each busied out port in the access endpoint. The **release access-endpoint** command returns all the ports associated with the specified access endpoint to operation.

**WARNING:**
This command is service disrupting and may cause extraneous alarms.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout board	location	Board address (PCSSpp) Examples: busyout board 01c11 busyout board 02c15	init inads craft	none	None

Output

The following example shows the output from the **busyout board 1c07** command, and assumes that board in cabinet 1, carrier c, slot 7 is an analog board with three administered ports. The responses display on a test-by-test basis with one line of data for each test result.

busyout board 01C07

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01C07	ANL-BD		PASS	
01C0702	ANL-LINE		PASS	
01C0701	ANL-LINE	51001	PASS	
01C0703	ANL-LINE		PASS	

Command successfully completed

Field descriptions

- Port
- Port address (cabinet-carrier-slot-circuit)
- Maintenance Name
- The name of maintenance object

Alt. Name	Alternate way to identify maintenance objects.
If the Object is The field contains	
station	extension
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
private CO line	P/xxx (where xxx = private CO line group number)
Result	Test result: Pass, Abort, or Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout cdr-link

This command busyouts a maintenance object associated with the specified call detail recording (cdr)-link.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout cdr-link	link-id	Link identifier (primary or secondary) Examples: busyout cdr-link primary busyout cdr-link secondary	init inads craft nms	Primary	None

Output

The following example shows the output from the **busyout cdr-link primary** command.

busyout cdr-link primary				SPE A
COMMAND RESULTS				
Port	Maintenance Name	Alt. Name	Result	Error Code
1	CDR-LNK		PASS	
Command successfully completed				

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit); 1 = primary, 2 = secondary link
Maintenance Name	The name of maintenance object

Alt. Name	Alternate way to identify maintenance objects.
If the Object is The field contains	
station	extension
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
private CO line	P/xxx (where xxx = private CO line group number)
Result	Test result: Pass, Abort, or Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout data-module

This command puts the specified data module in a maintenance busy state, even uninstalled data modules. No periodic or scheduled tests is performed on the busied out data module or data channel until it is released and no call processing can be executed on the data modules or over the data channels. Warning alarms are generated (error type 18) on each maintenance object busied out, so that INADS can access the state of the objects. The **release data module** command returns the specified data module (or data channel) to operation.

On a system with the duplication option, a busyout of a Network Control Data Channel (DATA-CHL) or a Processor Interface Port Data Channels (PI-PT) are preserved across SPE interchanges. The data channel extension must be released before the data channel can be brought back into service.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout data-module	extension	Extension number (per dial-plan) Example: busyout data-module 31300	init inads craft nms	None	None

Output

The following example shows the output from the **busyout data-module 300** command.

busyout data-module 300

SPE A

COMMAND RESULTS

Result	Test result: Pass, Abort, or Fail								
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.								

busyout journal-printer

This command places the maintenance object associated with a specified pms-log or wakeup-log link in a maintenance busy state. No periodic or scheduled tests are performed on the busied out maintenance object until it is released. Also, no activity occurs over the links (for example, no data is transferred to the printer) and the link drops. Warning alarms are generated (Error type 18) on each busied out maintenance object, so that INADS can access object status. The **release journal-printer** command will return the object to operation.

A link is comprised of several components. It involves a far end data module, a simulated data channel on a PKTINT board, a manager that initiates and maintains the link, and a controller/protocol that services the link. A controller/protocol is usually a transient process that exists for as long as the link is up. A link is considered up if a physical connection is established. A link can be considered to be up while no useful work can be performed over it, in this

case the link is insane and should be torn down. These links provide asynchronous data connections from the switch to peripherals.

For general information on journal printer links, refer to the description of the [“busyout pms-link”](#) command.

For information on what a journal printer is and does, refer to the description of the [“status journal-link”](#) command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout journal-printer	pms-log	Link to pms (in output, port name for pms link =1)	init inads craft nms	None	See below
	wakeup-log	Link to the wakeup logging facility (in output, port name = 0) Examples: busyout journal-printer pms-log busyout journal-printer wakeup-log			

Feature Interactions

Maintenance of a particular component on a link sometimes interferes with the maintenance of the link itself. For example, maintenance can put a link component in a busy state causing link set-up to fail. Frequent attempts at re-setup of a link may delay the recovery of a faulty component, due to the maintenance test of a component only taking place when the component is idle. Therefore, disable the attempted re-setup of a link with the busyout command and the link will remain intact. If the link is already down, the busyout command stops periodic re-setup attempts on the link.

Output

The following example shows the output for the **busyout journal-printer wakeup-log** command.

busyout journal-printer wakeup-logSPE A

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
0	JRNL-LINK		PASS	

Command successfully completed

Field descriptions

Port	Physical object port address: 0 = wakeup log, 1 = pms log
Maintenance Name	The name of the maintenance object
Alt. Name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout link

This command places maintenance objects associated with a specified link in a maintenance busy state. No periodic or scheduled tests are performed on the busied out maintenance objects until they are released. The link is marked out of service and is inaccessible to call processing. Warning alarms (error type 18) are generated on each busied out maintenance object, so that INADS can determine the state of the objects. The **release link** command reactivates the objects.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout link	link-id	Processor Interface circuit pack 1a1 or 1b1 = 1 – 4 Processor Interface circuit pack 1a2 or 1b2 = 5 – 8 Examples busyout link 1	init inads craft	none	none

Output

The following example shows the output from the **busyout link 1** command. The responses display on a test-by-test basis with one line of data for each test result.

```
busyout link 1                               SPE A

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result      Error Code
01C0301   PI-LINK              PASS

Command successfully completed
```

Field descriptions

Port	Port address represents link-id
Maintenance Name	The name of the busied out maintenance object
Alt. Name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout mis

This command places the management information system in the maintenance busy state. No periodic or scheduled maintenance is performed until it is released. When the object is busied out no call processing activity may be performed over the link. A warning alarm (error type 18) is generated on the busied out mis, so that INADS can determine its state. The command, **release mis**, reactivates the busied out mis.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout mis		Example: busyout mis	init inads craft cust rcust	None	None

Output

The following example shows the output from the **busyout mis** command. The responses display on a test-by-test basis with one line of data for each test result.

```
busyout mis                                SPE A

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result      Error Code
MIS

Command Successfully Completed
```

Field descriptions

Port	Not applicable
Maintenance Name	Name of busied out maintenance object: MIS
Alt. Name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout modem-pool

This command places specified installed and uninstalled modem pool groups or group members in the maintenance busy state. No periodic or scheduled tests are performed on the busied out modem pool groups or group members until they are released. When the object is maintenance busy it is deactivated (no call processing activity may include the busied object). A single group member can be busied out by specifying the group and member number. All members in a modem pool group can be busied out by specifying the modem pool group number. Warning alarms (error type 18) are generated on each busied out maintenance object, so that INADS can determine the state of the objects. The command, **release modem-pool**, reactivates the specified modem pool group or group member.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout modem-pool	<i>group</i> <i>member</i>	Group number = 1 – 5 Member number = 1 – 32 (a member is a pair of analog and digital line ports — two pair for integrated pool modem. Examples busyout modem-pool 1 busyout modem-pool 4/3	init inads craft	none	none

Output

busyout modem-pool 1			SPE B	
COMMAND RESULTS				
Port	Maintenance Name	Alt. Name	Result	Error Code
01C0701	MODEM-PT		PASS	
01C0703	MODEM-PT		PASS	
Command successfully completed				

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	Name of busied out maintenance object: MODEM-PT
Alt. Name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout packet-control

This command places the packet-control circuit pack in a maintenance busy state, and tears down each point-to-point signaling link that terminates on this packet-control. No periodic or scheduled test is performed on the busied out packet-control until it is released. A warning alarm (error type 18) is generated on the busied out packet-control, so that INADS can determine the state of the object. The **release packet-control** command reactivates the board and initiates recovery on all point-to-point signaling links terminated on this packet-control.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout packet-control	location	Location applies to duplicated configurations only. Location represents a carrier that contains packet-control in the system. Valid locations = 1A or 1B. Examples busyout packet-control 1A busyout packet-control 1B	init inads craft	simplex systems (optional) = cabinet 1, carrier A duplex systems = cabinet 1, carrier of choice.	See below

Feature Interactions

- In a duplicated system, the packet-control busyout of standby process complex is not allowed.
- When the packet-control in the active control complex is busied out, all connectivity across the Packet Bus is severed. Thus, all ISDN-BRI point-to-point signaling links that have been established through the active packet-control are torn down by the **busyout packet-control** command. The **release packet-control** command re-establishes all Packet Bus connectivity.

Output

The following example shows the output from the **busyout packet-control 1A** command. The responses display on a test-by-test basis with one line of data for each test result.

busyout packet-control 1A

SPE A

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
1A	PKT-CTRL		PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier)
Maintenance Name	Type of busied out maintenance object (PKT-CTRL).
Alt. Name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout pms-link

This command places all maintenance objects associated with a property management system link in the maintenance busy state. No periodic or scheduled maintenance is performed on the busied out maintenance objects until they are released. When the object is maintenance busy the object is deactivated (no call processing activity may include the busied object) and the link is dropped. Warning alarms (error type 18) are generated on each busied out maintenance object, so that INADS can determine the state of the objects. The command, **release pms link**, reactivates the busied out objects on the link.

These links provide asynchronous data connections from switches to peripherals; they are composed of a:

- Far-end data module
- Simulated data channel on a NETCON board
- Manager that initiates and maintains the link
- Controller/protocol that services the link

For information on PMS, see the description of the ["status pms-link"](#) command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout pms-link		Example: busyout pms-link	init inads craft	none	See below

Feature Interactions

Maintenance of a particular component on a link sometimes interferes with the maintenance of the link itself. For example, maintenance can put a link component in a busy state causing link set-up to fail. Frequent attempts at re-setup of a link may delay the recovery of a faulty component, due to the maintenance test of a component only taking place when the component is idle.

Therefore, disable the attempted re-setup of a link with the busyout command and the link remains intact. If the link is already down, the busyout command stops periodic re-setup attempts on the link.

Output

The following example is a display of the **busyout pms-link** command.

```
busyout pms-link                               SPE A

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result      Error Code
          PMS-LINK
Command Successfully Completed
```

Field descriptions

Port	Always blank
Maintenance Name	Name of maintenance object: PMS-LINK
Alt. Name	Not applicable.
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout port

This command places the specified port on a circuit pack in a maintenance busy state. No periodic or scheduled tests are performed on the busied out port until it is released. When the object is maintenance busy, it is deactivated (no call processing activity may include the busied object). Warning alarms (error type 18) are generated on each busied out maintenance object, so that INADS can determine the state of the objects. The command, **release port**, reactivates the administered port on a circuit pack at a specified location.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout port	location	Port location: PPsspp Examples: busyout port 01c1101 busyout port 02c1501	init inads craft	none	see below

Output

The following example is a display of the **busyout port** command.

```

busyout port 01C0701                                     SPE A
                                     COMMAND RESULTS

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Alt. Name	Alternate way to identify maintenance objects.
	If the Object is The field contains
	station extension
	trunk xxx/yyy (where xxx = trunk group number and yyy = member number)
	private CO lineP/xxx (where xxx = private CO line group number)
Maintenance Name	Type of busied out maintenance object.
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout pri-endpoint

This command places all PRI endpoint ports (B-channels) associated with the specified PRI endpoint in a maintenance busy (system technician busy) state. No periodic or scheduled tests are performed on the busied out PRI endpoint ports until they are released. When the PRI endpoint port is maintenance busy it is deactivated (no call processing activity may include the busied object). Warning alarms (error type ???) are generated on each busied out port. The command, **release pri-endpoint**, reactivates all ports (B-channels) associated with the specified PRI endpoint extension and the switch attempts to negotiate with the far-end PRI terminal adapter to reactivate each PRI endpoint port (B-channel).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout pri-endpoint	extension	PRI endpoint extension number Examples: busyout pri-endpoint 25012 busyout pri-endpoint 77868	init inads craft nms	none	If active calls resides on specified PRI endpoints, the busyout command drops the call. Once the PRI endpoint is maintenance-busy, call attempts from far-end PRI terminal adapters are denied with a cause value 17.

Output

busyout pri-endpoint 22501				SPE A
COMMAND RESULTS				
Port	Maintenance Name	Alt. Name	Result	Error Code
01B2001	PE-BCHL	22501	PASS	
01B2002	PE-BCHL	22501	PASS	
01B2003	PE-BCHL	22501	PASS	
01B2004	PE-BCHL	22501	PASS	
01B2005	PE-BCHL	22501	PASS	
01B2006	PE-BCHL	22501	PASS	
Command Successfully Completed				

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	Type of busied out maintenance object: PE-BCHL
Alt. Name	Extension number of PRI endpoint
Result	Test result: Pass, Fail, Abort
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout sp-link

This command places the system printer link into a maintenance busy state. No periodic or scheduled maintenance is performed on the busied out system printer link until it is released. Warning alarms (error type 18) are generated on

each busied out maintenance object, so that INADS can determine the state of the object. Placing the system printer link in a busyout state blocks access to the system printer. The **release sp-link** command reactivates the system printer link.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout sp-link		Examples: busyout sp-link	init inads craft	none	none

Output

busyout sp-link			SPE A	
COMMAND RESULTS				
Port	Maintenance Name	Alt. Name	Result	Error Code
	SYS-PRNT		PASS	
Command Successfully Completed				

Field descriptions

Port	Not applicable
Maintenance Name	Type of maintenance object that is busied out: SYS-PRNT
Alt. Name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout spe-standby

This command raises the Fault Severity Level of the Standby SPE (see reference 5) of the standby Switch Processing Element (SPE) by raising a Warning Off-board alarm against STBY-SPE. Because a Warning Off-board STBY-SPE alarm is defined to have the highest Fault Severity of all alarms the affect the health of an SPE (refer to the Reset System MUS), the chance that an SPE interchange will occur is diminished, but does not guarantee that an SPE interchange will not occur. Once the standby SPE is busied out, an SPE interchange occurs if the standby SPE is hard selected with the SPE Select switches or the active SPE goes into SPE down mode. This command also stops any activity currently executing on the standby SPE and disables memory shadowing to the standby SPE. Periodic and scheduled testing cannot start on the standby SPE while it is busied out. The busyout state of the standby SPE and

the STBY-SPE Warning alarm are maintained across a reset system 1 (Warm restart) and a reset system 2 (Cold 2 restart) but are removed after all other levels of restart.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout spe-standby		Examples: busyout spe-standby	init inads craft	none	See below

Feature Interactions

- When a busyout of the standby SPE is performed, the fault severity level of the standby SPE is set to the highest possible value and memory shadowing is turned off. This is done to lessen the probability that the system switches to the standby SPE. However, in some cases a “spontaneous” (hard) interchange of the SPEs may still occur.
- This command can be used as a mechanism to turn off memory shadowing of the standby SPE.
- If the standby SPE is in poor health (less than optimum), memory shadowing can not be disabled, or communication to the standby is impossible a busyout of the standby SPE are still successful.

Output

The following example is a display of the **busyout spe-standby** command.

busyout spe-standby			SPE A	
COMMAND RESULTS				
Port	Maintenance Name	Alt. Name	Result	Error Code
01B	STBY-SPE		PASS	
Command successfully completed				

Field descriptions

Port	Standby SPE cabinet and carrier location (01A or 01B)
Maintenance Name	Always STBY-SPE
Alt. Name	Always blank
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout station

This command places the installed and uninstalled administered voice terminal extension (station) in a maintenance busy state. No periodic or scheduled tests are performed on the busied out station until it is released. When the object is maintenance busy it is deactivated (no call processing activity may include the busied object). Warning alarms (error type 18) are generated on each busied out maintenance object, so that INADS can determine the state of the objects. The command, **release station**, reactivates the specified voice terminal extension.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout station	extension	Extension number (per dial-plan) Examples: busyout station 10020 busyout station 32770	init inads craft	none	none

Output

The following example is a display of the **busyout station** command.

busyout station 1002

SPE A

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01C1102	DIG-LINE		PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	Type of busied out maintenance object
Alt. Name	Alternate means to identify maintenance object: extension number
Result	Test result: Pass, Fail, Abort
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout tdm

This command places the specified tdm bus in a maintenance busy state. No periodic or scheduled tests are performed on the busied out bus until it is released. When the object is maintenance busy it is deactivated (no call processing activity may include the busied object). Warning alarms (error type 18) are generated on each busied out tdm bus, so that INADS can determine the state of the objects. The command, **release tdm**, reactivates the specified tdm bus.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout tdm	<i>pn number</i>	pn number = TDM bus Port Network number to be busied out.	init inads craft	none	If a bus is busied out, no calls are torn down. and no new calls are set up. Dedicated tone time slots must be moved to another bus (the other half of the duplicated bus) before a busyout of a particular bus is allowed.
	<i>bus</i>	bus = "a" or "b" specifies desired half of TDM bus. Each 512 time slot TDM bus configures as two duplicate 256 time slot buses. This division allows duplication of control channels and dedicated tone time slots. "a" bus = the default control bus; "b" bus = the default tone bus. Examples: busyout tdm 1a			

Output

The following example is a display of the **busyout tdm** command.

```
busyout tdm port-network 1 bus a                                SPE A

```

Field descriptions

Port	Port address and associated TDM number and bus (PNA or PNB)
Alt. Name	Not applicable

Maintenance Name	Type of busied out maintenance object: TDM-BUS
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout tone-clock

This command places the specified tone/clock in a maintenance busy state. No periodic or scheduled tests are performed on the busied out object until it is released. When the object is maintenance busy it is deactivated (no call processing activity may include the busied object). Warning alarms (error type 18) are generated on each tone clock circuit pack busied out, so that INADS can determine the state of the objects. The command, **release tone-clock**, reactivates the specified tone/clock.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout tone-clock	location	Physical location (PC) Examples: busyout tone-clock 01c busyout tone-clock 03d	init inads craft	1 (one)	none

Output

The following example is a display of the **busyout tone-clock** command.

busyout tone-clock 1a

SPE A

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01A	TONE-PT		PASS	
01A	TDM-CLK		PASS	
01A	TONE-BD		PASS	

Command successfully completed

Field descriptions

Port	Tone/clock board address (cabinet-carrier)
Maintenance Name	Circuit pack name: TONE-PT, TDM-CLK, TONE-BD

Alt. name	Not applicable
Result	Test result: Pass, Abort, Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

busyout trunk

This command places the specified installed or uninstalled trunk group or trunk group member in a maintenance busy state. No periodic or scheduled tests are performed on the busied out trunk groups or trunk group members until they are released. When the object is maintenance busy it is deactivated (no call processing activity may include the busied object). A single group member can be busied out by specifying the group and member number. All members in a trunk group can be busied out by specifying the trunk group number. Warning alarms (error type 18) are generated on each busied out maintenance object, so that INADS can access the state of the objects. The **release trunk** command reactivates the specified trunk group or group member.

 **NOTE:**
If the user enters **busyout trunk <group number>/**, the lowest port-location in the group is busied out. **This s NOT recommended.**

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout trunk	<i>group</i>	Trunk group number (1–99)	init inads craft	none	none
	<i>member</i>	Number of a trunk within a trunk group (1 – 99) Examples: busyout trunk 78 busyout trunk 78/1			

Output

The following example is a display of the **busyout trunk** command.

busyout trunk 78/1

cancel hardware-group

This command temporarily or permanently aborts the execution of a **test hardware-group** command. To resume testing, enter **resume hardware-group** or **test hardware-group**.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
cancel hardware-group		Examples: cancel hardware-group	init inads	none	See below

Feature Interactions

- Scheduled and Periodic Maintenance
When a **test hardware-group** is entered, all activity related to scheduled background maintenance, periodic background maintenance, and data audits suspends for the duration of the **test hardware-group** command. All activity related to scheduled background maintenance, periodic background maintenance, and data audits restarts if the **test hardware-group** command is canceled.
- Status Hardware-group
The **status hardware-group** command displays the state of a canceled **test hardware-group** command as canceled.

change circuit-packs

This command allows users to administer circuit packs that are inserted into the system port, expansion control, and switch node carriers. It is used to configure the system when circuit packs are not physically inserted.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
change circuit-packs	cabinet number	Cabinet number of circuit packs to change Examples: change circuit-packs 1 change circuit-packs 2	init inads craft cust nms	1 (one)	none

Output

The following example shows the output from the **change circuit-packs 1** command (SCC) All five pages are shown here.

```
change circuit-packs 1                               Page 1 of 5

Field descriptions

Cabinet	Administered cabinet number
Cabinet Layout	Type of cabinet (single-carrier)
Carrier	In-use cabinet carrier
Carrier Type	Carrier function (port, processor, or expansion control)
Slot	Slot numbers (0 - 21).

Code	Circuit pack code (TN number) to identify the circuit pack type
Sfx	Lists the suffix, if applicable
Name	Alphanumeric circuit pack name

change synchronization

Each system contains a hierarchy of sources used for timing synchronization. DS1 inputs to the external stratum 3 clock affect stratum 3 synchronization hierarchy. Primary and secondary fields reflect Stratum 4 synchronization. If all fields are blank, the tone clock board within each PN provides timing for that PN.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
change synchronization		Examples: change synchronization change synch	init inads craft cust rcust bcms	none	DS1 interface, BRI trunk, or UDS1 board selected as either a primary or secondary synch source cannot be removed on the DS1 circuit pack administration form or the regular circuit pack administration form.

Output

The following example shows the output for the **change synchronization** command. "4" was entered in the stratum field.

```
change synchronization                                Page 1 of 1

      SYNCHRONIZATION PLAN

      SYNCHRONIZATION SOURCE (circuit pack location)
      Stratum: 4
      Primary: _____ Secondary: _____
Location Name Slip      Location Name Slip

NOTE: DS1 and BRI trunk source will result in stratum 4, type II synchronization
```

The following output example shows the output for the **change synchronization** command. "3" was entered in the stratum field.

change synchronization

Page 1 of 1

SYNCHRONIZATION PLAN

SYNCHRONIZATION SOURCE (DS1 circuit pack location)

Stratum: 3

Port Network: 1

Field descriptions

- Stratum: Current synchronization stratum (3, 4)
- Primary: First choice system synchronization source (blank entry = no synchronization); field valid only if stratum 4 synchronization is specified.
- Secondary: Second choice system synchronization source (blank = no synchronization); valid if stratum 4 synchronization selected
- Location: Circuit pack location of all administered DS1 circuit packs (port network, carrier and board slot)
- Name: User-defined name for the DS1 circuit pack (blank = no user-defined name assigned)
- Slip: If DS1 circuit pack has slip alarm, y; if not, n.
- Port Network: Display-only field specifying the port network that supplies synchronization through the tone clock circuit pack (valid for stratum 3 synchronization)

change system-parameters
maintenance

This command specifies and displays scheduled maintenance operations and maintenance support functions. It also activates and deactivates INADS alarm origination during repairs. To deactivate alarm origination:

1. Make a note of the current entries in the Alarm Origination and CPE Alarm fields so you can restore them later.
2. Change the **Alarm Origination to OSS Numbers** field to “neither.”
3. Change the **CPE Alarm Activation Level** field to “none.”
4. If daily scheduled maintenance must remain idle during a maintenance procedure, set the **Start Time** field to a time after the session ends. If daily Scheduled Maintenance is running and needs to be deactivated, set the **Stop Time** field to one minute after the current time.

5. Press Enter and verify that the screen displays the message:
- Command successfully completed

➤ NOTE:

For earlier releases of system software, disable Cleared Alarm Notification and Restart Notification before submitting the form.

➤ NOTE:

When finished working on the switch be sure to return all fields to their original settings.

Command Line

The following fields describe how to administer the **change system-parameters maintenance** form.

Operations Support Parameters

Product Identification	Identifies switch to an Operations Support System (OSS): 10-digit number starting with 1.
First OSS Telephone Number	Switch reports alarms first to the First OSS telephone number (for example, INADS or Trouble Tracker). The number must be obtained from the National Customer Support Center (NCSC) or the TSC. (# and * are not allowed in the telephone number.)
Abbrev Alarm Report	Enables the Abbreviated Alarm Report feature for the first OSS. (yes)
Second OSS Telephone Number	The switch reports alarms secondly to the second OSS telephone number. For example, INADS or DEFINITY SNMP. The number must be obtained from the National Customer Support Center (NCSC) or the TSC. (# and * are not allowed in the telephone number.)
Abbrev Alarm Report	Enables the Abbreviated Alarm Report feature for the second OSS. (no)
Alarm Origination to OSS Numbers	Indicates one of four options for alarm origination (neither): ”both” = Major and Minor alarms result in an automatic call to both administered OSS telephone numbers. ”first-only” = Major and Minor alarms result in an automatic call to the first administered OSS number. ”neither” = alarm origination does not occur; reports are not sent to either number. ”second no-backup” = Major and Minor alarms result in an automatic call to the first administered OSS telephone number. If calling the first OSS telephone number fails four times, the switch calls the second administered OSS telephone number until calling the first OSS telephone number is successful. ⇒ NOTE: Before Release 5, the name of this field is Alarm Origination Activated. If Alarm Origination is deactivated, Cleared Alarm Notification and Restart Notification deactivate, even though they may still be activate in the administration.
Cleared Alarm Notification	The switch originates calls to the OSS and sends an alarm resolution message once all previously-reported Major and Minor alarms are resolved. Activate Alarm Origination to enable Cleared Alarm Notification. (no)
Restart Notification	Enables the switch to originate calls to the OSS and report any system restarts caused by switch problems. Activate Alarm Origination to enable Restart Notification.

Suspension
Threshold

Some problems cause alarms to be generated and resolved repeatedly. To detect these problems, the switch suspends Cleared Alarm Notification when it has reported the specified number of Cleared Alarm notifications in a 24 hour period. A suspended Cleared Alarm Notification reactivates with a successfully-completed "logoff" command, a system reset, or when the threshold is changed. This field is irrelevant if Cleared Alarm Notification or Alarm Origination are disabled. (1-15)

Test Remote
Access Port

Indicates if remote access testing on the SYSAM circuit pack is active. This field should be set to **yes** when an INADS line is connected to the switch and a maintenance contract is in effect to maintain alarm origination capability.

If no equipment is connected to the remote access port, or if a trunk for remote access and alarm origination is not provided, running tests on the remote access port on the SYSAM results in test failures. This causes unnecessary maintenance alarms and allows potentially destructive tests to be run. To prevent this set this field to **no**.

CPE Alarm
Activation
Level

Indicates the minimum level (Major, Minor or Warning) to activate Customer-Provided Equipment (CPE) alarm. If the level is **none**, the CPE does not activate for any alarm. (none)

⇒ **NOTE:**

When the switch goes into Emergency Transfer, the CPE alarm activates regardless of the CPE Alarm Activation Level setting.

Packet Bus
Activated

If this field is set to **yes**, maintenance software assumes that a Packet Control circuit pack is installed. If packet endpoints (for example, ASAI, and/or BRI) are administered, and maintenance testing runs on both the Packet Control circuit pack and Packet Bus (set this field to **yes** after a packet control circuit pack is installed.). If a Packet Control circuit pack is not installed in the system, a major alarm is raised against the PKT-CTRL MO.

Change this field from **yes** to **no** if no packet endpoints are administered, to ensure that no packet endpoints can be administered if the packet bus deactivated.

Set this field to **yes** after a Packet Control circuit pack is installed.

If a Packet Control circuit pack is not installed, then this field should be set to **no** (the only exception is system translations that do not have all required hardware). (no)

Customer Access
to INADS Port

To prevent customer login ID access to system administration and maintenance interface control, set this field to **no**. Lucent Technologies services has sole access to this field. (no)

Repeat Dial
Interval (MMS)

Number of minutes that the system must wait before attempting another call origination to an OSS. Lack of a far-end acknowledgment triggers the timer.

Scheduled Maintenance

An automated series of maintenance tests and operations runs daily according to the schedule and settings specified in the following fields

Table 8-1. Scheduled Maintenance Settings

Start Time	Hour and minute (24-hour notation) when daily scheduled maintenance starts
Stop Time	The hour and minute when scheduled daily maintenance ceases. If any daily maintenance operations are not completed by this time, the system notes its stopped sequence location and includes those operations during the next scheduled daily maintenance.
Daily Maintenance	This display-only field lists the standard test series run by maintenance software during daily maintenance.
Save Translation	Indicates days that translation data in memory automatically saves to the Mass Storage System disk and/or tape devices during scheduled maintenance. The operation saves to disk, then completes a backup to tape. Translation data saves to both SPEs, if systems have duplicated SPEs. (daily, days of the week, or no) "No" prevents automatic saves.
Control Channel Interchange	Each port network has a pair of TDM busses called A and B. Each has a set of time slots dedicated to the control channel. One bus (at a time) carries the control channel in each PN. (daily, days of the week, or no) "No" prevents interchanges. (no)
System Clocks Interchange	For High and Critical Reliability systems, this option initiates a Tone-Clock interchange in each port network possessing duplicated Tone-Clock circuit packs. Each port network interchanges into the standby Tone-Clock for 20 seconds and then back to the originally-active Tone-Clock. This field indicates the days that interchanges occur. (daily, days of the week, or no). "No" prevents interchanges. (no) The system performs a Tone-Clock interchange, activating the stand by Tone-Clock. After the newly-active Tone-Clock circuit pack is tested, it provides system clocks for its native port network. Then the system interchanges to the originally active Tone-Clock circuit pack.
SPE Interchange	This field indicates the days SPE interchanges execute during scheduled maintenance, for duplicated SPE systems. (daily, days of the week, or no). "No" prevents scheduled interchanges. (no)

Continued on next page

Table 8-1. Scheduled Maintenance Settings — Continued

EXP-LINK Interchange	This field indicates if expansion links between port-networks interchange as part of scheduled maintenance. The value, "daily", means that EXP-LINK interchanges automatically occur everyday. The value "no" means that EXP-LINK interchanges do not automatically occur as part of scheduled maintenance. Values represented by the days of the week mean that EXP-LINK interchanges automatically occur automatically on specified days. Since EXP-LINK interchanges apply to duplicated systems, simplex systems do not display this field. (no)
Minimum Threshold for TTRs	When the number of touch tone receivers (TTRs) in service falls below this number (4 to 200), a WARNING alarm is raised against TTR-LEV. These are also known as dual-tone multifrequency receivers (DTMRs). There are 4 TTRs on each TN748 Tone Detector circuit pack, and up to 50 TN748s in a system. To alarm the first occurrence of a TTR being taken out of service, set this field to 4 times the number of TN748s. If this number is set to more than three less than the total number of TTRs, a port network with only one TN748 could lose all of its TTRs before this alarm is raised.
Minimum Threshold for CPTRs	When the number of call progress tone receivers in service falls below this number (2 to 100), a WARNING alarm raises against TTR-LEV. These are also known as general purpose tone detectors (GPTDs). There are 2 CPTRs on each TN748 Tone Detector circuit pack, and up to 50 TN748s in a system. To alarm the first occurrence of a CPTR being taken out of service, set this field to 2 times the number of TN748s. If this number is set to more than one less than the total number of TTRs, a port network with only one TN748 could lose all of its CPTRs before this alarm is raised.
Minimum Threshold for Call Classifier Ports	When the number of call classifier ports (CLSFY-PTs) in service falls below this number, a WARNING alarm is raised against TTR-LEV. Valid entries are 1 to 200. There are 8 ports on each TN744 Call Classifier circuit pack, and up to 25 TN744s in a system. To alarm the first occurrence of a CLSFY-PT being taken out of service, set this field to 8 times the number of TN744s. If this number is set to more than 7 less than the total number of CSLFY-PTs in the system, a port network with only one TN744 could lose all of its CLSFY-PTS before the alarm is raised. If there are no TN744s in the system, leave this field blank.

Table 8-1. Scheduled Maintenance Settings — Continued

Test Type 100, Test Type 102, Test Type 105	This field specifies extensions assigned to receive tie-trunk calls from other switches that have test line origination capability. The system responds by sending a sequence of test tones. Test Type 100 tests far end to near end loss and C-message by sending: ■ 5.5 seconds of 1004 Hz tone at 0dB ■ Quiet until disconnect; disconnect is forced after one minute Test Type 102 tests far end to near end loss by sending: ■ 9 seconds of 1004 Hz tone at 0dB ■ 1 second of quiet ■ This cycle is repeated until disconnect; disconnect is forced after 24 hours. Test Type 105 tests 2-way loss, gain slope, and C-message and C-notch noise by sending: ■ nine seconds of 1004 Hz at -16dB ■ one second of quiet ■ nine seconds of 404 Hz at -16dB ■ one second of quiet ■ nine seconds of 2804 Hz at -16dB ■ 30 seconds of quiet ■ one half second of Test Progress Tone (2225 Hz) ■ approximately five seconds of quiet ■ forced disconnect
ISDN-PRI Test Call Extension	This field indicates the extension used by far-end ISDN nodes to place calls to the system, for testing ISDN-PRI trunks between the far-end and the system.

Continued on next page

Table 8-1. Scheduled Maintenance Settings — Continued

ISDN-BRI Service SPID	This field shows if the link associates with the Service SPID. If the link is associated with the Service SPID. This number is the test SPID (0 – 99999) (under BRI-SET MO). Otherwise, this field is blank. Service SPID is a feature used by the system technician to check building wiring between the switch and the BRI endpoint.
DSO Loop-Around Test Call Extension	The extension used to set up a DSO loop around connection for testing non-ISDN DS1 trunks The DSO Loop-Around Test Call feature is used primarily for testing DSO channels associated with non ISDN-PRI trunks. The loop-around is activated by dialing the test extension number. Multiple DSO Loop-Around connections can be established by placing multiple calls to the loop-around extension. For more information see “Facility Test Calls” in Chapter 5, “Routine Maintenance Procedures”.
Loss Plan	Leave this field blank if no extra loss is required. If extra loss is required, enter digits as shown below. Use this field if additional loss is required to maintain transmission quality for conference calls by entering the digits shown below.

No. Of Parties To Be Conferenced	Enter Digit
3	2
4	3
5	4
6	5
7	6

SPE Optional Boards:	These fields indicate if a Disk circuit pack is present, and identifies administered Packet Interface slots. If a Packet Interface circuit pack is present, the corresponding Packet Interface field is set to y when the system boots. No change to that field is allowed. If the system is equipped with duplicated SPEs, a Packet Interface field is set to y if either SPE carrier contains a Packet Interface circuit pack in the corresponding position. If a Packet Interface circuit pack is not present, the value for the Packet Interface field is read from translation data, and stored on disk or tape. If the field is set to n, a Packet Interface circuit pack may be administered by changing the corresponding Packet Interface field to y.

Modem Connection

On page 3 of the example forms, 11 fields disappear when the “Modem Connection?” field is set to internal. In this example the “Modem Connection” field is set to “external” revealing the 11 fields.

The first 2 fields on page 3 establish the data format for transmitting serial data from the switch to the modem. The field names are, “Data Bits:”, and “Parity?”. The two valid combinations for these 2 fields are:

- Data Bits = 8, Parity = None
- Data Bits = 7, Parity =(odd, even, mark, or space)

Modem Connection	Valid entries are <i>internal</i> or <i>external</i> . The default is (internal).
Modem Name	This 20-character field accepts alpha-numeric characters to provide unique qualifiers for specified modems. ()
RTS/CTS Enabled	This field informs modems that communication with data source UARTs drive with RTS/CTS flow control. This 6-character field defaults to (\Q3). This field is case in-sensitive.
Asynchronous Data Mode	This field configures the modem as an asynchronous communications device. This 8-character field defaults to (&M0&Q0). This field is case in-sensitive.
DTE Auto-Data Speed	This option adjusts the speed of data sources (DTE) UART to outgoing (modem-to-modem) data rates. The maximum speed is 9600 baud. This 6-character field defaults to blank () and is case insensitive.
Disable Data Compression	This field deactivates default data compression algorithms in use by most consumer modems. This 6-character field defaults to blank (). Similar commands support the AT commands that control this capability; however, these commands do not operate the same. Intel modems require “H%C0” to disable V.42bis & MNP Class 5 data compression algorithms; however, Paradyne products use “%C0” to disable both algorithms. This field is case in-sensitive; blank is its default. ()
Enable Error Control	This field activates V.42 LAPM and MNP error control protocols, if available. This 6-character field defaults to blank (). This V.42/MNP/Buffer mode attempts to negotiate V.42 error controls with the remote modem, then transitions to MNP. If this fails, no error control is used. This field is case in-sensitive.

Misc. Init. Param	This 20-character field defaults to blank (). This field supports unspecified initialization parameters. The AT commands specified in this free-form field to be sent to the external modem, always initialize last. This field is case in-sensitive.
Auto-Answer Ring Count	This field controls the number of rings required before modems automatically answer incoming calls. This 6-character field defaults to (S0=10). Typically, the maximum permissible value is 255. 1-255 denote the number of incoming ring cycles. This field is case in-sensitive.
Dial Type	This field controls inter-register signaling used between modems and Central Offices. This 3-character field defaults to (T) for tone dialing. P indicates Pulse dialing, This field concatenates with the dial string. This field is case in-sensitive.
Adjustable Make/Break Ratio	This field can be of particular importance when using a modem that may be transferable from country to country. This field controls make/break ratios of pulses and DTMF dialing. Intel product information supports make/break options for pulse dialing. Intel uses "&P0" to select 39% make ratios 61% break ratios for communication within the U.S. and Canada. "&P1" sets a 33% make ratio and 67% break ratio for the U.K. and Hong Kong. This 5-character field defaults to blank () and is case in-sensitive.
Dial Command	This 3-character field defaults to (D). It denotes the modem's dialing command. This field is case in-sensitive.
No Answer Time-Out	Most off-the-shelf external modems provide timers that abandon outbound data calls after predetermined intervals. Some modems permit this timer to be disabled, allowing outbound calls to ring indefinitely. AT&T Paradyne does not provide this capability, because having outbound call attempts ring indefinitely is generally undesirable. The internal modem must disable this parameter set it to at least 255 seconds. This parameter is not administrable. For external modem connections, this parameter transmits first to the external modem. Type approval applications can override this hardcoded constant, specifically in the U.K and other Western European nations, with the "Misc. Init. Param:" field. (S7=255)

clear audits

This command clears cumulative and/or peak hour's data collected for each data relation audit. This command clears old data to display data collected since the last **clear audits** command when the **status audits** command is invoked. Refer to the **status audits** manual page for more information).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear audits	<i>cumulative</i>	Clears data collected about the peak hour since the last reboot or clear audits cumulative command	init inads	none	See below
	<i>peak-hour</i>	Clears peak hour data Examples: clear audits cumulative clear audits peak-hour			

Feature Interactions

Status audits displays data cleared by the **clear audits** command. After **clear audits** executes successfully, the **display audits cumulative** and/or **display audits peak-hour** commands display information collected since the last **clear audits** command. The start date displays on the status audits screen reflecting the time that **clear audits** executed.

clear errors

This command moves errors and resolved alarms to cleared-error lists, making room for new incoming error messages. This command does not clear active alarms from the alarm log. This command must be used with care to prevent overwriting cleared entries. When additional entries are needed to log new errors, the system clears error entries first. Use the **display errors** command to list the cleared errors.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear errors		Examples: clear errors	init inads craft	none	none

clear interface

This command reinitializes counter values maintained by the Processor Interface (PI) circuit pack. The **status interface** command, used in the development environment, displays the counters. The PI circuit pack, a front end processor, implements the packet and link layers of the BX.25 protocol, and the ISDN procedure-D protocol.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear interface	location	Processor interface address (cabinet-carrier-position): 1 = first processor 2 = second processor Examples: clear interface 01a1 clear interface 01a2 clear interface a2	init inads craft	none	none

clear isdn-testcall

This command cancels in-progress ISDN-PRI test calls. Once a running test call is cleared, another can begin.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear isdn-testcall	group number	Trunk group number.	init inads craft	none	none
	member number	Trunk within a trunk group. Examples: clear isdn-testcall 80/1 clear isdn-testcall 78/2			

clear link

This command clears the hardware error counters associated with ports on the Processor Interface circuit pack (displayed with the **status link** command).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear link	link-id	Link number (1-8) assigned through communication-interface links form. Examples: clear link 1 clear link 8	init inads craft	none	none

clear mst

This command precedes a trace. If this command is active during a trace, it clears unwanted data.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear mst		Examples: clear mst	init inads	none	none

clear pkt

This command resolves packet bus problems and sends a forced packet bus **clear stimuli** command over the packet bus.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear pkt	<i>port network location</i>	Physical location of the packet bus (1 - 3) Examples: clear pkt port-network 1	init inads craft	none	none

clear port

This command works with the **mark port** command. This command removes marks from ports frees them for service.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
clear port	<i>location</i>	Port location (PCsspp) Examples: clear port 01c1102	init inads cust nms	none	none

copy update-file

In Duplex systems, the **copy update-file** copies update files from active SPEs to standby SPEs. This command recovers field update (“patch”) files that are downloaded to the switch when the Standby SPE is unavailable. The switch makes validation checks on the standby as it receives the file. If newer, valid update files exist on the standby, use the override option to force the copy.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
copy update-file	override	Copies update files from active SPEs to standby SPEs, regardless of the dates. Examples: copy update-file copy update-file override	init inads	none	see below.

Feature Interactions

- The form display for the **list configuration software-vintage** command has been modified to allow INADS to determine the hardware configuration, software vintage, and patch identifier.
- Because patches are applied on restarts before the system is in normal operation, no interaction with routine periodic or scheduled maintenance exists.
- The flash checksum test acts as a backup check to ensure entire field update files are applied correctly. When the flash Checksum Test fails, a MAJOR on-board alarm is raised on the processor/memory circuit pack. Maintenance runs a data consistency test on a daily basis to check that copies of translations, announcements, and software files are consistent across both processors in a High or Critical Reliability System. If the test detects a difference, a minor, off-board alarm is generated.
- When checking software, the test compares the memory resident software version and the patch identifier. It also searches for the presence of field update files. If found, it compares the old and new patch identifiers to ensure that the same patch file id is loaded on each processor. If the software or update files are inconsistent, the **list configuration software** command displays the patch file status.

disable administered-connection

This command stops both scheduled and periodic testing and stops processing of in-line errors for all or selected administered connections.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
disable administered-connection	ac number all	Number of the administered connection Selects all administered connections Examples: disable administered-connection all disable administered-connection 1 disable administered-connection 128	init inads craft cust rcust mis	none	none

disable mst

This command stops the message trace facility. If the trace was not already disabled, the command inserts a GAP marker into the trace. The user should execute the **disable mst** command when the trace is complete. If left enabled, the trace continues to use CPU time until the time limit expires. Entering **disable mst** command has no effect on the system if the trace is already disabled. To view the results of the trace, enter the **list mst** command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
disable mst		Example: disable mat	init inads	none	none

disable suspend-alm-orig

This command stops entries from the active Suspend Alarm Origination table. This command disables all board entries that match a specific physical board location.

 **NOTE:**
This command does *not* disable port entries.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
disable suspend-alm-orig	board location	Physical location of the replaced or corrected board (does not support port location): PCss Examples: disable suspend-alm-orig 1C03 disable suspend-alm-orig 1E07	init inads craft cust rcust	none	none

disable synchronization-switch

This command stops the automatic clock switching capability of the maintenance subsystem. The clock refers to the oscillator on a tone/ clock or DS1 interface. The synchronization subsystem (TDM bus clock, DS1 trunk board, and maintenance and administration software) provides error-free digital communication between the switch and other PBXs, COs, or customer equipment.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
disable synchronization-switch			init inads craft	none	none

disable test-number

This command prohibits selected maintenance tests from running. To run a disabled test number, enter the **enable test-number** command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
disable test-number	<i>number</i>	Maintenance test number	init	none	none
	<i>print</i>	Report sent to printer	inads		
	<i>schedule</i>	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: disable test-number 710 disable test-number 710 print disable test-number 510 schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

display alarms

This command creates an Alarm Report. The user completes an option screen to select the parameters for the report.

The system creates the reports from the logs of the maintenance subsystem. The subsystem monitors the system hardware and logs problems as errors or alarms. The type of alarm indicates the impact of the problem, as defined below:

Warning alarm—A minor interference which does not noticeably impair service.

Minor alarm—A problem which could disable a local area of the system and noticeably impair service.

Major alarm—A problem which widely degrades the system and seriously impairs service. The system automatically calls INADS to report major alarms.

Resolved alarm—A problem which has been corrected, and the system is correctly functioning. The system stamps resolved alarms with the date and time the problem was corrected. The system handles any errors associated with the alarms as “resolved.”

System Reboots and the Alarm Logs

The system saves the alarm and error logs to the *active* SPE memory card if any of the following events occur:

- The **save translation** command is executed.
- Translations are saved as part of scheduled maintenance.
- A reboot takes place.
- The PPN is about to lose all power after having been on battery backup.

The attempt to save the alarm and error logs may be unsuccessful if the MSS is not available.

Whenever the system reboots, the logs are restored from the SPE disk that becomes active with the reboot. Since the logs are saved to the disk on the SPE that was active *before* the reboot, the versions restored at reboot time may not be current. This condition occurs if:

- The attempt to save at reboot did not succeed.
- The SPE disk that is rebooted is not the same disk to which the logs were last saved.

In such a case, the logs do not contain the most recent errors and alarms. To determine if the restored logs are complete, look for indications that would have preceded the reboot.

System resets, that are less severe than a reboot, rarely affect the error and alarm logs.

NOTE:

If the error and alarm logs contain SYSTEM errors, then use the **display initcauses** command to search for information that system could *not* log during reset operation.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display alarms	<i>print</i> <i>schedule</i>	Report sent to printer Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display alarms display alarms print display alarms schedule	init inads craft cust rcust bcms browse	all alarms displayed	See below

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

- If the user disables the alarm origination with the **change system parameters-maintenance** command, then the Ack? (Acknowledged) field on the Alarm Report is blank regardless of the true acknowledged state of the alarm.

Options screen

When you enter the **display alarms** command, the system first displays the options screen. Select the options you want to view on the report. The figure below is an example of the options screen for Alarm Reports.

display alarms

Page 1 of 1

ALARM REPORTS

The following options control which alarms will be displayed.

ALARM TYPES

Active? y_ Resolved? n_
Major? y_ Minor? y_ Warning? y_

REPORT PERIOD

Interval: m_ From: __/__/__:__ To: __/__/__:__

EQUIPMENT TYPE (Choose only one, if any, of the following)

Cabinet: ____
Port Network: __
Board Number: ____
Port: ____
Category: ____
Extension: ____
Trunk (group/member): __/__

The fields on the options screen are described below:

ALARM TYPES	Enter y (yes) or n (no) in any of the 5 alarm type fields
Interval	Enter one of the codes below: m = last month h = last hour d = last day w = last week a = all (default)
From	Month/day/year (example: 01/01/97); if the From date is blank, the report contains all the active alarms for the month <i>prior</i> to the current date.
To	Month/day/year (example: 01/15/97); if the To date is not entered, the report contains all the active alarms starting with the From date to the current date.
Cabinet	Administered cabinet number (1-3)
Port Network	1-3
Board Number :	Board address (PCSS); example: 01A20
Port	Port address (PCSSpp); example: 01A2031
Category	Object code for the equipment category. Press HELP in this field to view a list of the object codes.
Extension	Extension number (per dial-plan)
Trunk	Enter a group number or a group and member number: ■ Enter <i>only</i> the group number (01-99) to display <i>all</i> members in the group. Example: 01/___ ■ Enter <i>both</i> the group number (01-99) and member number (01-99) to display a <i>specific</i> member in a group.Example: 01/99

Output

After you complete the options screen, the system displays a 1- or 2-page Alarm Report. To toggle between the pages and to exit the report, use the keys described below:

- For 513 and 715 terminals, use **F8** for NEXT PAGE and PREV PAGE commands
- For all other terminals, use **F7** for NEXT PAGE and PREV PAGE commands
- Use **Esc** for the CANCEL command

The figure below is an example of an Alarm Report.

display alarms

ALARM REPORT								
Port	Maintenance Name	On Brd?	Alt Name	Alarm Type	Svc State	Ack? 1 2	Date Alarmed	Date Resolved
02A	TONE-BD	y		MAJOR		y n	05/22/20:34	00/00/00:00
01C07	ANL-BD	y		MINOR		n n	05/22/20:26	00/00/00:00
01C0702	ANL-LINE	n	311	WARNING	IN		05/22/20:26	00/00/00:00
01C0701	ANL-LINE	n	1051	WARNING	IN		05/22/20:26	00/00/00:00
01C0703	ANL-LINE	n	1053	WARNING	IN		05/22/20:26	00/00/00:00

01C1505	CO-TRK	n	78/01	WARNING	OUT		05/22/20:26	00/00/00:00
02A0201	TONE-PT	n		WARNING			05/22/20:34	00/00/00:00
02A	TDM-CLK	n		WARNING			05/23/13:43	00/00/00:00
PN 02B	TDM-BUS	n		WARNING			05/23/14:53	00/00/00:00

Command successfully completed

Field descriptions

- Port

Lists the location codes for the alarmed object, as follows:
 - Circuit packs locations display as: cabinet-carrier-[slot]-[circuit]. Example: **01C0702**.
 - Port network locations display as: port network number-bus. Example: **PN 02B**. PN 02 = Port Network (PN) number and A or B = bus.
 - Fiber link locations display as: fiber link number-PNC side. Example: **x A-PNC**. “X” = fiber link number and “A” = PNC side [A or B].
- Maintenance Name

Lists the logical name of the maintenance object with the alarm.
- On Brd

A **y** (yes) indicates the fault was found on the associated circuit pack. A **n** (no) indicates the fault is **not** connected to the circuit pack.

Alt Name	Identifies the location of maintenance object, as follows: ■ Station = extension number ■ Trunk = Group number (78/__) or group and member numbers (78/01) ■ Private CO Line = private CO line (P) and group number. (P/xxx)
Alarm Type	Alarm level: MAJOR, MINOR, or WARNING
Service State	Identifies the service state of the station and trunk ports, as follows: ■ RDY = ready for service ■ OUT = out of service ■ IN = in service ■ [Blank] = No associated service state
Ack?	Headings 1 and 2 identify the first and second OSS telephone numbers, respectively. The entries below indicate the acknowledged alarm state: ■ Y (yes) = alarm has been acknowledged ■ N (no) = alarm has not been acknowledged ■ C (cleared) = alarm was first acknowledged, then resolved and cleared [Blank] = no attempt was made to report the alarm  NOTE: If the user disables the alarm origination with the change system-parameters maintenance command, then the Ack? field is blank regardless of the true acknowledged state of the alarm.
Date Alarmed	Indicates the month, day, hour, and minute of the alarm.
Date Resolved	Indicates the month, day, hour, and minute of the resolution. For active alarms, this field contains zeros (0).

display cabinet

This command displays the cabinet description and location and the carrier description for a selected cabinet number.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display cabinet	<i>print</i> <i>schedule</i>	Report sent to printer Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display cabinet 1	init inads craft cust rcust	none	none

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The example below shows the output for the **display cabinet 1**.

```
display cabinet 1
                                CABINET

CABINET Description
    Cabinet: 1
    Cabinet Layout: five-carrier
    Cabinet Type: processor
    Number of Portnetworks: 1
        Room: 30n46
        Floor: first
        Building: main

CARRIER Description
    Carrier      Carrier Type      Number
    C            port              PN   01
    B            not-used           PN   01
    A            processor          PN   01
    X            Fan                PN   01
    D            not-used           PN   01
    E            switch-node        SN   01
```

Command Successfully Completed

Field descriptions

Cabinet	Administered cabinet number
Cabinet Layout	Type of cabinet (five-carrier or single-carrier-stack)
Cabinet Type	Type of port network (processor or expansion)
Number of Port networks	Number of port networks (1 or 2)
Room	Room where cabinet is located, if administered on the cabinet form.
Floor	Floor where cabinet is located, if administered on the cabinet form.
Building	Building where cabinet is located, if administered on the cabinet form.
Carrier	Letter identifying the carrier (A-E or X not applicable)
Carrier Type	Port, processor, switch-node, fan, or not-used
Number	Administered port network number <i>or</i> switch node number

When you enter the command: **display cabinet 3** and the cabinet is a stack of single-carrier-cabinets, the system displays a screen similar to the figure below. The fields on the screen are the same as described above.

```
display cabinet 3

                                CABINET

CABINET Description
      Cabinet: 3
      Cabinet Layout: single-carrier-stack
      Cabinet Type: expansion-portnetwork
      Number of Portnetworks: 1
                        Room: 30n46
                        Floor: first
                        Building: main

CARRIER Description
      Carrier      Carrier Type      Number

      D           not-used          PN   03
      B           port              PN   03
      A           expansion-control  PN   03
```

display communication-interface

The **display communication-interface** command must contain one of the three qualifiers defined below:

The **display comm hop-channels** command displays the translation data for hop channels. A hop channel is a bi-directional network channel between two interface links for DCS message hopping. A hop channel is used to tandem DCS messages from one interface link to another interface link.

The **display communication-interface links** command displays the translation information for each communication interface link. A link is an electronic communication channel transmitted over the Packet Bus for carrying packet-switched data. There are 16 links that terminate at one end on the Packet Interface circuit pack in the SPE. At the physical and link layers, the link terminates at the other end on a port on the PBX's switching matrix. At a higher level, the link continues over a transmission facility to another endpoint, such as a DCS node or AUDIX. The link carries application messages between the SPE and other switches or adjuncts.

The **display comm processor-channel** command displays the translation information for each of the local processor channels. A processor channel is one several data streams which are multiplexed by the X.25 protocol onto a single data link. The system has 128 total processor channels; up to 64 can be assigned to a single link.

See also ["status link"](#) for more details.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display communication-interface	hop-channels	See above	init inads craft cust rcust	none	none
	links	See above			
	processor-channel	See above			
	print/	Report sent to printer			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output for Hop-channels qualifier

When you enter the command **display comm hop**, the systems displays the Hop Channel Assignment screen, similar to the figure below. The number of the local processor channel, used to hop the interface link channels, is not shown.

display communication-interface hop-channels				Page 1 of 4			
HOP CHANNEL ASSIGNMENT							
Link/Channel A		Link/Channel B		Link/Channel A		Link/Channel B	
3	1	4	12				

Field descriptions

Link/Channel A	Identifies the first of the two link/channels joined by the hop channel. Links range from 1 to 16. Channels range from 1 to 64. The link/channel must not be assigned to a local processor channel. Also, the link must not be assigned to a PRI local processor channel.
Link/Channel B	Identifies the second of the two link/channels joined by the hop channel. Links range from 1 to 16. Channels range from 1 to 64. The link/channel pair must not be assigned to a local processor channel. Also, the link must not be assigned to a PRI local processor channel.

Output for Links Object

When you enter the command: **display communication-interface links**, the systems displays the Interface Links screen, similar to the figure below.

display communication-interface links						SPE A
INTERFACE LINKS						
Link	Enabled	X.25 Extension	Destination Number	Establish Connection	Connected Data Module	Identification
1:	y	5464	external	y	5460	AUDIX ID1
2:	n	5461	external	y		AUDIX-ADM-CONN1
3:	y	5466	external	y		CMS-ADM-CONN-2
4:	n					
5:	n					
6:	n					
7:	n					
8:	n					
9:	n					
10:	n					
11:	n					
12:	n					
13:	n					
14:	n					
15:	n					
16:	n					

Field descriptions

Link	The physical link number.
Enabled	A y (yes) indicates the link is enabled for normal operation. A n (no; default) indicates that the message flow over the link is suppressed. The link can only be enabled if the corresponding data module has been administered.
X.25 Extension	The extension of the TN577 Packet Gateway port through which the link is routed.
Destination Number	The entry "external" indicates the link goes to equipment connected locally to an external port on a Packet Gateway circuit pack. Such ports must show a y in the Establish Connection field.
Establish Connection	This field indicates whether the local switch is responsible for any part of call set-up with the far-end data module. If the physical link is through a pair of data modules, each switch terminating the link must set up a connection to its PDM/TDM. If the physical link is over a DS-1 interface, it is possible for one switch to set up the entire connection without any initiation by the other end. The ISDN signaling links must be set to "y" at both ends of the interface.
Connected Data Module	The extension of a PDM/MPDM directly connected to a PGATE port cable or to an adjunct in an administered connection arrangement.

Identification This field records the type and identification number of the machine connected to this link. This field is for informational purposes only.

Output for Processor-Channel Object

When you enter the command: **display comm proc**, the systems displays Processor Channel Assignment screen, similar to the figure below.

display communication-interface processor-channels						Page	1 of 8
PROCESSOR CHANNEL ASSIGNMENT							
Proc	Application	Interface	Local	Remote	Adjunct		
Chan		Link Chan	Port	Port	Name	Machine-ID

11:							
12:							
13:							
14:							
15:							
16:							

Field descriptions

- Proc Chan

The field identifies one of the processor channels on the processor link. The valid range for a processor link is 1 to 16. Each interface link corresponds to a port on a PGATE board. The Processor channel is not administered.
- To specify a network channel to a remove machine, use this link/logical channel pair and the one specified in the interface link and interface channel field.
- Application

This field specifies the type of application that connects to this processor channel. The following lists the valid entries:
- Interface Link

The interface link to which the processor channel is connected.
- Interface Chan

The channel on the interface link to which the processor channel is connected.
- Local Port

The switch application port used by the local session.

Remote Port	The application port used by the remote session.
Adjunct Name	The name of the adjunct connected to this processor channel. These are defined in the Adjunct Name Form. Only AUDIX and MSA channels require entries in this field: AUDIX, MSAAMWL, MSAHLWC, MSALLWC, and MSAMCS.
Machine-ID	The network machine ID for the remote machine. Machine IDs are required only for the AUDIX adjunct and DCS connections.

display disabled-tests

The **display disabled-tests** command lists the numbers for all maintenance tests that have been disabled by INADS. These tests are not available for background or demand testing.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display disabled-tests	<i>print</i>	Report sent to printer	init inads craft cust rcust	none	none
	<i>schedule</i>	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output from the **display disabled-tests** command.

```
display disabled-tests                                SPE A

                                     DISABLED TEST INFORMATION

Test Number

710

Command successfully completed
```

display errors

This command creates an Alarm Report. The user completes an option screen to select the parameters for the report.

The system creates the reports from the logs of the maintenance subsystem. The subsystem monitors the system hardware and logs problems as errors or alarms.

Errors can result from in-line firmware errors, periodic tests, failures detected while executing a test command, software inconsistency, or a data audit discrepancy.

System Reboots and the Error Logs

The system saves the alarm and error logs to the *active* SPE memory card if any of the following events occur:

- The **save translation** command is executed.
- Translations are saved as part of scheduled maintenance.
- A reboot takes place.
- The PPN is about to lose all power after having been on battery backup.

The attempt to save the alarm and error logs may be unsuccessful if the MSS is not available.

Whenever the system reboots, the logs are restored from the SPE disk that becomes active with the reboot. Since the logs are saved to the disk on the SPE that was active *before* the reboot, the versions restored at reboot time may not be current. This condition occurs if:

- The attempt to save at reboot did not succeed.
- The SPE disk that is rebooted is not the same disk to which the logs were last saved.

In such a case, the logs do not contain the most recent errors and alarms. To determine if the restored logs are complete, look for indications that would have preceded the reboot.

System resets, less severe than a reboot, rarely affect the error and alarm logs.

NOTE:

If the error and alarm logs contain SYSTEM errors, then use the **display initcauses** command to search for information that system could *not* log during reset operation.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display errors	high resolution	Highlights the time stamps on the Error Report for the first and last occurrences of the error.	init inads craft cust nms browse	all errors displayed	none
	print	Report sent to printer			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display errors display errors print display errors schedule display errors high-resolution print			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Input form

When you enter the **display errors** command, the system first displays the options screen. You select the options you want to view on the report. The figure below is an example of the options screen for an Error Report.

display errors

Page1 of 1

ERROR REPORT

The following options control which errors will be displayed.

ERROR TYPES

Trunk (group/member):

Field descriptions

Error TypeEnter a specific error type. If the field is blank, the system displays all errors. Press HELP in this field to view a list of codes.

Error List	Enter one of the error lists below: active-alarms (default) errors cleared-errors The title for the Hardware Error Report includes the name of the selected error list.
Interval	Enter one of the codes below: m = last month h = last hour d = last day (default) w = last week a = all
From	Enter 2-digit numbers for the month/day/year (Example: 01/01/97). The default is the earliest time of the existing error records in the log.
To	Enter 2-digit numbers for the month/day/year (Example: 01/01/97). The default is the current date.
Cabinet	Enter 1, 2, or 3 (the administered number)
Port Network	Enter 1, 2 or 3
Board Number :	Enter a 5-digit equipment code for: Cabinet = 01-03 (if omitted, the default is 01) Carrier = A-E Slot = 00-20 Example: 01A20
Port	Enter a 7-digit equipment code for: Cabinet = 01-03 (if omitted, the default is 01) Carrier = A-E Slot = 00-20 Circuit = 01-31 Example: 01A2031
Category	Enter the object code for the equipment category. Press HELP in this field to view a list of the object codes
Extension	Enter the extension number
Trunk	Enter a group number or a group and member number: ■ Enter <i>only</i> the group number (01-99) to display <i>all</i> members in the group. Example: 01/___ ■ Enter <i>both</i> the group number (01-99) and member number (01-99) to display a <i>specific</i> member in a group. Example: 01/99.

Form output

After you complete the options screen, the system displays a 1- or 2-page Hardware Error Report. To toggle between the pages and to exit the report, use the keys described below:

- For 513 and 715 terminals, use **F8** for NEXT PAGE and PREV PAGE commands
- For all other terminals, use **F7** for NEXT PAGE and PREV PAGE commands
- Use **Esc** for the CANCEL command

The figure below is an example of an Hardware Error Report -- Active Alarms, **without** the high-resolution qualifier in the command line.

```
display errors                                     Page 1   SPE A

Field descriptions

- Port

Lists the location codes for the alarmed object, as follows:

 - Circuit packs locations display as: cabinet-carrier-[slot]-[circuit]. Example: 01C702.
 - Port network locations display as: port network number-bus. Example: **PN 02B**. PN 02 = Port Network (PN) number and A or B = bus.
- Maintenance Name

Lists the logical name of the maintenance object with an error logged against it.
- Alt Name

Identifies the location of maintenance object, as follows:

 - Station = extension number
 - Trunk = Group number (78/__) or group and member numbers (78/01)
 - Private CO Line = private CO line (P) and group number (P/xxx)

Error Type	Lists the error number for the type of problem encountered for this maintenance object. The technician must use this error number in conjunction with the logical name information to determine the exact nature of the error.
Aux Data	Lists additional information concerning the maintenance object error condition. Like the error type, this data is specific to the maintenance object type. However, unlike the error code, only the most recent value of the auxiliary data is retained for each error record.
First Occur	Displays the month, day, hour, and minute (and second if the high-resolution command line option is used) that the error was first recorded.
Seq Cnt	Sequence Count - This number indicates the order of errors logged within a second for the time stamps associated with the first occurrence and last occurrence of an error. This information is displayed only if the high-resolution command line option is entered. There may be gaps for the sequence numbers within a given second since the last occurrence of an error may replace an existing entry that had been assigned the missing sequence number. Gaps may also appear in the numbers since sequence counts are also used with software event information not shown in the hardware error log.
Last Occur	Displays the month, day, hour, and minute (and second if the high-resolution command line option is used) of the most recent error. Note: if the system is unable to retrieve the time of day when the error occurred, a 'dummy' date is stamped in the log and appears as: 00/00/01:07 .
Err Cnt	Error Count - The total number of times that the error type has occurred for this maintenance object. If the number of errors exceeds 3 digits, the system enters the number 256 , which indicates that a larger number of errors occurred, but could not be displayed correctly.
Err Rt	Error Rate - The average rate at which the errors have occurred from the first occurrence to the present. If the number of errors exceeds 3 digits, the system enters the number 256 , which indicates that a larger number of errors occurred, but could not be displayed correctly.

- Rt/Hr

Rate per Hour - An approximation of the rate that this error occurred in the last hour.If the number of errors exceeds 3 digits, the system enters the number **256**, which indicates that a larger number of errors occurred, but could not be displayed correctly.
- Al St

Alarm Status - A character indicating the status of this MO in the error and alarm logs. The allowed values are:

a = Active alarm entry

r = Resolved alarm entry

c = Resolved alarm entry as a result of the long "clear" option of the test command

s = Resolved alarm entry as a result of a software requested (non-demand) system restart

t = Resolved alarm entry as a result of a technician requested system restart

n = Not alarmed.
- Ac

Active? - A **y** (yes) entry indicates the maintenance object is still active. A **n** (no) entry indicates the object is no longer a problem.

The figure below is an example of an Hardware Error Report -- Active Alarms, **with** the high-resolution qualifier in the command line.

When you enter the command **display errors high-resolution**, the system adds the Seq Cnt (sequence count) column. The number in the column indicates the order of errors logged within a second for the time stamps associated with the first occurrence and the last occurrence of an error. Refer to the field description above for more details.

Command successfully completed

display events

A vector event is the occurrence of something unexpected during a vector-routed call due to resource exhaustion or faulty vector programming. (For example, route-step failures are typically due to the programming of an invalid extension.) These types of failures are not due to faulty hardware or system software error and do not constitute incorrect feature operation. This command allows you to diagnose and correct vectoring problems due to the above-mentioned causes. See *DEFINITY Communications System Generic 3 Call Vectoring and Expert Agent Selection (EAS) Guide*, 555-230-520, for information on how to interpret this report.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display events			init inads craft cust rcust	none	none

Input form

The following entry form is displayed to allow limiting the report to events of a certain type or from a certain time period. Enter the desired parameters and press Enter.

- Category

“Vector” specifies the type of event report to display and is the only valid entry.
- Report Period

The fields in this section allow you to view only those vector events that occurred within a specific time period. If these are left blank, all vector events recorded are displayed.
- Interval:

This field specifies a display of all events within the last time period of the type Enter the first letter of one of the following selections: *all, month, day, hour, minute.*
- Start/Stop Time

The starting and ending times, in 24-hour notation, of the interval to be reported.
- Vector Number

The number of the vector (1-256) for which events is reported. If this field is left blank, events for all vectors is reported.
- Event Type

Specific types of vector events are associated with numbers from 50000 to 50999. Entering one of these numbers limit the report to events of this type. If this field is left blank, events for all types of vectors are reported.

Output

See *DEFINITY Communications System Generic 3 Call Vectoring and Expert Agent Selection (EAS) Guide*, 555-230-520, for more information on how to interpret this report. In particular, the Event Data 2 field are associated with possible causes and repair strategies for the event.

Event Type	A number from 50000 to 50999 that identifies what type of vector event occurred.
Event Description	A text string describing the event.
Event Data 1	If in the format <i>number/number</i> such as “200/10”, this indicates the vector number and step number associated with the event. If in the format “Split <i>number</i> ” such as “Split 2”, this indicates the split number.
Event Data 2	Additional data concerning the event encoded as a hex number.
First Occur	The date and time when the vector event first occurred.
Last Occur	The date and time when the vector event last occurred.
Evnt Cnt	The total number of times, up to 255, that vector events of this type have occurred.

The following example shows the input form for **display events**:

display initcauses

The **display initcauses** command displays a history of recovery steps taken by the system. *This command displays information for restarts of the active processor only.* Each time the system performs some type of recovery (due to user request or a hardware or software problem), the recovery information is stored. The software error log also contains information pertaining to restarts. If a reset 4 (reboot) occurs, the software error log are also stored on tape. Information in the software error log should be used in conjunction with information in the initcauses log.

The history of the last 16 restarts performed by the system are recorded to the initcauses buffer in chronological order. This buffer fills an entire screen with information if it is completely full. Power failures in the processor complex wipe out the entire initcauses buffer which is stored by the software. In duplex systems, both processors have to lose power before the information is lost.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display initcauses	<i>print</i> <i>schedule</i>	Report sent to printer Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display initcauses display initcauses print display initcauses schedule	init inads craft nms	none	none

Field descriptions

Cause	Reason for the restart:
	■ Active Down: (High or Critical Reliability system only) The Active SPE went into SPE Down mode. The Duplication Interface initiated an SPE-interchange to the Standby SPE. If this initcause triggers an SPE interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the preceding description of display initcauses for a complete explanation. If a high or critical reliability system does a PEI with a warm start, the system software often requests a Cold 2 restart to recover properly only minutes after the warm start has occurred. ■ Bad Handshake: (High or Critical Reliability system only) The Duplication Interface received inconsistent handshakes from the Active SPE. Thus, the Duplication Interface initiated an SPE-interchange to the Standby SPE. If this initcause triggers an SPE interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the preceding description of display initcauses for a complete explanation. If a High or Critical Reliability System does a PEI with a warm start, the system software often requests a COLD 2 restart to recover properly only minutes after the warm start has occurred. ■ Bad Memory: A defective memory circuit pack generating too many errors caused a restart. ■ System Technician Request: The restart was performed because of system technician demand. A system technician-requested reset system 4 command entry should always precede an upgrade software command entry. ■ Failed Interchange: A “hot-start” interchange (system technician-demanded, scheduled, or software-requested) failed because shadowing was disabled. ■ From Monitor (mon): (For Development Environment only) ■ Initialized: This is always the first entry in the history and is present until more than 15 restarts have been performed. It indicates power-up and also occurs if the Maintenance/Tape Processor is reset during initialization.

- **LMM Request:** A sanity time-out was requested by the LMM firmware. The three processor circuit pack LEDs blink until the sanity timer goes off. The LMM requests a restart like this when it gets into trouble, usually with memory.
- **Maintenance Reset:** The Maintenance/Tape Processor or Duplication Interface reset the system. This refers to resets of the SPE by maintenance in SPE Down mode in which maintenance periodically tries to awaken the SPE.
- **No Handshake:** (High or Critical Reliability System only) The Duplication Interface lost handshaking with the active SPE. Thus, the Duplication Interface initiated an SPE-interchange to the Standby SPE. A defective tape drive may cause the Active SPE to miss handshakes with the Duplication Interface which, in turn, could result in an initialization cause of "No Handshake." Check the Hardware Error Log for TAPE-related error types and alarms and follow the recommended repair procedures in the TAPE Maintenance documentation. If this initcause triggers an SPE interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the preceding description of **display initcauses** for a complete explanation. If a High or Critical Reliability System does a PEI with a warm start, the system software often requests a Cold 2 restart to recover properly only minutes after the warm start has occurred.
- **Oryx Request:** A sanity time-out was requested by the Oryx operating system. The three processor circuit pack LEDs blink until the sanity timer goes off. Oryx requests a restart like this when it gets into trouble, usually with software.
- **Sanity Timer Reset:** The sanity timer on the processor timed out and reset the system. This event usually indicates a software fault.
- **Scheduled Interchange:** A scheduled SPE-interchange occurred.
- **Software Request:** Software requested the system restart. In a system equipped with High or Critical Reliability, software can also request SPE-interchanges when it detects problems. See the Software Requested Interchanges Caused by Alarm Conditions table ([Table 6-1](#)) in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#). If this initcause triggers an SPE interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the opening description for a complete explanation.

- **SPE-Select Lead Change:** (High or Critical Reliability system only)
The system could not determine why the SPE changed its status from Active or Standby. However, this change usually indicates a transition from Active to Standby. If a High or Critical Reliability System does a PEI with a warm start, the system software often requests a Cold 2 restart to recover properly only minutes after the warm start has occurred.
- **SPE-Select Switch:** (High or Critical Reliability system only) The SPE-Select switches on the Duplication Interface circuit packs were thrown to select the Standby SPE, which became the Active SPE, using the restart level shown. It is also possible to get an initialization cause of SPE-Select Switch when SPE B is active and power to carrier B is lost. In this case, an SPE switch to SPE A occurs and the initialization cause can show either SPE-Select Switch or SPE Down. If this initcause triggers an SPE-interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the preceding description of ["display initcauses"](#) for a complete explanation.
- **Stby-SPE Core Dump:** (High or Critical Reliability system only) The Standby SPE had finished a core dump when an interchange took place that made the Standby SPE the Active SPE. If this initcause triggers an SPE-interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the preceding description of ["display initcauses"](#) for a complete explanation. If a High or Critical Reliability System does a PEI with a warm start, the system software often requests a Cold 2 restart to recover properly only minutes after the warm start has occurred.
- **Stby-SPE Tests:** (High or Critical Reliability system only) The Standby SPE was in the process of running tests at the request of the Active SPE when an interchange occurred. If this initcause triggers an SPE-interchange when the Standby is NOT in Maintenance mode, the previous entry in the log may actually represent a restart that occurred on the Standby SPE. See the preceding description of ["display initcauses"](#) for a complete explanation. If a High or Critical Reliability System does a PEI with a warm start, the system software often requests a Cold 2 restart to recover properly only minutes after the warm start has occurred.
- **Unknown:** A restart that could not be classified. The Software Error Log may contain more information about the restart.
- **Upgrade Software:** (High or Critical Reliability system only) This indicates that the system was upgraded to a new software generic using the Standby SPE to load the new software via the **upgrade software** command. A system technician-requested **reset system 4** command should be the previous entry.

- **LMM Put Fail:** This initcause occurs when the LMM has failed to place the request for initcause message in the DPR. This could occur if the MTP does not respond to the DPR handshake. Level of Restart: Warm (escalation turned on).
- **LMM Get Fail:** This initcause occurs when the LMM does not receive a response to the request for initcause message from the MTP. This could occur if the MTP is not taking messages out of the DPR. Level of Restart: Warm (escalation turned on).
- **Dupint Unknown:** This initcause occurs when the LMM receives an UNKNOWN initcause from the Dupint. This could occur in a High or Critical Reliability System where the MTP thinks a PEI has occurred but the dupint disagrees. Level of Restart: Warm (escalation turned on).
- **MTP Reset Unknown:** This initcause occurs when the LMM has reset the MTP during the process of trying to get initcause from the MTP. Level of Restart: Warm (escalation turned on).
- **S-vintage Mismatch:** This initcause occurs when a mismatch in the duplication super vintage is detected by the LMM. Level of Restart: Reboot (no escalation).
- **Monitor Reset:** (For Development Environment Only) This initcause occurs when "ini 1" is executed from the Flash Monitor. This initcause can occur only in systems with SBB. Level of Restart: Reboot (no escalation).
- **Bad GDT:** (For Development Environment Only) This initcause occurs when the LMM fails to transfer control to Oryx/Pecos because of absence of entry in GDT to point at O/P. This usually occurs in a system with no data. Again, this should only occur in systems with SBB.

Action The level of recovery performed by the system. The recovery levels follow:

- Reset system 1 (Warm)
- Reset system 2 (Cold-2)
- Reset system 3 (Cold-1)
- Reset system 4 (Reboot)
- Reset system 5 (Extended Reboot)
- Reset system interchange (High or Critical Reliability System only - hot restart interchange)

Escalated Whether the restart was escalated to a higher level to clear the problem. There is a software escalation strategy which can cause a higher level of restart than the one previously performed to be executed if the need arises.

Carrier

The “carrier” statement indicates the carrier on which the recovery was performed (possible values are **1A** and **1B**). In most cases, this “carrier” is the Active SPE carrier when the restart occurs. However, it is possible in a High or Critical Reliability System that this carrier was the Standby carrier. See the preceding description of [“display initcauses”](#) for a complete explanation.

Time

The date (month and day) and time of the restart.

display memory-configuration

This command indicates the total memory available for the active, and if present the standby, processor(s). This command is a single page display with hidden fields for the standby-processor; these hidden fields are visible if a standby processor is available in the system.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display memory-configuration	long	Displays the standby SPE Flash ROM and DRAM configuration.	init inads craft cust browse	none	none
	print	Report sent to printer			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display memory-configuration display memory-configuration long			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following output example is for the **display memory long** command.

display memory-configuration longSP_A

PROCESSOR MEMORY-CONFIGURATION
(M bytes)

	SPE_A	SPE_B
Flash ROM:	16	16
Total DRAM:	12	12
SIMM A:	4	4

Command:

display port

This command displays the port location, the equipment connected to the port, and the means by which the port can be identified (for example, an extension number, the trunk group and member, and so on).

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display port	location	Port address (PCSSpp)	init	none	none
	print	Report sent to printer	inads craft		
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display port 1c0801 display port 1c0802 print display port 2c1504 schedule	cust browse		

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output for the **display port 1c0801** command.

```
display port 1c0801                                SPE A

                                PORT INFORMATION

                                Port: 01C0801
                                Equipment Type: Station
                                Identification: 1021
```

Field descriptions

- Port:
- Port address (cabinet-carrier-slot-circuit)
- Equipment Type:
- Hardware that is physically connected to the specified port.

Identification:

Depends on the hardware that is physically connected to the port:

If hardware is	The field contains
station	station extension
trunk	trunk group and member number)
modem pool	modem pool group number

display synchronization

This command calls up the synchronization form where the administered synchronization stratum and reference sources are displayed. (No changes can be made to the system synchronization with this command.)

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display synchronization	print	Report sent to printer	init inads craft cust rcust bcms browse	none	See below
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display synchronization display synchronization print display synchronization schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

- A DS1 interface or a UDS1 board that has been selected as either a primary or secondary synchronization source cannot be removed on the DS1 circuit pack administration form or the regular circuit pack administration form.

Output

The following example shows the output for the **display synchronization** command.

display synchronization

Page 1 of 2

SYNCHRONIZATION SOURCE (DS1 circuit pack location)

Stratum: 4
Primary: Secondary:

DS1 CIRCUIT PACKS

Location	Name	Slip	Location	Name	Slip
02B10	D92D1 ds1 2b10	n			
02B11	d92D1 ds1 2b11	n			
01C10	D92D1 ds1 1c10	n

SYNCHRONIZATION PLAN
DS1 CIRCUIT PACKS

Location	Name	Slip	Location	Name	Slip

Field descriptions

- Stratum: Synchronization stratum that is used (3 or 4)
- Primary: First choice system synchronization source (blank = no synchronization); valid only if stratum 4 synchronization specified
- Secondary: Second choice system synchronization source (blank = no synchronization); valid only if stratum 4 synchronization specified
- Location: Circuit pack location (cabinet-carrier-slot) of all administered DS1 circuit packs are listed here.
- Name: User-defined name administered for the DS1 circuit pack. Blank means no user-defined name administered.
- Slip: If the DS1 circuit pack has slip alarm, field shows y; otherwise it shows n.
- Port Network: Only valid for stratum 3 synchronization; specifies the port network supplying synchronization through the tone clock circuit pack.

display system-parameters maintenance

This command displays the translation data for maintenance-related system parameters.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display system-parameters maintenance	print	Report sent to printer	init inads craft super-user Maintain Switch Circuit Packs permissions	none	none
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: display system-parameters maintenance display system-parameters maintenance print display system-parameters maintenance schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following display shows a typical result when **display system-parameters maintenance** is entered.

Command Line

Field descriptions

Defaults for data entry fields are listed in parentheses.

Product Identification	10-digit number (starting with 1) that identifies the switch to an Operations Support System (OSS), for example, INADS.
First OSS Telephone Number	First telephone number that the switch dials to report alarms; must be obtained from the National Customer Support Center (NCSC) or the TSC. (# and * are not allowed in the telephone number.)
Abbrev Alarm Report	Enables the Abbreviated Alarm Report feature for the first OSS. (yes)
Second OSS Telephone Number	Second telephone number that the switch dials to report alarms; must be obtained from the National Customer Support Center (NCSC) or the TSC. (# and * are not allowed in the telephone number.)
Abbrev Alarm Report	Enables the Abbreviated Alarm Report feature for the second OSS. (no)

Alarm Origination to OSS Numbers	One of four options for alarm origination (neither): ■ If both, all Major and Minor alarms result in an automatic call to both OSS telephone numbers. Both OSS telephone numbers must be administered. ■ If first-only, all Major and Minor alarms result in an automatic call to the first OSS number only. The switch does not call the second OSS telephone number even if the number is administered. The first OSS telephone number must be administered ■ If neither, alarm origination does not take place. Warning alarms are not reported to either numbers. ■ If second-as-backup, all Major and Minor alarms result in an automatic call to the first OSS telephone number. If calling the first OSS telephone number fails four attempts, the switch starts to call the second OSS telephone number as a backup until calling the first OSS telephone number becomes successful. Both OSS telephone numbers must be administered. Before Release 5, the name of this field is Alarm Origination Activated. If Alarm Origination is deactivated, both Cleared Alarm Notification and Restart Notification are disabled, even though they may still be activated in the administration.
Cleared Alarm Notification	Enables the switch to originate a call to the OSS and send an alarm resolution message whenever all previously-reported Major and Minor alarms are resolved. Alarm Origination must be activated in order for Cleared Alarm Notification to work. (no)
Restart Notification	Enables the switch to originate a call to the OSS and report any system restarts caused by problems with the switch.
Suspension Threshold	The threshold for suspending Cleared Alarm Notification (1-15). Some problems may cause alarms to be generated and then resolved repeatedly. To detect these problems (by not sending additional Cleared Alarm notifications to indicate a problem-free system), the switch suspends Cleared Alarm Notification when it has reported this administrable number of Cleared Alarm notifications in a 24-hour period. A suspended Cleared Alarm Notification is only enabled again with a successfully completed "logoff" command, a system reset, or when the threshold is changed. This field is irrelevant if Cleared Alarm Notification or Alarm Origination is disabled.
Test Remote Access Port	Specifies whether testing of the remote access port on the SYSAM circuit pack is enabled. This field should read yes whenever there is an INADS line connected to the switch and there is a maintenance contract in effect so that alarm origination capability is maintained.

CPE Alarm Activation Level

Indicates the minimum level (Major, Minor or Warning) at which the Customer-Provided Equipment (CPE) alarm is activated. If the level is none, the CPE does is not activated for any alarm. (none)

 **NOTE:**

The CPE alarm is always activated when the switch goes into Emergency Transfer, regardless of the CPE Alarm Activation Level setting.

Packet Bus Activated

Enables the system Packet Bus.
If this field read yes, then maintenance software assumes that there is a Packet Control circuit pack installed in the system. The packet endpoints (for example, ASAI, and/or BRI) may be administered, and maintenance testing runs on both the Packet Control circuit pack and on the Packet Bus (This field should read yes after a packet control circuit pack is installed.). If a Packet Control circuit pack is not installed in the system, then a major alarm is raised against the PKT-CTRL MO. This field can only be changed from "yes" to "no" if there are no packet endpoints administered, thus ensuring that there can be no packet endpoints administered if the packet bus is not activated.

This field should be set to "yes" after a Packet Control circuit pack is installed.
If a Packet Control circuit pack is not installed, then this field should be set to "no" (the only exception is when setting up translations for a system for which not all of the required hardware is available). (no)

Customer Access to INADS Port

Provides the capability to prohibit access to system administration and maintenance interface, via the INADS port when using customer login ID's. This field can only be activated by Lucent services through system-parameters maintenance administration.(no)

Repeat Dial Interval (MMS)

Indicates the number of minutes that the system must wait before attempting another call origination to an OSS. This timer is triggered by the lack of a far-end acknowledgment. (7)

Scheduled Maintenance

A series of maintenance tests and operations runs automatically every day according to the schedule and settings specified in the following fields.

Start Time

The hour and minute (24-hour notation) at which daily scheduled maintenance begins. (22:00)

Stop Time	Time (hour and minute) when scheduled daily maintenance stops. If any daily maintenance operations are not completed by this time, the system notes where in the sequence it stopped and perform those operations during the next scheduled daily maintenance.
Daily Maintenance	This display-only field simply represents the series of tests that are always run by maintenance software as part of daily maintenance.
Save Translation	This field indicates on which days translation data in memory automatically saves to the Mass Storage System disk and/or tape devices during scheduled maintenance. The save operation is first made to disk, followed by a disk backup to tape. On systems with duplicated SPEs, translation data is saved on both SPEs. Valid entries are daily , days of the week, or no . "No" specifies that no automatic saves are to be executed. (daily)
Control Channel Interchange	Each port network has a pair of TDM busses called A and B, each of which has a set of time slots dedicated to use by the control channel. At any one time, the control channel in each PN is carried on only one of the two busses. This field indicates on which days the control channel in each port network will be switched from one of the paired TDM busses to the other. Valid entries are daily , days of the week, or no . "No" specifies that no interchange be executed. (no)
System Clocks Interchange	On High and Critical Reliability systems, this option causes a Tone-Clock interchange in each port network with duplicated Tone-Clock circuit packs. Each port network interchanges into the standby Tone-Clock for 20 seconds and then back to the Tone-Clock that was originally active. This field indicates on which days the interchanges are to take place. Valid entries are daily , days of the week, or no . "No" specifies that interchanges be executed. (no)
SPE Interchange	On systems with duplicated SPEs, this field indicates on which days an SPE interchange will be executed during scheduled maintenance. Valid entries are daily , days of the week, or no . "No" specifies no scheduled interchanges. (no)
EXP-LINK Interchange	This field indicates whether or not the expansion links between port-networks are interchanged as part of scheduled maintenance. The value "daily" means that EXP-LINK interchange occurs automatically everyday. The value "no" means that EXP-LINK interchange is not done automatically as part of scheduled maintenance. Values represented by the days of the week mean that EXP-LINK interchange occurs automatically on the specified day only. Since EXP-LINK interchange only applies to duplicated systems, simplex systems do not display this field. (no)

Minimum
Threshold for
TTRs

When the number of touch tone receivers (TTRs) in service falls below this number (4 to 200), a WARNING alarm is raised against TTR-LEV. These are also known as dual-tone multifrequency receivers (DTMRs). There are 4 TTRs on each TN748 Tone Detector circuit pack, and up to 50 TN748s in a system. To alarm the first occurrence of a TTR being taken out of service, set this field to 4 times the number of TN748s. If this number is set to more than three less than the total number of TTRs, a port network with only one TN748 could lose all of its TTRs before this alarm is raised.

Minimum
Threshold for
CPTRs

When the number of call progress tone receivers in service falls below this number (2 to 100), a WARNING alarm is raised against TTR-LEV. These are also known as general purpose tone detectors (GPTDs). There are 2 CPTRs on each TN748 Tone Detector circuit pack, and up to 50 TN748s in a system. To alarm the first occurrence of a CPTR being taken out of service, set this field to 2 times the number of TN748s. If this number is set to more than one less than the total number of TTRs, a port network with only one TN748 could lose all of its CPTRs before this alarm is raised.

Minimum
Threshold for
Call Classifier
Ports

When the number of call classifier ports (CLSFY-PTs) in service falls below this number, a WARNING alarm is raised against TTR-LEV. Valid entries are 1 to 200. There are 8 ports on each TN744 Call Classifier circuit pack, and up to 25 TN744s in a system. To alarm the first occurrence of a CLSFY-PT being taken out of service, set this field to 8 times the number of TN744s. If this number is set to more than 7 less than the total number of CSLFY-PTs in the system, a port network with only one TN744 could lose all of its CLSFY-PTS before the alarm is raised. If there are no TN744s in the system, leave this field blank.

Test Type 100,
Test Type 102,
Test Type 105

An extension assigned to receive tie-trunk calls from other switches with test line origination capability. The system responds by sending a sequence of test tones. Test Type 100 tests far-end to near-end loss and C-message by sending:

■ 5.5 seconds of 1004 Hz tone at 0dB

■ Quiet until disconnect; disconnect is forced after one minute

ISDN-PRI Test
Call Extension

The extension used by a far-end ISDN node to place a call to the system to test the ISDN-PRI trunks between the far-end and the system.

ISDN-BRI
Service SPID

This field shows whether or not the link is associated with the Service SPID. If the link is associated with the Service SPID, this field contains a "yes" and the extension field is blank; otherwise, this field is blank. Service SPID is a feature used by the system technician to check building wiring between the switch and the BRI endpoint.

DSO Loop-Around
Test Call
Extension

Extension number for the test call. This test extension number is used to establish a loop-around connection on the selected trunk.

The DSO Loop-Around Test Call feature is used primarily for testing DSO channels associated with non-ISDN-PRI trunks. The loop-around is activated by dialing the test extension number. Multiple DSO Loop-Around connections can be set up by placing multiple calls to the loop-around extension.

The DS0 Loop Around feature provides a loop around connection for incoming non-ISDN DS1 trunk data calls. This feature is similar to the far-end loop around connection provided for the ISDN Test Call feature. This DS0 loop around is provided primarily to allow a network service provider to perform facility testing at the DS0 level before video teleconferencing terminals are installed at the PBX.

The feature is activated on a call-by-call basis by dialing a test call extension specified on the second page of the System Parameters Maintenance form. No special hardware is required. When the test call extension is received by the PBX, a non-inverting, 64 kbps connection is set up on the PBX's Time Division Multiplexed bus. More than one loop around call can be active at the same time.

For calls routed over the public network using the ACCUNET Switched Digital Service (SDS) or Software Defined Data Network (SDDN), the data transmission rate is 56 Kbps, since robbed bit signaling is used. For calls established over a private network using common channel signaling, the full 64 kbps data rate is available.

When the incoming trunk group is used only for data calls (SDS), the Communications Type on the associated Trunk Group form should be set to "data." When the incoming trunk group is used for robbed bit alternate voice and/or data (SDN/SDDN), the Communications Type on the Trunk Group form should be set to "rbavd" (robbed bit alternate voice data). For private network trunks using common channel signaling, the Communications Type on the associated Trunk Group form can be set to "avd."

Loss Plan

Use only when extra loss is required to maintain quality of transmission on conference calls. Leave this field blank if no extra loss is required. If extra loss is required, enter digits as shown below.

No. of Parties to Be Conferenced	Enter Digit
3	2
4	3
5	4
6	5
7	6

SPE Optional
Boards:

These fields indicate whether a Disk circuit pack is present in the system, and which Packet Interface slots are administered. If a Packet Interface circuit pack is physically present, the corresponding Packet Interface field is set to **y** when the system boots, and no change to that field is allowed. If the system is equipped with duplicated SPEs, a Packet Interface field is set to **y** when either SPE carrier contains a Packet Interface circuit pack in the corresponding position. If a Packet Interface circuit pack is not present, then the value for the Packet Interface field is read from translation data stored on disk or tape. If the field is set to **n**, a Packet Interface circuit pack may be administered by changing the corresponding Packet Interface field to **y**.

Modem Connection

On page 3 of the example forms shown below, there are 11 fields that are hidden when the Modem Connection? field is set to **internal**. In this example the Modem Connection field is set to **external** and these additional 11 fields are visible.

The first 2 fields on page 3 help setup the data format for the serial data from the switch to the modem. The field names are Data Bits: and Parity?. There are only two valid combinations for these 2 fields:

- Data Bits = 8, Parity = None
- Data Bits = 7, Parity = (odd, even, mark, or space)

The remaining fields are listed below:

Modem Connection	Valid entries for this field are “internal” or “external”. The default is set to internal. (internal)
Modem Name	20-characters alpha-numeric field for a unique modem name

RTS/CTS Enabled	Notifies the modem that communication with the data source UART will be driven with RTS/CTS flow control (6 characters long, default = \Q3). Field is case insensitive, however, the default is in upper case. (\Q3)
Asynchronous Data Mode	Configures the modem as an asynchronous communications device (8 characters long, default = &M0&Q0). Field is case insensitive, however, the default is in upper case.
DTE Auto-Data Speed	Speed of the data source (DTE) UART to the outgoing (modem-to-modem) data rate (maximum = 9600 baud); field is 6 characters long and case insensitive; default = blank
Disable Data Compression	Turns off the default data compression algorithms that are in use by most consumer modems; field is 6 characters long and case insensitive; default = blank. The AT commands that control this capability are supported by similar commands; however, these commands do not operate in the same manner: ■ The Intel modems require the use of “H%C0” to disable V.42bis & MNP Class 5 data compression algorithms ■ Paradyne products use “%C0” to disable both algorithms.
Enable Error Control	Turns on the V.42 LAPM and MNP error control protocols, if available, on the modem; field is 6 characters long and case insensitive; default = blank. This V.42/MNP/Buffer mode first attempts to negotiate V.42 error control with the remote modem. If this fails, then the modem transitions to MNP, and if this fails then no error control is used.
Misc. Init. Param	Supports any initialization parameters not already specified; field is 20 characters long and case insensitive; default = blank. The AT commands specified in this free-form field are always the last initialization parameters to be sent to the external modem.
Auto-Answer Ring Count	Number of rings before the modem automatically answers an incoming call; field is 6 characters long and case insensitive; default is “S0=10” (in upper case). The values 1-255 denote the number of incoming ring cycles.
Dial Type	Type of inter-register signaling to be used between the modem and the Central Office; field is 3 characters long, case insensitive, and is concatenated with the dial string. T = tone dialing (default in upper case) P = pulse dialing

Adjustable Make/Break Ratio	Controls the make/break ratios of pulses and DTMF dialing and can be of particular importance when using a modem that may be transferable from country to country. Field is 5 characters long and case insensitive; default = blank. Intel uses different pulse dial options: ■ “&P0” = 39% make and 61% break within the U.S. and Canada. ■ “&P1” = 33% make and 67% break for the U.K. and Hong Kong.
Dial Command	Modem dial command; field is 3 characters long and case insensitive; default = “D” as the default.
No Answer Time-Out	Most off-the-shelf external modems provide a timer that abandons any outbound data call after a predetermined interval. Some modems provide for this timer to be disabled, thus allowing an outbound call to ring indefinitely. AT&T Paradyne does not provide this capability with their modem line, because it is generally undesirable to have an outbound call attempt ring indefinitely. The internal modem must have this parameter disabled or set to at least 255 seconds. This is a non-administrable parameter. For the external modem connection, this parameter will be the first initialization string to be transmitted to the external modem. This field will be visible on the administration form in display mode only. This hardcoded constant can be overridden for type approval applications, specifically in the U.K and other Western European nations, by the use of the “Misc. Init. Param:” field. (S7=255)

display time

The **display time** command brings up the time form. The system time displays on this form. This command does not allow for any changes to be made to the system time.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
display time	print schedule	Report sent to printer Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen.¹ Examples: display time display time print display time schedule	init inads craft cust browse	none	Date and time are generally used by the switch.

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output for the **display time** command.

```
display time

                        DATE AND TIME

DATE
  Day of the Week:  Sunday      Month:  January
  Day of the Month:   1         Year:   1990

TIME
                Hour:  6         Second:  20
               Minute:  8
```

Field descriptions

- Day of the Week
- The day of the week that the system has stored.
- Day of the Month
- The numerical day of the month.
- Month
- The month of the year stored by the system.
- Year
- The current year stored by the system.
- Hour
- The hour of the current day.
- Minute
- The number of minutes into the hour.
- Second
- The number of seconds into the minute stored by the system.

download update-file

The update file is transferred to the switch asynchronously from either an INADS host or a personal computer (PC) using the XMODEM protocol.

Remote download

Remote users can dial into the switch by either using the “call” command (from an INADS host) or by dialing the switch directly with a modem. Once the connection has been established, the user logs into the switch as a remote system access terminal (SAT) using the inads login.

NOTE:

Only the INADS and INIT logins have the necessary permission to send an update file to the switch.

1. Type the **download update-file** command and press ENTER. “Please wait...” displays on the screen.

After completing some initialization, “Please start file transmission now...” displays.

2. Start an XMODEM session on the remote end and send the update file.
 - a. INADS host: enter **~dload <file_name>** to start the file transmission.
 - b. PC: follow the instructions in the emulator’s manual for invoking an XMODEM session to send the update file.

Each block is written to tape or flash card as it is received by the switch. The link level of XMODEM provide error detection and retransmission. Additional protection is provided within the application level. After the entire file has been written to tape or flash card, it is read back and each update file block is validated, and the file checksum is also checked. If the file appears to be sound, the status word in the header block is changed to indicate that it is a valid update file.

There may be a delay (up to 5 minutes on a duplex system) between the end of the file transmission and command completion. This delay is caused by the patch application of any immediate sub-patches and, if on a duplex system, the automatic copy of the update file to the standby SPE, which takes place after receiving a valid update file.

In a High or Critical Reliability System, the connection to the INADS host computer can be dropped by the INADS side, but the process of copying the patch file to the standby processor continues. The standby is placed in maintenance mode and a call placed between active and standby SPE over the data channels. The file is transmitted in the same way for both tape and flash card systems. The same checks are made on the receiving side as were made

during and after the original download. If no errors are found, the file is marked valid.

There is no feedback to the user on the status of the standby copy. If an error is encountered during the copy or validation process on the standby, an error is logged in the software error log. Because the data consistency audit discovers that the two patch files are inconsistent, the user must manually copy the valid file on the active processor over to the standby processor.

The software does not indicate when the copy has completed, so scripts run by the TSC must not issue an immediate reset on High or Critical Reliability Systems. This interrupts the copy and guarantees that the field update files on the two processors are inconsistent. This problem can be avoided by using one of the following techniques:

- Use two scripts: the first to apply the patch and a second (run later) to issue the reset that applies the patch. This requires two calls to each duplicated switch.
- Put a delay into the scripts, causing the scripts to wait a period of time after downloading the file and before issuing the reset. This requires only one call, but the amount of delay time required is not well defined, as it varies by system load.
- Use a manual means of detecting when the copy has completed: either a “PASS” on the data consistency audit or a match on the List Configuration Software form. This requires only one call and introduces less delay in requesting the reset.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
download update-file			init inads	none	See below

Feature Interactions

- The form displayed for the list configuration software-vintage command has been modified to reflect the changes imposed by the flash architecture. The **list configuration software** command allows INADS to determine with one query the hardware configuration, software vintage, and patch identifier.
- There is no interaction with routine periodic or scheduled maintenance, because patches are only applied on restarts before the system is in normal operation.
- The flash checksum test acts as a backup check to ensure that the entire field update file was applied correctly. It can fail because of a bad checksum update from a poorly constructed update file or because the patching operation has aborted. When the flash Checksum Test fails, a MAJOR on-board alarm is raised on the processor/memory circuit pack. Maintenance runs a data consistency test on a daily basis to check that

copies of translations, announcements and software files are consistent across both processors in a High or Critical Reliability System. If the test detects a difference, a minor, off-board alarm is generated.

- When checking the software, the test compares the memory resident software version and patch identifier. It also checks for the presence of a field update file and, if found, compares the old and new patch identifiers to make sure the same patch file id loaded on each processor. If the software or update files are inconsistent, the **list configuration software** command can be used to display the status of the patch file.

Recovery procedures

In the event of a failure encountered during the download and application of the update file, follow the recommended recovery procedures. The instructions apply to both simplex and duplex switches; additional detail is given when needed.

Error on the download transmission

If the error displayed on the terminal indicates that the download step in the process failed, there are several culprits:

1. The transmission line could have been noisy. Retry after making all the following checks. Failed attempts take up room in the hard patch file and may require a warm start to clear the file.
2. The user may have downloaded the tape/MIPS version of the patch instead of the flash version.
3. The vintage of the update file may not match the vintage of software currently running in the system. Check the customer's vintage using **list configuration software** and patch vintage provided in the documentation.
4. The switch may have had difficulty in writing to the hard patch file. Check the hardware error log for processor/memory board failures.
5. The hard patch file may be full. Issue a **reset system 1**. This should cause valid files to be applied and invalid ones to be erased.

Error on Application of the Patch

A patch may not have been applied for the following reasons:

1. The memory card is write-protected. Remove this protection and issue a **reset system x** command
2. The patch identifiers are inconsistent. Run **list configuration software** and compare the old_patch identifier with the values in the update file.

3. The LMM encountered a problem with the patch file. This is unlikely because the same checks (and more) were performed when the file was downloaded, prior to marking the file valid. This implies that the memory that stored the update file was corrupted.
 - a. Apply the back out file immediately to back out the changes.
 - b. Run the flash checksum test to make sure the system is back to its prepatch state.
 - c. Check the validity of the file again
 - d. Try redownloading and applying the patch immediately.
4. The LMM reports a hard error. Symptoms of this are an entry in the hardware error log for the processor/memory board (if you're lucky), or extremely odd switch behavior followed by SPE down mode (if you're not). The problem is that the LMM cannot complete the programming of memory with the result that memory is in a corrupted state. The only recovery is to get or order new software and processor/ memory circuit packs.

In a High or Critical Reliability System, the failure causes a interchange to the standby processor. The hardware on the standby must be repaired and the patch redownloaded. (There was nothing wrong with the patch.)

Good application - bad patch

This error is not caused by a failure in the download or application, but by a fault in the patch file itself. To recover from this type of problem, the back out file that backs out the patch should be downloaded and applied. This requires that the system be sane enough to receive the file correctly and be able to apply it.

In a High or Critical Reliability System, the user has approximately 8 minutes to recognize that a problem exists and force an interchange to the standby processor. If this can be done, the file on the newly-active processor can be invalidated using a file containing a destroy tuple or the *wp byte* command. The standby processor can be restored to a normal state using the back out file.

Inconsistent software versions on a duplicated switch

As indicated by a failure in the data consistency test, inconsistent software can be caused by problems in copying the update file to the standby or validation test failures on the standby. Unlike the tape or MIPS systems which revert to the same version of software as a result of a refresh, a flash system remains inconsistent until some manual intervention occurs:

1. Use the **list config software** command to determine the status of the vintages, patch identifiers, and patch file data on both the active and standby processors.

1. If one processor looks as if it has been patched (updated patch identifier and no update file) and the other looks as if the patch file is still present (no patch identifier and valid update file), the application of the patch can be forced by making that processor active and requesting the system restart indicated in the accompanying documentation.
2. If one processor has a copy of the update file and the other doesn't (neither has been patched), the file can be copied using the **copy update-file** command.
3. If patch identifiers disagree but neither side has a valid update file, the missing patch should be redownloaded to the system. During the download process, the file should pass the vintage test and then be copied to the standby processor. Validation tests are then be run on both processors. The patch is applied to memory on the next restart. This procedure is less disruptive to the customer if the unpatched processor is the standby at the time of the restart.

enable administered-connection

This command restarts scheduled and periodic maintenance for a single or all administered connections and can be used to track the maintenance processing of administered connections without interference from other maintenance processing. This command also restarts the processing of in-line errors for all or the selected administered connection.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
enable administered-connection	<i>ac number</i> <i>all</i>	The number of the administered connection All administered connections are enabled. Examples: enable administered-connection 128 enable administered-connection all	init inads craft cust rcust mis	none	none

enable mst

Enables the message trace that is controlled according to the parameters created with the **change mst** command. If executed while the trace is enabled, the command has no effect and returns a screen message indicating that the command was successful.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
enable mst			init inads	none	none

enable suspend-alm-orig

This command enables Suspend Alarm Origination for a board (including all ports and endpoints on the board) or for a port (including all endpoints on the port) for both on- and off-board alarms or for off-board alarms only. Many control circuit packs do not have a board location, so this command cannot support all circuit packs. Each enable command becomes a new entry or replaces an existing entry in the Suspend Alarm Origination table. A new entry that matches both the physical location and off-only, on-, and off-board specifications of an active entry replaces the active entry in the Suspend Alarm Origination table.

On the command line, specify a time-out duration of 1 - 72 hours. The **off-board-only** is optional; if the keyword is not specified, the entry suspends Alarm Origination for both on-and off-board alarms.

This command may be particularly useful for:

- Improved control over customer requests. For example, to suspend off-board DS1 alarms temporarily for customers that periodically disconnect DS1 trunks for testing or other business-related purposes.
- Improved control over external (non-Lucent) problems such as suspending off-board DS1 alarms before a customer resolves facility problems (for example, a T1 trunk that has developed an off-board condition).
- Improved control over internal (Lucent) problems that cannot be resolved immediately. For example, the command can be used to suspend Alarm Origination for a bad circuit pack detected late Friday night and dispatch personnel cannot respond until Monday.

 NOTE:

Also see other Suspend Alarm Origination related commands, including **disable suspend-alm-orig** and **list suspend-alm-orig**.

Action/ Object	Qualifiers	Qualifier Description	Permissions	Defaults	Feature Interactions
enable suspend- alm- orig	board/port location off-board- only expires-in- hrs	Physical location of the hardware optional; if not specified, both on-and off-board alarms suspended No. of hours (1-72) Examples: enable suspend-alm-orig 1B03 expires-in-hrs 3 enable suspend-alm-orig 1B0701 expires-in-hrs 72 enable suspend-alm-orig 1B07 off-board-only expires-in-hrs 24	init inads craft cust rcust	Both on- and off-board alarms if the off-board- only keyword is not specified	none

enable synchronization-switch

This command re-enables automatic clock switching or returns the maintenance subsystem back to the normal state. The synchronization subsystem consists of the TDM bus clock, DS1 trunk board, and SPE-resident maintenance and administration software and provides error free digital communication between the switch and other PBXs, COs, or customer-premise equipment (CPE).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
enable synchronization-switch			init inads craft	none	none

enable test-number

This command enables a previously disabled test number. At the next request by maintenance or the technician, this test number runs.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
enable test-number	<i>number</i>	The specific test number to re-enable Example: enable test-number 102	init inads craft	none	The display disabled-tests command gives a list of all disabled tests.

format card-mem

This command erases and formats the active processor Flash Read-Only Memory card before writing translation, announcements, coredump, and firmware data.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
format card-mem	<i>translation</i> <i>announcements</i> <i>coredump</i> <i>firmware</i>	Erases and formats the memory card for: translations only translations and announcements translations, announcement, and coredump translations, announcements coredump, and firmware	init inads craft cust browse system	none	none

Output

The server shows the active SPE and returns Command completed successfully if completed.

get vector

This command displays the conditions and the Switch Processing Element (SPE) associated with a core dump of memory to tape or memory card. The dump occurs on the tape or disk of the previously active SPE or the SPE previously specified using the **set vector** command in systems with duplicated SPEs.

**CAUTION:**
The vector is cleared when a system restart of the proper level is performed regardless of whether the core is actually dumped.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
get vector	long	Core dump timestamps printed; if SPEs are duplicated, timestamps are printed for both SPEs.	init inads craft	none	none
	print	Report sent to printer. Examples: get vector get vector print get vector long get vector long print			

Output

```
get vector

                                GET RESULTS

Core Dump Vector                Set Vector Command Option
0                               spe-active

Core Dump Time
SPE_A
SPE_B

Command successfully completed
```

Field descriptions

Core Dump Vector A hexadecimal value representing the condition(s) that cause(s) a core dump. This hexadecimal value is a bit map of the four reset conditions (from least to most significant bit):

- warm start
- cold 2 restart
- cold 1 restart
- reboot.

A value of 0 indicates that the vector is cleared or not set. See the Vector-Condition Mapping table that follows.

Vector-Condition Mapping

value	warm-start	cold-2	cold-1	reboot
0	n	n	n	n
1	y	n	n	n
2	n	y	n	n
3	y	y	n	n
4	n	n	y	n
5	y	n	y	n
6	n	y	y	n
7	y	y	y	n
8	n	n	n	y
9	y	n	n	y
a	n	y	n	y
b	y	y	n	y
c	n	n	y	y
d	y	n	y	y
e	n	y	y	y
f	y	y	y	y

Set Vector Command Option The user-specified SPE prior to the core dump. For simplex SPE systems this field is always spe-active unless the vector is cleared or not set. In duplex SPE systems, the field is either spe-active or spe-standby unless the vector is cleared or not set. If the vector is cleared or not set in either a duplex or simplex SPE system, this field is blank.

Core Dump Time

The time of the core dump for SPE A and SPE B. If the system has a simplex SPE, a timestamp for SPE A (or the active SPE) and non duplicated SPE" are displayed for SPE B. If the core dump cannot be accessed, can ' t access displays for the corresponding SPE. For example, in a High or Critical Reliability System where SPE B is not refreshed, SPE B displays can ' t access instead of a timestamp. If the MSS device storing the core dump timestamp is busy for any reason, device busy displays at the terminal.

list configuration

Hardware configuration reports list, for each circuit pack in the group specified, the type, code, suffix, and vintage of the requested circuit packs as installed in the switch, and all ports assigned to the circuit pack.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list configuration	hardware-group	Enter a group listed in the Hardware Groups section below.	init inads craft cust rcust	none	none
	print	Report sent to printer.			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹			
		Examples: list configuration carrier 2c schedule list configuration port-network 5 list configuration stations print			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

 **NOTE:**

The **list configuration software-version** command is discussed separately under its own heading.

Hardware Groups

Enter one of the following hardware groups:

carriers all

Displays all circuit packs administered and/or physically inserted in the port, switch node, and control carriers on the system.

board PCSS	Displays all assigned ports on the circuit pack specified by cabinet, carrier, and slot.
carrier c	Displays all circuit packs and assigned ports on a specified carrier.
control	Displays all circuit packs in the control complex.
ds1	Displays all the DS1 (TN722, TN767, and TN464) port circuit packs administered and/or physically inserted.
port-network pn#	Displays all circuit packs located in a specified port network. (List cabinet gives the port network number(s) associated with a particular cabinet.) Circuit packs on switch node carriers are not displayed when the port-network qualifier is entered. To display switch node circuit packs, use the all , carrier or board qualifiers.
stations	Displays all circuit packs that can be assigned stations, including DS1 circuit packs for remote stations.
trunks	Displays all circuit packs that can be used for administering trunks.

Output

The following display shows the output from the **list configuration all** command.

```
list configuration all                                     Page 1

01C16      TN767D  000024   robbed-bit          unknown
01C18      TN464F  000002   isdn-pri            none
```

Field descriptions

Signaling	This field is displayed only when list configuration ds1 is entered. The contents of the field are the same as the signaling mode administered for the ds1 circuit pack or none if the circuit pack is not administered.
Name	This field is displayed only when list configuration ds1 is entered. The contents of the field are the same as the signaling mode administered for the ds1 circuit pack or none if the circuit pack is not administered.
CSU MOD	This field is displayed only when list configuration ds1 option is selected. The field contains the identification number of the Integrated CSU module present on the DS1 circuit pack (TN767E or later / TN464F or later) or none. If the circuit pack is a TN464E or TN767D, unknown displays. If the circuit pack is a TN464D or TN767C or earlier suffix DS1 board, then n/a displays.

list config software-version

This command displays

- Software version numbers and compatibility indexes of the software load modules stored in system memory (RAM) and on the Mass Storage System devices (tape).
- The dates and times when translation and announcement data were last saved to the MSS.
- Information about any software update files that have been applied to the system. See “Software Upgrade” in [Chapter 5, “Routine Maintenance Procedures”](#) for an explanation of software versions and compatibility indexes.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list configuration software-version	<i>memory-resident / long</i> ¹	Data for the active SPE or both SPEs (High or Critical reliability systems) ²	init inads craft	none	none
	<i>print</i>	Report sent to printer.			
	<i>schedule</i>	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ³ RAM-resident files only. Fields for tape data contain n/a			

1. On high and critical reliability systems, only fields for the active SPE are displayed unless the long option is specified.
2. Fields in the SPE-B column are blank for standard reliability systems.
3. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

If the tape or memory card contains a core dump file, fields for tape or memory card data display coredump. When a core dump is present, all other files on the device are marked invalid.

If the memory card cannot be read at the time the command is entered, the relevant fields display no tape or memory card. (This does not indicate that the system does not recognize the presence of the device.)

The following display shows the output from the **list configuration software-version** command.

```
list configuration software-version                                Page    1

                                SOFTWARE VERSIONS

Field descriptions, Page 1

Update File Section Displays information pertaining to software field-update files or “patches.”

Creation (GMT) Tape and (GMT) Disk	When the update file was originally created, in Greenwich Mean Time (GMT). Note that this is <i>not</i> the time at which the update file was written to the MSS device.
Old-Version Tape and Disk	The software version for which the update was created.
Old-Identifier Tape and Disk	Which previous update file this update file expected to find stored in the MSS when it was applied.
New-Identifier Tape and Disk	Uniquely identifies the current update file.

Software Version Section Displays information related to the current software-load module stored in memory and in the MSS.

Memory Resident	Version number of the RAM-resident load module.
Mem Card Resident	Version of memory card resident load module. If a memory card is not installed, this field will display “no card”.
Update-identifier (Patch Identifier)	This uniquely identifies the update file, if any, that has been applied to memory.
Update-state (Patch State)	The status of the software field-update (“patch”) file id is displayed.

Translation Date Section

Displays information related to the translation files as stored in memory and the MSS.

Memory Resident

Date and time when translation data was last read from the MSS into memory. This is stored in SPE memory and is not modified by changes to translation data. A **save translation** command updates this date. If Date invalid is displayed, the timestamp does not contain the expected information.

Mem Card Resident

The date and time when translation data was last saved to the memory card. If a memory card is not installed, this field will display no card.

Field descriptions, Page 2

P1 FW Version Section

Displays information related to the Processor Interface (PI) circuit pack (resident copy and corresponding tape file) firmware.

PI 1 Resident

The version of firmware in the first PI circuit pack in the control carrier.

PI 2 Resident

The version of firmware in the second PI circuit pack in the control carrier.

Flash Resident

The version of PI firmware residing on the system flash memory.

Announcement Date Section

Displays information related to the announcement files. Information is displayed for the memory resident copy as well as the corresponding MSS file

Mem Card Resident	The last date and time that announcement data was saved to the memory card. If the memory card is not installed, this field displays no card.
PKT-CTRL FW Version Section	displays information related to the Packet Control firmware. Information is displayed for the Packet Control circuit pack resident copy as well as the corresponding tape file
Pkt-ctrl Resident	The version of firmware in the Packet Control circuit pack.
Flash Resident	The version of the Packet Control circuit pack residing on the system flash memory.

Some things to note when using the **list configuration software-version** command are:

1. For simplex systems, the fields under column “SPE_B are always blank and the optional **Long** qualifier is not part of the command line.
2. For a High or Critical Reliability System, the fields under the column of the standby SPE are blank if the optional **long** modifier is not given.
3. If the tape or memory card contains a core dump file system, fields for the tape or memory card will contain **coredump**. This is because in a coredump file system all files other than the **coredump** file are marked as invalid.
4. If for any reason, MSS cannot be read when the command is issued, the string **no tape** or **none** for no memory card will be placed in the appropriate fields on the screen. This does not mean that the system thinks there is no tape, only that the software was unable to read the appropriate information when requested.
5. If the command is issued using the **memory-resident** option, the fields on the form associated with the tape will contain the string **n/a**.
6. When the status of the update field is displayed, the following strings will be used (for more information refer to step c of this list):
 - a. **none in memory** — no update has been applied to memory.
 - b. **immediate partially applied** — an error condition that is valid only when an update that is in the process of being applied fails. Check the validity of the update file that was sent, and then check the hardware error log for tape errors, and follow standard maintenance procedures.
 - c. **all immediate applied deferred pending** — a valid update file was received by the switch, and all the immediate sub-patches were applied. This state indicates that there are deferred sub-patches in the update file, and a system reset of the proper level has not occurred since the update file was received.

- d. deferred partially applied — an error condition that is valid only when a update that is in the process of being applied fails. Check the validity of the update file that was sent, and then check the hardware error log for tape errors, and follow standard maintenance procedures.
- e. entirely applied to memory — the update associated with the memory-resident identifier has been completely applied to memory.

list disabled-mos

This command displays all the MOs that have been maintenance disabled in the system.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list disabled-mos	<i>print</i> <i>schedule</i>	Report sent to printer. Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list disabled-MOs list disabled-MOs print list disabled-MOs schedule	init inads	none	none

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

```
list disabled-MOs

      DISABLED MAINTENANCE OBJECT INFORMATION

Maintenance Name  Location  Status
ALL              Enabled
DIG-LINE         02A1203  Disabled

Command successfully completed
```

Field descriptions

Maintenance Name	The type of maintenance object (or group of maintenance objects) that have been disabled. All is also valid.
Location	The physical location of the disabled maintenance object that has been disabled. This field displays blanks if all maintenance objects have been disabled (disable all) or all MOs of a specific type have been disabled (disable MO-all).
Status	Whether the maintenance object or group of maintenance objects is Enabled or Disabled.

list history

The list history command generates a log listing of the most recently completed “data affecting” administration and maintenance commands. Data commands are those administration and maintenance commands that change the data state associated with any object and qualifier in the system. Administration data commands affect translation data, while maintenance data commands affect state information. For example, **change station** is a data command, whereas **display station** is not.

All information in the transaction log is saved on tape as translation data when the **save translation** command is performed (LIFO order). When the switch COLD I starts or reboots, the saved translation, and thus the transaction log, is loaded from tape. In this way, the translation data and the data in the transaction log remain compatible.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list history	<i>print</i> <i>schedule</i>	Report sent to printer. Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list history list history print list history schedule	init inads craft cust browse nms	none	See below

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The translation log is written to the memory card as translation data when the **save translation** command is executed. The translation data is time stamped when saved. This time stamp is noted when translation is loaded from the memory card and included in all recent change history reports.

When a user requests a recent change history report, there could be other users concurrently issuing data commands and altering the contents of the transaction log. Therefore, if the user pages the entire way through the report, the oldest entries in the transaction log (maximum 250 commands) may have been overwritten by data commands issued by these other users. Should this occur, the final entries of the report show the data commands issued by the other users since the recent change history report was originally requested.

Also, use of the **set time** command to alter the system clock could make it look as if the recent change history report is not in true LIFO order.

Output

```
list history                               Page 1   SPE A

Field descriptions

Date The date the command was issued in (mm/dd format)

Time The time the command was issued (in hh:mm format)

Port The port type to which the user was connected when the command was issued.

Port Number	Board	List History Display
0 - 30	EPN Maintenance Board Port	MAINT
31 - 40	System Access Port	SYS-PORT
41	Maintenance Board Port	SYSAM-LCL
42	Remote Maintenance Board Port	SYSAM-RMT

Login User login

Actn The first word (verb) of the command, specifying the operation to be performed. This field is truncated after four characters to allow enough space for objects and qualifiers. Four characters is enough to uniquely identify each action.

Object The qualifier, or second phrase of the command, specifying the particular thing being acted upon by the command. Twelve characters is enough to uniquely identify each object.

 **NOTE:**
Where the object is multiple words in length, only the first word will be displayed in the object field. All succeeding words will be treated as qualifiers. This field is truncated after twelve characters to allow enough space for qualifiers.

Qualifier One or more qualifiers describing the characteristics of the action/object pair. This field is truncated after 31 characters to keep information for a command on a single line.

list isdn-testcall

This command displays the ISDN-PRI trunks in use for ISDN-PRI test calls. This command is useful to determine which trunk is in use for an outgoing ISDN-PRI test call.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list isdn-testcall	<i>print</i> <i>schedule</i>	Report sent to printer. Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list isdn-testcall list isdn-testcall print list isdn-testcall schedule	init inads craft	none	none

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

```
list isdn-testcall

          ISDN-PRI TESTCALLS
B-Channel Start Time   Duration  M/T Port
078/001   25/12:36      120       1B1102

Command successfully completed
```

Field descriptions

B-Channel	The trunk in use for the ISDN-PRI test call (trunk group number/ member number).
Start Time	The time the test call started (dd/hh:mm format).
Duration	The expected duration of the test call.
M/T Port	The TN771 Maintenance/Test circuit pack's digital port address (in cabinet/carrier/slot/circuit format) in use for the outgoing asynchronous ISDN-PRI test call.

list marked-ports

This command lists all the ports that have been marked unusable with the **mark port** command (maximum of fifteen marked ports per page).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list marked-ports	print	Report sent to printer.	init inads craft cust rcust bcms browse	none	none
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list marked-ports list marked-ports print list marked-ports schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

```
list marked-ports

      Port      MARKED-PORT INFORMATION
      Board-Type
1C0101    DIG-BD
1C0601
1C0702    DIG-BD

Command successfully completed
```

Field descriptions

- Port
- The port address (cabinet-carrier-slot-circuit) of the marked port.
- Board-Type
- The type of circuit pack containing the marked port. If this circuit pack information is no longer available because the circuit pack was removed after the port was marked, the Board-Type field is blank.

list measurements

This command lists performance measurements of a DS-1 link indicating the quality of the DS-1 physical interface between the system and a far end system. The **ds1 summary** option provides a summary report while the **ds1 log** option provides a detailed report.

 **NOTE:**
The **list measurements** command has many more options than documented here. Only those options dealing with DS1 board are documented below.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list measurements	<i>log</i>	Detailed report generated	init inads craft cust rcust browse nms bcms	none	none
	<i>summary</i>	Summary report generated			
	<i>ds1_location</i>	The physical location of a DS1 circuit pack entered as cabinet-carrier-slot.			
	<i>print</i>	Report sent to printer.			
	<i>schedule</i>	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list measurements ds1 log 2a18 list measurements ds1 summary 2a18 print list measurements ds1 summary 2a18 schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

```
list measurements ds1 summary 2a19                               SPE A

Command successfully completed
```

Field descriptions (list measurements
ds1-summary)

- Counted Since: The start time and date when the associated measurement counters were cleared or the DS1 circuit pack was administered.
- Number of Seconds Elapsed Into Current 15-min Interval: The number of seconds from the beginning of the current 15-minute interval (0 - 900).
- Total of Valid 15-min Intervals in Past 24-hr Period: The total number of 15-minute intervals in the past 24-hour period that contain valid data (0 - 96).

Category	The four categories correspond to four measurement error counters. The four categories are "","","" and "". The meanings of each category follow: ■ Errored Seconds: the value of the errored seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid). ■ Bursty Err Secs: the value of the bursty errored seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid). ■ Severely Err Secs: the value of the severely errored seconds counter for the specified 15-minute interval(0 - 900 or N/A if data for the 15-minute interval is invalid). ■ Failed Seconds: the value of the failed seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid).
Worst_15-Min_Interval	The date(Date), end time(Time), and error count (Count; from 0 to 900 in increments of four) of the 15-minute interval in the previous 24-hour period that contains the maximum value for each of the four error categories.
Total of 24-Hour Count	The sum of all valid 15-minute counts for the previous 24-hour period for each of the four error categories (0 - 65535).
Current 15-Minute Interval	The error count for the current (incomplete) 15-minute interval for each of the four error categories (0 - 900 or N/A if data for the 15-minute interval is invalid).

```
list measurements ds1 log 2a19                                SPE A

Switch Name:                               Date: 1:26 pm  THU APR 16, 1992

4/16  13:20    0      0          0         0        y

Command successfully completed
```

Field descriptions (list measurements ds1 log)

Counted Since:	The start time and date when the associated measurement counters were cleared or the DS1 circuit pack was administered.
DATE	The date of the 15-minute interval.
TIME	The time of the 15-minute interval.
ERRORED SECONDS	The value of the errored seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid).
BURSTY ERR SECS	The value of the bursty errored seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid).
SEVERELY ERR SECS	The value of the severely errored seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid).
FAILED SECONDS	The value of the failed seconds counter for the specified 15-minute interval (0 - 900 or N/A if data for the 15-minute interval is invalid).
VALID INTERVAL	This field indicates whether the data for the specified 15-minute interval is valid. Data is considered valid when a count for that 15-minute interval. If the field has a value of y, the data for the four error categories is valid; otherwise, the data is invalid. Data is considered valid when a count for that 15-minute interval is retrieved and none of the following invalid conditions occur: — If a system warm start or a system cold start occurred during the interval — If the DS1 circuit pack was not inserted during the interval — If the system time was changed during the interval — If the system was too busy to respond to a poll request for the interval.

list mst

This command displays the messages in the trace buffer and can be used when the trace is disabled or active, but if active, older messages may be sporadically omitted if wraparound is selected and the message rate is high. The command can be used repeatedly without destroying the integrity of the buffer.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list mst	from message number	Message number to start the display; if the number is not in the buffer, then that is indicated on the display, and no additional messages are displayed. Omitting this qualifier causes messages to be displayed starting with the oldest FIFO and continuous messages.	init inads	FIFO order	See documentation on the system printer feature.
	count number	Message count; can be used to limit the trace			
	continuous	Display updates as new messages enter the trace buffer (FIFO). This option is most useful in conjunction with "auto-page." The command terminates only when canceled by the user.			
	LIFO	Newest message displayed first.			
	FIFO	Messages displayed in the order received.			
	[auto-page]	The screen will automatically page when full. Used in combination with continuous (above), provides a way to "watch" as messages arrive.			
	print	Report sent to printer.			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list mst continuous list mst continuous auto-page list mst LIFO list mst from 222 count 7			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

```
list mst

Table 8-2. Summary of MST Message Types — Continued

Code	Description
0xA0	X.25 Outgoing application data message
0xA1	X.25 Incoming application data message
0xA2	X.25 Application error message
0xB0	X.25 Outgoing session layer control message
0xB1	X.25 Incoming session layer control message
0xCF	X.25 Message confirmation
0xD0	X.25 Outgoing processor channel control message
0xD1	X.25 Incoming processor channel control message
0xD2	X.25 Link control message
0xD3	X.25 Link status message
0xE2	X.25 Session Timer Expirations
0xF0	X.25 Error Message (Outgoing Message Lost)
0xF1	X.25 Unrecognized Messages
0xF2	X.25 Error Message (DIP ICOM Record Aborted) (R2 Only)
0xF9	Snapper instrumentation message
0xFA	Snapper continuation message (for large msgs)

Detailed description of Messages**

Note that the X.25 messages discussed below really follow the BX.25 Message Protocol.

The terminology Message[n] used below refers to the byte at offset n in the message being displayed.

MST message types contain a version number. Whenever the structure of the MST message changes, the version field in the MST buffer is changed. Version 1 (default) displays a blank in the version field which is immediately after the MST message type field. Subsequent versions display the version number after the MST message type field and are connected with a hyphen ("-"). For example: Version 2 of the X.25 Application error/notification message has added the text of the pm state table stimulus which was ignored.

Version 1 of MST message type 0xA2 would appear on the 'list mst' output:

Number	Date/Time	Type	Message
1	11:41:22:425	A2	17 10

Version 2 of MST message type 0xA2 would appear on the list mst output:

Number	Date/Time	Type	Message
90	12:41:14:112	A2-02	17 10 21 03 32 05 01 80

Vector Trace

Message type: 0x10

Message format:

- Message[1-4] = call identifier (CID) (defined in \$BASEPJ/hdrs/capro.h)
- Message[5-6] = vector number (defined in \$BASEPJ/hdrs/dpm_calls.h)
- Message[7] = step number (defined in \$BASEPJ/hdrs/callr.h)
- Message[8] = step type (defined in \$BASEPJ/hdrs/dpm_calls.h)
- Message[9] = step state (defined in \$BASEPJ/hdrs/dpm_calls.h)
- Message[10-12] = VDN
- Message[13] = port network number
- Message[14] = endpoint number
- Message[15] = angel number
- Message[16] = circuit number
- Message[17-20] = trunk number
- Message[21+] = auxiliary data (based on step type)

Vector Event Trace (D92 Only)

Message type:

0x11

Message format:

Message[1-4] = cid (defined in \$BASEPJ/hdrs/capro.h)

Message[5-6] = event

Message[7+] = auxiliary data (based on event)

Events are defined in \$BASEPJ/hdrs/evnt_defs.h. Events based on the call_p will have the following auxiliary data:

Message[7-8] = vector number

Message[9-10] = step number

Events based on the grp_m will have the following auxiliary data:

Message[7-10] = hunt group number

IMT (D92)

The messages described in this section cannot be controlled directly through any of the MST screens. They are enabled/disabled through TCM but their output goes to the MST buffer. See [IMT] for details on these messages.

A read-only field in the "change mst" screen, "Other Tracing?", alerts the user that one or more of these types of messages is enabled.

0x21 - IMT proc_errs

Message format:

Message[1-4] = process number(lname)

Message[5-8] = sequence number (defined in *.p/hdrs/main_err.h, for example: \$BASEPJ/gmtce.ss/hmm.p/hdrs/main_err.h)

Message[9-12] = data 1

Message[13-17] = data 2

0x22 - IMT crec

Message format:

Message[1+] = call record (defined as CALLR typedef in \$BASEPJ/hdrs/callr.h)

0x23 - MT_IMT (miscellaneous IMT hooks)

This message type is for miscellaneous IMT hooks. The only sub-type currently available is for a debug button (dbut). The button number is provided in the debug button MST message so that more than one button can be administered (through IMT) to convey different meanings. For example, depression of button N could signify the start of the problem symptoms, while depression of button N + X could signify the end of the problem symptoms. Note that the button number being logged represents the position of a button on a particular set type, and will be different depending on set type and module type (feature, coverage, display, ...), etc. The mapping of the button number stored in the IMT_BUT_DEBUG MST message to a position on the set is not trivial, however, the debug buttons can be administered through TCM, debug button filtering enabled through TCM and MST enabled using the 'enable mst' command and the resultant messages sent to MST when each button is depressed can be examined for the button data and noted.

Message format:

Message[1] = 0x01 (debug button sub-type, IMT_BUT_DEBUG)
Message[2-3] = button number
Message[4-7] = user id

0x40 - internal message tracing of call_p, conn_m, grp_m, serv_d, suser_m

Message formats: conn_m, grp_m, and suser_m:

Message[1-4] = user identifier
Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)
Message[7+] = standard message (depends on hook type)

serv_d (map-type messages):

Message[1-4] = user identifier
Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)
Message[7] = STIM type
Message[8-11] = service identifier
Message[12] = port network number
Message[13] = endpoint number
Message[14] = angel number
Message[15] = circuit number
Message[16+] = message

serv_d (other serv_d messages):

- Message[1-4] = user identifier
- Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)
- Message[7] = STIM type
- Message[8-11] = service identifier
- Message[12-13] = interpreted STIM
- Message[14-17] = aux data 0
- Message[18-21] = aux data 1
- Message[22-25] = aux data 2
- Message[26-29] = aux data 3
- Message[30] = hwtype field
- Message[31] = hwdata field

call_p:

- Message[1-4] = call identifier
- Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)
- Message[7] = supervisor
- Message[8] = digit prep
- Message[9+] = message

CCMS

Message types:

- 0x30 uplink
- 0x31 downlink

Message format:

- Message[1] = port network number
- Message[2] = endpoint number
- Message[3] = angel number
- Message[4] = circuit number
- Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)

- Message[7] = message length
- Message[8] = angel id
- Message[9+] = standard CCMS message

Packet (D92)

Message type:

0x32 uplink

Message format:

- Message[1-4] = user identifier
- Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)
- Message[7-10] = link identifier
- Message[11-12] = message type (defined in \$BASEPJ/hdrs/pcd_calls.h)
- Message[13+] = standard packet message

Message type:

0x33 downlink

Message format:

- Message[1] = port network number
- Message[2] = endpoint number
- Message[3] = angel number
- Message[4] = circuit number
- Message[5-6] = hook identifier (defined in \$BASEPJ/hdrs/mstencode.h)
- Message[7-10] = link identifier
- Message[11+] = standard packet message

ASAI

ASAI messages listed on the MST screen consist of a 4 octet header and a variable length body. The header contains the ASAI port address encoded with 8 hexadecimal digits. This same encoding is also used for BRI and PRI.

In message types other than 50 and 51 (Level 2 Primitives), following the port address is a one octet field called the qualifier. The meaning of the qualifier varies according to the type (as specified by the MST encode) of ASAI message

traced. The body which is a real ASAI message (except for Level 2 Primitives) follows the qualifier.

When the display is administered for abbreviated format, the body contains only the initial part of the ASAI message (all information in beginning of message up to and including the Q.931 IE tag) plus the cause IE (if present).

0x50 - ASAI level 2 uplink primitive

Message[1] = Port Network Number of ASAI port

Message[2] = reserved

Message[3] = Carrier Address of ASAI port

Message[4] = Port number of ASAI port

Message[5] = SAPI

Message[6] = TEI

R1:

Message[7,8] = Link ID

Message[9] = Uplink encode
0x01 - ASAI Link State
0x02 - TEI Management Message
0x03 - XID Message

Message[10] = R1/R3 Link States:
0x00 - the link has gone down
0x01 - the link has come up
0x02 - the link id has changed
0x03 - the link has gone hyperactive
0x04 - the link has recovered
0x05 - the audit recovery stim
0x06 - the link has been reset
0x07 - link state hyper (too many SABMEs) disconnect
0x08 - broadcast link audit

= R1/R3 TEI Management Message
0x01 - Identity request
0x05 - Identity Check Response
0x07 - Identity Verify Request

= R1/R3 XID Messages
0x01 - XID Request
0x02 - XID Response

R3:

Message[7-10] = Link ID

Message[11] = Uplink encode
0x01 - ASAI Link State
0x02 - TEI Management Message
0x03 - XID Message

Message[12] = ASAI Link State:
0x00 - the link has gone down
0x01 - the link has come up
0x02 - the link id has changed
0x03 - the link has gone hyperactive
0x04 - the link has recovered
0x05 - the audit recovery stim
0x06 - the link has been reset
0x07 - link state hyper (too many SABMEs)
disconnect
0x08 - broadcast link audit

= TEI Management Message
0x01 - Identity request
0x05 - Identity Check Response
0x07 - Identity Verify Request

= XID Messages
0x01 - XID Request
0x02 - XID Response

0x51 - ASAI level 2 downlink primitive

Message[1] = Port Network Number of ASAI port

Message[2] = Reserved

Message[3] = Carrier Address of ASAI port

Message[4] = Port number of ASAI port

Message[5] = SAPI

Message[6] = TEI

R1:

Message[7,8] = Link ID

 NOTE:

The Link ID has no meaning for the link establish request, therefore the Link ID field will contain 0xff 0x.ff

- Message[9] = Downlink encode
 - 0x01 - ASAI Link Events
 - 0x02 - TEI Management Message
 - 0x03 - XID Message
- Message[10] = ASAI Link Events:
 - 0x02 - link release request
 - 0x0f - link establish request sent to and received by the lower level
- = TEI Management Message
 - 0x02 - Identity Assigned
 - 0x04 - Identity Check Request
 - 0x06 - Identity Remove
- = XID Messages
 - 0x01 - XID Request
 - 0x02 - XID Response
- Message[11] = 0xCA - Cancel Byte

 NOTE:

The cancel byte will only be present if the message was built, but could not be sent.

R3:

- Message[7-10] = Link ID

 NOTE:

The Link ID has no meaning for the link establish request, therefore the Link ID field will contain 0xff 0xff 0xff 0x.ff

- Message[11] = Downlink encode
 - 0x01 - ASAI Link Events
 - 0x02 - TEI Management Message
 - 0x03 - XID Message

- Message[12] = ASAI Link Events:
 - 0x02 - link release request
 - 0x0f - link establish request sent to and received by the lower level

- = TEI Management Message
 - 0x02 - Identity Assigned
 - 0x04 - Identity Check Request
 - 0x06 - Identity Remove

- = XID Messages
 - 0x01 - XID Request
 - 0x02 - XID Response

- Message[13] = 0xCA - Cancel Byte

 NOTE:

The cancel byte will only be present if the message was built, but could not be sent.

0x52 - ASAI maintenance uplink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI port
- Message[5] = 0
- Message[6+] = standard or abbreviated ASAI message format

0x53 - ASAI maintenance downlink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI 3 ort
- Message[5] = 0
- Message[6+] = standard or abbreviated ASAI message format

0x54 - ASAI unrecognized uplink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI port
- Message[5] = failure cause

Failure causes

- 0x2a (42.) - Overload Controls in Effect
- 0x32 (50.) - Requested Feature Not Administered
- 0x45 (69.) - Requested Feature Not Implemented
- 0x51 (81.) - Invalid CRV
- 0x5f (95.) - Invalid Message
- 0x60 (96.) - Mandatory Information Element Missing
- 0x61 (97.) - Message Non-Existent/Not Implemented
- 0x63 (99.) - Information Element non-existent
- 0x64 (100.) - Invalid Information Element Contents
- 0x6f (111.) - Protocol Error

Message[6+] = standard or abbreviated ASAI message format

 **NOTE:**
An unrecognized message displayed in abbreviated format may be missing information (such as cause) because the message was not able to be parsed.

0x55 - ASAI unrecognized downlink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI port
- Message[5] = failure reason

Failure reasons

- 1 - link flow controlled
- 2 - internal software error - see software error log
- 3 - packet interface problem - see error log

Message[6+] = standard or abbreviated ASAI message format

0x56 - ASAI association uplink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI port
- Message[5] = association type

Association Type

- 0 - unknown
- 1 - call control
- 2 - domain control
- 3 - notification
- 4 - adjunct routing
- 5 - set value

- 6 - value query
- 7 - request feature

Message[6+] = standard or abbreviated ASAI message format

0x57 - ASAI Association downlink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI port
- Message[5] = association type
- Message[6+] = standard or abbreviated ASAI message format

0x58 - ASAI error uplink

- Message[1] = Port Network Number of ASAI port
- Message[2] = Reserved
- Message[3] = Carrier Address of ASAI port
- Message[4] = Port number of ASAI port
- Message[5] = failure cause

Failure causes

- 1 - 127 are code standard zero cause values
- 128 - 255 are code standard three cause values (+ 128)

Message[6+] = standard or abbreviated ASAI message format

ISDN

0x60 - ISDN PRI uplink

- Message[1] = Port Network Number of D-channel port
- Message[2] = Reserved
- Message[3] = Carrier Address of D-channel port
- Message[4] = Port number of D-channel port
- Message[5+] = standard ISDNPRI format

 **NOTE:**
In abbreviated format, the header of the Q.931 message, the cause IE (if present) and the channel id Information Element (IE) (if present) are the only IEs present.

0x62 - ISDN PRI downlink

- Message[1] = Port Network Number of D-channel port
- Message[2] = Reserved
- Message[3] = Carrier Address of D-channel port
- Message[4] = Port number of D-channel port
- Message[5+] = standard ISDNPRI format

 **NOTE:**
In abbreviated format, the header of the Q.931 message, the cause IE (if present) and the channel id IE (if present) are the only IEs present.

0x64 - ISDN BRI uplink

- Message[1] = Port Network Number of BRI port
- Message[2] = Reserved
- Message[3] = Carrier Address of BRI port
- Message[4] = Port number of BRI port
- Message[5] = SAPI
- Message[6] = TEI

R1:

- Message[7,8] = Link ID
- Message[9+] = standard ISDNBRI format

R3:

- Message[7-10] = Link ID
- Message[11+] = standard ISDNBRI format

 **NOTE:**
In abbreviated format, the header of the Q.931 message, the cause IE (if present) and the channel id Information Element (IE) (if present) are the only IEs present.

0x66 - ISDN BRI downlink

- Message[1] = Port Network Number of BRI port
- Message[2] = Reserved
- Message[3] = Carrier Address of BRI port
- Message[4] = Port number of BRI port
- Message[5] = SAPI
- Message[6] = TEI

R1:

- Message[7,8] = Link ID
- Message[9+] = standard ISDNBRI format

R3:

Message[7-10] = Link ID

Message[11+] = standard ISDNBRI format

NOTE:

In abbreviated format, the header of the Q.931 message, the cause IE (if present) and the channel id IE (if present) are the only IEs present.

An additional cancel byte (0xCA) may be present after the standard ISDNBRI formatted message if the message was not sent. The cancel byte will not be appended if the abbreviated format is selected.

0x68 - ISDN BRI level 2 uplink primitive

Message[1] = Port Network Number of BRI port

Message[2] = Reserved

Message[3] = Carrier Address of BRI port

Message[4] = Port number of BRI port

Message[5] = SAPI

Message[6] = TEI

R1:

Message[7,8] = Link ID

Message[9] = Uplink encode
0x01 - BRI Link State
0x02 - TEI Management Message
0x03 - XID Message

Message[10] = R1/R3 Link States:
0x00 - the link has gone down
0x01 - the link has come up
0x02 - the link id has changed
0x03 - the link has gone hyperactive
0x04 - the link has recovered
0x05 - the audit recovery stim
0x06 - the link has been reset
0x07 - link state hyper (too many SABMEs)
disconnect
0x08 - broadcast link audit

= R1/R3 TEI Management Message
0x01 - Identity request
0x05 - Identity Check Response
0x07 - Identity Verify Request

= R1/R3 XID Messages
0x01 - XID Request
0x02 - XID Response

R3:

Message[7-10] = Link ID

Message[11] = Uplink encode
0x01 - BRI Link State
0x02 - TEI Management Message
0x03 - XID Message

Message[12] = BRI Link State:
0x00 - the link has gone down
0x01 - the link has come up
0x02 - the link id has changed
0x03 - the link has gone hyperactive
0x04 - the link has recovered
0x05 - the audit recovery stim
0x06 - the link has been reset
0x07 - link state hyper (too many SABMEs)
disconnect
0x08 - broadcast link audit

= TEI Management Message
0x01 - Identity request
0x05 - Identity Check Response
0x07 - Identity Verify Request

= XID Messages
0x01 - XID Request
0x02 - XID Response

0x6A - ISDN BRI level 2 downlink primitive

- Message[1] = Port Network Number of BRI port
- Message[2] = Reserved
- Message[3] = Carrier Address of BRI port
- Message[4] = Port number of BRI port
- Message[5] = SAPI
- Message[6] = TEI

R1:

- Message[7,8] = Link ID

 **NOTE:**
The Link ID has no meaning for the link establish request, therefore the Link ID field will contain 0xff 0xff

- Message[9] = Downlink encode
 - 0x01 - BRI Link Events
 - 0x02 - TEI Management Message
 - 0x03 - XID Message
- Message[10] = BRI Link Events:
 - 0x02 - link release request
 - 0x0f - link establish request sent to and received by the lower level
- = TEI Management Message
 - 0x02 - Identity Assigned
 - 0x04 - Identity Check Request
 - 0x06 - Identity Remove
- = XID Messages
 - 0x01 - XID Request
 - 0x02 - XID Response
- Message[11] = 0xCA - Cancel Byte

 **NOTE:**
The cancel byte will only be present if the message was built, but could not be sent.

R3:

- Message[7-10] = Link ID

NOTE:

The Link ID has no meaning for the link establish request, therefore the Link ID field will contain 0xff 0xff 0xff 0x.ff

- Message[11] = Downlink encode
 0x01 - BRI Link Events
 0x02 - TEI Management Message
 0x03 - XID Message
- Message[12] = BRI Link Events:
 0x02 - link release request
 0x0f - link establish request sent to and received by
 the lower level
- = TEI Management Message
 0x02 - Identity Assigned
 0x04 - Identity Check Request
 0x06 - Identity Remove
- = XID Messages
 0x01 - XID Request
 0x02 - XID Response
- Message[13] = 0xCA - Cancel Byte

NOTE:

The cancel byte will only be present if the message was built, but could not be sent.

0x6C - ISDN PRI level 2 uplink primitive

- Message[1] = Port Network Number of D-channel port
- Message[2] = Reserved
- Message[3] = Carrier Address of D-channel port
- Message[4] = Port number of D-channel port
- Message[5] = change type

R1/R3 change types:

0x01 - session up notification

0x02 - Session down notification

0x6D - ISDN PRI level 2 downlink primitive (not implemented)

- Message[1] = Port Network Number of D-channel port
- Message[2] = Reserved

- Message[3] = Carrier Address of D-channel port
- Message[4] = Port number of D-channel port
- Message[5] = change type

R1/R3 change types:
0x01 - link establish request
0x02 - link release request

0x6E - ISDN PRI Unrecognized Messages

- Message[1] = Port Network Number of D-channel port
- Message[2] = Reserved
- Message[3] = Carrier Address of D-channel port
- Message[4] = Port number of D-channel port
- Message[5] = type of failure

Types of failure:
0x01 - outgoing ISDNPRI
0x02 - incoming ISDNPRI

- Message[6+] = standard ISDN format

0x6F - ISDN BRI Unrecognized Messages

- Message[1] = Port Network Number of BRI port
- Message[2] = Reserved
- Message[3] = Carrier Address of BRI port
- Message[4] = Port number of BRI port
- Message[5] = SAPI
- Message[6] = TEI

R1:

- Message[7,8] = Link ID
- Message[9] = type of failure

Types of failure:

0x01 - outgoing ISDN
0x02 - incoming ISDN

Message[10+] = standard ISDNBRI format

R3:

Message[7-10] = Link ID

Message[11] = type of failure

Types of failure:

0x01 - outgoing ISDN
0x02 - incoming ISDN

NOTE:

In abbreviated format, the header of the Q.931 message, the cause IE (if present) and the channel id IE (if present) are the only IEs present.

An additional cancel byte (0xCA) may be present after the standard ISDNBRI formatted message if the message was not sent. The cancel byte will not be appended if the abbreviated format is selected.

General

0x71 - GAP marker

Message[1] = GAP reason

Message[2] = GAP count (since last clear - high byte)

Message[3] = GAP count (since last clear - low byte)

GAP reasons:

0x01 - disabled, disable mst command executed
0x02 - disabled, mst timer expired
0x03 - disabled, buffer full on no-wrap
0x04 - disabled, restart occurred
0x05 - disabled, by stop trigger or count
0x06 - disabled, audit error
0x07 - not disabled, stopped by stop trigger or count

0x72 - Time changed while trace enabled

Message[1] = 0x00
Message[2] = timestamp indication

timestamp indication:

0x00 - MST timestamp is old time
0x01 - MST timestamp is new time

X.25 Application Data

The processor channel number is the R1/R3 term, and R2 calls it the port number. The processor channel number is equal to the Application port number in R1. In R3, the processor channel admin screen should be inspected to determine the mapping.

0xA0 - X.25 outgoing application message

Message[1] = processor channel number
Message[2] = sequence number
Message[3] = buffer id
Message[4] = 0x00
Message[5+] = application message¹

1. Application messages will contain the session layer data headers and the data.

In abbreviated mode, the application message is not saved.

0xA1 - X.25 incoming application message

Message[1] = processor channel number
Message[2] = sequence number
Message[3+] = application message

In abbreviated mode, the application message is not saved.

Application Control

0xA2 - X.25 application error or notification

NOTE:

The 'X.25 application error message' category contains notifications as well as errors.

0xA2, 0xF0 and 0xF2 messages will be turned on by responding 'y' to the 'Application Errors?' field.

Version 1:

Message[1] = processor channel number

Message[2] = application error/notification

Version 2:

Message[1] = processor channel number

Message[2] = application error/notification

Message[3+] = pm stimulus ignored (For message[2] == 0x10 only)

Errors/Notifications:

R1/R3:

- 0x01 - no outgoing buffer available
- 0x05 - pvc session down
- 0x06 - pvc session up
- 0x07 - pvc session connect
- 0x08 - pvc session restart
- 0x09 - message buffer overload uplink
- 0x0A - message buffer overload downlink
- 0x0B - message buffer exhaustion
- 0x0C - max # of outgoing msgs allowed
- 0x0D - bad msg type in message buffer routine
- 0x0E - no message buffers available
- 0x0F - message buffer pointer error
- 0x10 - pm state table stimulus ignored
- 0x11 - bad session connect message

Session Layer Control

NOTE:

The session layer header is considered part of the session layer message.

0xB0 - X.25 outgoing session layer control message

Message[1] = processor channel number
Message[2] = session layer message type
Message[3] = buffer id
Message[4] = 0
Message[5+] = session layer message

session layer message type:

0x00 - session connect
0x01 - session accept
0x02 - session reject
0x03 - session disconnect
0x04 - reserved
0x05 - reserved
0x06 - resynch
0x07 - reserved
0x08 - resynch acknowledge

In abbreviated mode, the session layer message is not saved.

0xB1 - X.25 incoming session layer control message

Message[1] = processor channel number
Message[2] = session message type
Message[3+] = session message

session message type:

0x00 - session connect
0x01 - session accept
0x02 - session reject
0x03 - session disconnect
0x04 - reserved
0x05 - reserved
0x06 - resynch
0x07 - reserved
0x08 - reserved

In abbreviated mode, the session layer message is not saved.

0xCF - message confirmation

This confirmation is X.25 far end confirmation.

- Message[1] = processor channel number
- Message[2] = internal buffer id
- Message[3] = count of outgoing buffers confirmed

Processor Channel Control

0xD0 - outgoing control message

- Message[1] = processor channel number
- Message[2] = message event

Message events for R1:

- 0x00 - Request Reset of Logical Channel
- 0x05 - Ack. Reset of Logical Channel
- 0x06 - Flow Control Uplink
- 0x07 - Release Uplink Flow Control
- 0x0A - Flow Control Downlink
- 0x0B - Release Downlink Flow Control

Message events for R3:

- 0x00 - Request Reset of Logical Channel
- 0x08 - Connect Processor Channel
- 0x09 - Disconnect Processor Channel
- 0xD1 - X.25 incoming control message

- Message[1] = processor channel number
- Message[2] = message event

R1 Message events:

- 0x01 - Performed Requested Reset of Logical Channel
- 0x06 - Resetting Logical Channel
- 0x0A - Level 3 Restart¹

R3 Message events:

1. If this event occurs, one restart for each logical channel will be written into the MST trace.

- 0x01 - Performed Requested Reset of Logical Channel
- 0x06 - Resetting Logical Channel
- 0x08 - processor channel connected
- 0x09 - processor channel disconnected

Link Control

0xD2 - link control

- Message[1] = interface link number
- Message[2] = message event

R1 Message events:

- 0x00 - Busy Out Link
- 0x01 - Release Busied Out Link
- 0x0A - Level 3 Restarting

R3 Message events:

- 0x00 - Stop Link
- 0x01 - Start Link
- 0x0A - Level 3 Restarting

0xD3 - link status (R3 Only)

- Message[1] = interface link number
- Message[2] = message event

R3 Message events:

- 0x02 - Session Down
- 0x03 - Session Up

Session Sanity

0xE2 - X.25 Session Timer Expirations

- Message[1] = processor channel number
- Message[2] = timer

Timers:

0x00 - ST2(session connect)
0x01 - ST3(retransmission)

Message[3] = countdown from A1

0x02 - ST4(resynchronization)

No count

0x03 - ABT1(abort session 1)

Message[3] = protocol machine state where timeout occurred

0x04 - ABT2(abort session 2)

Message[3] = protocol machine state where timeout occurred

0x05 - State Timer

Message[3] = protocol machine state where timeout occurred

0x06 - Message Timer

Message[3] not used

Protocol Machine States:

BAD_STATE	0x00 /* 0 is very common, don't use as a state */
PT_UNALLOC	0x01 /* port is un-allocated */
QUIESCENT	0x02 /* quiescent - allocated but not used */
ENTER_wSA	0x03 /* entering wSA - reset issued, not ABT/CON */
W_ACCEPT	0x04 /* Waiting for Session Accept*/
DATA_XFER	0x05 /* Data Transfer State*/
DATA_RESYNC	0x06 /* Resynchronization state */
PRI_ALLOC	0x07 /* pri port allocated but not yet used */
PRI_CONN	0x08 /* pri port connected */
HIGH_STATE	0x08 /* Highest value a port state can be*/

X.25 Errors

0xF0 - X.25 Error Message (Outgoing Message Lost)

Note that 0xA2, 0xF0 and 0xF2 messages will be turned on by responding 'y' to the 'Application Errors?' field.

Version 1:

- Message[1] = processor channel number
- Message[2] = sequence number
- Message[3+] = message

Version 2:

- Message[1] = processor channel number
- Message[2] = sequence number
- Message[3] = reason code
- Message[4+] = message

Reason Codes:

- 0x00 /* message lost */
/* 1 reserved */
- 0x02 /* message ignored, sequence number is within window but less
* than expected
*/
- 0x03 /* message ignored, bad sequence number */
- 0x04 /* message ignored, other port has sent a disconnect message */
- 0x05 /* message ignored, send request is rejected*/
- 0x06 /* message ignored, from ig_l3 */
- 0x07 /* message ignored, from l3_err */
- 0x08 /* sequence number is within window but less
* than expected (resync)
*/
- 0x09 /* bad sequence number (resync) */

In abbreviated mode, the application message is not saved.

0xF1 - Unrecognized X.25 Messages

- Message[1] = processor channel number
- Message[2] = Failure type
- Message[3+] = session message

Failure types:

- 0x00 - Reserved
- 0x01 - Unknown session layer message type
- 0x02 - unrecognized control message

0xF2 - BX.25 Error Message (DIP ICOM Record Aborted)

R2 only

list suspend-alm-orig

This command lists active entries in the Suspend Alarm Origination table. Even though this command only lists active entries, an entry that expires during the list process still appears in the output. If the Suspend Alarm Origination table is empty, the output contain only the title and field headings.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
list suspend-alm-orig	print schedule	Report sent to printer. Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: list suspend-alm-orig list suspend-alm-orig print list suspend-alm-orig schedule	init inads craft	none	none

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

```
list suspend-alm-orig

                Suspend Alarm Origination Entries

Physical      Board      Expires At
01C03         off-only   06/11/15:06
01E0407       on-and-off  06/11/17:26
01E0406       on-and-off  06/12/45:34
```

list testcalls

This command generates an Automatic Transmission Measurement System (ATMS) report. The ATMS allows the voice and data trunk facilities to be measured for satisfactory transmission performance. The performance of the trunks is evaluated according to measurements produced by a series of analog tests and are compared against user-defined threshold values. The purpose of the report is to provide measurement data to help determine the quality of trunk lines. The measurement report contains data on trunk signal loss, noise, singing return loss, and echo return loss.

The measurements are produced by a set of analog trunk tests. The tests are initiated by a maintenance demand test or by a set of scheduled tests. The largest portion of these measurements are generated through scheduled testing during system quiet hours (hours where the traffic volume is low). Each trunk test performed by the system stores the results in a database. The trunk measurements in this database reflect the state of each trunk at the time of its last test.

Action/Object	Qualifiers/Options	Qualifier/Option Description
list testcalls	<i>detail</i>	Detailed measurement report displayed
	<i>summary</i>	Summary measurement report displayed
	<i>grp group number</i>	Measurements for a specific trunk group displayed. When used with the <i>to-grp</i> option, this option is the starting trunk group in a range of user-specified trunk groups.
	<i>to-grp group number</i>	Measurements for all trunk groups from 1 to the specified "to-grp" trunk group are displayed. When used with the <i>grp</i> option, this option is the ending trunk group in a range of user-specified trunk groups.
	<i>mem member number</i>	Measurements for a specific trunk group member displayed. When used with the <i>to-mem</i> option, this option is the starting trunk group member in a range of user-specified trunk group members.

Action/Object	Qualifiers/Options	Qualifier/Option Description
	<i>to-mem member number</i>	Measurements for all trunk group members from 1 to the specified "to-mem" trunk group member displayed. When used with the mem option, this option is the ending trunk group member in a range of user-specified trunk group members.
	<i>port location</i>	Measurements for a specific trunk circuit (port) displayed
	<i>result result identifier</i>	This option is used to filter out all measurement results that do not match the user-specified result, that is, only measurement results that match the user specified result are displayed. Examples of results are pass, marg, fail, etc.
	<i>not-result result identifier</i>	This option is used to filter out all measurement results that do match the user-specified result, that is, only measurement results that do not match the user specified result are displayed. Examples of results are pass, marg, fail, etc.
	<i>count count number</i>	This option is used to specify (limit) the number of records displayed.
	<i>print</i>	Report sent to printer
	<i>schedule</i>	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Examples

```
list testcalls detail

Detail report field descriptions

Group	The trunk group number selected.
Type	The trunk group type.
Vendor	The vendor of this trunk group.
TTL Type	The kind of test line for this trunk group.
Threshold Values	The list of marginal and unacceptable threshold values defined on the trunk group form. The following fields appear on the lower section of the form. Many of the column headings contain the abbreviations "FE" for far end and "NE" for near end. These abbreviations define which end took the measurements.
Trk Mem	The trunk member within the trunk group.

Test Date	The month and day this trunk was tested.
Test Time	The time of day this trunk was tested.
Tst Rslt	This field describes the results of the trunk transmission test.
1004Hz-loss Min	Far-to-near and near-to-far measurements of 1004-Hz loss from low-level tone.
1004Hz-loss Max	Far-to-near and near-to-far measurements of 1004-Hz loss at 0 dBm.
Loss dev at 404Hz	Transmission tests at low frequency. These tests measure a maximum positive and negative deviation of +9 and -9 dB from the 1004-Hz loss measurements.
Loss dev at 2804Hz	Transmission tests at high frequency. These tests measure a maximum positive and negative deviation of +9 and -9 dB from the 1004-Hz loss measurements.
C-msg Noise	Maximum noise interference (in dBnC: decibels above reference noise, which is B(EQ)10 sup -12E(EQ) watts) terminating on a voice terminal within the voice-band frequency range (500 to 2500 Hz) between 15 and 55 dBnC.
C-ntch Noise	Maximum signal-dependent noise interference on a line between 34 and 74 dBnC.
SRL-LO	Singing return loss from 0 to 40 dB between the sum of the circuit (repeater) gains and the sum of the circuit losses. SRL-LO occurs most often in the frequency range of 200 to 500 Hz.
SRL-HI	Singing return loss from 0 to 40 dB between the sum of the circuit (repeater) gains on a circuit and the sum of the circuit losses. SRL-HI occurs most often in the frequency range of 2500 to 3200 Hz.
ERL	Echo return loss from 0 to 40 dB between the level of signal strength transmitted and the level of signal strength reflected. ERL occurs most often in the frequency range of 500 to 2500 Hz.

The following example is the output from the **list testcalls summary grp 80** command.

```
list testcalls summary grp 80                                SPE A

```

Summary report field descriptions

Trk Grp Num	The trunk group number which is being summarized. Only outgoing or two-way analog trunks will be listed.
Num Of Trks	The total number of members per trunk group.
Last Test Date	The date of the oldest measurement in the trunk group.
Last Test Time	The time of the oldest measurement in the trunk group.
Trunks Passed Transm Test	The number of trunks that have passed the trunk transmission tests.
Trunks Failed Marginal Threshld	The number of trunks that failed a marginal threshold, but not an unacceptable threshold according to the threshold values defined on the trunk group form.
Trunks Failed Unaccept Threshld	This is taken from the unacceptable threshold administered on the Trunk group form.
Trks In-Use	The number of trunks that were in-use at the time of testing.
Trks Not Test	The number of trunks that were not tested due to error conditions.
Busied Out Trunks	The number of trunks that were busied out at the time. This could be due to hardware problems, incorrect threshold values, etc.

mark port

The **mark port** command marks faulty ports as defective to prevent their use in other administrative operations (for example, adding a data-module or station). Ports on any type of circuit pack may be marked except for installed circuit packs that are administered automatically (for example, Tone Detector, Tone Generator, Announcement, Speech Synthesizer, Call Classifier and

Maintenance/Test circuit packs). If the port can be administered manually, and it is unassigned, the port is marked as faulty. The **clear port** command reactivates the port. The **list marked-ports command** displays marked ports in a list format. All marked port information is saved as part of translations.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
mark port	location	Physical location: PCSSpp Examples: mark port 1c0208 mark port 2a1001	init inads craft	none	none

monitor bcms

The **monitor bcms** command displays output for agents and splits and summarizes the bcms condition. This on-line status report automatically updates every 30 seconds (or by pressing the `Update` key) until the command is canceled by pressing the `Cancel` key. Three display options are available: skill, split, and system.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
monitor bcms	<i>split</i> <i>split number</i> <i>system</i> <i>system number</i> <i>skill</i> <i>skill number</i>	see below	init inads craft cust rcust bcms browse	none	none

Qualifier Description

- split*

Specifies that the command display status information for a specified split number (an ACD hunt group).
- split number*

The split's identity to the switch and BCMS; an ACD hunt group number (split number). This parameter is entered only when the "split" parameter is entered.
- system*

This specifies that the command display split queue status as well as cumulative split information for all the BCMS measured splits.
- system number*

ACD hunt group numbers (split numbers) separated by spaces and/or split number ranges separated by a hyphen ("-").
- skill*

This specifies that the command display status information for a specified skill number.
- skill number*

The skill's identity to the switch and BCMS; an ACD hunt group number (skill number). This parameter is entered only when the "skill" parameter is entered.

Output

The following examples shows the output from the **monitor bcms system** command.

monitor bcms system									
Page 1 of 1									
BCMS SYSTEM STATUS									
Date: 14:02 THU OCT 17 1991									
SPLIT	CALLS	OLDEST	AVG	AVAIL	#	AVG	#	AVG	AVG
	WAIT	CALL	ANSW	AGENT	ABAND	TIME	ACD	TALK	AFTER
Service	3	1:03	:45	0	3	:30	20	2:30	1:25
Sales	5	:33	:15	0	11	:45	36	1:32	:35

Field descriptions

Date:	The current date and time which is updated every 30 seconds or when the UPDATE key is pressed.
SPLIT	The name of the split being reported, if no name is administered then the split extension is displayed in the form "EXTxxxxx". Splits are displayed in split number order. This field is translation data.
CALLS WAIT	The number of calls currently waiting in this split's queue. If any of these calls are Direct Agent Calls, the field is preceded by an asterisk. This field is real-time status data.
OLDEST CALL	The amount of time that the oldest call has waited in queue. This field is real-time status data.
AVG ANSW SPEED	The average speed of answer for this split during the current period. This includes time in queue and time ringing at the agent's voice terminal. Calls that intraflow (calls that overflow from one ACD split to another split) d not have queue time from previous splits included in the average. The calculation is Total Answer Time/Total Automatic Call Distribution (ACD) Calls. This field is measurement data and includes only those calls that have completed (terminated).
AVAIL AGENT	The number of agents in this split currently available to receive an Automatic Call Distribution (ACD) call from this split. This field is real-time status data.
# ABAND	The number of calls that have abandoned during the current period. This field is measurement data.

AVG ABAND TIME	The average time abandoned calls waited in queue before abandoning during the current period. The calculation is Total Abandon Time/Total Calls Abandoned. This field is measurement data and includes only those calls that have completed (terminated).
# ACD	The number of Automatic Call Distribution (ACD) calls handled by this split during the current period. This includes calls that intraflow into the split. This field is measurement data.
AVG TALK	The average talk time for Automatic Call Distribution (ACD) calls handled by this split during the current period. This does not include ring time at the agents' voice terminal. The calculation is Total ACD Talk Time/Number of ACD Calls. This field is measurement data and includes only those calls that have completed (terminated).
AVG AFTER CALL	The average After Call Work (ACW) time for Automatic Call Distribution (ACD) calls handled by this split during the current period. ACD calls with no ACW time are included in the average. Time spent on direct incoming or outgoing calls while in ACW are not included in the average. The calculation is (Total ACW Time - Total ACW Incoming Time - Total ACW Outgoing Time)/Total ACD Calls. This field is measurement data and includes only those calls that have completed (terminated).

The second example shows the output from the **monitor bcms split 1** command.

```
monitor bcms split 1                               Page 1 of 1   SPE A

BCMS SPLIT (AGENT) STATUS

AGENT      EXT      STATE  TIME    ACD  EXTN IN  EXTN OUT
          CALLS    CALLS    CALLS
```

Field descriptions

Split:	The number of the split requested. This field is translation data.
Split Name:	The name of the split requested. If no name exists the split extension is displayed in the form "EXT xxxxx". This field is translation data.
Date:	The current date and time which is updated every 30 seconds or when the UPDATE key is pressed.
Calls Waiting:	The number of calls currently waiting in this split's queue. If any of these calls are Direct Agent Calls, the field is be preceded by an asterisk. This field is real-time status data.
Oldest Call:	The time in minutes:seconds that the current oldest call has waited in this split's queue. This field is real-time status data.
Staffed	The number of agents currently logged into this split. This field is real-time status data.
Avail	The number of agents currently available to receive an Automatic Call Distribution (ACD) call in this split. Agents are in either the Auto-in or Manual-in work modes and are not currently on a call. If the agent is on another split's call or in After Call Work (ACW) for another split, this agent is not considered available and is not recorded here. This field is real-time status data.
ACD	The number of agents in this split currently on an Automatic Call Distribution (ACD) call for this split. This includes ACD calls that are being handled by this split that arrive as coverage from another split. This field also includes outbound calls (Outgoing Call Manager) that are distributed through the ACD. Note that if an agent puts an ACD call on hold, but does not enter another state (for example, the agent does not enter the AVAIL state), the agent is still seen as in the ACD state. This field is real-time status data.
ACW	The number of agents in this split currently in After Call Work (ACW) for this split. This field is real-time status data.
AUX	The number of agents in this split currently in AUX work for this split. If an agent is on another split's call or in After Call Work (ACW) for another split, this agent is not considered in AUX work and is not be recorded here. This field is real-time status data.
Extn	The number of agents in this split currently on non-ACD (Automatic Call Distribution) calls, either incoming or outgoing directly to or from their extensions. If the agents are also in After Call Work (ACW) or AUX they are recorded as Extn rather than ACW or AUX. This field is real-time status data.

OtherSplit	The number of agents in this split on another split's call or in After Call Work (ACW) for another split. Only used if agents belong to multiple splits. This field is real-time status data.
AGENT	The name of the agent associated with the extension. If no name exists this field is left blank. This field is translation data.
EXT	The extension of the agent. This field is translation data.
STATE	The current state of the agent for this split. This possible states are Avail, ACD, ACW, AUX, Extn In, Extn Out, OtherSplit, and Unstaff. If an agent is staffed, the agent must also be in one of the above states. This field is real-time status data.
TIME	The clock time that the agent entered the current state in hours:minutes. This field is real-time status data.
ACD CALLS	The number of Automatic Call Distribution (ACD) calls (inbound and outbound), that the agent has completed for this split during the current period (half hour or hour). The maximum number of calls is 255, and if this maximum is exceeded, 255 is displayed. This field is measurement data.
EXTN IN CALLS	The number of non-ACD (Automatic Call Distribution) calls that the agent has received (incoming) and completed during the current period. The maximum number of calls is 255, and if this maximum is exceeded, 255 is displayed. This field is measurement data.
EXTN OUT CALLS	The number of non-ACD (Automatic Call Distribution) calls that the agent has made (outgoing) and completed during the current period. The maximum number of calls is 255, and if this maximum is exceeded, 255 is displayed. This field is measurement data.

monitor health

This command displays the current system alarm summary, maintenance busy summary, user summary, critical system status, and cabinet status that are updated each minute.

After this command terminates, all users are logged off.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
monitor health			init inads craft cust nms browse	none	If standby SPE Emergency Transfer Select Switches change and handshakes are down, the displayed Emerg Trans field is incorrect until handshake reinitializes. When the monitor health command terminates, users are logged off of the system.

Field descriptions

- Major
- The number of logged major alarms (0 – 200).
- Minor
- The number of logged minor alarms (0 – 200).
- Warning
- Number of warnings logged in the alarm file (0 – 200).
- Trunks
- Number of busied out maintenance trunks.
- Stations
- Number of busied out maintenance stations.

Others	Combined number of busied out maintenance objects excluding trunks and stations.
Static	Proportion of the CPU currently dedicated to high priority items. This percentage is rounded to the nearest integer, therefore 0 percent means that the occupancy is less than one half of a percent.
SM	Proportion of the CPU currently dedicated to system management or periodic and scheduled maintenance. If large amounts of periodic or scheduled maintenance testing performs, this occupancy percentage can be high without affecting service. This percentage is rounded to the nearest integer, therefore 0 percent means that the occupancy is less than one half of a percent.
CP	Proportion of the CPU currently dedicated to call processing. This occupancy has priority over SM and IDLE occupancy categories and takes processor time away from these occupancy categories, if needed. This percentage is rounded to the nearest integer, therefore 0 percent means that the occupancy is less than one half of a percent.
Idle	Proportion of the CPU currently available. This percentage is rounded to the nearest integer, therefore 0 percent means that the occupancy is less than one half of a percent.
Active SPE	A or B indicate the currently-active processor complex. When the active processor complex is locked on-line with lock switching on DUPINT, the "lock" option displays; otherwise, "auto" displays.
Duplicated?	Duplication status of SPE components are indicated. Duplication = "y"; no duplication = "n".
SPE Power	Current power source for the processor complex. The normal state is "commercial". When commercial power is unavailable, in-use battery backup is indicated with "backup".
Time Source	Current timing source is displayed. The display values for this field vary according to timing sources selected. If the site administers the optional Stratum-3 hardware, "external" displays and "internal" displays when an internal source, such as a tone clock, is used. Primary and secondary timing sources must be administered when using the Stratum-4 option. "primary" = primary administered source is in use "secondary" = secondary administered source is in use. "local" = neither the primary or secondary sources are in use.
# Logins	Number of current users.
Cab	Assigned cabinet number, ranging from 1 to the highest cabinet number in the system.

Emerg Trans	Current setting of the emergency transfer switch for each cabinet. Five options are available: auto-on ("auto+" or "a+"), auto-off ("auto-" or "a-"), "on", "off", and "n.a.". If "auto+" or "auto-" option are enabled, emergency transfers automatically activate when cabinets fail ("+" indicates that emergency transfer is activated, while "-" indicates that emergency transfer is inactive). When "on" is displayed, emergency transfer automatically activates. The "off" option shows that cabinets cannot activate emergency transfers. In duplicated SPE systems, switch settings for both processors of the PPN (cabinet 1) display. In this case, "auto+" is abbreviated "a+", "auto-" is d "a-", and "off" is "of". "on" does not changed. If "n.a." displays, emergency transfer switch settings are not available.
Mj	Number of major alarms associated with the cabinet. An asterisk fills the field when the number exceeds 99.
Mn	Number of minor alarms associated with the cabinet. An asterisk fills the field when the number exceeds 99.
Wn	Number of warnings associated with the cabinet. An asterisk fills the field when the number exceeds 99.
PNC	Displays current Port Network Connectivity (PNC) status for each port network within a cabinet. When multiple port networks exist within a cabinet, a slash separates Carriers A, B, and C (listed first) from Carriers D and E (up/up). Availability of the Expansion Archangel Link (EAL) determines the PNC status of a port network. "Up" denotes EAL availability. When the EAL is not available, then "dn" (down) displays.
Time of Day	Displays current time of day acquired from the system.

monitor security-violations

This command displays information about failed attempts to access the system, including the time of the violation, the login entered, and the port accessed during the failed login attempt. The system logs trunk group numbers, members, and extensions for remote access violations. The system logs remote and local invalid access attempts with a total of 16 entries maintained for each access type. This online status report automatically updates every 30 seconds until the command is canceled by pressing the CANCEL key.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
monitor security-violations	print	Report sent to printer. Examples: monitor security-violations monitor security-violations print	init inads craft cust rcust bcms browse	none	none

Output

The following example is a display of the **monitor security-violations** command.

```
monitor security-violations                                SPE A

                        SECURITY VIOLATIONS STATUS

                        Date:   9:12 MON DEC 30 1991

SYSTEM MANAGEMENT VIOLATIONS      REMOTE ACCESS VIOLATIONS

Date  Time  Login  Port   Ext   Date  Time  TG No.  Mbr  Ext
12/30 09:12 init  MGR1             12/30 12:42 80      1   1111
12/30 09:12 init  MGR1
12/30 09:12 init  MGR1
```

Field descriptions

Date:	Current date and time.
Date	Date of the logged security violation shown as MM/DD (where MM = month and DD = day).
Time	Time of the logged security violation shown as HH:MM (where HH = the hour and MM = minute of the invalid access attempt).
Login	Login ID entered for the login violation attempt.
Port	Type of port used when login violation occurred. The following is a table of valid port types:
MGR1	MGR1 represents a connection to a system SAT port. Connections are either hardwired or dialed-up.
Ext	Extension assigned to the data module that failed during "logging in" session. If a data module is not used, this field is blank.
Date	Date of the logged security violation shown as MM/DD (where MM = month and DD = day).
Time	The time of the logged security violation shown as HH:MM (where HH = the hour and MM = the minute).
TG No.	The trunk group number associated with the trunk from the failed remote access attempt (remote access violations only).
Mbr	The trunk group member number associated with the trunk from the failed remote access attempt (remote access violations only).
Ext	Extension that interfaces with remote access features (remote access violations only).

monitor system

The **monitor system view1** and **view2** commands summarize the system's condition. This on-line status report automatically updates every minute (or by pressing the UPDATE key) until the command is canceled by pressing the CANCEL key. For security reasons, the cancel command automatically logs of technicians.

Overall system status is available with either view option. "View1" displays attendant, maintenance, and traffic status. Attendant and maintenance status update every minute and traffic status updates hourly. "View2" displays all "view1" items, except hunt group measurements that are omitted from traffic status portions. These screens contain simplified high-level information about the system's health. The **monitor system conn** command displays connection's status in the connection manager process. Data is collected frequently in the connection manager for key information items used to create this report.

The single option to the command line entry, is **monitor system conn** and its parameter is *pnn*. The command line parameter *pnn* indicates the desired 3 pnns.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
monitor system	<i>view 1</i> <i>view 2</i> <i>conn</i> <i>pnn ###</i> <i>pnn ###</i> <i>pnn ###</i>	see below Examples: monitor system view1 monitor system view2 monitor system conn monitor system conn pnn 1 5 7	init inads craft cust nms browse	none	none

Qualifier Description

- view1**

This screen displays attendant status, maintenance status, last hour's measurement of trunk groups, hunt groups, attendant groups, and the time of day.
- view2**

This screen displays a subset of view1 form entries. It includes view1 forms except the last hour's hunt group measurements.
- conn**

This option displays the connection monitor output for key information.
- entering no options**

Omitting "pnn # # #" arguments on the command line displays the default configuration of Pnn's 1, 2 and 3.
- pnn # # #**

Entering "pnn # # #" (where a pnn number from 1 to 3 replaces "#", and displays data for specified pnns.
- entering no options**

Omitting the "pnn # # (# argument on the command line displays default configurations of Pnn's 1, 2 and 3.

pnn # # # Entering “pnn # # #”, where “#” is replaced by a pnn number from 1 to 3, displays data for specified pnn.

Output

Below are displays of **monitor system view 1** and **monitor system view 2**.

monitor system view1

Field descriptions

Console #	A list of console numbers that are activated or deactivated.
Activated:	The attendant console is active. An attendant console activated if: ■ its handset/headset is plugged in ■ it is not busied out, and the system is in day service and the console is a day or day/night or principle console, or the system is in night service and the console is a night or day/night console.
Deactivated:	The attendant console is inactive. The attendant console deactivated if it does not meet activated conditions.
# of alarms for trunks	The number of existing minor and major trunk port alarms.
# of alarms for other resources	The number of existing minor and major alarms on all maintainable objects in the system, except trunks and stations.
First OSS number has been informed?	Questions if the first OSS telephone number reports and acknowledges alarms. If “Alarm Origination” is disabled or there are no active alarm, the field is “n”.
Measurement Hour	The starting time for taking measurements. For example, if the measurement hour is shown as 1800, traffic status data display is the time period from 6 PM to 7 PM (The measurement is taken hourly).
Grp no	A number between 1 and the maximum trunk or hunt group number.
Grp dir	Group direction: incoming, outgoing or two way.
Calls qued	Total calls that arrive and are placed in the trunk group queue.
Calls aban	Total abandoned calls by the caller.
%Out blkg:	The ratio of outgoing calls that are not carried (due to overload conditions) on a trunk group to outgoing calls offered.
% Time ATB:	The percentage of time within polling intervals that all trunks in the trunk group are unavailable for use.
Time of day	The current time of day acquired from the system.

The following example is a display of the **monitor system conn** command.

```

      Time Slot Status
Pnn   Bus   State *Idle Count      Pnn   Bus   State

Field descriptions

Time Slot Status	4 numbers are associated with time slot status for each specified pnn; the two buses (0 and 1) have a maintenance and a normal state, and a number of idle counts. These fields represent real-time status data.
Bus Status	Two numbers are associated with the two buses for each pnn. Shown are the pnn number; the associated bus (0 or 1); and the bus's state (avail or unavail). These fields represent real-time status data.
Callrate	The callrate field represents call rates currently executing on the switch. This is a counter that is bumped for each call attempt. This field represents real-time status data.
Interval	This field represents the interval applied to the call rate. It is normally a 36 second time period. This field represents constant status data.
Max_callrate	This field represents the maximum call rate achieved since the last hour. If, at 20 minutes past 12:00, the system executes this command, the maximum call rate obtained during the past 20 minutes displays. This field represents real-time status data.
Next_hour	This field contains a value of 0 or 1 depending related to measurements taken this hour or the next. This hour reflects maximum call rates. When this flag is set, statistics accumulate for the next hour and shortly thereafter.

tot_ts_req	This field holds the total time slots in use during the time period elapsed since the top of the last hour. Data is internally collected every 100 seconds. When the timer fires and the data collection occurs, a check is made as to how many time slots are currently in use. That's where the total comes from. There are three numbers displayed for this field on the form; one for each of the pnns requested. This field represents real-time status data.
ts_denied	This field records total time slots requests denied since the beginning of the last hour. Data is collected internally every 100 seconds. Three numbers display for this field; one for each requested pnn. This field represents real-time status data.
tot_fts_req	This field represents the total number of requested fiber time slots. This field increments each time a fiber time slots is allocated since the last top of the hour measurement polling. Three values display; one for each requested pnn. This field represents real-time status data.
ts_count	The value in this field represents the requests for time slots during the last 100 second interim. An internal timer initiates polling every 100 seconds. Three numbers display for this field on the form; one for each requested pnn. This field represents real-time status data.
ts_total	This field represents the total number of time slots requested since the top of the last hour. This field represents real-time status data.
fts_count	The value in this field represents the requests for fiber time slots during the last 100 second interim. An internal timer initiates polling every 100 seconds. Three numbers display for this field; one for each requested pnn. This field represents real-time status data.
fts_total	This field indicates the total number of fiber time slots during the last 100 second interim. This field represents real-time status data.
Requests-TN74 8 TTRs	This field reflects the total number of requested touch tone receivers that are currently-active. It decrements when tone receivers are freed and increments when they are requested. This field applies strictly to the TN748 board. This field represents real-time status data.
Requests-TN74 8 CPTRs	This field reflects the total number of requested call progress tone receivers that are currently active. It decrements when call progress tone receivers are freed and increments when they are requested. This field applies strictly to the TN748 board. This field represents real-time status data.
Requests-TN74 4 CPTRs	This field reflects the total number of requested call progress tone receivers that are currently active. It decrements when call progress tone receivers are freed and increments when they are requested. This field applies strictly to the TN744 board. This field represents real-time status data.

- Requests-TN74
4 TTRS

This field reflects the total number of requested touch tone receivers that are currently active. It decrements when tone receivers are freed and increments when they are requested. This field applies strictly to the TN744 board. This field represents real-time status data.
- Requests-TN74
4 MFC

This field reflects the total number of requested multi-frequency receivers that are currently active. It decrements when multi-frequency receivers are freed and increments when they are requested. Note that this field applies strictly to the TN744 board. This field represents real-time status data.

monitor traffic

This command provides information on the number of trunk group and hunt group calls waiting to be serviced, and the time the oldest call in the group has been waiting for service.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
monitor traffic	<i>trunk-groups</i> <i>hunt-groups</i>	see below Examples: monitor traffic trunk-groups monitor traffic trunk-groups 4 monitor traffic hunt-groups	init inads craft cust rcust bcms browse	none	none

Qualifier Description

- trunk-groups*

The number of trunk group calls waiting to be serviced, members in the group, and number of members that are active on calls in the group. This field displays up to 60 administered trunk groups. Technicians specify the starting trunk group. If technicians enter 5, the displayed trunks start at 5. Numbers 1-4 do not appear.
- hunt-groups*

This field displays the waiting time for oldest call in each hunt group. Screen data updates every minute; only changed fields refresh. Unadministered hunt groups have blank values.

Output

The following output example is a display of the **monitor traffic hunt-groups** command.

```
monitor traffic hunt-groups

      HUNT GROUP STATUS      22:49 SAT DEC 31 1988
#   S   A   Q   W   LCIQ   #   S   A   Q   W   LCIQ
1   15  10  10   0   20    17
2                                     18
3                                     19
4                                     20
5                                     21
6                                     22
7                                     23
8                                     24   10   5   0   0   10
9                                     25
10                                    26
11                                    27
12                                    28
13                                    29
14                                    30
15                                    31
16                                    32

(#: Group;  S: Grp Size;  A: Active Members;  Q: Q Length;  W: Calls Waiting)
(LCIQ: Longest Call In Queue in seconds)
```

Field descriptions

- # Group number for trunk group or hunt group.
- S Number of members administered for each trunk or hunt group.
- A Number of group members that are active on a call. This does not include busied out members.
- Q The length of queues administered for groups.
- W Number of calls waiting in group queues to be serviced.
- LCIQ The longest call in queue (LCIQ) indicates the time in seconds the oldest call in the hunt group queue has been waiting to be serviced.

```
monitor traffic trunk-groups

          TRUNK GROUP STATUS   22:49 SAT DEC 311988
#  S  A  Q  W  #  S  A  Q  W  #  S  A  Q  W  #  S  A  Q  W
1  15 10 0  0
2  22 21 10 10
9  31 12 20 0
65 5  5  10 8
99 12 0  0  0

( #: Group;  S: Grp Size;  A: Active Members;  Q: Q Length;  W: Calls Waiting)
```

monitor trunk

This command displays internal software status information. This command helps to locate facilities to which the trunk is communicating.

If a trunk group number is entered without a member number, and with or without “/”, it is member 1. If a trunk group and member number are both entered, status for specified members displays.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
monitor trunk	group	1 – 99. If a group number is entered with out a member number, the member number defaults to 1.	init inads craft cust rcus bcms browse	1 (one)	none
	member	1 – 99. If a member number is entered, the member status displays. Examples: monitor trunk 78 monitor trunk 80/ monitor trunk 78/1 monitor trunk 80/2			

Output

The following example shows the output from the **monitor trunk 78/1** command.

```
monitor trunk 78/1

                                TRUNK STATUS

Trunk Group/Member: 078/001      Service State: in-service/idle
                               Port: 01C1505      Maintenance Busy? no
Signaling Group ID:              CA-TSC State:
Connected Ports:
```

Field descriptions

Trunk Group/Member	Trunk group and group member number. (1-99/1-99).
Port	The port location (cabinet-carrier-slot-circuit) for trunks.
Signaling Group ID	If the trunk is ISDN, this field contains the number of the ISDN Signaling Group. Otherwise, this field is blank.()
Connected Ports	Port locations (cabinet-carrier-slot-circuit) connected to the trunk.
Service State	In-service/active, in-service/idle, out-of-service, out-of-service-NE (Near End), out-of-service-FE (Far End), maint-NE/active, maint-FE/active, maint-NE/idle, maint-FE/idle, pending-in-service, pending-maint, or disconnected. NE (Near End) and FE (Far End) refer to the “end” of the trunk that has placed the facility in its current state.
Maintenance Busy	This field identifies maintenance testing that occurs on the trunk.
CA-TSC State	The state of temporary signaling connections. (connection set up to pass call information over PRI signaling links).

recycle carrier

This command recycles power for specified carriers. When power units are replaced in carriers, this command recycles that carrier's power. **Processor carriers and their duplicates and EPN control carriers or SCC carriers cannot be recycled. Carriers with active, recycled EIs, experience disrupted communications with their cabinets. Carriers with active, recycled tone-clock boards experience disrupted service for ports in port networks.** For more details on recycling and trouble shooting power units, refer to “Troubleshooting Control Carrier Power Units” in [Chapter 5, “Routine Maintenance Procedures”](#).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout mis	location	Physical location of desired carrier. Carrier b-e. (b not applicable for SPE duplex PPNs)	init inads craft	cabinet = 1 none for carrier	see below

Feature Interactions

Carrier “a” cannot recycle its power. When carrier “b” of the PPN contains SPE duplication hardware, it cannot recycle its power.

Recycling maintenance objects results in:

Recycled component	Result
Port Carriers	Interrupted service
Carriers with active EIs	Disrupted communication with that cabinet
Carriers with active tone-clock boards	Interrupted service for ports port network
Carrier	The list configuration command causes circuit packs to display red LEDs and NO BOARDs.

The **test tdm command** accelerates retirement of these problems.

Output

The following output example displays the **recycle carrier c** command.

```
recycle carrier c

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01C      CARR-POW              126        PASS

Command successfully completed
```

Field descriptions

Port	Port address (cabinet-carrier) for tested maintenance objects. This field displays cabinet and carrier values.
Maintenance Name	CARR-POW.
Alt. Name	Not applicable.
Test Number	T126.
Test Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

refresh spe-standby

This command immediately places Standby SPEs into Standby Mode. This command preempts in-progress Standby SPE maintenance activity, resets the Standby SPE Processor, and refreshes the Standby SPE's DRAM memory (that is, all of Active SPE DRAM memory is shadowed to the Standby SPE memory). Refresh reactivates memory shadowing that is disabled while standby SPE is in maintenance mode When Standby SPEs return to Standby Mode, their memory up-date with Active SPE memory.

Because it preempts Standby SPE maintenance activities, the **refresh spe-standby** command should be used judiciously. The following potential side-effects can occur:

- Tests that detect faults and/or lack of faults on Standby SPE components might not run. Accordingly, alarms are not raised or retired.
- Translation saves might not execute so translations data on Active and Standby SPE mass storage devices do not reflect the changes made since the last translation save.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
refresh spe-standby			init inads craft	none	Standby SPEs must be in maintenance mode before the refresh command can be invoked.

release access-endpoint

This command removes all ports associated with the specified access endpoint from a maintenance busy state. Periodic and scheduled tests subsequently resume on the released ports. Maintenance completes background initialization testing on the released ports. For details of the test sequence, refer to [3].

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release access-endpoint	extension	number associated with desired access endpoint. Examples: release access-endpoint 25012 release access-endpoint 77868	init inads craft nms	none	none

Output

The following example shows the output from the **release access-endpoint 22502** command and assumes that the access endpoint ports for extension 22502 are in cabinet 1, carrier C, slot 11, circuit 1 to 6.

```
release access-endpoint 22502           page 1 of 1

      COMMAND RESULTS

Port Maintenance Name Alt. Name Result  Error Code
01C1101 WAE-PORT   22502    PASS
01C1102 WAE-PORT   22502    PASS
01C1103 WAE-PORT   22502    PASS
01C1104 WAE-PORT   22502    PASS
01C1105 WAE-PORT   22502    PASS
01C1106 WAE-PORT   22502    PASS

Command Successfully Completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of released maintenance.
Maintenance Name	The type of released maintenance object. (wideband access point =WAE-PORT, single port access endpoint = TIE-DS1.
Alt. Name	Alternate way to identify maintenance objects. This field contains the extension number of the access endpoint.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release board

This command activates administered maintenance objects on the circuit pack at specified locations. Tests are executed to ensure its usability.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release board	location	Physical location: PCsspp Examples: release board 01c11 release board 02c15	init inads craft nms	none	none

Output

The following example shows the output from the **release board 1c07** command and assumes that the board in cabinet 1, carrier c, slot 7 is an analog board with three ports administered.

```
release board 01C07

                                COMMAND RESULTS

Port   Maintenance Name  Alt. Name  Result  Error Code
01C07   ANL-BD
01C0702 ANL-LINE
01C0701 ANL-LINE          51001   PASS
01C0703 ANL-LINE          PASS

Command successfully completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot) of released maintenance object.
Maintenance Name	The type of maintenance object that is being released.
Alt. Name	Alternate way to identify maintenance objects.
If the Object is The field contains	
station	extension
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
private CO line	P/xxx (where xxx = private CO line group number)
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release cdr-link

This command removes maintenance objects associated with specified call detail recording (cdr)-links from a maintenance busy state.

These links provide asynchronous data connections from switches to peripherals; they are composed of a:

- Far end data module
- Simulated data channel on a PKTINT board
- Manager that initiates and maintains the link
- Controller/protocol that services the link

For information on what a CDR link is and does, see the description of the [“status cdr-link”](#) command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release cdr-link	link-id	primary secondary Examples: release cdr-link primary release cdr-link secondary	init inads craft	none	none

Output

The following example shows the output from the **release cdr-link primary** command.

```
release cdr-link primary

                        COMMAND RESULTS

Port  Maintenance Name  Alt. Name  Result  Error Code
PRI-CDR                                     PASS

Command successfully completed
```

Field descriptions

Port	Not applicable. ()
Maintenance Name	Type of released maintenance object. (primary cdr-link = PRI-CDR, secondary cdr-link = SEC-CDR)

Alt. Name	Not applicable. ()
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release data-module

This command activates the specified data module (or data channel). Hardware tests are executed to verify that the equipment is functioning.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release data-module	extension	Extension number associated with desired data module or data channel. Examples: release data-module 310	init inads craft cust nms	none	none

Output

The following example shows the output from the **release data-module 300** command.

```
release data-module 310

                                COMMAND RESULTS

Port   Maintenance Name  Alt. Name  Result  Error Code
01C1103    DIG-LINE

Command successfully completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of the maintenance object that is busied out or released, or the number of the data channel.
Maintenance Name	The type of maintenance object that is being busied out or released.

Alt. Name	Alternate way to identify maintenance objects.	
	If the Object is	The field contains
	station	extension
	trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
	private CO line	P/xxx (where xxx = private CO line group number)
Result	Success status of a busied out object (PASS, ABORT, FAIL)	
Error Code	System-generated description of a command failure.	

release journal-printer

This command activates maintenance objects associated with a specified pms-log or wakeup-log link. Hardware tests are executed to verify that the equipment is functioning.

For general information on journal printer links, see the description of the [“busyout pms-link”](#) command.

For information on journal printers, see the description of the [“status journal-link”](#) command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release journal-printer	pms-log	releases links to pms printers. (1)	init inads craft nms	none	see below
	wakeup-log	Releases links to wakeup logging facilities. (0) Examples: release journal-printer pms-log release journal-printer wakeup-log			

Feature Interactions

Specific component maintenance performed on a link sometimes conflicts with link maintenance, itself. (busied out objects create link setup failure) Frequent link re-setup attempts may delay faulty component recovery. For best results, technicians should use busyout to disable attempted link re-setup.

Output

The following output example is a display of the **release journal-printer wakeup-log** command.

```
release journal-printer wakeup-log

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result  Error Code
0          JRNL-LINK                               PASS

Command successfully completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of busied out or released maintenance object. (wakeup log = 0; pms log = 1)
Maintenance Name	Type of busied out or released maintenance object.
Alt. Name	Not applicable.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release link

The **release link** command activates MOs associated with a specified link. Hardware tests are executed to verify that equipment is functioning properly.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release link	link-id	Number associated with each link (1–8). 1through 4 reside on Processor Interface circuit packs “1a1” or “1b1” 5 through 8 reside on Processor Interface circuit pack “1a2” or “1b2.” Examples: release link 1 release link 8	init inads craft	none	none

Output

The following output example is a display of the **release link 1** command.

```
release link 1
```

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01C0301	PI-LINK		PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of the busied out or released maintenance object. Port address represents the link-id.
Maintenance Name	The type of maintenance object that is being released.
Alt. Name	Not applicable.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release mis

The **release mis** command activates management information systems. Hardware tests are executed to verify that equipment is functioning properly.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release mis			init inads craft cust rcust	none	none

Output

The following output example is a display of the **release mis** command.

```
release mis

                                COMMAND RESULTS

Port      Maintenance Name      Alt. Name      Result      Error Code
          MIS
          PASS

Command Successfully Completed
```

Field descriptions

Port	Not applicable.
Maintenance Name	MIS
Alt. Name	Not applicable.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release modem-pool

The **release modem-pool** command deactivates specified modem pool groups or group members. Specifying group numbers, member numbers releases single group members. Specifying modem pool group numbers releases members in a modem pool group.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release modem-pool	<i>group</i> <i>member</i>	1-5. pair of analog and digital line ports (or two pair for the Integrated modem-pool case). 1-32. Examples: release modem-pool 1 release modem-pool 4/3	init inads craft	none	none

Output

The following example shows the output from the **release modem-pool 1** command.

```
release modem-pool 1                SPE B

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result  Error Code
01C0701    MODEM-PT              PASS
01C0703    MODEM-PT              PASS

Command successfully completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of busied out maintenance object.
Maintenance Name	MODEM-PT.
Alt. Name	This field is not applicable to this command.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release packet-control

This command activates the packet-control circuit pack, and reestablishes each terminated point-to-point signaling link on this packet-control. This command is the complement to the **busyout packet-control** command. (deactivates packet control and destroys terminated point-to-point signaling links).

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release packet-control	location	simplex = location parameter not used. Duplicated = packet control carrier (1A or 1B) Examples: release packet-control 1A release packet-control 1B	init inads craft	simplex = cabinet 1, carrier A. duplex = cabinet 1. (no default carriers.)	see below

Feature Interactions

High or Critical Reliability Systems disallow attempts to release the packet-control that resides in the standby control complex.

When packet-controls in the active control complex are released from previous busied-out states, connectivity across Packet Buses reestablish. ISDN-BRI point-to-point signaling links reestablish with the **release packet-control** command.

Output

The following output example is a display of the **release packet-control 1A** command.

```
release packet-control 1A

                                COMMAND RESULTS

Port  Maintenance Name  Alt. Name  Result  Error Code

1A      PKT-CTRL                PASS

Command successfully completed
```

Field descriptions

Port	Cabinet-Carrier where Packet-Control resides.
Maintenance Name	PKT-CTRL.
Alt. Name	Not applicable.
Result	Success status of a busied out object (PASS, ABORT, FAIL).
Error Code	System-generated description of a command failure.

release pms-link

The **release pms-link** command deactivates MOs that are associated with a property management system link.

These links provide asynchronous data connections from switches to peripherals; they are composed of a:

- Far end data module
- Simulated data channel on a NETCON board

- Manager that initiates and maintains the link
- Controller/protocol that services the link

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release pms-link			init inads craft	none	see below

Feature Interactions

Specific component maintenance performed on a link sometimes conflicts with link maintenance, itself. (busied out objects create link setup failure) Frequent link re-setup attempts may delay faulty component recovery. For best results, technicians should use busyout to disable attempted link re-setup.

Output

The following output example is a display of the **release pms-link** command.

```
release pms-link

                                COMMAND RESULTS

Port      Maintenance Name      Alt. Name      Result      Error Code
          PMS-LINK
Command Successfully Completed
```

Field descriptions

- Port
- This field is left blank.
- Maintenance Name
- PMS-LINK
- Alt. Name
- Not applicable.
- Result
- Success status of a busied out object (PASS, ABORT, FAIL)
- Error Code
- System-generated description of a command failure.

release port

The **release port command** deactivates specified ports on circuit packs.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release port	location	Physical location: PCsspp Examples: release port 01c1101 release port 02c1501	init inads craft	none	none

Output

The following output example is a display of the **release port 1c0701** command. Assume that the port in cabinet 1, carrier c, slot 7, circuit 1 is an analog port.

release port 01C0701

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01C0701	ANL-LINE		PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of released maintenance object.								
Maintenance Name	The type of maintenance object that is being released.								
Alt. Name	Alternate way to identify maintenance objects. <table><tr><th>If the Object is</th><th>The field contains</th></tr><tr><td>station</td><td>extension</td></tr><tr><td>trunk</td><td>xxx/yyy (where xxx = trunk group number and yyy = member number)</td></tr><tr><td>private CO line</td><td>P/xxx (where xxx = private CO line group number)</td></tr></table>	If the Object is	The field contains	station	extension	trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)	private CO line	P/xxx (where xxx = private CO line group number)
If the Object is	The field contains								
station	extension								
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)								
private CO line	P/xxx (where xxx = private CO line group number)								
Result	Success status of a busied out object (PASS, ABORT, FAIL)								
Error Code	System-generated description of a command failure.								

release pri-endpoint

The **release-PRI endpoint** command removes PRI endpoint ports (B-channels) associated with specified PRI endpoint from maintenance busy states. Periodic and scheduled tests resume on released ports. The switch attempts to negotiate

with the far-end PRI terminal adapter activating PRI endpoint port (B-channel). Maintenance does background initialization testing on released ports. For details of the test sequence, refer to [3].

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release pri-endpoint	extension	extension number associated with desired PRI endpoint.	init inads craft nms	none	none

Output

The following output example is a display of the **release pri-endpoint 22501** command. Assume that the PRI endpoint ports for extension 22501 are in cabinet 1, carrier B, slot 20, circuit 1 to 6.

release pri-endpoint 22501

page 1 of 1

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01B2001	PE-BCHL	22501	PASS	
01B2002	PE-BCHL	22501	PASS	
01B2003	PE-BCHL	22501	PASS	
01B2004	PE-BCHL	22501	PASS	
01B2005	PE-BCHL	22501	PASS	
01B2006	PE-BCHL	22501	PASS	

Command Successfully Completed

Field descriptions

- Port
- Port address (cabinet-carrier-slot-circuit) of released maintenance object.
- Maintenance Name
- PE-BCHL.
- Alt. Name
- Alternate way to identify maintenance objects. (PRI endpoint extension)
- Result
- Success status of a busied out object (PASS, ABORT, FAIL)
- Error Code
- System-generated description of a command failure.

release sp-link

The **release sp-link** command reactivates busied out system printer links and resolves active alarms for system printer links.

The system printer link is a link from the switch to an external printer. Administering system printer extensions to call system printers creates the links.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release sp-link			init inads craft	none	none

Output

The following output example is a display of the **release sp-link** command.

```

release sp-link          SPE A

                          COMMAND RESULTS

Port   Maintenance Name  Alt. Name  Result  Error Code
      SYS-PRNT
Command Successfully Completed

```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of busied out maintenance objects. ()								
Maintenance Name	The type of maintenance object that is being busied out.								
Alt. Name	Alternate way to identify maintenance objects.								
	<table border="1"> <thead> <tr> <th>If the Object is</th> <th>The field contains</th> </tr> </thead> <tbody> <tr> <td>station</td> <td>extension</td> </tr> <tr> <td>trunk</td> <td>xxx/yyy (where xxx = trunk group number and yyy = member number)</td> </tr> <tr> <td>private CO line</td> <td>P/xxx (where xxx = private CO line group number)</td> </tr> </tbody> </table>	If the Object is	The field contains	station	extension	trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)	private CO line	P/xxx (where xxx = private CO line group number)
If the Object is	The field contains								
station	extension								
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)								
private CO line	P/xxx (where xxx = private CO line group number)								
Result	Success status of a busied out object (PASS, ABORT, FAIL)								
Error Code	System-generated description of a command failure.								

release spe-standby

The **release spe-standby** command removes busyout statuses of standby SPEs. Memory shadowing restores, a memory refresh of the standby SPE occurs, and 1 minute later the equivalent of scheduled standby SPE maintenance returns the standby SPE's Fault Severity Level to its appropriate value.

Standby SPE releases are allowed if communication to the standby is down.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release spe-standby			init inads craft	none	see below

Feature Interactions

When standby SPEs release a memory, a refresh executes and the standby Fault Severity Level lowers to its appropriate level. One minute later, the equivalent of scheduled standby SPE maintenance executes and a spontaneous SPE interchange might occur, depending of Fault Severity Levels of the two SPE's.

If the standby SPE is in poor health, memory shadowing must not enable (communication to the standby is impossible, if it is enabled). Then the standby SPE releases successfully.

Output

The following output example is a display of the **release spe-standby** command and assumes that the standby SPE is located in carrier "B."

```
release spe-standby          SPE A

                                COMMAND RESULTS

Port  Maintenance Name      Alt. Name  Result  Error Code
01B      STBY-SPE                      PASS

Command successfully completed
```

Field descriptions

- Port

Port address displays the standby SPE's cabinet and carrier location. (01A or 01B)
- Maintenance Name

STBY-SPE

Alt. Name	Not applicable. ()
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release station

This command removes specified administered voice terminal extensions from a maintenance busy state.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release station	extension	extension number associated with the desired voice terminal Examples: release station 10020 release station 32770	init inads craft cust	none	none

Output

The following output example is a display of the **release station 1002** command.

release station 1002

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01C1102	DIG-LINE		PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of the released maintenance object.
Maintenance Name	Type of released maintenance object.
Alt. Name	Alternate way to identify maintenance objects. This field contains an extension when the object is a station.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release tdm

This command removes specified tdm buses from a maintenance busy state.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release tdm	<i>port-network pn number</i> <i>bus bus</i>	specifies the Port Network number of the TDM bus to be released. ("a" or "b") specifies desired half of the TDM bus. Each 512 time slot TDM bus is configured as two duplicate 256 time slot buses. This division allows for duplication of control channels and dedicated tone time slots. The default control bus (carrying the control channel) is the "a" bus, while the default tone bus (carrying dedicated tones) is the "b" bus. (1 - 3) Examples: release tdm port-network 1 bus a release tdm port-network 1 bus b	init inads craft	none	System tears down busied out buses. No new calls can be administered on busied out buses

Output

The following output example is a display of the **release tdm port-network 1 bus a** command.

```
release tdm port-network 1 bus a

                                COMMAND RESULTS

Port      Maintenance Name    Alt. Name    Result    Error Code
PN 01A      TDM-BUS

Command successfully completed
```

Field descriptions

Port	Port network number (preceded by "PN") and bus ("A" or "B") associated with the TDM bus.
Maintenance Name	TDM-BUS

Alt. Name	Not applicable.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release tone-clock

This command removes specified tone/clocks from maintenance busy states.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release tone-clock	location	Physical location: PCsspp Examples: release tone-clock c	init inads craft	1 (one)	none

Output

The following output example is a display of the **release tone-clock 1a** command.

```
release tone-clock 1a

                                COMMAND RESULTS

Port      Maintenance Name  Alt. Name  Result  Error Code
01A       TONE-PT          PASS
01A       TDM-CLK          PASS
01A       TONE-BD          PASS

Command successfully completed
```

Field descriptions

Port	The tone clock circuit pack maintenance object displays the cabinet and carrier of the specified tone/clock board.
Maintenance Name	TONE-PT, TDM-CLK and TONE-BD
Alt. Name	Not applicable.
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

release trunk

The **release trunk** command removes specified trunk groups or trunk group members from a maintenance busy state. Specifying the group number, releases a single group member and the member number. Specifying the trunk group number releases members in a trunk group.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
release trunk	<i>group</i> <i>member</i>	Group number (1–99) Member number (1–99) Examples: release trunk 78 release trunk 78/1	init inads craft	none	none

Output

The following output example is a display of the **release trunk 78/1** command.

```
release trunk 78/1
```

COMMAND RESULTS

Port	Maintenance Name	Alt. Name	Result	Error Code
01C1505	C0 TRK	78/01	PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit) of the released maintenance object.								
Maintenance Name	The type of maintenance object that is being released.								
Alt. Name	Alternate way to identify maintenance objects.								
	<table border="1"> <thead> <tr> <th>If the Object is</th><th>The field contains</th></tr> </thead> <tbody> <tr> <td>station</td><td>extension</td></tr> <tr> <td>trunk</td><td>xxx/yyy (where xxx = trunk group number and yyy = member number)</td></tr> <tr> <td>private CO line</td><td>P/xxx (where xxx = private CO line group number)</td></tr> </tbody> </table>	If the Object is	The field contains	station	extension	trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)	private CO line	P/xxx (where xxx = private CO line group number)
If the Object is	The field contains								
station	extension								
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)								
private CO line	P/xxx (where xxx = private CO line group number)								
Result	Success status of a busied out object (PASS, ABORT, FAIL)								
Error Code	System-generated description of a command failure.								

reset board

This command performs a soft reset of every specified, administered port on the port circuit pack. Ports must be busied out before the port circuit pack resets.

 **WARNING:**
This command is service disrupting and may cause extraneous alarms.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
reset board	<i>location</i> <i>repeat number</i>	Physical location: PCsspp Number of times each board reset repeats (1– 00) Examples: reset board 01c11 reset board c08 reset board 03d12 r 3	init inads craft nms	carrier = 1 repeat number = 1	none

Output

The following output example is a display of the **reset board 1c07** command and assumes that the board in port network 1, carrier c, slot 7 is an analog board with three ports administered.

```
reset board 1C07
```

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01C07	ANL-BD		53	PASS	

Command Successfully Completed

Field descriptions

- Port

Port address (cabinet-carrier-slot) of the reset maintenance object.
- Maintenance Name

Type of reset maintenance object.

Alt. Name	Alternate way to identify maintenance objects.
If the Object is	The field contains
station	extension
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
private CO line	P/xxx (where xxx = private CO line group number)
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Error Code	System-generated description of a command failure.

reset interface

This command resets the Processor Interface circuit pack, reads its associated software from tape, restarts applications processes, re-establishes permanent switched calls, and sets up each enabled link. If the interface cannot be established, a Major alarm raises on the interface and all enabled links deactivate. When the Message Server Adjunct (MSA), Distributed Communications System (DCS), Audio Information Exchange (AUDIX), or Call Management System (CMS) are initially administered, links for these applications and submitting the form restarts the interface. Before Processor Interface circuit packs are replaced, technicians must power down the switch and restart it. (unless the system is equipped with High or Critical Reliability)

For troubleshooting, see **status interface**, **status link**, and **status processor-channel** commands to locate problems before performing a **reset interfaces**. (link traffic is interrupted)

**WARNING:**
The interface command interrupts operation of the AP, DCS, AUDIX, CMS or ISDN-PRI.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
reset interface	location	(cabinet-carrier-position) of the processor interface (PI board). The position determines cleared processor interface circuit pack. first processor interface = 1 second processor interface = 2 Examples: reset interface 01a1 reset interface a2 reset interface 01b1 reset interface 01b2	init inads craft	none	none

reset maintenance

This command resets technician-specified EPN maintenance circuit packs. Specifying cabinets 2 or 3 resets EPN maintenance circuit packs in carrier “a” of the specified cabinet.

This command also drops a SAT terminal session on the reset EPN maintenance circuit pack. If this command runs from a EPN maintenance SAT terminal, reset results do not display.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
reset maintenance	location	Physical location of the EPN maintenance circuit pack (carrier number). Examples: reset maintenance 02 reset maintenance 2 reset maintenance 3a	init inads craft	none	SAT is dropped before reset results can display, when command runs from EPNSAT. Examine error and alarm logs for “MAINT” entries to determine reset success.

Output

The following output example is a display of the **reset maintenance 02a** command.

```
reset maintenance 02A

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result  Error Code
02A              MAINT              306      PASS

Command successfully completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot) of the reset MO.
Maintenance Name	MAINT
Alt. Name	Not applicable. ()
Result	Success status of a busied out object (PASS, ABORT, FAIL)
Test No.	306.
Error Code	System-generated description of a command failure.

reset spe-standby

The **reset spe-standby** command converts standby SPEs from standby mode to maintenance mode with the defined restart level. This command applies to high or critical reliability systems.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
reset spe-standby	level	1 = Warm Restart 2 = Cold-2 3 = Cold1 4 = Reboot 5 = Extended Reboot Examples: reset spe-standby 1 reset spe-standby 2 reset spe-standby 3	init inads craft	none	see below

Feature Interactions

This command invokes standby SPE initialization like low level maintenance. Software never escalates requested reset levels. Technicians always determine reset levels.

If the standby SPE contains a software memory card and the requested restart level is 4 or 5, the standby SPE reloads system software before rebooting.

reset system

This **reset system** command is increasingly destructive as reset levels increase.

This command switches control from currently-active SPEs to standby SPEs in a High or Critical Reliability System through HOT restart interchanges. **Once planned interchanges start, they cannot abort from the CANCEL key.** If **reset system interchange** commands are rejected because standby SPE Fault Severity Levels are higher than active SPEs, the **health-override** command can force a HOT interchange.

The **reset system interchange** command does not disrupt in-progress calls. However, it drops links (including CDR and PMS) to local and remote administration terminals. It also drops and re-establishes connections on the Network Control Circuit Pack data channels. During the interchange, callers cannot place calls, but current calls are unaffected.

When a system restart occurs with the corresponding vector bit set, a core dump is written to memory card, only if the memory card is the special core dump card), the vector is cleared, and the requested restart is performed.

All successful reset system commands log users off.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
reset system	<i>level</i> <i>interchange</i> <i>health-override</i>	See below Examples: reset system 1 reset system 2 reset system interchange health-override	init inads craft	none	see below

level Reset levels are entered numerically:

1 = Warm Restart

2 = Cold-2

3 = Cold1

4 = Reboot

5 = Extended Reboot

interchange System control passes to standby SPEs as active and standby SPEs change roles. The optional “health-override” qualifier can be entered to bypass Fault Severity Levels of standby SPEs to force an interchange. SPE alarm components determine Fault Severity levels. Each component is assigned a severity level, and the most severe SPE alarm defines Fault Severity Levels for SPEs. The following table lists maintenance objects, their alarms, severities and interchange restart levels that affect SPE Fault Severity Levels.

Maintenance Object	Alarm Level	On/Off Board	Fault Severity Level	Restart Level
STBY-SPE	WARNING	OFF	120	None
MEM-BD	MAJOR or MINOR	ON	110	Hot or Warm
MEMORY	MAJOR or MINOR	ON	110	Hot or Warm
STBY-SPE	MAJOR	ON	100	None
PROCR	MAJOR	ON	70	Hot or Warm
SW-CTL	MAJOR	ON	65	Cold 2
MEM-CARD	MAJOR	OFF	65	Cold 1
12V-PWR	MIN	ON	65	Hot
DUPINT	MAJOR	ON	61	Hot
CARR-POW	MAJOR	ON	61	Cold 2

Maintenance Object	Alarm Level	On/Off Board	Fault Severity Level	Restart Level
SHDW-CIR	MAJOR	ON or OFF	60	Warm
SHDW-LINK	MAJOR	ON	60	Warm
SW-CTL	MINOR	ON	40	Hot
PR-MAINT	MINOR	ON	30	Hot
PI-BD	MAJOR or MINOR	ON	20	Hot
PKT-CTRL	MAJOR	ON or OFF	20	Hot
PKT-CTRL	MINOR	ON or OFF	15	Hot
PI-PT	MAJOR	ON	15	Hot
DATA-CHL	MINOR	ON	15	Hot
DATA-CON	MINOR	ON	15	Hot
DATA-BD	MINOR	ON	15	Hot
MEM-CARD	MINOR	ON or OFF	10	Hot
PR-MAINT	MINOR	OFF	8	Hot

A **reset system interchange** command aborts if:

- The standby SPE is down
- The active SPE is locked active
- Communication to the standby SPE is not possible
- Memory shadowing to the standby SPE is not functioning
- The standby SPE is not fully refreshed
- The standby SPE is busied out

health-override

If HOT restart interchanges fail because Fault Severity Levels of standby SPEs are higher than active SPEs, the health-override command tries to force a switch. If the switch occurs, new active SPE Fault Severity Level raises to prevent a software-initiated HOT SPE interchanger. This artificial raising of active Fault Severity Levels lasts for one hour, then Fault Severity Levels of both SPEs returns to their normal values.

Feature Interactions

- The **reset command** invokes system initialization like low level maintenance. Software never escalates requested reset levels. Technicians determine the levels.

- Two hardware switches are associated with active and standby SPEs. These hardware switches override demand maintenance activities requested by system technicians. If active SPEs are locked active with these hardware switches, interchanges do not occur until the active is unlocked.
- Successful SPE interchanges logoff PPNSAT terminals.
- Restart levels null the effect of the health-override option.

restore announcements

This command copies announcement data from the active MSS devices to announcement boards.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
restore announcements	<i>print</i> <i>schedule]</i>	Report sent to printer. Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: restore announcements	init inads craft cust rcust	Tape-based: Announcement copies from active processor's tape to the announcement board. Card-mem based: Announcement data copies from active processor's to the announcement board.	see below

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

 **WARNING:**
Manager I is blocked for other activities until the command completes (up to 45 minutes)

- If no announcement data module and no NETCON data module are administered, the system denies the command.
- If the announcement data module port is out of service or active (for example, performing an announcement playback), the system denies the command.

- If users are in integrated announcements sessions, the system denies the command.
- If the board is currently uploading or downloading, the system denies the command. Users cannot save or restore announcement after the **restore announcements** command commences.
- If no tape is in the tape drive when users attempt a copy, the command aborts.
- If the MSS is in use by another user or maintenance, the **restore announcements** command is not allowed.
- Unsaved or corrupted announcement files on the MSS, disallow the **restore announcements** command.

To prepare for a failure, users should copy announcement files to announcement boards. If errors result from hardware or firmware failures, MSS software logs hardware errors with maintenance. When errors occur, the system continually attempts to download boards in 10-minute intervals until a download succeeds, announcements record, or downloads initiate from the SAT. Then, error messages display indicating corrective action. If errors result from hardware or firmware failure, MSS software logs a hardware error with maintenance. Maintenance software invokes tests to diagnose and attempt to correct the problem. If maintenance software fails to correct problems, alarms raise indicating additional corrective action.

When the system crashes and/or a spontaneous processor interchange occurs, the restore operation fails. Valid announcement files do not appear on the announcement board. To copy the announcements from the active processor's MSS device to the announcement board, restart the command on the newly-active processor. When announcements completely copy to announcement boards, calls do not connect to announcements on the ANN board.

When announcement boards are plugged in or reset, maintenance performs a series of tests, including a DRAM Checksum test. Tests fail due to power losses to boards, resulting in automatic downloading of announcement files.

Output

The following output example is a display of the **restore announcements** command on a simplex SPE system.

```
restore announcements           Page 1 of 1 SPE A

                                RESTORE ANNOUNCEMENTS

Processor  Command Completion Status      Error Code
SPE-A      Success                      0
```

Field descriptions

Processor	Displays the processor that houses the MSS device used to copy announcement data.
Command Completion Status	Specifies successful completion of the command.
Error Code	System-generated description of a command failure.

resume hardware-group

The **resume hardware-group** command resumes the previous **test hardware-group** command its canceled position. Entering another **test hardware-group** disables the **resume hardware-group** command.

A canceled **test hardware-group** command appears as “canceled” on the **status hardware-group** screen. A resumed **test hardware-group** command appears as “active” on the **status hardware-group** screen.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
resume hardware-group			init inads	none	none

Feature Interactions

Cancel hardware-group

Cancelling a test hardware-group command deactivates the test command. The status hardware-group screen displays the state as “canceled”.

When the **resume hardware-group** command is entered to resume a previously-canceled **test hardware-group** command, the state of the test command changes to ‘active’ on the **status hardware-group** screen.

save announcements

This command copies announcement data from the announcement board to the MSS. The Card-Mem stores announcements for the system. By default, announcement data writes to the MSS device in a simplex processor (SPE) system, or to both MSS devices in a High or Critical Reliability System. Also, the save announcements command can write to the MSS device on either processor, in a High or Critical Reliability System.

If there integrated announcement boards exist, this command is allowed. The system denies the **save announcement** command if no announcement data modules and no NETCON data modules are administered.

Simplex

In a simplex system, no options for the **save announcements** command exist. This command saves announcement files to the MSS device.

Duplex

If no options are specified, the system saves announcements to both processors' MSS devices.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
save announcements	spe-active	forces the system to write announcement data to specified devices in active processors.	init inads craft cust rcust	none	see below
	spe-standby	forces the system to write announcement data to specified device s in standby processors. Examples: save announcements save announcements spe-active save announcements spe-standby			

Feature Interactions

 **WARNING:**
Manager I is blocked for other activities until the command completes. (up to 45 minutes).

- If no announcement and no NETCON data module are administered, the system denies the command.
- If the announcement data module port is out of service or active (performing an announcement playback), the system denies the command.
- If no announcements are on the board or a user is in an integrated announcements session, the system denies the command.

- If the board is currently uploading or downloading, the system denies the command. Users cannot record integrated announcements after the **save announcements** command commences even though 15 channels are available for announcement playback (one is reserved for uploading and downloading).
- If no tape is in the tape drive or the tape is write-protected, the command aborts during a save. The command also aborts if no NETCON data module is available.
- The save announcements command is not allowed if the MSS is in use. The MSS may be in use by either another user or by maintenance.
- The standby processor must be in service with shadowing enabled, so that the system can save announcements to the standby processor.
- When MSS devices on both processors in High or Critical Reliability Systems are specified, the save announcements command saves announcement data from announcement boards to active MSS devices, then to standby MSS devices. The system reports the status of each save operation to users separately. When one save operation fails, the save operation to another device continues, causing saved announcement data to be inconsistent between MSS devices.
- In case of a failure, technicians make announcement files consistent across both MSS devices. Files become inconsistent due to hardware failures or spontaneous processor interchanges. If announcement files are inconsistent due to hardware failures that occur during the **save announcements** command, error messages display indicating corrective action. Maintenance software that monitors hardware logs hardware errors to maintenance. Then, maintenance software invoke tests to diagnose and attempt corrective action. If maintenance software fails to correct the problem, an alarm raises displaying corrective action.
- The **save announcements** command writes two time-stamped, identical copies of announcement data to selected devices. The time-stamp for both copies is the same. Each copy contains a timestamp and the state of the copy. (good or bad)
- If good copies of announcement files are not available, the restore announcements command cannot execute until the **save announcements** command completes. Announcements on the board are still usable.

Output

The following output example is a display of **save announcements** command on a simplex SPE system.

```
save announcements           Page 1 of 1  SPE A

                        SAVE ANNOUNCEMENTS

Processor  Command Completion Status      Error Code
SPE-A      Success                      0
```

Field descriptions

Processor	Displays processors when announcement data writes to its devices. (SPE-A and SPE-B)
Command Completion Status	This field specifies if the command succeeded.
Error Code	Successful save = 0. Failed save = 2.

save translation

This command allows users to save to tape or memory card the in-memory translation data. This command runs as part of scheduled maintenance and/or on demand by the technician. All translation data in memory during system operation is volatile, meaning that if the switch goes down, the system loses all data.

Simplex

The system defaults to save translation to the tape/memory-card on SPE_A.

Duplex

The system defaults to save translation to the tape/memory-card on both SPE-A and SPE-B.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
save translations	spe-active	identifies that save translations should occur on the active processor's MSS device.	init inads craft cust	Simplex = SPE A; Duplex = SPE A & SPE B	Command cannot be performed if data is being changed by an administrative command.
	spe standby	identifies that save translations should occur on the standby processor's MSS device. Examples: save translation save translation spe-active save translation spe-standby			

Output

The following output example is a display of the **save translation** command on a duplex system.

```
save translation

                                SAVE TRANSLATION

Processor  Command Completion Status      Error Code
SPE-A     Success                        0
SPE-B     Success                        0

Command Successfully Completed
```

Field descriptions

- Processor
- Identifies the processor carrier where translation data saves. (SPE-A, or SPE-B.)
- Command Completion Status
- Displays a variety of messages, identifying the success or failure of the command.

set expansion-link

The set expansion-link command sets the Expansion-Interface Link between:

- the PPN and an EPN
- two EPNs to a specific Interface Link circuit pack between PPN and EPN.

 **NOTE:**
This command can corrupt any active data links between the PPN and an EPN or between two EPNs.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set expansion-link	link-identifier	1A01, 1A02, 1B01, 1B02, 2A01, 2A02, 2B03, 3A01, 3A02, 3AB02, 3B03). Examples: set expansion-link 02a01 set expansion-link 3a02	init inads craft	none	none

set options

This command enables the technician (that is, remote user with INADS permission) to select which types of maintenance categories report alarms automatically and which types require customer call-in. Judicious use of this command can reduce the number of ineffective alarms to the TSC. For effective results, technicians should use the **set options** command default settings specified in this section. Technicians should not change these settings. Special circumstances (for example, special studies) may require temporary changes under the guidance of Tiers 3 and 4.

 **NOTE:**
Alarms do not upgrade.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set options			init inads	see below	none

Form Input

The following example is a display of the **set options** command.

set options

Page 1 of 8

10: 1	20: 1	30: 1	40: 1	50: 1	60: 1	70: 1	80: 1	90: 1	

 **NOTE:**
Remaining Trunk Group information displays on pages 3-8, and is not documented in this Manual.

The first page of the Alarm Reporting Options Form, provides the following alarm options: the four trunk alarm severity groups, the adjunct alarms, off-board DS1 alarms, and PI-LINK alarms, memory card translation capacity alarms, and other off-board alarms. The second page, known as the Alarm Reporting Options Form, provides alarm severity groups to each trunk group.

1. The following alarm options are available:

■ Minor

Maintenance testing discovers raised alarms, downgrades them to minor alarms, and deactivates alarmed resources. LEDs on the port board and maintenance board follow standard minor alarm LED protocol and call receiving OSSs.

■ Warning

Maintenance testing discovers raised alarms, downgrades them to warnings and deactivates alarmed resources. The Alarm Log pinpoints customer-reported trunk or station problems. Alarm LEDs light on the port circuit pack and Maintenance circuit pack as before, but no attendant LEDs or stations reporting alarms are affected. No call is placed to INADS.

■ Report

The report option treats alarms the same as warnings with one exception: alarms report to INADS with a special WARNING category. When this type of alarm is received, INADS logs the occurrence and creates a trouble ticket or closes it immediately. Retry strategy for this type of call is similar to normal Major or Minor alarm reports. However, the acknowledgment LED on the attendant console or alarm reporting station does not reflect the status of the call.

■ Yes

Alarms raise normally without filtering alarm data.

■ No

Alarms that raise on trunks, stations, or adjuncts in this category drop. Error information displays as before, but alarm is evident. LED is inactive and calls are not sent to INADS. Because resources are deactivated without any record, this option is recommended only when other options do not provide desired results.

Technicians can administer alarm options on a system-wide basis for the following categories:

- Major on-board station alarms
- Minor on-board station alarms
- Major off-board station alarms
- Minor off-board station alarms

Trunk alarms have four alarm severity groups with administrable alarm options in the categories listed below. For G1, technicians can administer alarm options on a system-wide basis for the following categories:

- Major on-board trunk alarms
- Minor on-board trunk alarms

- Major off-board trunk alarms
- Minor off-board trunk alarms

Technicians assign alarm severity options to the following Adjunct categories:

- Major on-board adjunct alarms
- Major off-board adjunct alarms
- Minor on-board adjunct alarms
- Minor of-board adjunct alarms

Technicians can administer options for Minor off-board DS1 Interface circuit pack alarms and Minor off-board Memory Card Capacity Alarms on a system-wide basis.

The system inspects alarm reporting options information in the Alarm Reporting Options Form as translation data and preserves it through all restart levels.

This command affects the MO alarming listed below. Neither the trunk nor the station category applies to alarms raised on the common portion of the circuit pack.

If the option associated with the alarm type is set to “n,” the system drops the alarm report. Alarm error information remains intact, but no records of alarms and no LEDs light on the port circuit pack, the Maintenance circuit pack, the attendant console, or alarm reporting station to indicate a problem.

If technicians set the option “warning” or “report,” port circuit pack LEDs and LEDs on the Maintenance circuit pack are affected the same as warning alarms.

Default parameters are:

- The system downgrades all station, trunk (except on-board trunk alarms), and Minor DS1-BD alarms to warning alarms.
- On-board Major and Minor trunk alarms, and the Memory Card Capacity alarm continue to raise alarms and report to INADS.

Station MOs Affected By This Command

NOTE:

Although alarms on some MOs appear as warnings, they should be investigated with user-reported problems.

- Analog Lines (ANL-LINE, ANL-NE-L, ANL-16-L)
- Digital Lines (DIG-LINE)
- Hybrid Lines (HYB-LINE)
- MET Lines (MET-LINE)

- ISDN-BRI Lines (BRI-PORT, BRI-SET)

If more than 75% of the members of the trunk group alarm, minor alarms escalate to major alarms. If the trunk category option is set to “warning,” “minor,” “report,” or “no,” this no longer happens. Maintenance reactivates individual trunk members according to Major and Minor alarm criteria.

Trunk MOs Affected By This Command:

NOTE:

Although alarms on these MOs may appear as warnings, the alarms should be investigated with user-reported problems.

- Auxiliary Trunks (AUX-TRK)
- Central Office Trunks (CO-TRK)
- Direct Inward Dialing Trunks (DID-TRK)
- Direct Inward and Outward Dial Trunks (DIOD-TRK)
- DS1 Central Office Trunks (CO-DS1)
- DS1 Direct Inward Dialing Trunks (DID-DS1)
- DS1 Tie Trunks (TIE-DS1)
- ISDN Trunks (ISDN-TRK)
- Tie Trunks (TIE-TRK)

Circuit Pack MOs Affected By This Command

NOTE:

Although alarms on some MOs appear as warnings, the alarms should be investigated with user-reported problems.

NOTE:

The alarm severity of group one downgrades trunks that are not members of Trunk Groups, (for example, PCOLs).

- DS1 Interface Circuit Pack (DS1-BD)

Adjunct-Related MOs Affected By This Command

NOTE:

Although alarms on some MOs appear as warnings, the alarms should be investigated with user-reported problems.

- ASAI Adjunct (ASAI-ADJ)

- AT&T Adjunct Port (ATT-PORT)
- Ethernet ASAI Port (LGATE-PT)
- Ethernet ASAI Adjunct (LGATE-AJ)
- Ethernet AT&T Port (ATTE-PT)
- Ethernet AT&T Adjunct (ATTE_AJ)
- ISDN-BRI Ports connected to Adjuncts (ABRI-PORT)

Adjuncts are administered as stations; however, the administration of alarm severity for the station alarm group does not affect alarm severity levels for adjuncts. Similarly, the administration of alarm severity for the adjunct alarm group does not affect the alarm severity levels for other stations.

PI-Link and Associated Link MOs Affected by this Command:

NOTE:

Although alarms on some MOs appear as warnings, the alarms should be investigated with user-related problems.

- See Processor Interface Link ["PI-LINK (Processor Interface Link)"] for other associated Link Maintenance Objects.

Memory Card MOs Affected by This Command

NOTE:

While this option does not automatically downgrade CAP-MEM alarms, changes to this options may downgrade alarms to warnings. This alarm raises when memory card translation capacity exceeds 98% and is intended to alert Services that larger flash cards may be required.

- Memory Card Capacity (CAP-MEM)

Other MOs Affected by this Command

NOTE:

Although alarms on some MOs appear as warnings, the alarms should be investigated with user-related problems.

- EPN Maintenance Circuit Pack (MAINT)
- Expansion Interface (EXP-INTF)
- ISDN-PRI Signaling Group (ISN-SGR)
- Journal Printer (JNL-PRNT)
- PMS Link (PMS-LINK)

- PMS log printer (PMS-LOG)
- Primary CDR Link (PRI-CDR)
- Secondary CDR Link (SEC-CDR)
- SPE Select Switches (SPE-SELEC)
- Synchronization (SYNC)
- System Communication Interface (PI-SCI)
- System Printer (SYS-PRNT)
- TDM Clock (TDM-CLK)
- Tone Generator Circuit Pack (TONE-BD)

set signaling-group

This command upgrades secondary D-channel in specified signaling groups to primary D-channels. Current primary D-channel then revert to secondary D-channels.

A signaling group is a collection of B-channels that designate single D-channels or a set of D-channels signals over an ISDN-PRI.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set signaling-group	group identifier	administered number associated with each signaling group. Examples: set signaling-group 1 set signaling-group 2	init inads craft	none	none

set synchronization

This command sets DS1 trunks or active tone/clock circuit packs that supply references for synchronization. The **set synchronization** command works after the **disable synchronization** command disables synchronization. Technicians may administer DS1 trunks or active tone/clocks with the **set synchronization** command. DS1 or tone/clocks remain synchronization references until the **set synchronization** command runs with another board or until the **enable synchronization** command runs.

After the **enable synchronization** command runs, administered primary or secondary synchronization sources become synchronization references. If no primary or secondary source is administered, synchronization uses active tone/clock boards as synchronization references after synchronization is enabled.

The synchronization subsystem provides error-free digital communication between the switch and other PBXs, COs, or customer premise equipment. System components involved in synchronization include: TDM bus clock, DS1 trunk board, maintenance and administration software resident in the SPE.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set synchronization	location	Physical location: PCsspp (DS1 trunk or active tone/clock) that supplies a synchronization reference. Examples: set synchronization 01c08 set synchronization 02a01 set synchronization 01a set synchronization 02c	init inads craft	none	none

set tdm

This command establishes the TDM bus on a port network that houses control channels and dedicated tones.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set tdm	port network pn number bus bus override	specifies the Port Network number of the TDM bus. ("a" or "b") specifies desired half of the TDM bus. Configure each 512 time slot TDM bus as two duplicate 256 time slot buses, allowing duplication of control channels and dedicated tone time slots. A port network number (1 - 3) forces the setting of a deactivated bus, or a bus whose dedicated tone time slots are active. Examples: set tdm port-network 2 bus a set tdm port-network 2 bus b override	init inads craft	none	see below

Feature Interactions

New calls go to time slots reserved for tones on the bus that have not other time slots when:

- Time slots on a specified bus are in use
- Dedicated tone time slots are on the other half of the bus

A **set** command to buses that have calls on dedicated tone time slots drops these calls.

set time

This command allows system technicians to change the day of the week, the day of the month, the month, year, hour, and minute. The second field resets to zero (0) whenever the time on the clock is altered, but cannot be modified by the technician. The day of the week, entered as a text string, translates to an integer for internal storage.

The system clock time remains the same if no changes are entered on the form.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set time			init inads craft cust rcust bcms browse	The system assigns a time, if the system clock is not set	The date and time are available to software from a system primitive.

Output

The following example is a display of the **set time** command.

set time

Page 1 of 1

DATE AND TIME

DATE

Day of the Week: _____ Month: _____

Day of the Month: __ Year: ____

TIME

Hour: __ Second:

Minute: __

Field descriptions

- Day of the Week: Monday through Sunday.
- Day of the Month: 1-31. The system also checks for leap year.
- Month: January through December.
- Year: 1970-2999

Hour : 0-23.

Minute : 0-59

Second : The system sets this field to zero when the time of day clock is set.

set tone-clock

This command sets the active tone/clock for a PN that has a duplicated tone/clock circuit pack. Technicians should reset the default active tone clock in each PN after using the **set tone-clock** command. If it is not in use, a single failure can cause an unnecessary service outage. The schedule maintenance tone-clock switch option does not reset the tone-clock to the default active if it was not active at the beginning of the test.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set tone-clock	location	Physical location (PC) of the tone/clock to be tested	init inads craft	1 (one)	none
	override	Forces the set command into effect regardless of the tone/clock circuit pack's health. Examples: set tone-clock 01b set tone-clock 1b set tone-clock 01b override set tone-clock a			

set vector

This command specifies restart levels for core dumps. This command places core dumps on primary Mass Storage System (a tape in a tape system and core dump memory cards in a memory card system) devices for later examination. The **set vector** command allows technicians to tailor restart levels that copy memory to primary Mass Storage System devices.

 **NOTE:**

Software never requests an extended reboot.

To force an immediate core dump, in a simplex or duplex system, technicians should set the appropriate bit using this command, then enter the **reset system** command at a level that forces core dumps corresponding to set vector bits.

When a system restart occurs in a simplex Switch Processing Element (SPE) system with the corresponding vector bit set, the core dump writes to secondary storage (the primary MSS device). Once core dumps write, the vector clears and the restart executes. **This command disrupts service in a simplex system.**

The active SPE executes a core dump when:

- A system restart occurs on the active SPE in a High or Critical Reliability system with the corresponding vector bit set.
- The active SPE-active option is selected when the vector bit is set.

 **CAUTION:**
This command disrupts service in a simplex system.

The active SPE executes a core dump when:

- A system restart occurs on the active SPE in a High or Critical Reliability system with the corresponding vector bit set.
- The SPE-standby option is selected when the vector bit is set.

The active SPE executes a core dump when:

- A system restart occurs on the active SPE in a High or Critical Reliability system with the corresponding vector bit set.
- The active SPE-maint option is selected when the vector bit is set.

The vector clears after all core dumps.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
set vector	<i>spe-standby</i> <i>spe-active</i> <i>spe-maint</i>	see below. SIMPLEX SYSTEM Examples: set vector f set vector 9 DUPLEX SYSTEM Examples: set vector f spe-standby set vector f spe-active set vector f spe-maint set vector 9	init inads craft	spe-standby (High or Critical Reliability Systems)	none

Vector-Condition Mapping

value	WARM	COLDII	COLDI	REBOOT
0	n	n	n	n
1	y	n	n	n
2	n	y	n	n
3	y	y	n	n
4	n	n	y	n
5	y	n	y	n
6	n	y	y	n

Vector-Condition Mapping

value	WARM	COLDII	COLDI	REBOOT
7	y	y	y	n
8	n	n	n	y
9	y	n	n	y
a	n	y	n	y
b	y	y	n	y
c	n	n	y	y
d	y	n	y	y
e	n	y	y	y
f	y	y	y	y

spe-standby The default option for a High or Critical Reliability System. If a restart occurs on active SPEs and the corresponding vector bit is set, a core dump occurs on the standby SPE (after the standby SPE has performed a memory refresh).

spe-active Option for a High or Critical Reliability System; default for simplex SPE systems. If a restart occurs on active SPEs and the corresponding vector bit is set, core dumps occur on the active SPE. **This option disrupts service.**

spe-maint Available for High or Critical Reliability Systems. If restarts occur on active SPEs and the corresponding vector bit is set, core dumps occur on standby SPEs without the standby SPE a memory refresh.

status access-endpoint

This command displays diagnoses internal software and helps to locate facilities with which Access Endpoints communicate.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status access-endpoint	extension	extension number of the access endpoint	init inads craft cust nms browse	none	none
	print	prints reports to SAT printers. Examples: status access-endpoint 25012 status access-endpoint 77868 status access-endpoint 66078 print			

Output

The following output example is a display of the **status access-endpoint 22502** command. Assume that access endpoint ports for extension 22502 are in cabinet 1, carrier C, slot 11, circuit 1 to 6 — that access endpoints are connected on an active call to ports 7 to 12 of the board in location 1B19 (cabinet 1, carrier B, slot 19). This means that port 01C1101 connects to 01B1907, port 01C1102 connects to 01B1908, and port 01C1103 connects to 01B1909.

```
status access-endpoint 22502                page 1 of 1

ACCESS-ENDPOINT STATUS

      Extension: 22502
(Starting) Port: 01C1101
Communication Type: wideband
              Width: 6

      Service State: in-service/active

      Connected Ports: 01B1907 01B1908 01B1909
                      01B1910 01B1911 01B1912

Command Successfully Completed
```

Field descriptions

Extension	The extension of the access endpoint to be displayed.
(Starting) Port	Port locations of the access endpoint. For wideband access endpoint, the location shown is that of the starting port.
Communication Type	The valid voice and data communication type that the access endpoint is administered. The options are: 56k-data, 64k-data, voice-grade-data, and wideband.
Width	For communication types of 56k-data, 64k-data, and voice-grade data, the width value is 1. For communication type of wideband, this field displays the number of DS0s that makes up the access endpoint.
Service State	Whether the access endpoint is in-service or out-of-service. One of the following states displays: in-service/active, in-service/idle, and out-of-service.
Connected Ports	Port location connected to the access endpoint for an active call. For wideband access endpoint connection, all ports connected to the wideband access endpoint are listed.

status administered-connection

The **status administered-connection** provides automatic end-to-end connections between two access/data endpoints.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status administered-connection	ac number print	number assigned to an administered connection. reports print to SAT printers. Examples: status administered-connection 1 status administered-connection 50 status administered-connection 128 print	init inads craft cust rcust bcms browse	none	none

Output

The following output example is a display of **status administered-connection 3** command.

```
status administered-connection 3                                page 1 of 1

ADMINISTERED-CONNECTION STATUS

Connection Number:
  Enabled?
  Originator:
  Destination:
  Connection State:
  Failure Cause:
  Number of Retries:
  Auto Restorable?
```

Field descriptions

- Connection Number: Number assigned to the administered connection.
- Enabled? Is administered connection enabled? (y or n).
- Originator: Extension of originating access/data endpoint.
- Destination: Destination address used to route administered connections.
- Connection State: Current status of the administered connection. (connected, restored, failed, waiting to retry, attempting to restore, attempting to connect, not scheduled, and disabled).

- Failure Cause:Reason that the administered connection is attempting to connect, to restore, or failed to restore. If the administered connection was scheduled to be active but is disconnected, this field shows the most recent failure reason.
- Number of Retries:Number of consecutive failed establishment attempts.
- Auto Restorable?When an administered connection is connected, this field indicates if auto restoration attempts when a failure occurs.

status attendant

This command diagnoses internal software. This command help to locate facilities to which the attendant console communicates.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status attendant	console number print	number assigned to an attendant (1 –16). Report sent to printer. Examples: status attendant 1 status attendant 2 status attendant 2 print	init inads craft cust rcust bcms browse	none	none

Output

The following output example is a display of the **status attendant 1** command.

```
status attendant 1

ATTENDANT STATUS

Console Number: 1           Service State: in-service/night service
Port: 01C1106 Maintenance Busy? no
Connected Ports:

Command successfully completed
```

Field descriptions

- Console NumberNumber assigned to the attendant (1-16).
- PortPort location of the attendant (cabinet-carrier-slot-circuit).
- Service StateIn-service/idle, in-service/active, out of service, or disconnected.

Usage State	Idle or active.
Maintenance Busy State	Is maintenance testing the object? (y or n)
Connected Ports	Port locations to which the attendant is communicating (cabinet-carrier-slot-circuit).

status audits

This command displays results of Data Relation Audits that are built into the switch. Data Relation Audits check for inconsistencies between selected data items in the switch, and report inconsistencies. Data Relation Audits are useful during development and testing phases of projects to uncover software errors. In the field they help the switch to recover from data corruption before service is interrupted.

This command displays the date and time that the requested interval begins, the number of times that the full sequence of audits executes (audit cycles), and status information about each audit that detected a problem or aborted during the interval. The status information contains:

- The name of the audit
- The number of times that an audit ran and corrected an error
- The number of times that an audit ran and detected an irreparable error
- The number of times that an audit ran and aborted
- The date and time that the audit first detected a problem (only for cumulative)
- The time of the most recent error detected by the audit (only for cumulative).

Audit data information cumulates from the last reboot or the last **clear audits cumulative** command, and for peak hours since the last reboot or the last **clear audits peak-hour** or **clear audits cumulative** commands.

 **NOTE:**
Single process restarts, warm starts, cold 2 restarts, cold 1 restarts, or processor interchanges do not clear this data.

Audits can execute directly using the “test MO” command (for example, **test MO I 8192 p 512 t 0** executes the Station Connections Audits, audit lnames and numbers (pnames) included in the Table Of Audits.) When the “test MO” command executes an audit, report results display on the screen. In general, errors discovered from a demand tests are not logged in the error logs. To be consistent with other error logging, and to avoid confusion, errors that are discovered from a demand test that executes an audit are not displayed.

The screen does not automatically update. It reflects the system at the time of the request.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status audits	peak-hour	Data collected since the last reboot or since the last clear audits cumulative command.	init inads	none	see below
	cumulative	Data for the peak hour since the last reboot or since the last clear audits cumulative or clear audits peak-hour command. Determined by summing			
	print schedule	Prints report. Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: status audits cumulative status audits cumulative print status audits cumulative schedule status audits peak-hour status audits peak-hour print status audits peak-hour schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The **clear audits** command affects the data displayed by **status audits cumulative** and **status audits peak-hour**. The **clear audits cumulative** command clears data collected to date, resets the start time kept for that data, and clears peak hour data. The **clear audits peak-hour** command clears data kept for the peak hour so that a new peak hour can be established.

When the **schedule** option is specified, a scheduling form is displays allowing the technician to schedule command execution. Refer to the Report Scheduler and System Printer feature specification [3] for details about the scheduling form.

Output

The following example is a display of the **status audits** command.

```
status audits cumulative

Audit information displays with one line of data displayed audit that has detected an error or aborted. Audits that did not detected any errors or aborted do not display. The output sorts in descending order, based on the sum of the values in the # Cycles Fixed Data, # Cycles Could Not Fix Data, and # Cycles Audit Aborted fields.

Field descriptions

Start Date	Date and time that interval begins. "cumulative" = date and time of the last reboot or execution of the "clear audits cumulative" command. "peak-hour" = date and time of the beginning of the peak hour since the last reboot or execution of a "clear audits cumulative" or "clear audits peak-hour" command.
# of Audit Cycles Completed	Number of audit cycles completed in the specified interval. (0 – 999999) Asterisks indicate numbers that exceed 999999. The switch executes audits in a set order. After all audits execute, the switch restarts the sequence.  NOTE: Since this field shows the number of completed audit cycles, it is possible that individual audit values, can be larger than the values described below (if the switch is partially through another audit cycle.) Audit Cycles numbers do not apply to these audits that execute as part of scheduled maintenance.
Audit Name	Audit's name that detected an error or aborted. A few audits do not run in the normal audit sequence. Instead, they execute as part of scheduled maintenance and are marked with "(SCH)" following the audit name.
# Cycles Fixed Data	Number of times that the audit ran, in the specified interval, and found a fixable problem. (0–65534) Asterisks are used form numbers that exceed 65534.
# Cycles Could Not Fix Data	Number of times that the audit ran, in the specified interval, and found an unfixable problem. The audited switch data is inconsistent when this happens. (0–65534) Asterisks are used for numbers that exceed 65534.
# Cycles Audit Aborted	Number of times that the audit ran, in the specified interval, and aborted due to an internal error. (0–65534) Asterisks are for numbers that exceed 65534.
First Error	Date and time that the audit first detected fixed data, could not fix data or audit aborted problems since the last "clear audits cumulative" command. Format: MM:DD:hh:mm (for example, 03/27/14:31 for 2:31 pm, March 27th). This field appears with the "status audits cumulative" display.

Most Recent Error

Date and time that the audit last detected fixed data, could not fix data or audit aborted problems since the last "clear audits cumulative" command. Format: MM:DD:hh:mm (for example, 03/27/14:31 for 2:31 pm, March 27th). **This field appears with the "status audits cumulative" display.**

Table of Audits

The following table shows the names of the audits that are run as part of time available maintenance, the audit number (pname) and a short description of each audit. These audits execute using lname MO_DR_AUDIT (8192). These audits may execute using the *test MO* command with lname 8192, pname "audit number," and test number 0 (for example, *test MO / 8192 p 607 t 0* executes the AC state audit).

Audit Name	Audit Number	Description
AC-ISG	607	AC state audit
ADJUSR	595	Adjunct user record audit
ADMTRM	559	Administration terminal audit
ANUR-A	589	Announcement user record audit
AN-ADM	574	Announcement group administration audit
AN-CALLS	572	Announcement group calls audit
AN-QUE	577	Announcement group queue audit
AQSA	545	ACB queue slot allocation audit
ASLINK	606	ASAI link status audit
ASYLED	605	ASAI yellow LED audit
ATACT	558	Attendant active audit
ATAV	557	Attendant availability audit
ATDRCNT	576	Attendant resource count audit
AT-ADM	529	Attendant group administration audit
AT-CALLS	515	Attendant group calls audit
AT-QUE	523	Attendant group queue audit
AUR-A	540	Attendant user record audit
AU-CIDP	596	Announcement user cid/port audit

Audit Name	Audit Number	Description
AWOH-UR	614	Admin Without Hardware Split User Record Audit
B2B-TAB	617	Board-to-Board Link Audit
BR-CALLS	629	Bridged extensions audit
BUTLK	560	Button lock audit

MUV	555	Message user verification audit
MWIA	550	Message waiting indicator audit
MWL-NOAP	599	Message waiting lamp no AP audit
PA-ADM	533	Paging group administration audit
PA-CALLS	519	Paging group calls audit
PCLK	566	PCOL member lock audit
PC-ADM	535	Personal CO line group administration audit

Audit Name	Audit Number	Description
PC-CALLS	521	Personal CO line group calls audit
PINC-TAB	612	Packet Inter-Port Network Connection Sub-Table audit
PI-ADM	534	Pickup group administration audit
PLIP-LNK	602	LIP link audit
PN-HMM	578	HMM pname table audit
PRI-CR	598	PRI call record audit
PRI-TBUF	592	TSCUUI buffer audit
PUR-A	541	Phantom user record audit
SDSBUF	581	Service dispatcher stim buffer audit
SDSID	571	Service dispatcher SID audit
SE-ADM	538	Terminating extension group administration audit
SE-CALLS	537	Terminating extension group calls audit
STNLK	562	Station lock audit
SUR-A	539	Station user record audit
S-INC-TAB	611	Service Inter-Port Network Connection Sub-Table audit
S-PT-TAB	610	Service-Port Connection Sub-Table audit
S-TAB	620	Service Table Audit
TEGLK	565	TEG member lock audit
TKLK	564	Trunk lock audit
TONE-TS	608	Tone Time Slot Subtable Audit
TR-ADM	536	Trunk group administration audit
TR-CALLS	522	Trunk group calls audit
TR-QUE	525	Trunk group queue audit
TSC-PRI	520	ISDN-PRI TSC resource audit
TSRA	547	Time slot record allocation audit
TTI-STATE	618	TTI State Audit
TTI-TRANS	619	TTI Translation Audit
TTR-SID	514	Touch tone receiver audit

Audit Name	Audit Number	Description
TTR-TAB	622	Touch Tone Receiver Table Audit
TUR-A	542	Trunk user record audit
T-TS-TAB	613	Tone Time Slot Connection Sub-Table Audit
UGMA	551	User group membership audit
UPUSR-LNK	603	Up-link user link record audit
URMB	548	User record maintenance busy audit
X25-CHAN	615	X.25 Channel Status Audit
X25-LINK	616	X.25 Link Status Audit

The following table shows the names of audits that run as part of scheduled maintenance, the audit number (pname) and a short description of each audit. These audits execute using lname MO_SCH_AUDIT (8193). These audits may execute using the *test MO* command with lname 8193, pname “audit number,” and test number 0 (for example, *test MO / 8193 p 556 t 0* executes the Message Waiting Lamp Audit audit).

Audit Name	Audit Number	Description
MWL	556	Message Waiting Lamp Audit
PRI-USR	597	PRI user record audit
SUR-FREE	625	Station User Record Free List Audit

status bri-port

This command displays the service state, maintenance state and layer 1 state of an ISDN-BRI port. This form also displays information about point-to-point signaling links that transport over the port.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status bri-port	<i>location</i> <i>print</i>	Physical location: PCsspp Report sent to printer. Examples: status bri-port 1c0701 status bri-port 1c0701 print	init inads craft cust nms browse	none	none

Output

The following example shows the output from the **status bri-port 1c1701** command.

```
status bri-port 1c1701                               Page 1 of 1  SPE A

                                STATUS BRI-PORT

Link3
```

Field descriptions

- Port:
- ISDN-BRI port address.
- Service State:
- ISDN-BRI port is "in-service" or "out-of-service."
- Maintenance Busy?:
- specifies if maintenance testing is executing on the ISDN-BRI port ("yes" or "no").
- Layer 1 State:
- BRI Layer 1 (physical) state on the port. Valid states are "activated," "pend-activation," and "deactivated."

■ "activated" state = layer 1 frames are passing between the port and BRI endpoints.

■ "pend-activation" state = the port is in-service, the layer 1 interface device is on, layer 1 frames are sending to the BRI endpoints connected to this port, but BRI endpoints are not responding.

■ "deactivated" state = the layer 1 interface device on the BRI is off, because the port goes out-of-service.
- TEI Value
- Layer 2 addressing parameter used by the switch to exchange information over point-to-point signaling links between BRI endpoints. Each point-to-point signaling link has an associated TEI. This field displays the addressing parameter value. (0–127)

Layer2 State:	Point-to-point signaling link layer 2 state. Valid states are "un-assigned," "assigned," "established," "l3-established" or "hyperactive." ■ "un-assigned" = the link is in TEI-UNASSIGN state at Layer 2. ■ "assigned" state = the link is in the AWAIT_EST (Await Establish) state at layer 2. (If BRI endpoints support TEI allocation procedures, they successfully execute and a TEI is assigned to the endpoint by the switch. ■ "established" = the link is in the MF_EST_NORM (Multi-Frame Established Normal) state at layer 2. The switch successfully initiates the link can now exchange layer 3 frames with the endpoint. If the endpoint does not support SPID initialization procedures, the endpoint extension associated with the link also displays. This is the normal state for the link in the point-to-point wiring configuration. ■ "l3-established" = link is in the MF_EST_NORM state at layer 2 and SPID initialization procedures successfully complete. The endpoint extension associated with the link also displays. This is the normal state for the link in the multi-point wiring configuration. ■ "hyperactive" = traffic on this link goes over threshold. The link suspends and is deemed hyperactive.
Endpt Extension	Voice/data endpoint extension associated with the link if the link is in the "established" (point-to-point configuration) or "l3-established" (multipoint configuration) layer 2 state. Otherwise, this field is blank.
Endpt SPID	This field displays the SPID administered on the voice/data endpoint associated with the link. Note that this information is displayed only if the link is in either the "established" (point-to-point configuration) or the "l3-established" (multipoint configuration) layer 2 state. Otherwise this field is blank.
Service SPID	Indicates if the link is associated with the Service SPID. If the link is associated with Service SPIDs, the field contains a "yes" and the endpoint extension field is blank; otherwise, this field is blank. Service SPID checks building wiring between the switch and the BRI endpoint.

Status Interpretation

The following table provides information on the status bri-port form.

Table 8-3. Status BRI-Port Command Interpretation

Endpoint Types	TEI Range	Layer 2 State	Voice Extension	Service SPID	Description / Recommendation
ASAI, BRI	0-126	Assigned	blank	blank	Transitory state for BRI endpoints and ASAI adjuncts. The switch attempts link establishment. 1. Check endpoints and wiring by following SPID Facility Test Procedures described in the BRI-SET (ISDN-BRI Set/ASAI Adjunct) Maintenance documentation. 2. Verify repairs by executing the status bri-port PCSSpp command. Determine that L2 state of the signaling link is "L3-Established" for ASAI adjuncts and BRI endpoints supporting MIM (management information messages) initialization, and "Established" for fixed TEIBRI endpoints and automatic TEIBRI endpoints not supporting MIM initialization.  NOTE: A MIM is a level-3 message that conveys management and maintenance information between communications systems and BRI terminals.
ASAI	0-63	Established	blank	blank	Transitory state for ASAI adjuncts. ASAI signaling is connects at Layer 2. Layer 3 Restart procedure does not complete between switch and adjunct. 1. Check the adjunct by following the manufacturer's recommended repair procedures. 2. Verify repairs by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established.

Table 8-3. Status BRI-Port Command Interpretation — Continued

Endpoint Types	TEI Range	Layer 2 State	Voice Extension	Service SPID	Description / Recommendation
BRI	0-126	Established	ext	blank	Normal state for non-MIM initializing, fixed and automatic TEIBRI endpoints.
BRI, ASAI	64-126	Established	blank	blank	Transitory state for automatic TEIBRI endpoints which support MIM initialization. 1. Verify that SPID administration on the switch and endpoint are consistent. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established. Otherwise, proceed to Step 2. 2. Try to replace the endpoint. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established.
BRI	64-126	L3-Established	ext	blank	Normal state for automatic TEIBRI endpoints supporting MIM initialization.
BRI, ASAI	64-126	L3-Established	blank	yes	Technicians conduct SPID facilitation tests on the port. Links are not associated with BRI port endpoints. See description of SPID Facility Test Procedures in the “BRI-SET, ASAI-ADJ, BRI-DAT” Maintenance documentation.
BRI	64-126	L3-Established	ext	yes	Technicians conduct SPID facilitation tests on the port. Links are associated with port endpoints. See description of SPID Facility Test Procedures in the “BRI-SET, ASAI-ADJ, BRI-DAT” Maintenance documentation.

Continued on next page

Table 8-3. Status BRI-Port Command Interpretation — Continued

Endpoint Types	TEI Range	Layer 2 State	Voice Extension	Service SPID	Description / Recommendation
BRI	0-126	L3-Established	blank	blank	Invalid SPID assigned to link. 1. Change the SPID value in the BRI endpoint to match the SPID administered to the BRI endpoint on the port. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the BRI endpoint is L3-Established.
BRI (cont'd)	0-126	L3-Assigned	ext	blank	Transitory state for BRI endpoints which support MIM initialization. 2. Wait for five seconds and repeat the command. If the state has not changed, continue with Step 2. 3. Make sure SPID administration on the switch and endpoint are consistent. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established. Otherwise, go to Step 3. 4. Try to replace the endpoint. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established.

Continued on next page

Table 8-3. Status BRI-Port Command Interpretation — Continued

Endpoint Types	TEI Range	Layer 2 State	Voice Extension	Service SPID	Description / Recommendation
BRI (cont'd)	0-126	L3-Assigned	ext	yes	Transitory state for BRI endpoints which support MIM initialization when SPID Facility Test initializes the station. 5. Wait for five seconds and repeat the command. If the state has not changed, continue with Step 2. 6. Make sure SPID administration on the switch and endpoints are consistent. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established. Otherwise, go to Step 3. 7. Try to replace the endpoint. Verify the repair by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established.
ASAI	0-126	Hyperactive	ignore	ignore	Link has sent too many messages per unit time.
BRI					Signaling suspends. System timeouts in 60 seconds and attempts reactivate the link. If links remain in this state while no activity occurs at BRI endpoints: 1. Ensure that SPID switch administration and endpoints are consistent. Verify repairs by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established. 2. Replace the endpoint. Verify repairs by executing the status bri-port PCSSpp command. Determine that the L2 state of the signaling link is L3-Established.

Table 8-3. Status BRI-Port Command Interpretation — Continued

Endpoint Types	TEI Range	Layer 2 State	Voice Extension	Service SPID	Description / Recommendation
ASAI	0-126	L3-Restarting	ext		The switch sends a Restart message to the adjunct but has not received a Restart Acknowledgment message from the adjunct.
ASAI	0-126	L3-Restarted	ext		After receiving a Restart Acknowledgment message, the switch sends a Heartbeat message to the adjunct and awaits a response.
ASAI	0-126	L3-Established	ext		Normal state for ASAI adjunct.

status card-mem

Memory cards are portable, compact memory cards that contain banks of flash EPROM chips. Non-volatile memory cards are eraseable and randomly programmed with user data. Main memory stores system software in its “flash” section. Memory cards that save translations do not contain copies of the system software. During system reboot or system power down conditions, in-core system maintenance hardware error logs temporarily save in memory cards before the system goes down. Then, the error logs file reads back when the system restarts. The Hard Patch feature also uses the memory card as temporary storage when LMM applies patched files to the system software.

The **status card-mem** command displays the following memory card information located at active or standby SPEs:

- Is a valid memory card in place?
- Is the memory card write-protected?
- What is the capacity of the inserted memory card?
- What kind of system configuration - small or medium?
- What is the number of pulses counted in the last erase operation?
- What is the percentage of translation storage space used?
- What are the names of files stored in the memory card, and what is date and time (if available) when it was saved?

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status card-mem	location	Physical carrier position where the memory card resides in a High or Critical Reliability System Simplex switch configurations=not required. Duplex switch configuration= "A" for control carrier A in Processor Port Network (PPN), or "B" for control carrier B in PPN.	init inads craft cust rcust nms bcms browse	none	see below
	print	Report sent to printer. Examples: status card-mem status card-mem A status card-mem b print			

Feature Interactions

If the Announcement feature is unavailable in the system features configuration, the “Data Present” field is always “n” for the “announcements” file. The Announcement feature requires a memory card with a minimum capacity of 4 MB. If the memory card is less than 4 MB, Announcements cannot be save in the memory card.

Core Dump features require 10 MB memory cards for saving core dumps. If the memory card has a capacity less than 10 MB, the core dump operation fails.

Output

For following output example is a display of the status card-mem command.

```
status card-mem

                                MEMORY CARD STATUS

Location: 01A                    Write Protection: off
Status: inserted                 Capacity (MB): 4 Series 1
System Size: Medium             Number of Erase Pulses: 78
                                Translation Storage Space Used (%): 21

File Name      Data Present    Date      Time
translation    y              2/17/91   9:00
announcements  y              2/15/91   20:30

Command successfully completed
```

Field descriptions

Location	Physical location (carrier) of the memory card.Simplex system = 01A for carrier A of Processor Port Network. High or Critical Reliability Systems = 01A or 01B.
System Size	System configuration (Small or Medium). This information catches errors such as incorrectly-sized memory card inserted into the system.
Capacity	Inserted memory card capacity and the series number of the memory card. (a 3-digit format for the memory card size and a 1-digit format for the series number). Three memory card capacities are used in the DEFINITY D92 system. Memory card file contents are described below.

Capacity of Memory Card

Card Size	User	Customer File Names
1 Mb	Small w/o Announcements	translation
4 Mb	Medium w/o Announcements	translation
4 Mb	Small and Medium with Announcements	translation announcements
10 Mb	Maintenance (core dump)	translation announcements core_ dump
10 Mb	System Upgrade	system_software

Field descriptions

Status	“inserted” = valid memory card is in the memory card slot. When the status is “inserted,” the switch can perform I/O operation to the memory card “no card” = no memory card is inserted or the inserted memory card has a bad connection “unformatted”= the inserted memory card is unformatted or the switch cannot recognized it.
Write-Protection	“on” = the write-protection toggle on the memory card is on. “off” = the write-protection toggle on the memory card is off. If the “Write-Protection” field is “on,” the switch cannot store files to the memory card.
Number of Erase Pulses	Number of pulses counted in the last erase operation on a Series 1 memory card. This field is blank for Series 2 memory cards due to different algorithm of erase operations between the two series.

Translation
Storage Space
Used (%)

Percentage of reserved storage space for storing translation files in the memory card that saves translations to the memory card.

⇒ NOTE:

This percentage is valid for the specific memory card used in the *most recent* save translation operation (which is implemented with the **save translation** command or with scheduled maintenance and save translation enabled). If the memory card is replaced with another card, or if no save translation is performed on the new memory card, the percentage does **not** indicate the translation storage space used in the new card.

File Name

Each formatted memory card has reserved a fixed space in the card for each file. The starting address and size of each reserved slot is pre-determined according to the capacity of the memory card. The file name as defined in Table "Capacity of Memory Card" is shown in this field.

Data Present

The "Data Present" field is "y" when the file contains valid data. Otherwise, the "Data Present" field has a value of "n."

Date Time

This field shows the date and time when the file was saved into the memory card. For the "Software Upgrade" type of memory card, this field contains the system software release number instead of the time stamp. Due to the restriction of "core dump" file format, the year information is not available in the date/time string.

status cdr-link

This command displays the status of call detail recording (CDR) links. Link up or down status displays. If a link is down, the system displays the number of times the switch attempts link setup.

Call detail recording (CDR) links physically link SPEs to a recording device (for example, printer) for sending CDR call records. CDR link are composed of a data channel on the NETCON board or EIA port on the processor circuit pack, a digital port and a data module. Two CDR links can exist in the system.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status cdr-link	print	Report sent to printer. Examples: status cdr-link status cdr-link print	init inads craft cust rcust nms bcms browse	none	none

Output

The following example is a display of the **status cdr-link** command.

```
status cdr-link

                                CDR LINK STATUS

      Primary                      Secondary
Link State: up                  extension not administered
Number of Retries: 0
Maintenance Busy? no
```

Field descriptions

- Link State

Up, down, or unadministered extension.

“up” = link is up and available to the application. (normal state)

“down” = link is physically down.

“Extension not administered” = administer **system cdr feature** form.
- Number of Retries

The number of times the switch tries to initialize the link.
- Maintenance Busy

“yes” = maintenance object is busied out. “no” = maintenance object is not busied out.

status cleared-alarm-notif

Expert systems use the **status cleared-alarm-notif** command to detect chronic alarming conditions. If this command displays “Feature is suspended”, Expert Systems can identify open trouble tickets as chronic problems for special consideration.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
cleared-alarm-notif	1	First OSS telephone number status of Cleared Alarm Notification.	init inads craft cust rcust	first OSS telephone number for the Cleared Alarm Notification status.	none
	2	Second OSS telephone number status of Cleared Alarm Notification. Examples: status cleared-alarm-notif status cleared-alarm-notif 1 status cleared alarm-notif 2			

status conference

Technicians use the **status conference** command to solve the following multimedia problems:

1. A user cannot join or remain connected to a conference.
2. Automatic algorithms — audio AUTO mode and the Px64 video picture specifications downgrade the conference, causing poor video quality.
3. A user does not receive full service.
4. An audio add-on user cannot join or remain connected to a conference.
5. A conferee is not seen by other users due to interworking problems.
6. Users cannot participate in Multipoint Communications Service conferences.
7. Continuous conferences do not move endpoints in or out of quadrants.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status conference	status conference	Stored conference data.	init inads craft	conference-ID = all (all stored data).	none
	status conference 2 print	Conference 2 data (current or last completed). Sends report to SAT-linked printer. Examples: status conference status conference 2 print status conference [all \ conference-ID] [print \ schedule] status conference [all \ conference-ID] [endpoint \ endpoint id]			

Output

```
status 50                                     Page 1 of 2

                                STATUS OF CONFERENCE: 50  Status: in-use

Screen 8-1. status conference: page 1 of 2

It is possible for several records to display. Active conferences display first (in order of conference-ID), followed by completed conferences (most recently completed first). Conferences that have not begun have no data or information.

Conference data displays in 2 parts: the first screen describes the status of the conference and indicates the modes and levels of the conference. It also identifies in-use endpoints that cause conference operating modes to change. This screen is similar to the administration screens. The remainder of the screens display endpoint level data (up to 8 endpoints per screen), revealing ports and drop reasons.

[Screen 8-1](#) shows page 1 of a typical administration screen. The first screen appears when **status conference** is entered and at least 1 valid conference is found.

Field descriptions (status conference, page 1)

status	Current status of the conference (active, in-use, complete)
conference name	(MMCH DYNAMIC)

conference mode	(Voice-activated)
password	Not Applicable
password scope	Not Applicable
cascade mode	Conference cascade mode (blank)
audio mode	Current operating audio mode (G.711-A, G.711-mu, G.728, G.722)
class	Conference type (dedicated)
data mode	Conference data mode capability (none, any-mlp, ww-pcs)
MLP rate	Conference MLP Data Rate (blank).
start time/date	Conference start time in 24-hour notation with month and day.
stop time/date	End of conference in 24-hour notation with month and day. It is the actual end time if Status is complete; otherwise, it is blank.
admin bandwidth	Channel bandwidth administered on the Conference Record form. (64k)
no of channels	Number of channels required for each Px64 endpoint (2)
Chair	Current chair token holder. ()
conf bandwidth	Current operating channel conference bandwidth. Different from the administered bandwidth because of Rate Adaptation.
Rate adaptation	Does this conference support Rate Adaptation? (n, y)

Format (in/out)	The video format for single-screen conferences: CIF, QCIF, QCIF/CIF, H.CTS, H.CTX+, and SG4. non-H.261 conferences = input and output formats are always symmetric and the mode is the same for input and output. (H.CTX, H.CTX+, and SG4). H.261 mode non-continuous presence conferences = symmetric format (CIF and QCIF). Non-presentation, continuous presence conference in single-screen = symmetric format (CIF and QCIF). Presentation mode H.261 single screen continuous presence capable conferences = symmetric input and output formats QCIF/CIF (displayed as CIF) or asymmetric QCIF/CIF, if the administered format is upgradeable. For quad-screen conferences = the format is QCIF/CIF to reflect the QCIF input from all participants and output of CIF to all participants. For presentation mode quad-screen conference = the format is QCIF/CIF to reflect the input/output of all participants except the presenter. In quad-screen mode, presenter input is always CIF.
FPS	The CIF frame rate (frames per second) - ' - ', 30, 15, 10, 7.5. FPS indicates the rate that endpoints can receive frames. The MCU cannot detect maximum transmit frame rates or current frame rates. Frame rates change due to the amount of motion in the input image.
QFPS	The ACIF frame rate (frames per second) (' - ', 30, 15, 10, 7.5). The rate that an endpoint can generate/receive frames. Quad-screen VAS conferences = QFPS reflects the highest common QCIF frame rate of all endpoints and the video mixer board rate, that is lower than the rest of the participants. QCIF calculation accounts for the highest common CIF frame rate declared by all conference participants, since the QCIF rate cannot be greater than that of the highest common CIF rate. Quad-screen presentation conferences = QFPS reflects the highest common QCIF frame rate of all participants and the video mixer board rate. QFPS cannot be greater than the CIF frame rate that is announced by the presenter. QFPS field is blank for proprietary modes.
lo/hi interworking	Does this conference support Low Speed/High Speed Interworking? This field defaults to n.
Type	The type of conferee — Audio/Video (P64), Audio Add-on (AUD), Cascade Link (CAS), BONDing Call (BOND), BONDing Cascade Link (BCAS), UCC Controller (UCC), or Dedicated Access (DA). BONDing calls use up to 12 channels to form a single multimedia pipe.
Ext	Administered endpoint extension. ().

Meet-me number	The Meet-Me Number administered for the Meet-Me Extension. ()
Dial Type	“in” = dial-in to join endpoint to conference. “out” = dial-out to join endpoint to conference.
In Use	“y” = the endpoint is in use and is fully-connected on all media in an active conference. “c” = the endpoint is in use and is fully-connected; however, the endpoint has changed conference audio or video capability or conference rate due to rate adaptation. This condition requires analysis of this endpoint’s capabilities and mode fields to identify reduced capability. “e” = the endpoint is in use but has capability problems. The endpoint lacks one of the required capabilities (Vid, Bhl, MLP) to fully participate. For MLP capabilities, see the “T120” field. This condition requires analysis of this endpoint’s capabilities and mode field to identify the missing capability. “f” = the endpoint is in use but not connected to all media. The endpoint declared all required capabilities (channel/video/ audio/data) but is not fully connected to all conference media. This endpoint may be connecting, failed to connect, or is not a valid video source. This condition requires analysis of this endpoint’s capabilities and mode fields to identify the problem. “n” = the endpoint disconnected during a conference or unsuccessfully attempted to connect to a conference. “blank” = the field is blank until the first call from or to the endpoint.
Ch l	“y” = the endpoint has the required number of channels. “e” = the endpoint does not declare support for the correct number of channels and cannot participate fully in the conference. “n” = the endpoint declares the correct number of channels, but not all join the conference, due to a network or endpoint problem. “blank” = Audio add-on endpoints set the Ch l field to blank.

Aud	“y” = the endpoint has the required audio capability. Audio add-on endpoints always set the Aud field to y when the endpoint joins the conference. “c” = the endpoint is PCM only and it changes the conference video quality by changing the operating audio from G.728 to G.711. If administered audio modes are auto and the administered bandwidth is 112 kbps (56 k/channel) or 128 kbps (64 k/channel), the system initiates with the highest common audio, G.728. When the administered bandwidth is greater than 128 kbps, the system initiates with the highest common bandwidth, 7 kHz. “e” = A PCM-only endpoint that could not support the administered audio mode, G.728 (such as a data conference), or G. 278/G.711 endpoint that could not support the administered audio mode, 7 kHz. Such endpoints operate with PCM audio and interwork with current operating audio modes. blank = blank until the first call from or to the endpoint.
Vid	“y” = the endpoint has the required video capability and should be receiving video if the Chl, Aud, and Dat fields are y. “c” = downgraded conference video quality from changing CIF to ACIF or by decreasing the frame rate. The conference video mode defaults to CIF. If QCIF-only endpoints join the conference, the entire conference operates in QCIF, with downgraded video clarity. The conference frame rate is initially set to the highest frame rate that can be reduced by any endpoint. If the conference video mode is not administered with upgrade capability, the video parameters for a conference are “downgraded.” They are not “upgraded” until all endpoints disconnect from the conference. “e” = the endpoint does not declare video capability in its cap-set. “n” = audio only, not receiving video, due to audio or data problems. “blank” = Audio add-on endpoint defaults the Vid field to blank.
MLp	Control Link to the ESM (T.120 stack terminator) status, the endpoint MLP data capability, and the state of the data connection in the T.120 stack. This field defaults to blank, indicating that the Data Mode for the conference is none.
Gx	“y” = This endpoint has Still Frame Graphics capability. e = This endpoint does not have Still Frame Graphics capability. The conference retains still frame graphics capability when non-compliant endpoints join the conference. blank = This endpoint never joined the conference.

Rate Adpt	Rate adaptation/Interworking indicator (5, 6, y, c, e, n, blank). 5 and "6" apply to Low Speed/High Speed Interworking. All other values apply to Rate Adaptation. "5" = 56-kbps (Low Speed) endpoint joins a High Speed (128 kbps or above) conference. This endpoint connects with audio only capability but is not a valid video source and destination. "6" = 64-kbps (Low Speed) endpoint joins a High Speed (128 kbps or above) conference. This endpoint connects with audio only capability but is not a valid video source and destination. "y" = Endpoint joins the conference at 64 kbps, but because rate adaptation to 56 kbps is triggered by another endpoint, this endpoint rate adapts to 56 kbps. "c " = The administered conference bandwidth is 64 kbps. This endpoint joins the conference at 56 kbps. The first 56 kbps endpoint that joins 64 kbps rate adaptable conferences triggers rate adaptation (see Join Time below). "n" = Another endpoint triggers a 64-kbps conference to rate adapt to 56 kbps. This endpoint joins the conference at 64 kbps, but encounters problems in rate adapting to 56 kbps. This endpoint may have audio and may be receiving video, but is not a valid video source. "blank" Rate adaptation was not triggered by any endpoint. If this endpoint is in use and connected, it joins the conference at the administered bandwidth.
Bond Mode	BONDing Mode = blank for calls that are unrelated to bonding.
Ts	"t" = The endpoint detects voice energy (talking). "m" = The endpoint indicates to the MCU that it is muted. It is possible for an endpoint to mute, but not send any indication to the MCU. In this situation the MCU does not display a mute indication. "M" = UDD/CRCS Agent interface mutes the endpoint's audio. Both the endpoint and the UCC/CRCS Agent must mute the endpoint audio. "S" = The solo-audio state set by UCC/CRCS Agents mutes the endpoint's audio. While in solo-audio state, new endpoints that join the conference automatically mute. "blank" = Voice energy (talking) is not detected from the endpoint.

Vs

MCU endpoint video state (a, b, B, c, i, r, R, s, S, u, U, v, blank).

Quad-screen conferences = an * appears before the Vs value indicating that an endpoint belongs to the mixed image. # appears before Vs values indicating that an endpoint is set to be in the mixed image (via administration or UCC/CRCS Agent), but instead, Fill video displays in its place. This occurs when videos of an endpoint that are set in a quadrant cannot be used as a video sources, because the endpoint is not joined to the conference, suppresses its video, or has invalid video for its video source. Up to four endpoints may have an * or # before the Vs field value.

Quad-screen conferences in VAS mode = Mixed images broadcast to all endpoints.

Quad-screen conferences in presentation mode = Mixed images are return videos to the presenter.

Vs
(cont'd.)

a = Applies to quad-screen conferences. *a indicates that an endpoint belongs to the mixed image and is administered to one of the quadrants, but is not currently connected (Fill image displays).

b = Applies to full-screen conferences. This endpoint's video broadcasts to other sites. This conference is in VAS, broadcast, or presentation mode. Quad-screen VAS conferences are prefix with an * indicating that this endpoint's video belongs to the mixed image. Quad-screen presentation conferences, (b without an asterisk) identify the presenter as the broadcaster.

B = The UCC roll call feature causes the endpoint's video to broadcast to other sites. The UCC roll call feature performs in full-screen mode.

"c" = This endpoint's video broadcasts to other sites. The conference is in chair mode and the chair designates the broadcaster. Chair features perform in full-screen mode.

"i" = The endpoint is not a valid video source. #i represents continuous presence conferences with endpoints that are set in particular quadrants.

"r" = For full-screen conferences, the endpoint's video is the return video to the broadcaster. For continuous presence conference in presentation mode, *r represents a VAS quadrant that belongs to the mixed image.

"R" = The UCC browse feature causes the endpoint's video to return video to the broadcaster. UCC Browse feature perform in full-screen mode.

"s" = The endpoint suppresses this endpoint's video. For continuous presence conference with fixed quadrant participants, #s represents endpoints that are fixed in a particular quadrant.

Vs
(cont'd)

“S” = UCC/CRCS Agent interface suppresses this endpoint’s video. For continuous presence conference with fixed quadrant participants, #S represents endpoints that are fixed in a particular quadrant S displays when both the endpoint and the UCC/CRCS Agent suppress the endpoint video.

“u” = For full-screen conferences, this endpoint’s video broadcasts to other sites. The conference is in VAS mode and the UCC/CRSCS Agent interface designates the broadcaster. For quad-screen conferences, UCC/CRCS Agents designate this endpoint as set in a quadrant. An *u represents endpoints that belong to the quad image, and #U represents disconnected endpoints.

“U” = For quad-screen conferences UCC/CRCS Agents designate quadrants as VAS. *U indicates that this endpoint belongs to the quad image.

“v” This endpoint’s video broadcasts to other sites. The conference is in VAS mode but the endpoint asks to be a broadcaster with the “See-Me” request and is granted a MCV (Multipoint Command Visualize) token. The See-Me feature performs in full-screen mode.

“blank” = The endpoint’s video is not broadcast, return, video, or part of the mixed-image, but it is a valid video source.

6:									

Field descriptions (status conference, page 2)

Sum Grp	The VD audio Level 1 (L1) and Level 2 (L2) summer group parts for each assigned group (1-4). Summer parts are assigned only for conferences with over 6 participants. When a conference operates at an audio mode of 7 kHz (administered audio mode is 7 kHz, or auto with the bandwidth greater than 128 kbps), the system allocates "primary" and "secondary" L1 and L2 summer parts. Primary and secondary parts are allocated as adjacent port slots on the same board. Status conferences display primary summer ports. Secondary summer ports are one slot higher than displayed primary summer ports.
Join Time	Time (in 24-hour notation) when the channel joins the conference.
Drop Time	Time (in 24-hour notation) when the channel disconnects. If the first channel has a drop time, the endpoint is inactive. If a drop time exists without a join time, the call disconnects without joining the conference.
Drop Reason	Channel's disconnect because: "2-pri" = Administration errors cause mismatches in primary-secondary designation for cascade linking. This mismatch indicates that both MCUs are administered as primaries (see "Cascading" for a description of primary-secondary compatibility). "2-sec" = Administration errors cause mismatches in primary-secondary designation for a cascade link. This mismatch indicates that both MCUs are administered as secondaries (see "Cascading" for a description of primary-secondary compatibility). "Agent" = The reservation agent causes the call to disconnect. "Bandwidth" = A mismatch occurs between a call and the conference it attempts to join. "BondHshake" = Information channel parameters are unsupported or invalid, parameter negotiations terminate out of sequence, timers expire because secondary channels do not establish, or BONDing framing is undetected for one of the other channels. "Busy" = MCU detects that the conferee's terminal equipment is busy. This drop reason is detected by ISDN cause values (for example h0). See "Dial-out" for a description of CPTR usage. "Chair" = Chair Command Disconnect (CCD) or Chair Command Kill (CCK) signals disconnects the endpoint. "Conf End" = The conference ends when it reaches the stop time for a reserved conference or an active conference converts to file.

Drop Reason
(cont'd)

Endpoint Clearing received from DS1. The endpoint causes the disconnect. The endpoint notifies the MCU that it intends to disconnect.

Far-end Clearing received from DS1. The network or endpoint cause the disconnect.

“Handshake” = Framing is not located or is lost for over 40 seconds and the endpoint disconnects. (The endpoint cannot complete initialization due to problems with finding Frame Alignment Signal (FAS), Multi Frame Alignment (MFA) and getting a corrected coded cap-set.)

“IDtimeout” = The H.320 sends three unsuccessful responses to the MCU regarding the UIN/password Query. Timeout periods exist for each period.

“Internal” = MCU cannot allocate the necessary trunk resources to route the dial-out call for the specified dial-numbers. This problem can be associated with routing patterns or trunk associated translations, or it can indicate insufficient trunk resources.

“Network” = Clearing received from DS1. The network causes the disconnect. The endpoint with disconnect notification capability disconnects without notifying the MCU.

“Not-MCU” = The dial-out destination number(s) of the “CAS” extension terminates to a number that is not a dial-in cascade MCU extension.

“No-ring” = Calls are up for 30 seconds without ringing.

“Reorder” = The MCU CPTR resources detects that no network trunks are available to place the call. See “Dial-out” for a description of CPTR usage.

Drop Reason (cont'd)	“Pre-AnsDrop” = The call disconnects before an endpoint answers. The network, an endpoint, or a terminal adapter may cause the disconnect. This drop reason differs from ‘No-answer,’ which indicates that a 60-second timeout occurs during alerting. In this case, the call drops before the 60-second timer expires. Some busy endpoints connected through terminal adapters display this behavior. “Resource” = MCU cannot provide resources (VC or MMI) when the call arrives or loses the resources during the call. This can occur when they are Out of Service, busied out by craft, or in use by system maintenance. This drop reason can also occur if the DS1/MMI cable disconnects. If a resource problem exists when the call arrives, it gets a reorder (fast busy) and the MCU does not disconnected it. “Password” =The user entered a wrong password or the audio add-on user did not enter it within the specified time period. The audio add-on user has one attempt to enter a correct password and has about 10 seconds between digits (inter-digit timing). “System” = MCU restarts (level 2) disconnect all calls. “UIN-Inv” The user enters an invalid User Identification Number. “Unknown” = The system cannot determine the disconnect cause. “Wrong Num” The MCPTR resources SDN cause value detects an incorrectly-dialed destination number. See “Dial-out” for details. “UCC” = The controller intentionally disconnects the endpoint.
AC Num	Administered Connection Number. (1–128) AC numbers further diagnose problems by combining status conference information with the status administered connection command, and data stored in error and alarm logs.
Ports Trunk	The data endpoint used by the channel.
Ports Video	The MMI port for the channel.
Ports Aud	If the endpoint type is not “UCC,” the VC audio encoder port (which is always paired to a decoder port) for the channel (only the first channel). appears together with the ESM data port in the endpoint's channel 1 port slot position of the Port Aud/ESM column. For “UCC” endpoints, channel 1 port slot positions display allocated Call Classifier resources.
Ports ESM	Expansion Service Module MMI data port. This field defaults to blank.
Sum Grp	Endpoint's assigned summer group number. The summer group port assignments are on screen 1.
software	For Lucent Technologies use only.

Field descriptions (status conference endpoint)

The **status conference x endpoint y** command specifies that the conference is found. Data relevant for each endpoint displays in 6 pages. If technicians use the endpoint-ID **all**, every specified endpoint displays.

Screen 8-3. Page 1 of 6: status conference x endpoint y

Field descriptions

Endpoint	Slot number associated with the endpoint on the conference forms.
Product	Product identification number obtained from the endpoint.
Manufacturer/ Country	Manufacturer identification number and manufacturer's country code obtained from the endpoint.
Terminal Name	Blank.
Sum Grp	Endpoints belong to this Summer group number and the VC Audio Level (L1) and Level 2 (L2) summer ports for this group. These fields supply entries for conferences with over 6 participants.
Dial Out #1	Blank
Dial Out #2	Blank

In Use

Is the endpoint participating in the conference or connecting to the conference? - y, c, e, f, n, blank.

“y” = The endpoint is in use and fully-connected on all media in an active conference.

“c” = The endpoint is in use and fully-connected; however, the endpoint changes the conference audio or video capability, or the rate of the conference due to rate adaptation. This condition requires analysis of this endpoint's capabilities and mode fields to identify the reduced capability.

“e” = The endpoint active, but has capability problems. The endpoint lacks one of the required capabilities (Vid, Bhl, MLP) to be a full participant. For MLP capabilities, see the “T120” field. This condition requires analysis of this endpoint's capabilities and mode field to identify the missing capability.

“f” = The endpoint is active, but is not connected to all media. The endpoint declared all required capabilities (channel/video/audio/data) but is not fully-connected to all conference media. This endpoint may be connecting, failed to connect, or is not a valid video source. This condition requires analysis of this endpoint's capabilities and mode fields to identify the problem.

“n” = The endpoint connects then disconnects in a conference, or unsuccessfully attempts to connect to a conference.

“blank” = Blank until the first call is made from or to the endpoint.

Enh BAS

Enhanced Basic Service Flag - n, y

“y” = The endpoint supports the enhanced BAS commands/caps;

“n” = The endpoint supports the basic BAS commands/caps.

Chl

Data on the quantify and quality of channels (transfer rate)? - y, e, n, blank

“y” = The endpoint has the required number of channels.

“e” = The endpoint does not declare support for the correct number of channels and cannot participate fully in the conference.

“n” = The endpoint declares the correct number of channels, but not all channels join the conference, due to network or endpoint problems.

“blank” = Audio add-on endpoints set the Chl field to blank.

Aud	Does it have the required audio capability? - y, c, e, blank “y” = The endpoint has the required audio capability. Audio add-on endpoints set the Aud field y when the endpoint joins the conference. “c” = This PCM-only endpoint changes conference video quality by changing the operating audio from G.728 to G.711. If the administered audio mode is auto and the administered bandwidth is 112 kbps (56 k/channel) or 128 kbps (64 k/channel), the system begins with the highest common audio, G.728. When the administered bandwidth is greater than 128 kbps, the system begins with the highest common bandwidth, 7 kHz. “e” = A PCM-only endpoint that could not support the administered audio mode, G.728 (such as a data conference), or G. 278/G.711 endpoint that could not support the administered audio mode, 7 kHz. Such endpoints operate with PCM audio and interwork with operating audio modes. “blank” = Blank until the first call is made from or to the endpoint.
Vid	Does it have required video capability and is it receiving video? - y, c, e, n, blank “y” = The endpoint has the required video capability and receives video if the Chl, Aud, and Dat fields are y. “c” = The endpoint downgrades the conference’s video quality from CIF to ACiF, or by decreasing the frame rate. The conference video mode defaults to CIF, and if a QCiF-only endpoint joins the conference, the entire conference operates in QCiF, with downgraded video clarity. The conference frame rate is initially set to the highest frame rate that can be reduced by any endpoint. If the conference video mode is not administered with upgrade capability, the video parameters for a conference downgrade. They do not upgraded until all endpoints disconnect from the conference. “e” = The endpoint does not declare video capability in its cap-set. “n” = Audio only, not receiving video, due to an audio or data problem. “blank” = Audio add-on endpoints set the Vid field to blank.
Mlp	The relationship between the Control Link and the ESM (T.120 stack terminator), the endpoint MLP data capability, and the state of the data connection in the T.120 stack. This field defaults to blank, indicating that the Data Mode for the conference is none.
Gx	“y” This endpoint has Still Frame Graphics capability. “e” = This endpoint did not have Still Frame Graphics capability. The conference retains still frame graphics capability when a non-compliant endpoint joins the conference. “blank” = This endpoint never joins the conference.

Rate Adpt	Rate adaptation/Interworking indicator = 5, 6, y, c, e, n, blank. 5 and 6 apply to Low Speed/High Speed Interworking. All other values apply to Rate Adaptation. “5”= 56-kbps (Low Speed) endpoints join High Speed (128 kbps or above) conferences. This endpoint connects with audio only capability, but is not a valid video source and destination. “6” = 64-kbps (Low Speed) endpoints join High Speed (128 kbps or above) conferences. This endpoint connects with audio only capability, but is not a valid video source and destination. “y” = This endpoint joins the conference at 64 kbps, but because another endpoint triggers rate adaptation to 56 kbps, this endpoint rate adapts to 56 kbps. “c” = 64 kbps endpoints join the conference at 56 kbps. The first 56 kbps endpoint that joins 64 kbps rate adaptable conferences triggers rate adaptation (see Join Time below). “n” = Another endpoint triggers a 64-kbps conferences to rate adapt to 56 kbps. This endpoint joins the conference at 64 kbps, but encounters problems with rate adapting to 56 kbps. This endpoint may have audio and may be receiving video, but is not a valid video source. “blank” = No endpoint triggers rate adaptation. If this endpoint is active, it joins the conference at the administered bandwidth.
Bond Mode	BONDing Mode - blank. This field is blank for calls that are not related to bonding.
Ts	The talking state of the endpoint - t, m, M, S, blank. “t” = The endpoint detects voice energy (talking). “m” = The endpoint indicates that it is muted to the MCU. Endpoints may mute, but not send an indication to the MCU. “M” = UDD/CRCS Agent interface mutes the endpoint's audio. M displays when both the endpoint and the UCC/CRCS Agent mute the endpoint audio. “S” = the solo-audio state set by UCC/CRCS Agent mutes the endpoint's audio. While in solo-audio state, new endpoints joining the conference automatically mute. “blank” = The endpoint does not detect voice energy (talking).

Vs

The MCU video state for this endpoint. a, b, B, c, i, r, R, s, S, u, U, v, blank.

Quad-screen conferences = * appears before V values indicating that an endpoint belongs to the mixed image. A # appears before the V values indicating that an endpoint belongs to the mixed image (by administration or UCC/CRCS Agent). Instead, a Fill video displays in its place. This occurs when an endpoint's video that is set in a quadrant cannot be used as a video source because the endpoint is not connected to the conference, suppresses its video, or has invalid video for its video source. Up to four endpoints have an * or # before the Vs field value.

Quad-screen conference in VAS mode = The mixed image broadcasts to all endpoints. For quad-screen conference in presentation mode, the mixed image is return video to the presenter.

"a" = This value applies to quad-screen conferences. *a indicates that an endpoint belongs to the current mixed image and is administered to one of the quadrants. *a indicates that the endpoint is fixed in a quadrant, but is not currently connected (Fill image displays).

"b" = For full-screen conferences, this endpoint's video broadcasts to other sites. This conference is in VAS, broadcast, or presentation mode. For quad-screen VAS conference are prefixed an asterisk indicating that this endpoint's video is part of the mixed image because of VAS. For quad-screen presentation conferences, b identifies the presenter as the broadcaster.

"B" = The UCC roll call feature causes the endpoint's video to broadcast to other sites. The UCC roll call feature performs in full-screen mode.

"c" = This endpoint's video broadcasts to other sites. The conference was in chair mode and the chair designates the broadcaster. Chair features perform in full-screen mode.

Vs
(cont'd.)

"j" = The endpoint is not a valid video source. For continuous presence conference, #j represents endpoints that are fixed in a particular quadrant.

"r" For full-screen conferences, the endpoint's video is the return video to the broadcaster. For continuous presence conferences in presentation mode, *r represents a VAS quadrant that is part of the mixed image.

"R" = The UCC browse feature causes the endpoint's video to be the return video to the broadcaster. UCC Browse feature performs in full-screen mode.

"s" = The endpoint suppresses its video. For continuous presence conferences with fixed quadrant participants, #s represents an endpoint that is fixed in a particular quadrant.

"S" = UCC/CRCS Agent interface suppresses the endpoint's video. For continuous presence conference with fixed quadrant participants, #s represents an endpoint that is fixed in a particular quadrant. S displays when both the endpoint and the UCC/CRCS Agent suppress the endpoint video.

"u" = For full-screen conferences, this endpoint's video broadcasts to other sites. The conference is in VAS mode and the UCC/CRCS Agent interface designates the broadcaster. For quad-screen conferences, the UCC/CRCS Agent designates this endpoint as fixed in a quadrant. *u represents an endpoint that is part of the quad image, and #u represents a disconnected endpoint.

"U" = For quad-screen conferences, UCC/CRCS Agents designate a quadrant as VAS. *U indicates that this endpoint is part of the current quad image.

"v" = This endpoint's video broadcasts to other sites. The conference was in VAS mode, but the endpoint asks to be a broadcaster with the "See-Me" request and is granted a MCV (Multipoint Command Visualize) token. The See-Me feature performs in full-screen mode.

"blank" = The endpoint's video is not broadcast, return, video, or part of the mixed-image, but it is a valid video source.

enter command:

Screen 8-4. Page 2 of 6: status conference x endpoint y

Field descriptions

- Join TimeTime (in 24-hour notation) when the channel joins the conference.
- Drop TimeTime (in 24-hour notation) when the channel disconnects. If the first channel has a drop time, the endpoint is inactive. If a drop time occurs without a join time, the call disconnects without joining the conference.

Drop Reason

Channels disconnect because:

“2-pri” = Administration errors cause mismatches in primary-secondary designations for cascade links. This mismatch indicates that both MCUs are administered as primaries (see “Cascading” for a description of primary-secondary compatibility).

“2-sec” = Administration errors cause mismatches in primary-secondary designations for cascade links. This mismatch shows that both MCUs are administered as secondaries (see “Cascading” for a description of primary-secondary compatibility).

“Agent” = Reservation agents cause calls to disconnect (for example, agents change connected dial-out destination numbers).

“Bandwidth” = Mismatches occur when bandwidths of calls and the conferences they attempt to join are inconsistent.

“BondHshake” = Unsupported Information channel parameters or invalid, parameter negotiations that terminate out of sequence, timers that expire because secondary channels do not establish, or BONDing framing that goes undetected for another channels.

“Busy” = The MCU detects that the conferee’s terminal equipment is busy. An ISDN cause value detects this drop reason (for example h0). See “Dial-out” for a description of CPTR usage.

“Chair” = Chair Command Disconnect (CCD) or Chair Command Kill (CCK) signals disconnect the endpoint.

“Conf End” = The conference ends when the stop time is reached for a reserved conference or an active conference converts to file.

Drop Reason
(cont'd)

"Endpoint" = Clearing received from DS1. The endpoint initiates the disconnect. The endpoint notifies the MCU that it intends to disconnect.

"Far-end" = Clearing received from DS1. The network or endpoint initiate the disconnect.

"Handshake" = Framing is never found or is lost for over 40 seconds and the endpoint is disconnected. (the endpoint could not complete initialization due to problems with finding Frame Alignment Signal (FAS), Multi Frame Alignment (MFA) and corrected coded cap-sets)

"IDtimeout" = The H3.20 user unsuccessfully (three times) sends MCU responses regarding the UIN/password Query. Each timeout period is administered.

"Internal" = MCU has a problem allocating the necessary trunk resources to route dial-out calls for specified dial-numbers. This problem is associated with routing patterns or trunk-associated translation (for example, TAC specified in the dial-out number or routing pattern points to a trunk group without members), or indicates a lack of trunk resources (for example, all trunk members are maintenance busy or all in-service members are busy on a call).

"Network" = Clearing received from DS1. The disconnects the endpoint. The endpoint with the disconnect notification capability disconnects without notifying the MCU.

"Not-MCU" = The dial-out destination numbers of the "CAS" extensions terminate to numbers that are not dial-in cascade MCU extensions.

"No-ring" = The is up for 30 seconds and no ringing is detected.

"Reorder" The MCU CPTR resources detect that no network trunks are available to place the call. See "Dial-out" for a description of CPTR usage.

Drop Reason (cont'd)	“Pre-AnsDrop” = The call disconnects an endpoint answers. The network, an endpoint, or a terminal adapter may cause the disconnect. This drop reason differs from ‘No-answer,’ which indicates that a 60-second timeout occurs during alerting. In this case, the call drops before the 60-second timer expires. Some busy endpoints that are connected through terminal adapters display this behavior. “Resource” = MCU cannot provide resources (VC or MMI) when calls arrive or lose their resources during the call. Calls can lose resources when they are Out of Service, busied out by craft, or in use by system maintenance. If the DS1/MMI cable is disconnected, this drop reason can also occur. If a resource problem exists when the call arrives, it gets reorder (fast busy) and is not disconnected by the MCU. “Password” = The user enters a wrong password or the audio add-on user does not enter it within the specified time period. The audio add-on user gets one attempt to enter a correct password and has about 10 seconds between digits (inter-digit timing). “System” = MCU restarts (level 2) disconnect all calls. “UIN-Inv” = Users enter invalid User Identification Numbers. “Unknown” = The system cannot determine the disconnect cause. “Wrong-num” = The MCU CPTR resources SDN cause values detect an incorrectly-dialed destination number. See “Dial-out” for details. “UCC” = The controller intentionally disconnects the endpoint.
Drop Code	A detail code complementing the Drop Reason. Additional bonding-related information is available from the supplementary BONDing Drop Codes described above.
AC Num	Administered Connection Numbers. (1–128) AC numbers can further diagnose problems by combining status conference information with the status administered connection command, and data stored in the error and alarm logs.
Ports Trunk	The data endpoint that the channel is using.
Ports Video	The MMI port for the channel.
Ports Aud	If the endpoint type is not “UCC,” the VC audio encoder port (which is always paired to a decoder port) for the channel (only the first channel). appears together with the ESM data port in the endpoint’s channel 1 port slot position of the Port Aud/ESM column. For “UCC” endpoints, the channel 1 port slot position displays allocated Call Classifier resources.
Ports ESM	Expansion Service Module MMI data port. This field is always blank.
Ports BONDng	The MMI port used for channel BONDing.
Fr Err	Frame error counter. A circular hex counter (0-FF) to indicates framing error occurrences.

Screen 8-5. Page 3 of 6: status conference x endpoint y

Conference Info. This information primarily applies to full-screen conferences. The Broadcaster field applies to quad-screen presentation mode conferences.

Field descriptions

- Broadcaster
- The current broadcaster endpoint number. The following keywords qualify the broadcaster:
- "Broadcast" = A broadcast mode broadcaster.

"Chair" = The chair designates the broadcaster.

"See-Me" = The endpoint initiates a MCV broadcaster request.

"Presenter" = A presentation mode broadcaster.

"Rollcall" = The UCC designates the broadcaster by the Rollcall feature.

"UCC" = The UCC designates the broadcaster.

"VAS" = A Voice Activated Switching broadcaster.

Next Broadcaster	The endpoint number that is selected to be the next broadcaster.
Return Vid	The endpoint number that is the current return video. The return video is qualified with the following keywords: “blank” = VAS, Chair action, UCC action, or endpoint MCV requests force the previous broadcaster to be the return video. The broadcaster qualifier identifies the action that forced this endpoint to become return video. “Autoscan” = Auto scan return video, when conference mode broadcasts with auto scan. “Browse” = The UCC designates the return video with the Browse feature. “VAS” = A Voice Activated Switching return video.
Next Return Vid	Indicates the endpoint number selected to be the next return video.

Mode Commands/Communication Modes. This is a collection of incoming and outgoing bandwidth allocations for the multiplex. The Incoming data is the rate at which the MCU thinks the endpoint is communicating based on the Bit-rate Allocation Signal (BAS) codes received from the endpoint/codec and the capabilities the MCU has declared. The Outgoing data is the rate from the MCU toward the endpoint. The following are column definitions for this section of page 3.

Field descriptions

CONF	The desired conference operating mode. This may differ from the endpoint in (EPT - IN) or endpoint out (EPT - OUT) modes.
CMD	Labels for the various types of mode commands
STAT	Conference and incoming mode compatibility. “y” = mode compatibility “n” = modes incompatibility.
EPT - IN	defines the communication modes coming in from an endpoint.
EPT - OUT	Defines the communication modes sent to an endpoint based on the number of connected channels and the endpoint’s capabilities.

The following are field definitions for the Mode Commands/Communication Modes section of Page 3.

XRATE	One of the supported rates in Table 8-4 :

Table 8-4. Supported Transfer Rates s

XRATE	Bandwidth of the Call
2x64	2B (2x56 or 2x64)
128	112kbps or 128kbps
196	168kbps or 196kbps
256	224kbps or 256kbps
320	280kbps or 320kbps
384	336kbps or 384kbps
512	512kbps
768	768kbps
1472	1472kbps
1536	1536kbps'
1920	1920kbps

Field descriptions

- XRATE
(cont'd.)

XRATE may be 64 when the endpoint dials in, or in the event that problems occur. It implies that only one B channel is in use.
- AUDIO

Conference and endpoint Audio rates (kbps bandwidth) must be the same. Their modes are not necessarily the same. When the audio rate of the conference and the endpoint differ, the endpoint's audio interworks, but the endpoint's video is invalid. MCU may or may not send video to such an endpoint.

[Table 8-5](#) summarizes expected endpoint audio modes with different transfer rate configurations, facility bandwidths, and conference modes. It includes endpoints that support the highest common audio mode (HC audio) when the administered mode is auto. The highest common conference mode depends on the administered bandwidth. A '-' in the table indicates 'does not apply.'

Table 8-5. Audio Mode Configurations

Admin Mode (HC Audio)	All Support HC Audio	Xfer Rate	Facility BW	Conf Mode	Expected Endpoint Mode
auto (G.728)	yes	<=128k	-	G.728	G.728
auto (G.728)	no	<=128k	64k	G.711-A-56k	G.711-A-56k B.711-Mu-56k
auto (G.728)	no	<=128k	56k	G.711-A-48k	G.711-A-48k G.711-MU-48k
auto (G.722)	-	>128k	64k	G.722-56k	G.722-56k G.711-A-56k G.711-Mu-56k
auto (G.722)	-	>128k	56k	G.722-48k	G.722-48k G.711-A-48k G.711-Mu-48k
G.728	-	-		G.728	G.728
G.711	-	-	64k	G.711-A-56k	G.711-A-56k G.711-Mu-56k
G.711	-	-	56k	G.711-A-48k	G.711-A-48k G.711-Mu-48k
G.722	-	-	64k	G.722-56k	G.722-56k G.711-A-56k G.711-mu-56k
G.722	-	-	56k	G.722-48k	G.722-48k G.711-A-48k G.711-Mu-48k

Field Descriptions

AUDIO (cont'd.)	Other possible AUDIO mode values include neutral (neutralized I-channel), Au-off, and Frm (no audio signal) which never match conference modes and are unsupported by MCU.
56/64	The 65/64 field derestricts when operating at 64kbps, 128kbps, 192kbps, 256kbps, 320kbps, 384kbps, 512kbps, 768 kbps, 1472kbps, 1536kbps, or 1920kbps per channel speeds; it restricts when operating at 56kbps, 112kbps, 168kbps, 224kbps, 280kbps, 336kbps, 448kbps, and 672kbps per channel speeds. If technicians configure the conference for Nx56kbs operations, endpoint may signal by capabilities or modes that operate at the proper rate. In such a case, when technicians receive derestrict commands while they are in the restrict mode, that do not match conference communication modes, (MISC capability has restrict displayed on Page 4) the STAT 56/64 is y indicating 56/64 compatibility between the conference and the endpoint.
VIDEO	The Video mode: H.261 (recommended), H.CTX (proprietary), H.CTX+ (proprietary), or SG4 (proprietary) indicate that video is on in the direction indicated; and video-off when the video is off.

MLP	Multi Layer Protocol data mode. When technicians administer Data Modes as any -mlp or ww-pcs, MLP modes should be var -MLP. Other values affect video status. MLP modes should be MLP -off when technicians administer Data Modes as none. Other values in this mode affect video status.
H_MLP	The High Speed MLP mode. The HMLP mode should be H-MLP -off. Other values in this mode affect video status.
LSD	Low Speed Data mode. The LSD mode should be LSD -off. Other values in this mode affect video status.
HSD	High Speed Data mode. The HSD mode should be HSD -off. Other values in this mode affect video status.
CRYPT	Encryption mode. The CRYPT mode should be encrypt -off. Other values in this mode affect video status.
S/M	Single/Multi channel interoperability mode. 6B-H0-comp indicates that the sender is interoperating multiple channels and a single channel (for example, 6B and H0). Not-comp-6B-H0 indicates that the sender is not interoperating between 6B and H0. Normally this value is Not-comp-6B-H0. Other values in this mode affect video status.

Endpoint Miscellaneous (EPT MISC) Information. EPT MISC contains miscellaneous states and counters for an endpoint. Flags can y or n. Counters start with 0x00, increment to 0xff, and wrap around to 0x01. AIM and VIS are BAS commands that can be sent as input to MCU from an endpoint or as output from MCU to an endpoint

Field descriptions

AIM	Audio Indicate Mutes. “y” = For input, this endpoint mutes its audio. MCU does not VAS to an endpoint displaying mute. For output, all other endpoints in the conference mute their audio (have sent AIM to MCU). MCU in turn tells this endpoint (by sending it AIM) that there is no audio output from MCU. “n” = For input, this endpoint does not mute (only if endpoint audio mode is turned on). For output, an audio path opens across the bridge.
VIS	Video Indicate Suppressed. “y” = For input, this endpoint suppresses its video (video is muted). For output, the MCU is not sending video to this endpoint because there is no video broadcaster (broadcaster does not join or broadcaster’s video is invalid).

MIS	Multipoint Indicate Secondary-status. “n” = For output, the endpoint is a valid source (not necessarily at this moment). n is the correct state for the video. “y” = MIS was sent to an endpoint considered to be a secondary endpoint. The endpoint is included in the audio, but not video portion of the conference. Video is not sent.
MCV	Multipoint Command Visualize. “y” = For input, an endpoint requests to become a broadcaster. This is used during Still Frame Graphics and to force “presentation” mode.
TALK	“y” = The VC board detects voice energy from the endpoint. The TALK counter indicates the number of starts or stops.
VRCV	“y” = The endpoint is receiving video (MCU is sending video to the endpoint). The VRCV counter counts the number of times video sends or does not send to this endpoint.
BCTK	Single screen and quad-screen presentation mode conferences. “y” = The endpoint is the video broadcast source. The BCTK counter tallies the number of times this endpoint is the video broadcast source.
RTTK	Single screen conferences. “y” = The endpoint is the return video source. The RTTK counter tallies the number of times this endpoint is the return video source.
BCLS	Single and quad-screen presentation mode conferences. “y” = The endpoint is watching the video of the broadcast source.
RTLS	Single screen conferences. “y” = The endpoint is watching the video of the return source.
HYPR	“y” = Endpoint hyperactivity (MCU isolates endpoints from the MMCH conference due to “thrashing” behavior) affects the endpoint’s status as a video source (for 5 seconds of hyperactivity timer). The HYPR counter tallies the number of times this endpoint is hyperactive.
DMUTE	“y” = The VC board or the software in the MCU mute the decoder. VC boards mutes the decoder when it loses MMI or endpoint framing, when it receives invalid audio code words, and when endpoints are hyperactive. MCU software mutes the endpoint decoder of all endpoints besides the broadcaster. (when a mode of a conference is “broadcastw/scan” ,broadcast with auto scan) The DMUTE counter tallies the number of times the VC board mutes this endpoint’s decoder.
VFMT	Quad-screen conferences. This field always defaults to n, indicating QCIF format.
H.261	“y” = Video framing loss. The H.261 counter tallies the number of times framing is lost.

Frame Alignment Word (FAW) Information. The FAW section of page 3 provides channel Frame Alignment Word information for the communication

paths labeled CHL 1 and 2. For 2B calls, both CHL 1 and 2 are used. For 1-channel calls (112, bps, 128 kbps, 168 kbps, 196 kbps, 224 kbps, 256 kbps, 280 kbps, 320 kbps, 336 kbps, 384 kbps, 768 kbps, 1472 kbps, 1536 kbps, and 1920 kbps) only CHL 1 is used. A-OUT, A-IN, M-FRM, MFA, and MFN are flags with y or n.

Field descriptions

A-OUT	MCU has endpoint framing.
A-IN	Endpoint has MCU framing
M-FRM	Multichannel frame alignment of both channels in 2B is present.
MFA	Multiframe alignment word is present (required in 2B call).
MFN	Multiframe numbering is present (required in 2B call).
FAS	Frame Alignment Signal (FAS) channel number (1 or 2). This number should match the column header.
MCUFAL	MCU Frame Alignment Loss (MCUFAL). Counts the number of times the MCU reports lost endpoint FAW or multichannel synchronization (M-FRM) to the endpoint. The MCU a-bit toggles when the MCU gains or loses endpoint multichannel synchronization. This counter starts with 0x00, increments to 0xff, then wraps around to 0x01. The MCUFAL count also displays in the Fr Err field on Page 2
FEFAL	Far End Frame Alignment Loss (FEFAL). Counts of the number of changes the MCU detects in the endpoint's a-bit (A-OUT). The endpoint a-bit toggles when an endpoint gains or loses MCU framing. This counter starts with 0x00, increments to 0xff, then wraps around to 0x01.

Page 4 - Endpoint Capability Information

This section describes fields specific to endpoint-level command output.

status conference endpoint

Screen 8-6. Page 4 of 6: status conference x endpoint y

Endpoint Capability Information. Fields on this page display if an endpoint declares specific capability. For example, if an endpoint does not declare VID H.CTX capability, the H.CTX field does not display.

Field descriptions

VID	Video and frame rate types that the endpoint supports. "vfmt" = Does not display if the endpoint has no video capability. All values are blank if an active call or audio-only endpoint exists. Otherwise, values for this field include: ■ FCIF for full CIF ■ QCIF for quarter CIF. CIF support implies QCIF support. For larger screens, CIF typically displays sharper resolution video, ZCIF is blocked, but may run at higher frame rates with less clarity. Differences are less observable on very small displays. ■ cfps and qfps are maximum frame rates (frames/second) that the endpoint can receive video for CIF and QCIF operating modes. CIF frame rate values are 30fps, 15fps, 10fps, and 7.4fps. If the endpoint does not support CIF (that is, the vfmt field is QCIF), the cfps value should be blank. ■ da_sfg indicates support for H.261 Still Frame Graphics transfers. ■ H.CTX, H.CTX+ and SG4 are proprietary video format capabilities. ■ SG4_sfg indicates support for SG4 Still Frame Graphics
MISC	The restrict field and the 56/64 command mode with a restrict value indicate that endpoints operate at 56 kbps per channel. Endpoints on 56 kbps conferences must send one or both 2 indications that they are operating at 56 kbps before they become a video source in a 56 kbps conference. If they signal that they are operating at 56 kbps in a 64 kbps or 384 kbps conference, they become an audio-only source, but the MCU continues to send Selected Communication Mode (SCM) toward them when possible. A MISC capability of derestrict and a 56/64 command of derestrict together indicate that an endpoint operates at 64 kbps. If either is restrict, the conference operates at 56 kbps. Other field values include: ■ dcomp indicates support for WorldWorx PCS data compliance. ■ mbe indicates support for Multi Byte Extension. MBE exchanges passwords, terminal names, and other special capabilities, such as, WorldWorx PCS specific features support. ■ cic (Chair Indicate Capability) indicates chair control capability.

XR	Transfer rate capabilities. Endpoint speeds over current connections and Px64 Multiplexes. For 384 kbps (H0) calls, endpoints indicate 384 kbps support, that displays as 384. On 336 kbps calls, endpoints must signal 384 kbps support. If an endpoint does not indicate support for 384 kbps on a 384/336 kbps conference, the MCU provides Audio Only Communications Mode (ACOM). For a 2B conference, the MCU sets the rate to 2x64, expecting the endpoints to do likewise (64x2 displays; if this is not displayed, no 64x2 capability exists). Endpoints may remove 2x64 (or the current channel rate: 384, 768, 1472, 1536) from their capability. This is Mode 0 forcing and is a normal procedure. The MCU provides AOCM if the endpoint does not signal support that matches the conference configuration.
AUD	Audio. Audio protocols that the endpoint supports. 711m and 711a are PCM (G.711) and support Mu and A-law, respectively. Endpoints require at least one. The g728 field indicates if G.728 is supported (LB_CELP). This value depends upon the endpoint type and configuration. The g722_48 field indicates endpoint support for G.722 (7 kHz) at both 48 kbps and 56 kbps. The g722_64 field indicates endpoint support for G.722 at 64 kbps in an unframed (unsupported by the MCU) mode.
LSD	Low Speed Data conferencing capabilities.
HSD	High speed Data conferencing capabilities.
MLP	Multi Layer Protocol Data capabilities.
HMLP	High Speed MLP data conferencing capabilities.

Page 5 - Endpoint Call Status Information

This page summarizes call-related status for per-channel join counts, join/drop times, drop reasons, drop codes, and auxiliary bonding drop codes. In addition, it contains drop codes and software fields from the previous call. The data on the page is retained. The Endpoint Call Status Information section groups all call-related fields. The only new field in this section is Join Count; all other fields are described in [Screen 8-3](#) and [Screen 8-4](#).

status conference endpoint

Screen 8-7. Page 5 of 6: status conference x endpoint y

Field descriptions

Join Count

Tallies the number of times this endpoint joins this conference during this session. This counter starts with 0, increments to 64, and wraps around back to 1.

Page 6 - Administered Connections

This page summarizes information for administered connections associated with this endpoint. This data can be viewed while the conference is active.

status conference endpointpage 6 of 6

ADMINISTERED CONNECTIONS INFORMATION

Screen 8-8. Page 6 of 6: status conference x endpoint y

Field descriptions

Dial-out number

Numbers that are dialed out by administered connections for each channel in the call. The dial Out #1 and #2 on page 1 of the forms display the DCP endpoint number. This is particularly useful with bonding dial-out calls.

Connection
State

The call state of the AC. The following are connection states associated with dial-out ACs:

“enabled” = Transient in nature indicating that an AC is about to enter the “attempting to connect” state.

“disabled” = one of three options:

- The AC reaches an administered retry threshold, and all retries are stopped. To verify this, check the Error Log to see if an error type of 9 is logged against the AC.
- The AC is in a connected state with the far end disconnected.
- The initial channel call is not connected. No dial out call attempt is made for the additional channels until the initial channel has reaches a connected state.

“not scheduled” = Transient in nature, indicating that an AC is about to enter the “attempting to connect” state.

“waiting to retry” = The AC is inactive, waiting for the retry timer to expire. Once the timer expires, the AC sends a dial out call and enters the “attempting to connect” state. In this state, dial out calls fail at least once.

“attempting to connect” = The AC is active, but has not connected.

“connected” = The call associated with the AC is answered and joins cut-thru to the conference.

Retry Count

Tallies the attempted retries for this AC during join attempts and does not clear when the AC connects. However, it clears when the Redial feature attempts a new join. This differs from the Join Count which counts the number of times the channel joins the conference during this conference session.

Failure Cause

An ISDN or CPTR cause value (values lower than 0x7f) records when the last dial out call drops. Values above 0x7f are generated internally. [Table 8-6](#) lists all possible failure cause values displayed by this field and its associated description. The Failure Cause value logs in the Error Log and displays with the **display errors** command. (Err Type is normally displayed as a decimal.)

Table 8-6. Status AC - Failure Cause Values

Failure Cause (hexadecimal)	Description
0x00 (0t0)	N/A
0x01 (0t1)	Incorrect destination address
0x02 (0t2)	Reason unknown

Table 8-6. Status AC - Failure Cause Values — Continued

Failure Cause (hexadecimal)	Description
0x06 (0t6)	Reason unknown
0x10 (0t16)	Normal call clearing
0x11 (0t17)	Endpoint not available
0x12 (0t18)	ISDN timer expired
0x15 (0t21)	Reason unknown
0x12 (0t22)	Destination address changed
0x1C (0t28)	Bad destination or access denied
0x1D (0t29)	Access denied
0x1F (0t31)	Reason unknown
0x22 (0t34)	Trunks unavailable
0x26 (0t38)	Temporary or facility failure
0x29 (0t41)	Temporary or facility failure
0x2A (0t42)	Resources unavailable
0x2C (0t44)	Resources unavailable
0x32 (0t50)	Access denied
0x34 (0t52)	Access denied
0x36 (0t54)	Access denied
0x3A (0t58)	Resources unavailable
0x41 (0t65)	Required capability not implemented
0x42 (0t66)	Required capability not implemented
0x45 (0t69)	Required capability not implemented
0x51 (0t81)	ISDN protocol error
0x52 (0t82)	Required capability not implemented
0x58 (0t88)	Incorrect destination number
0x60 (0t96)	ISDN protocol error
0x61 (0t97)	ISDN protocol error
0x62 (0t98)	ISDN protocol error
0x64 (0t100)	ISDN protocol error
0x66 (0t102)	ISDN timer expired
0x7f (0t127)	Reason unknown

Continued on next page

Table 8-6. Status AC - Failure Cause Values — Continued

Failure Cause (hexadecimal)	Description
0xC2 (0t194)	Ring no answer
0xC8 (0t200)	Hi and dry - no feedback detected
0xC9 (0t201)	Cascade link administered wrong
0xCA (0t202)	CPTR not available to detect failure

status data-module

This command displays internal software state information for diagnosis. This command can help locate facilities to which the data module is communicating.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
busyout mis	extension print	data module extension Report prints if a printer is linked to the SAT. Examples: status data-module 30000 status data-module 32770 status data-module 32770 print	init inads craft cust rcust bcms browse	none	none

Output

For the following output example, the command that was entered is “status data-module 301”.

```
status data-module 301

DATA-MODULE STATUS

Data Ext/Stn Ext for Stn DM: 301      Service State: out-of-service
Port/Channel Number: 01C1103      Maintenance Busy? no
CF Destination Ext:
Connected Ports:
```

Field descriptions

Data Ext/Sta Ext for Stn DM	The data module extension number. The DTDM is an exception: the connected station extension is shown.
Port/Channel Number	The port location of the data module (cabinet-carrier-slot-circuit). If the data module specified is a data channel, the channel number is shown instead.
Service State	This entry displays the status of the data module; valid states are: — In-service/idle — The data module is present but not in use. — In-service/active — The data module is present and is in use. — Out-of-service — The data module has been removed from service — Disconnected — The data module no longer appears to be present
CF Destination Ext	This entry displays the call forwarding destination, if any, of the station.
Maintenance Busy?	Whether maintenance is testing the object, "yes" or "no".
Connected Ports	Port locations to which the data module is connected (cabinet-carrier-slot-circuit).

status hardware-group

Summary information for the active or last hardware group test displays. This display includes the number and percentage of tested maintenance objects, the percentage of tests passed, failed, and aborted, the time elapsed since initiating the hardware group test, the specific hardware group test command (see ["test hardware-group"](#) command) initiated, and the state (active/canceled/complete) of the hardware-group test.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status hardware-group	print	Report sent to printer. Examples: status hardware-group status hardware-group print	init inads craft cust rcust bcms browse	none	none

Output

The following output example is a display of the **status hardware-group** command.

```
status hardware-group                                page 1 of 1

      HARDWARE GROUP STATUS

Hardware Group Command State:    active
      Number of MOs Tested:      11070
Total Number of MOs to be Tested: 12300
      Percent Complete:          90%
Elapsed Test Time (hr:min:sec): 0:15:30
      Repetition Number:         1
      Percentage of Tests Passed: 82%
      Percentage of Tests Failed: 11%
      Percentage of Tests Aborted: 7%

      ENTERED HARDWARE GROUP COMMAND

      Command: test hardware-group system
      Test sequence: short
      Test repetition: repeat 3
      Output Options: failures
      Hardware Options: SPE-interchange
```

Field descriptions

Hardware Group Command State:	“active” = testing in progress, “canceled” = testing canceled, “complete” = command completed; no testing occurring.
Number of MOs Tested:	Number of MOs in the specified group (refer to test hardware-group command) that the hardware-group command tests, including MOs that were tested or aborted due to resource contention.
Total Number of MOs to be Tested:	Number of MOs in the group specified in the test hardware-group command.
Percent Complete:	Ratio of the completed MOs to the MOs to test in the command.
Elapsed Test Time:	It tracks completion time for the hardware-group command. If a test cancels, then restarts, the time for the cancel period is excluded. The time displays in HH:MM:SS format.
Repetition Number	Number of completed iterations that correspond to the 'repeat' or 'continuously' option.
Percentage of Tests Passed:	Percentage of tests that passed.
Percentage of Tests Failed:	Percentage of tests that failed.

Percentage of Tests Aborted:	Percentage of aborted tests
Command:	Hardware-group action objects and qualifiers.
Test sequence:	Short or long.
Test repetition:	Displays continuously or the keyword repeats with the entered repeat value.
Output options:	Selections that were chosen on the input form: auto-page, background, or failures.
Hardware options:	Selections that were chosen on the input form: all-ports, or SPE-interchange.

status health

This command displays the current system alarm summary, maintenance busy summary, user summary, critical system status, and cabinet status. This same page displays with the **monitor health** command, except that the **status health** output page does not update periodically.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status health	print	Report prints to SAT-linked printer. Examples: status health status health print	init inads craft cust nms browse	none	High or Critical Reliability Systems = If standby SPE Emergency Transfer Select Switches change and handshakes are down, the displayed Emerg Trans field is incorrect until handshakes reactivate.

Output

The following output example is a display of the **status health** command.

```
status health

SPE: A/Auto B/functional OCC: ST: 9% Cp: 25% Sm: 10% Idl:66%

```

Field descriptions

Major	Number of logged major alarms. (0–200)
Minor	Number of logged minor alarms. (0–200)
Warning	Number of warnings logged in the alarm file. (0–200)
Trunks	Number of maintenance busied out trunks.
Stations	Number of maintenance busied out stations.
Others	Combined number of maintenance busied out objects excluding trunks and stations.
Static	Proportion of the CPU that is dedicated to high priority items (for example, the operating system). This percentage is rounded to the nearest integer, therefore a percentage of 0 means that the occupancy is less than one half of a percent.
SM	Proportion of the CPU that is dedicated to system management or periodic and scheduled maintenance. If many periodic or scheduled maintenance tests perform, this occupancy percentage can be high without affecting service. This percentage rounds to the nearest integer; therefore, a percentage of 0=the occupancy is less than one half of a percent (for example, an 89.6% occupancy displays as 90%).
CP	Proportion of the CPU that is dedicated to call processing. This occupancy has priority over SM and IDLE occupancy categories, and if needed, takes processor time from these occupancy categories. This percentage is rounded to the nearest integer.
Idle	Available proportion of the CPU. This percentage is rounded to the nearest integer.
Active SPE	A or B indicate the active processor complex. When the active processor complex is locked on-line with lock switching on DUPINT, the “lock” option displays; otherwise, “auto” displays.
Duplicated?	Duplication status of the SPE component. “y” = duplication; “n” = no duplication.
SPE Power	Power source for the processor complex. (commercial) When commercial power is unavailable, battery backup is in use and is indicated with “backup”.
Time Source	The current timing source. Display values for this field vary according to timing sources selected. “external” = For Stratum-3 hardware, “internal” = an internal source, such as a tone clock. Primary and secondary timing sources must be administered for the Stratum-4 option. “primary”= the primary administered source is in use, “secondary” = the administered secondary source is in use. “local” = neither the primary or secondary sources are in use.
# Logins	Number of current users.

Cab	Assigned cabinet number (1 to the highest system cabinet number).
Emerg Trans	Settings for emergency transfer switches on the maintenance board for each cabinet. Available options are: auto-on ("auto+" or "a+"), auto-off ("auto-" or "a-"), "on", "off", and "n.a.". The system defaults to "auto+" or "auto-". In this state, emergency transfer activate automatically if the cabinet fails ("+"=emergency transfer is activate, "-" = emergency transfer is inactive). "on" = emergency transfer automatically activates. "off" = the cabinet cannot activate emergency transfers. Duplicated SPEs systems = switch settings for both processors of the PPN (cabinet 1) display. In this case, "auto+" is abbreviated "a+", "auto-" is abbreviated "a-", and "off" is abbreviated "of". "on" does not change. "n.a." = the emergency transfer switch setting is unavailable.
Mj	Number of major alarms associated with the cabinet. Asterisks are used to fill fields when numbers exceed 99.
Mn	Number of minor alarms associated with the cabinet. Asterisks are used to fill fields when numbers exceed 99.
Wn	Number of warnings associated with the cabinet. Asterisks are used to fill fields when numbers exceed 99.
PNC	Port Network Connectivity (PNC) status for each port networks within a cabinet. When multiple port networks exist, Carriers A, B, and C are listed first and separated from Carriers D and E by a slash (for example, up/up). Availability of the Expansion Archangel Link (EAL) determines PNC status of a port network. "up" denotes that the EAL is available. "dn" denotes that the EAL is unavailable.
Time of Day	Current time of day acquired from the system.

status interface

This command displays the number of counters maintained by the PI. (a front end processor implementing packet layers and link layers of the BX.25 protocol and the integrated services digital network (ISDN) procedure-D protocols.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status interface	location	(cabinet-carrier-position) of the processor interface (PI board). 1 = the first processor interface in the carrier; 2 = the second processor interface in the carrier.	init inads craft cust rcust bcms browse	1 (one)	none
	print	Report sent to printer. Examples: status interface a1 status interface 01a2 status interface 01b1 status interface b2 status interface b2 print			

Output

The following example is a display of the **status interface a1** command.

```
status interface a1

PROCESSOR INTERFACE STATUS

Base Level Occupancy(low): 10
Base Level Occupancy(high): 25
Primary Queue Audit Error: 4
Secondary Queue Audit Error: 10
Translation Audit Error: 12
Protocol Timer Audit Error: 0
Hardware Sanity Timeout: 1
Hardware Resource Error: 12
Hardware Overload Error: 8
```

status isdn-testcall

The **status isdn-testcall** command displays the progress of an outgoing ISDN-PRI test call. The status form displays the tested ISDN-PRI B-channel port number, bit error rate, number of bits transmitted, block error rate, number of blocks transmitted, start time, duration specified, duration of test call and reason of termination.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status isdn-testcall	group number	administered number associated with each trunk group.	init inads craft	none	see below
	group member	administered number identifying a particular trunk within a trunk group.			
	number print	Report prints to SAT-linked printer. Examples: status isdn-testcall 80/1 status isdn-testcall 78/1 print			

Feature Interactions

If the bit error rate or block error rate is greater than zero, the ISDN-PRI trunk may be in trouble. The statistical information displayed on the terminal may deactivate the ISDN trunk. This is subjective because the ISDN trunk may be used for data or voice. If the trunk is used for data and the rates are high, the trunk should be deactivated. If the trunk is used for voice, the trunk may not be deactivated. Also, high rates be at risk for some type of power hit.

Output

The following output example is a display of the **status isdn-testcall 80/1** command.

status isdn-testcall 80/1

Page 1 of 1

SPE A

ISDN TESTCALL STATUS

Port	Bit Error Rate	Number Of Bits	Block Error Rate	Number Of Blocks	Start Time	Duration Of Specified	Duration Of Test	Reason Of Termination
1B1401	0EE0	4EE7	0EE0	6EE2	25/12:36	120	100	in progress

Field descriptions

Port	(cabinet/carrier/slot/circuit) of the ISDN-PRI B-channel.
Bit Error Rate	The measured bit error count based on the comparison between sent and received bit patterns. (Number displays in scientific notation)
Number of Bits	Number of bits generated. (Number displays in scientific notation)
Block error Rate	The measured block error count based on the comparison between sent and received bit patterns. (Number displays in scientific notation).
Number of Blocks	Number of blocks generated. (Number displays in scientific notation)
Start Time	Test call start time. (dd/hh:mm).

Duration Specified	Specified run time for the test call. (1-120 minutes, or blank = default of 10 seconds).
Duration of Test	Run time for the test call, listed in minutes. "blank" = a default time.
Reason of Termination	Reason that the test call terminates: "finished," "canceled," "overflow," "no bits," "transmission," "internal fail," "data corrupt," "call dropped," "call rejected," and "in progress." "finished" = the test finishes in the specified time. "canceled" = the test call cancels with the clear isdn-testcall command. "overflow" = the transmitted bits overflow buffer allocation. "no bits" = no bits are received because the ISDN-PRI test call circuit connection is bad. "transmission" = a data transmission interrupts, probably from a power hit. "call dropped" = the call drops due to an abnormal termination, or inability to cut-through to the other side. "call rejected" = the originating call is not set up properly. "internal fail" = an internal error on the Maintenance/Test circuit pack. "in progress" = the test is still running; "data corrupt" = any other error condition.

status journal-link

The **status journal-link** command displays if the link is up or down. If the link is down, the system displays the number of times the switch tries to initialize the link. A journal printer documents automatic wake-up events, emergency access to attendant events, and housekeeping events when the property management system is not functional. A journal printer may also generate reports for automatic wake-up events and emergency access events at a scheduled time. If system configuration includes two printers, one is for housekeeping events only and the other is for automatic wake-up events and emergency access events.

For general information on journal printer links, see the description of the ["busyout journal-printer"](#) command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status journal-link	wakeup-log	printer that handles automatic wakeup and emergency access to attendant events and scheduled reports.	init inads craft cust rcust bcms browse	none	none
	pms-log	printer that handles pms down events.			
	print	Reports print to SAT-linked printer. Examples: status journal-link wakeup-log status journal-link pms-log status journal-link pms-log print			

Output

The following example is a display of the **status journal-link wakeup-log** command.

```
status journal-link wakeup-log

                                JOURNAL LINK STATUS

Link State: up
Maintenance Busy? no
```

Field descriptions

- Link State

If extensions are administered in the System Parameters Hospitality form, wakeup-logs or pms-log links are considered to be administered only.
- Maintenance Busy

Is maintenance testing performing on the link?

status link

The **status link** command displays the operational status associated with a specified processor interface link.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status link	<i>link number</i> <i>print</i>	A link number (1-8) associated with a specific link. Report sent to printer. Examples: status link 1 status link 8 status link 4 print	init inads craft cust rcust bcms browse	none	none

Definitions

Link	A synchronous connection between the system and an adjunct or another switch. The link consists of three protocol levels. The change communications-interface links command specifies the link number.
Level 1	Physical connection of a port on a Processor Interface board to hardware that serves the same purpose on the adjunct or switch (for example, a PI board or an SCP board on Audix). Several components can exist between these two endpoints (modems, DS1 facilities, cables, and so forth).
Level 2	Logical protocol that allows data communication between two endpoints. BX.25 = LAPB (Link Access Protocol on the B-channel) protocol. Level 2 = Frames sent. Protocol establishment requires one end to send a SABM (Set Asynchronous Balanced Mode) frame and the other to respond with a UA (User Acknowledgment) frame. Both sides send SABMs until they receive a UA. (level 2 is up and the Link Status field displays “restarting”) This should be a temporary condition, because level 3 comes up immediately.
Level 3	Logical protocol that allows multiplexing of many channels to one level 2 link. BX.25 specifies that this is the X.25 data phase protocol. Packets are sent at level 3, included in level 2 frames. This protocol establishes after level 2 establishes when one end sends a Restart packet, and the other sends a Restart Confirm packet.
Processor channel	Connection of an application running inside the SPE to a specified channel on a specified link. A number on the change communication-interface processor-channel form identifies processor channels. The link and level channel numbers and the application are specified on the link (for example, dcs) that uses the processor channel.

Field descriptions

Link Number	Processor Interface link number (1-8).
Link Status	Valid link states: — in-service — PI link is up and providing service. — maintenance busy — system technician busies out the PI link. — disconnected — PI link is down. Check the Hardware Error Log for more information.
Destination	Character string identifying the link destination type. Valid types are: "ISDN-LNK", "ISDN-TRK", "TIE-DS1", "PDMODULE", "TDMODULE", and "EIA LINK".

Dest Status	The status of the link destination. Valid states are: "in-service", "in-service/idle", "in-service/active", and "out-of-service", "manual OOS", "standby", "awaiting call", "disconnected", "out-of-service-NE", and "out-of-service-FE".
Port	The destination port, this port is logically connected to the Processor Interface.
Destination Information Field	One of the following is present depending on the type of link destination. — Sig Grp — The signaling group number, valid for "ISDN-LNK". — Trk/Mem — The trunk group/member, valid for "ISDN-TRK" and "TIE-DS1". — Ext — The data module extension, valid for "PDMODULE" and "TDMODULE".

The following fields represent counter values read from the Packet Interface board. These counters do not initialize on board insertion. To get a reliable readout, the **clear link** command should be issued for read counters.

Field descriptions

Hardware Device Check (receive)	When 40 to 80 seconds transpire without received link traffic, the timeout counter increments. This condition indicates that the link is down on the far end system. The SABM (Set Asynchronous Balance Mode) count also increments.
Hardware Device Check (transmit)	When 40 to 80 seconds transpire without received link traffic, the timeout counter increments. This condition indicates possible PI faults. The link is down and the SABM count increases. If the link is down at the near end and the far end, this counter increments along with the Hardware Device Check (receive) counter.
Far-End M00S Count	Number of times that the switch attempts to restart the link and the Far-End responds with the link status "manual-out- of-service." This condition occurs on ISDN-PRI Nonfacility Associated Signaling (NFAS) with D-channel backup. When this occurs, contact the Network and ask them to release the link.

Far-End FRMR	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.
Far-End DISC	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.
Timeout	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.
Software Initiated Link Down	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.
Level 2 I-frames retransmitted	Number of retransmitted frames in the LAPD (Link Access Procedure D) or X.25 layer 2. In general, this measures link quality. This count, which could indicate a very noisy link or synchronization problem, increments normally if a Hot Start PEI executes locally.
Level 2 Reset (SABM)	Number of X.25 SABMs or LAPD SABMs that are transmitted. SABMs to establish links. Every time this count increments a link establishment attempt fails. If the link is active and the count is not zero (after the clear link link-no command clears it) this condition indicates that the link goes down in that interval. Check the Hardware Error Log for additional information.
Invalid Frame Count	Number of received, invalid frames. This count measures link quality and could indicate a very noisy link or a synchronization problem. This might increment normally if a Hot Start PEI executes locally. If an administration error exists, this counter can increment with the Level 2 Reset counter. This counter may increment by message retransmissions.
Far-End SABM(E)/DM	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.
Protocol Error Detected	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.

Local Busy Out	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command.
Firmware Initiated Link Down	Informational only. No action is necessary. It is one of eight counters that tells the link's down history since the last clear link command. Please consult SCI-BD or PROTOCOL errors to determine the cause.
LOCAL/REMOTE PROCESSOR CHANNELS	Local/remote processor channel pairs. Each pair consists of a processor channel on the local machine and a processor channel on the remote machine that is connected in the communication session.

 **NOTE:**
For "ISDN-LNK" links, no correlation between the local and remote processor channels exists. Therefore, only the local processor channel is shown (the remote processor channel is blank).

status pms-link

This command displays the status of the property management system interface link. If the link is up, whether or not a data base swap is taking place between the switch and the property management system (PMS), is displayed. If the link is down, the number of times the switch has tried to set up the link is displayed.

A PMS is a standalone computer system that can be integrated with the switch to enhance the service capability for a hotel/motel.

For general information on PMS links, see the description of the ["busyout pms-link"](#).

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status pms-link	print	Report sent to printer Examples: status pms-link status pms-link print	init inads craft cust browse	none	none

Output

The following example shows the output from the **status pms-link** command.

```
status pms-link

PMS LINK STATUS

Physical Link State: down
Protocol State: down
Number of Retries: 3
Maintenance Busy? no
```

Field descriptions

Physical Link State	Up, down, or extension not administered; link is considered administered only if an extension is given in the System Hospitality form.
Protocol State	up, down, or blank if not administered.
Number of Retries	Number of times the switch has tried to set up the link (only displayed when the link is down; range 1-999)
Maintenance Busy	yes or no (technician has or has not busied out the link), blank if PMS link not administered.

status pri-endpoint

This command displays internal software state information for diagnosis and can help locate facilities with which a PRI endpoint is communicating. Status information for each of the B-channels making up the PRI endpoint display in addition to some overall PRI endpoint information.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status pri-endpoint	extension	PRI endpoint extension to be displayed (see dial-plan).	init inads craft nms browse	none	none
	print	Report sent to printer Examples: status pri-endpoint 25012 status pri-endpoint 77868 status pri-endpoint 66078 print			

Output

The following example shows the output for the status pri-endpoint 22501 command and assumes the following:

- PRI endpoint ports for extension 22501 are in cabinet 1, carrier B, slot 20, circuit 1 to 6.
- The ports 1 to 3 of the specified PRI endpoint are connected on an active call to ports 13 to 15 of board in location 1B19 (cabinet 1, carrier B, slot 19).
- Ports 4 and 5 of the specified PRI endpoint are idle.
- Port 6 of the specified PRI endpoint is out of service, and background maintenance testing is being performed on the port.

 **NOTE:**
A PRI endpoint can initiate and receive a call on any one or more of the B-channels making up the PRI endpoint.

status pri-endpoint 22501page 1 of 1

PRI-ENDPOINT STATUS

Extension: 22501Width: 6
Signaling Group ID: 3B-Channels Active: 3
Originating Auto Restoration? nB-Channels Idle: 2

Port	Service State	Test In Progress	Connected Port
01B2001	in-service/active	n	01B1913
01B2002	in-service/active	n	01B1914
01B2003	in-service/active	n	01B1915
01B2004	in-service/idle	n	
01B2005	in-service/idle	n	
01B2006	out-of-service-NE	y	

Command Successfully Completed

Note that the line listing of each B-channel's status may continue onto the next page. The user is prompted to press the `NxtPg` key to continue the display.

Field descriptions

Extension	PRI endpoint extension
Width	Administered number of B-channels associated with the specified PRI endpoint
Signaling Group ID	ID number of the signaling group that handles the signaling for the ports in the specified PRI endpoint
Originating Auto Restoration	Administered option for the auto restore feature (restores calls originated from this PRI endpoint in the case of network failure): y = restoration option enabled n = restoration option disabled
B-Channels Active	The number of B-channels active on a call
B-Channels Idle	The number of B-channels in the in-service/idle state
Port	Port locations (cabinet-carrier-slot-circuit) for each of the B-channels making up the PRI endpoint.
Service State	Service state of the B-channels: in-service/active, in-service/idle, out-of-service-NE, out-of-service-FE, maint-NE/active, maint-FE/active, maint-NE/idle, and maint-FE/idle. NE (Near End) and FE (Far End) refer to which “end” of the B-channel has placed the facility in the current state. NE refers to the switch and FE refers to the PRI terminal adapter (or any device that terminates the D-channel signaling on the facility).
Test In Progress	Whether or not there is any current maintenance testing on the port.
Connected Port	Connected port location (cabinet-carrier-slot-circuit) for each of the B-channels active on a call.

status processor-channel

This command displays the status of the specified processor channel and the values of its various counters. A processor channel is 1 of 64 logical channels associated with an SCI link. Each processor channel terminates in the switch processing element with a session.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status processor- channel	channel	Processor channel number (1-64).	init inads craft cust rcust bcms browse	none	none
	number print	Report sent to printer Examples: status processor-channel 1 status processor-channel 10 status processor-channel 64 status processor-channel 64 print			

Output

The following example shows the output from the **status processor-channels 1** command.

```
status processor-channels 1

PROCESSOR CHANNEL STATUS

Channel Number: 1
Channel Status: 6: In data transfer state
Reset Count: 3
Message Buffer Number: 1
Link Number: 4
Retransmission Count: 5
```

Field descriptions

Channel Number The processor channel number 1-64.

- Channel StatusState the channel is in:
1. Channel is not administered.

2. Channel is administered but not used.

3. Channel is in a state entering “wait session accept” (WSA).

4. Channel is in a state waiting for a “session accept” message from the far end.

5. Channel is waiting for action.

6. Channel is in data transfer state (channel up and running).

7. Channel is in resynchronization state.

8. Channel is waiting for acknowledge of disconnect message.

9. ISDN-PRI Channel is currently down.

10. ISDN-PRI Channel is in the data transfer state (that is, channel is up and running).
- Reset CountNumber of times reset has been issued for this channel
- Message Buffer NumberNumber of message buffers currently used for communication on this channel.
- Link NumberPhysical SCI link (i1-8) associated with the channel
- Retransmission CountNumber of times that message retransmission has occurred

status signaling-group

This command displays the state, type, port location, and state of the Primary and Secondary D-channels within the group. A signaling group is a collection of B-channels signaled for by a designated single D-channel or set of D-channels over an ISDN-PRI.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status signaling-group	group identifier	Administered group identifier number (1-8)	init inads craft cust browse	none	none
	print	Report sent to printer Examples: status signaling-group 1 status signaling-group 2 print			

Output

The following output example shows the output from the **status signaling-group 1** command.

status signaling-group 1Page 1 of 1SPE A

STATUS SIGNALING-GROUP

Group ID: 1
Type: facility associated signaling
Group State: in-service

Primary D-Channel

Link: 1Port: 01C1924Level 3 State: in-service

Secondary D-Channel

Link:Port:Level 3 State:

Field descriptions

- Group ID: Numerical ID of the signaling group (1-8)
- Type: facility associated signaling: all members are on a single DS-1 facility. Facility associated signaling groups support only the simplex D-channel configuration.

non-facility associated signaling: members can be carried by multiple DS-1 facilities.

The DS-1 facility is identified across the ISDN-PRI using an explicit facility identifier. In a simplex configuration one D-channel is used to signal for B-channel members, while in a duplex configuration two D-channels are used to signal for B-channel members (one channel is active and the other is used as a backup to the active channel).
- Group State: in-service: one of the D-channels signaling for the group is in service

out-of-service: neither D-channel in the group is in service
-  **NOTE:**
If there is no D-channel backup and the primary D-channel is out-of-service, then the signaling group is in an out-of-service state.
- Link: Link transporting the D-channel
- Port: Address of the port transporting either the primary or secondary D-channel

Level 3
State:

State of the primary or secondary D-channels:

in-service: a D-channel is "in-service" when it is in the multiple-frame-established state at layer 2 carrying normal call-control signaling at layer 3.

standby: a D-channel is "standby" when it is in the multiple-frame-established state at layer 2, and not carrying any layer 3 call-control messages on logical link 0,0.

wait: a D-channel is in a "wait" state when an attempt has been made by one side of the interface to establish layer 3 peer communications as part of the process of going to the "in-service" state, which is transitional in nature. Only when the ISDN SERVICE message is sent over the interface, and the far end of the interface responds with a SERVICE ACKnowledge message is the D-channel placed in the "in-service" state.

maintenance-busy: a D-channel is "maintenance-busy" when it is not in the multiple-frame-established state at layer 2. This state is entered automatically when an active D-channel is declared failed. A D-channel that has been placed in the "maintenance-busy" state may be placed in the "out-of-service" state without system technician intervention.

manual-out-of-service: a D-channel is "manual-out-of-service" when system technician intervention has caused it to be placed in the TEI-assigned state at layer 2. System Technician intervention is required to retrieve a D-channel from this state.

out-of-service: a D-channel is "out-of-service" when it is in the TEI-assigned state at layer 2, but is periodically requested by layer 3 to attempt to establish the link.

no-link: no link is administered for the D-channel

status sp-link

This displays a page of output summarizing the operational status of the system printer link: its link state, number of retries, and whether the link is maintenance busy.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status sp-link	print	Report sent to printer Examples: status sp-link status sp-link print	init inads craft cust rcust bcms browse	none	none

Output

The following example shows the output for the **status sp-link** command.

```
status sp-link                               SPE A

                                SYSTEM PRINTER LINK STATUS

Link State: up
Number of Retries:
Maintenance Busy? no
```

Field descriptions

- Link State:Operational mode of the link:
up: the link is administered and a call is setup between the switch and the system printer.
down: the link is administered, but a call is not setup between the switch and the system printer.
extension not administered: the link (no system printer extension) is not administered
- Number of Retries:Number of times the switch has tried to set up the link since a request to set up the link was received (1-999); if more than 999 retries have occurred, 999 still displays. (This field displays only if the Link State: field is down.)
- Maintenance Busy?Whether any maintenance testing is being performed on the system printer link:
yes and no: system printer link is administered
blank: system printer link is not administered.

status station

This command displays the internal software state information for diagnosis and to help locate the facilities to which the station is communicating.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status station	extension print	Station extension (per dial-plan) Report sent to printer Examples: status station 10020 status station 83277 status station 83277 print	init inads craft cust browse	none	none

Output

The following example shows the output for the **status station 1002** command.

```
status station 1002

                                GENERAL STATUS

      Type: 7405D                Service State: in-service/on-hook
      Extension: 1002            Maintenance Busy? no
      Port: 01C0702             SAC Activated? no
      Call Parked? no           User Cntrl Restr: none

```

Field descriptions

Type	Administered station type
Extension	Station or attendant extension
Port	Port location: cabinet-carrier-slot-circuit
Call Park	Whether the station has a call parked (yes or no)
Ring Cut Off Activated	Whether ring cut off is activated (yes or no)
CF Destination Ext	Call forwarding destination extension, if any.
Message Waiting	Whether there is a message waiting for the station. "AP-SPE", "AUDIX", "PMS" or blank if no messages are waiting.
Connected Ports	Port locations of the facilities to which the station is connected: cabinet-carrier-slot-circuit
Agent Logged In	Displays (underneath) the hunt groups (up to 3) that the agent is logged into
On ACD Call?	Whether the agent is on an ACD call currently (yes or no).
Work Mode	Work mode of each hunt group that an agent is logged into

Service State	In service/on-hook, in service/off-hook, out of service, or disconnected.
Maintenance Busy State	Whether maintenance is testing the object (yes or no)
SAC Activated	Whether send all calls is activated (yes or no)
User Cntrl Restr	One or two of the following: none, total, stat-stat, outward or terminate.
Group Cntrl Restr	One or two of the following: none, total, stat-stat, outward or terminate.
AWU Call at	Time that Automatic Wakeup Call is scheduled
User DND	Status of the do not disturb feature.
Group DND	Status of the group do not disturb feature.
Room Status	Whether a room is occupied or not (non-guest room, vacant, or occupied).

status synchronization

This command displays the location of the DS1 or tone-clock circuit pack that is used for an on-line synchronization reference. The synchronization subsystem provides error free digital communication between the switch and other PBXs, COs, or customer premise equipment. The subsystem is made up of: TDM bus clock, DS1 trunk board, maintenance and administration software resident in the SPE.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status synchronization	<i>print</i>	Report sent to printer Examples: status synchronization status synchronization print	init inads craft cust browse	none	none

Output

The following example shows the output for the **status synchronization** command.

```
status synchronization

                                SYNCHRONIZATION STATUS

Stratum Level:4
Maintenance Name: TONE-BD      Physical Location: 01A
Switching Capability: Enabled
Excessive Reference Switching: No
```

Field descriptions

Stratum Level	Synchronization stratum level (3 or 4)
Maintenance Name:	Either TONE - BD, DS1 - BD, or STRAT - 3.
Physical Location	Board location of the selected DS1 or tone-clock circuit pack (cabinet-carrier-slot for a DS1; cabinet-carrier for a tone-clock)
Switching Capability	Whether the on-line reference for synchronization can be switched (Enabled or Disabled)
Excessive Reference Switching	High-level description of how many times the synchronization reference has been switched. If excessive reference switching is taking place (sync error 1793 is at threshold), this field displays Yes; otherwise No displays.

status system

This command displays the status, mode, and operational attributes of the SPE(s), TDM and Packet busses, tone-clock circuit pack(s), expansion interface links (exp-links), and emergency transfer switch of single or all cabinets in the system.

 **CAUTION:**
The purpose of this command is to provide general information about the cabinet status. This information may not display correctly when the cabinet is in a transient period. In this case, wait for 1 minute and enter the command again.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status system	cabinet	1st-cabinet: PPN 2nd-cabinet: 1st EPN 3rd-cabinet: 2nd EPN ¹ all-cabinets: 3-pg. output - 1 for each cabinet ² Examples: status system 1st-cabinet status system 2nd-cabinet status system 3rd-cabinet status system all-cabinets	init inads craft cust rcust bcms browse	none	none

1. For PPN, and 1st and 2nd EPNs, one page of output displays.
2. The status displayed for a cabinet is always related to that cabinet except in the case of status for EPNs and the SPE attributes. SPE attributes always refer to PPN status regardless of which cabinet is being displayed.

Output

The following example shows the output from the **status system all-cabinets** command.

```
status system all-cabinets                                Page 1 of 3    SPE B

                                SYSTEM STATUS CABINET 1

SPE  MODE                                SELECT  SPE ALARMS  TONE/  SERVICE  SYSTEM  SYSTEM

                                01A02-03A01 in     active
                                01B02-03B02 in     standby
```

Field descriptions

SPE Switch Process Element (SPE) identifier: 1A or 1B

MODE	SPE modes are different for simplex systems than for duplicated systems. See SPE Modes section that follows.
SELECT SWITCH	SPE select switch position: ■ auto: the switch is in the middle position and automatically switches SPE depending upon conditions ■ spe-a: spe-a position ■ spe-b: spe-b position ■ <blank> always appears for the 1A and 1B SPE in a simplex system. In a system with High or Critical Reliability, blank implies a hardware problem with the Duplication Interface circuit pack.
PE ALARMS - MAJOR	Number of Major alarms associated with the SPE complex that affect the fault severity level of this SPE. If the system is simplex system, then the 1B SPE always shows blank.
SPE ALARMS - MINOR	Number of Minor alarms associated with the SPE complex that affect the fault severity level of this SPE. If the system is simplex system, then the 1B SPE always shows blank.
TONE/CLOCK	Location of the tone-clock circuit pack. Valid locations are 1A, 1B, 2A, 2B, 3A, and 3B.
SERVICE STATE	■ in: Tone-Clock is installed and is in-service ■ out: Tone-Clock failed certain maintenance tests and has been removed from service ■ <blank> In simplex systems there is no B-carrier Tone-Clock, and this field displays blank.
SYSTEM CLOCK	Shows which Tone-Clock supplies the system clock for the cabinet displayed: ■ active: Tone-Clock active and supplying system clock ■ standby: Tone-Clock is standby and ready to supply the system clock for this cabinet if the active clock fails. ■ down: Tone-Clock failed some maintenance activity and cannot supply the system clock for this cabinet. ■ unavail: EPN is currently down ■ <blank> If simplex, then the 1B Tone-Clock for the PPN displays blank; if no EPN, then both the 1A and 1B Tone-Clock for this EPN display blank.

SYSTEM TONE	Shows which Tone-Clock circuit pack supplies the system tones for the cabinet being displayed. ■ active: Tone-Clock active and supplying system tones ■ standby: Tone-Clock is standby and ready to supply the system tones for this cabinet if the active clock fails. ■ down: Tone-Clock failed some maintenance activity and cannot supply the system tones for this cabinet. ■ unavail: EPN is currently down ■ <blank> If simplex, then the 1B Tone-Clock for the PPN displays blank. If the system does not have an EPN, then both the 1A and 1B Tone-Clock for this EPN display blank.
TDM	The TDM Bus identifier (1A, 1B, 2A, 2B, 3A and 3B)
SERVICE STATE	Operational state of the TDM Bus circuit pack: ■ in: TDM Bus installed and is in-service ■ out: TDM Bus failed certain maintenance tests and has been removed from service
CONTROL CHANNEL	Whether the control channel is on this TDM Bus (y or n)
DEDICATED TONES	Whether the dedicated tones are on this TDM Bus (y or n)
PKT	Packet Bus identifier (same as the cabinet number: 1, 2, or 3). If the system is running on a X75XE cabinet, all the PKT fields are blank and the following message displays: S75XE does not support Packet Refer to Packet Bus Maintenance descriptions for more information.
SERVICE STATE	The operational state of the Packet Buses: ■ in: Packet Bus in-service and operating normally. ■ out: Packet Bus failed certain maintenance tests and has been removed from service. ■ reconfig: Maintenance/Test circuit pack has swapped one or more signal leads because of lead faults detected during testing (High or Critical Reliability only). ■ open lds: Maintenance/Test circuit pack cannot correct all of the Packet Bus faults. There are open leads, but the Packet Bus is still at least partly functional (High or Critical Reliability System only). ■ unavail: EPN is currently down. ■ <blank> System does not have the Packet Bus feature.

BUS ALARMS-MAJOR	Whether Major alarms exist for packet bus components (y or n)
BUS ALARMS-MINOR	Whether Minor alarms exist for packet bus components (y or n)
BUS FAULTS	Number of faulty bus leads (defined as shorted to another lead, stuck at some value, or an open lead: 0 - 24). This field may take on any integer between 0 and 24. This field displays blank if: ■ Maintenance/Test circuit pack not present ■ Packet Bus port of the Maintenance/Test circuit pack has been taken out-of-service ■ System does not have the Packet Bus feature
OPEN BUS LEADS	Number of open bus leads between the Maintenance/Test circuit pack and bus terminator (0 - 24). This could mean physical damage to the backplane or its connectors or a missing bus terminator. This field displays blank if: ■ Maintenance/Test circuit pack is not present ■ Packet Bus port of the Maintenance/Test circuit pack has been taken out-of-service ■ System does not have the Packet Bus feature.
EMERGENCY TRANSFER	Location of the Processor or EPN Maintenance circuit pack containing the Emergency Transfer Select Switch (1A and 1B for the PPN, and 2A or 3A for the EPNs)

SELECT SWITCH	Emergency Transfer Switch position on the Processor(s) or the EPN maintenance circuit pack and the state of Emergency Transfer in the cabinet display: ■ on: If this is a Simplex PPN or an EPN, then designated analog phones in this cabinet are cut through to CO trunk lines only in an emergency situation. In a High or Critical Reliability System, the Emergency Transfer Switches on both SPEs in the PPN must be in the on position before Emergency Transfer is invoked for the PPN. ■ off: Regardless of Simplex or Duplex, PPN, or EPN, Emergency Transfer is off and cannot be invoked. The switch should only be in this state when a service technician is on sight. ■ auto-on: The switch is in the or auto position, however, because of a serious system fault, system software has invoked Emergency Transfer. ■ auto-off: Switch in the auto position; because system has no serious faults, system software has not invoked Emergency Transfer ■ unavail: EPN is down ■ <blank> If the system is Simplex, then the 1B Emergency Transfer indication for the PPN displays a blank. If the system does not have an EPN, then both the 1A and 1B Emergency Transfer indications for the EPN displays a blank.
EXP - LINK	Expansion Links that originate from this cabinet and the locations of the two Expansion Interface circuit packs that make up the link. If the Expansion Link does not exist in the system then a dash (-) displays. ■ Expansion Link identifiers for the PPN or Cabinet 1: 1A01 - 2A01, 1B01 - 2B02, 1A02 - 3A01, 1B02 - 3B02 ■ Expansion Link identifiers for the first EPN or Cabinet 2: 1A01 - 2A01, 1B01 - 2B02, 2A02 - 3A02, 2B03 - 3B03 ■ Expansion Link identifiers for the second EPN or Cabinet 3: 1A02 - 3A01, 1B02 - 3B02, 2A02 - 3A02, 2B03 - 3B03
SERVICE STATE	Operational state of the Expansion Interface Link: ■ in: Expansion Interface Link installed and is in-service ■ out: Expansion Interface Link failed certain maintenance tests and has been removed from service ■ <blank> Expansion Interface Link does not exist

MODE	■ active: Expansion Interface Link is in-service and providing the active connectivity between the two cabinets. ■ standby: Expansion Interface Link is in-service and ready to provide connectivity between the two cabinets should the active link fail. ■ down: Expansion Interface Link is out-of-service and cannot provide connectivity between the two cabinets. ■ <blank> Expansion Interface Link does not exist
CABINET TYPE	■ MCC: Medium Carrier Cabinet (up to 5 carriers, simplex or duplex as a PPN) ■ SCC: Single Carrier Cabinet (up to 4 carriers, simplex or duplex as a PPN) ■ EMCC: Enhanced Medium Carrier Cabinet (up to 5 carriers, can only be a simplex or duplex PPN cabinet) ■ ESCC: Enhanced Medium Carrier Cabinet (up to 4 carriers, can only be a simplex or duplex PPN cabinet) ■ MICRO: Micro or wall-mounted cabinet (always exists alone as an A carrier in a simplex PPN)

SPE Modes

Simplex SPE Modes

active	1A SPE in a simplex system is always the active SPE
blank	No 1B SPE in a simplex system

Duplex Active SPE Modes

active	This SPE is the active SPE.
active/ override-on	This the active SPE; however, it was forced active through a reset system interchange health-override command.
selected	This is the active SPE; however, the SPE select switches do not allow this to become the standby SPE.

Duplex Standby SPE Modes

Standby Mode

standby	SPE is held reset, memory shadowed from the active SPE, and ready to take over as the active SPE.

Busyout Modes

busyout/idle	SPE busied out and there is no current maintenance activity. The active SPE can be either active or selected.

busyout/entering	SPE busied out and in the process of restarting the switch software on this SPE. After the switch software finishes its initialization, the standby SPE is available for maintenance functions on the standby SPE.
busyout/testing	SPE busied out, however, the switch software on this SPE has been restarted and is currently in the process of executing a test command.
busyout/ not-refreshed	SPE busied out, however, the busyout spe-standby command was executed at a time when the standby memory was not refreshed. The standby SPE is not able to perform any maintenance or SAT-requested activities until a successful refresh spe-standby command is executed.
busyout/ list-config	SPE busied out, however, the switch software on this SPE has been restarted and is currently executing a list configuration command.
busyout/status	SPE busied out, however, the switch software on this SPE has been restarted and is currently in the process of executing a status card-mem command.

Maintenance Modes¹

maint/init	SPE in maintenance mode (system restarted within the last 10 minutes). During this time, the standby SPE is not placed into standby mode just in case a core dump is being written to the tape or memory card on the standby SPE.
maint/idle	SPE in maintenance mode, but no current maintenance activity. The active SPE can be either active or selected.
maint/entering	SPE currently restarting the switch software on this SPE. After the switch software on this SPE finishes its initialization, the standby SPE is available to perform maintenance functions.
maint/testing	SPE in maintenance mode executing a test command.
maint/ not-refreshed	SPE in maintenance mode executing a destructive background maintenance test that has temporarily left the standby memory not refreshed. After the current test finishes, background maintenance refreshes the standby SPE.
maint/not-tested	SPE in maintenance mode because previously the active SPE had been selected with the SPE select switches. Since the active SPE was not selected, the standby has not been tested to ensure the standby can enter standby mode. Once the standby is tested successfully, the standby returns to standby mode.
maint/list-config	SPE in maintenance mode and currently executing a list configuration command.
maint/save~trans	SPE in maintenance mode and is currently executing a save translation command.

maint/ save~announce	SPE in maintenance mode and currently executing a save announcement command.
maint/status	SPE in maintenance mode and currently executing a status card-mem command.
maint/patching	SPE in maintenance mode and currently applying a software patch to the standby SPE memory.
maint/periodic	SPE in maintenance mode and currently performing periodic background maintenance (performed every two hours if some component of the standby SPE is alarmed).
maint/scheduled	SPE in maintenance mode and currently performing daily scheduled background maintenance.
maint/analysis	SPE in maintenance mode and currently performing background maintenance testing in response to a reported trouble by some component in the active or standby SPE complex that relates to the standby SPE.
maint/upgrade	SPE in maintenance mode and currently performing a software upgrade.

Down Modes²

down/bad_upgrade	SPE in down mode (software upgrade attempt failed). The standby SPE remains in down mode until a successful software upgrade is performed.
down/idle	SPE in down mode, however, no maintenance activity is currently taking place. The active SPE could be either active or selected.
down/entering	SPE in down mode, but is currently trying to restart the switch software on this SPE. As soon as the switch software on this SPE finishes its initialization, the standby SPE is ready to perform background or SAT requested maintenance activity.
down/mismatch_soft	SPE in down mode because the software vintage in flash memory of the standby SPE does not match the vintage in the active SPE. The standby SPE remains in down mode until a successful software upgrade is performed.
down/testing	SPE in down mode attempting to execute a test command.
down/ not-refreshed	SPE in down mode executing a destructive background maintenance test that has temporarily left the standby memory not refreshed. After the current test finishes, background maintenance refreshes the standby SPE.
down/analysis	SPE in down mode and currently performing background maintenance testing to determine if the problem has been corrected.

1. Maintenance modes occur when the standby SPE is taken out of standby mode to perform a maintenance or SAT requested function. Unlike the busyout and down modes, being in maintenance mode implies this SPE can be returned to standby mode when the requested activity is completed, assuming there are no faults in the standby SPE complex. The active SPE could be either active or selected when the standby SPE is in one of the Maintenance modes.
2. The standby SPE is placed in down mode when a fault occurs in the standby SPE complex that would prevent that SPE from performing system functions. Down mode is always associated with STBY-SPE alarms and errors. The active SPE could be either active or selected when the standby SPE is in one of the Down modes.

status trunk

This command displays internal software state information for diagnosis and can help locate facilities to which the trunk is communicating. If a trunk group number is entered without a member number, a list showing the status for each member in the specified group displays. If a both the trunk group and member numbers are entered, the status for only the specified member is displays.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status trunk	group	Administered group number (1 - 99). If group number entered without a member number, a list showing the status of each member in the group displays.	init inads craft cust rcust bcms browse	none	none
	member	Administered member number within a trunk group (1 - 99)			
	print	Report sent to printer. Examples: status trunk 78 status trunk 80 status trunk 78/1 status trunk 80/2 status trunk 80/2 print			

Output

Group/member

The following example shows the output for the **status trunk 78/1** (trunk group/member) command.

```
status trunk 78/1

                                TRUNK STATUS

Trunk Group/Member: 078/001      Service State: in-service/idle
Port: 01C1505                  Maintenance Busy? no
Signaling Group ID:              CA-TSC State:
Connected Ports:
```

Field descriptions (group/member)

Trunk Group/Member	Trunk group number/group member number (1-99/1-99)
Port	Port location (cabinet-carrier-slot-circuit)
Signaling Group ID	If trunk is ISDN, then this field displays the number of the ISDN Signaling Group to which this group belongs; otherwise, the field is blank.
Connected Ports	Port locations (cabinet-carrier-slot-circuit) connected to the trunk
Service State	Trunk service state: in-service/active, in-service/idle, out-of-service-NE, out-of-service-FE, maint-NE/active, maint-FE/active, maint-NE/idle, and maint-FE/idle. NE (Near End; switch) and FE (Far End; PRI terminal adapter or any device that terminates the D-channel signaling) refer to which "end" of the B-channel has placed the facility in the current state.
Maintenance Busy	Whether any maintenance testing is being performed
CA-TSC State	State of the temporary signaling connection (used to pass call information over PRI signaling links)

Group only

The following example shows the output from the **status trunk 78** (trunk group only) command.

status trunk 78

TRUNK GROUP STATUS

Member	Port	Service State	Mtce Connected Ports
			Busy
078/001	01C1505	in-service/idle	no
078/002	01C1506	in-service/idle	no

Field descriptions

Member	Trunk group number/group member number (1-99/1-99).
Port	Port location (cabinet-carrier-slot-circuit)
Service State	Trunk service state: in-service/active, in-service/idle, out-of-service-NE, out-of-service-FE, maint-NE/active, maint-FE/active, maint-NE/idle, and maint-FE/idle. NE (Near End; switch) and FE (Far End; PRI terminal adapter or any device that terminates the D-channel signaling) refer to which “end” of the B-channel has placed the facility in the current state.
Mtce Busy	Whether any maintenance testing is being performed
Connected Ports	Port locations (cabinet-carrier-slot-circuit) connected to the trunk

status tsc-administered

The status tsc-administered command displays the operational status of TSC’s administered for an administered signaling group. The status represents the state of the TSC according to switched services.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status tsc-administered	signaling group	Administered signaling group number	init inads craft	none	none
	#/tsc index	Number associated with each TSC in a signaling group			
	print	Report sent to printer			
		Examples: status tsc-administered 1 status tsc-administered 1/1 status tsc-administered 1/2 print			

Output

The following example shows the output for the **status tsc-administered 1/1** command.

```
status tsc-administered 1/1

ADMINISTERED NON-CALL-ASSOCIATED TSC STATUS

TSC      TSC      Establish  Enabled  Congested
Index    State      as-needed  yes      no
1        inactive as-needed  yes      no
```

Field descriptions

TSC Index	The administered TSC index (1-64).
TSC State	State of the administered TSC: ■ inactive: the administered TSC is not functioning (for example, D-channel out-of-service, or disabled) ■ active: indicates that the administered TSC is up and user information can be exchanged end-to-end. ■ pending-inactive: shows that the TSC is being released. ■ pending-active: the TSC is about to come up
Establish	The switch responsible for the origination of the administered TSC: ■ as-needed: TSC is established on an as needed basis ■ permanent: TSC is permanently established
Enabled	Indicates if the administered TSC's have been enabled ("yes" or "no").
Congested	Administered TSC congestion history (whether or not the network can handle the receipt of USER INFORMATION messages for the administered TSC): ■ yes: TSC is congested ■ no: TSC is not congested ■ clear: TSC congestion was cleared during its active period

status tti

This command displays the status (active/not active) of the tti background maintenance task, and, if it is active, it displays whether tti ports are being generated or removed, the number of tti-supported boards that have processed,

and the number of tti-supported boards that have not yet been processed. The display also includes the elapsed time since the background maintenance task started.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
status tti	print	Report sent to the printer Examples: status tti status tti print	init inads craft cust nms browse	none	TTI background maintenance task is activated by enabling the TTI system parameter on the System-parameters Features form.

Output

The following example shows the output for the **status tti** command.

status tti

Page 1 of 1

TTI STATUS

TTI Background Task State: generating tti ports

TTI State: voice

of Boards Completed: 30

of Boards Left to Process: 120

Percent Complete: 25

Elapsed Time since Task Started: 0:15

Field descriptions

- TTI Background Task State:
- State of the tti background maintenance task:
- generating tti ports:

■ removing tti ports:

■ suspended:

■ not active:

■ completed - all ports translated: the last execution of the background task completed normally

■ completed - some ports not translated: the task completed due to resource exhaustion with some ports left untranslated
- TTI State:
- The tti state: displays off (TTI feature not enabled for the system), or if enabled, then the field displays what kind of tti ports are being generated or removed (voice, data).

# of Boards Completed:	Number of TTI-supported boards that have been processed by the background maintenance task: ■ completed: board has either had all its unadministered ports translated as TTI ports or its TTI ports have been removed and are now unadministered ports. This depends on whether the TTI background task is generating or removing tti ports.
# of Boards Left to Process:	Number of TTI-supported boards that have not yet been processed by the background maintenance task.
Percent Complete:	Ratio of the of number of boards completed compared to the number of boards left to process.
Elapsed Time since Task Started:	Elapsed time since the TTI background task was started. If the task is "not active", then this field is blank. If the task is "completed" it indicates the length of time (hh:mm format) it took to complete the task. If the task is "suspended", then it displays the elapsed time at the point the task was suspended.

test access-endpoint

This command performs hardware diagnostic tests on all port circuits that are associated with the specified access endpoint extension.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test access- endpoint	extension	Access endpoint extension (# of digits determined by dial-plan)	init inads craft nms	Test sequence = short; repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (includes a destructive test)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test access-endpoint 25012 test access-endpoint 45002 sh test access-endpoint 45892 l test access-endpoint 24389 sh r 4 test access-endpoint 34899 l r 6 test access-endpoint 34912 l r 5 schedule test access-endpoint 93483 r 2 test access-endpoint 10022 c test access-endpoint 92349 schedule			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output for the **test access-endpoint 22502** command, and assumes the access endpoint ports for extension 22502 are in cabinet 1, carrier C, slot 11, circuit 1 to 6. The responses are displayed on a port-by-port and test-by-test basis with one line of data for each test result.

```
test access-endpoint 22502 short                                page 1 of 1

                                TEST RESULTS

Port      Maintenance Name  Alt. Name Test No. Result      Error Code
01C1101   WAE-PORT                22502      36    PASS
01C1102   WAE-PORT                22502      36    PASS
01C1103   WAE-PORT                22502      36    PASS
01C1104   WAE-PORT                22502      36    PASS
01C1105   WAE-PORT                22502      36    PASS
01C1106   WAE-PORT                22502      36    PASS

Command Successfully Completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	The name of maintenance object (wideband access endpoint = WAE-PORT; single port access endpoint = TIE-DS1)
Alt. Name	The extension number of the access endpoint
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test alarms

This command allows automatic testing all of the hardware associated with the active alarms in the alarm log. This command provides an initial query form to help the user narrow the selection of alarmed objects. After submitting the query form, the system tests the hardware associated with the selected alarm log entries. The results display in standard test output and status information display on the message line as the command progresses.

Several alarms may be logged against a single maintenance object, each alarm representing a different problem. Even if there are multiple entries in the alarm

log for a single object, the **test alarms** command only tests each physical object once.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test alarms	auto-page	New screen displays when current screen fills ¹	init inads craft nms	Test sequence = short; repeat = 1	See below
	failures	Only the failures (hardware, aborts, conflicts, EPN-down) display			
	step	Allows "stepping" to the next or previous alarm (current alarm not tested) ²			
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (includes a destructive test)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ³			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ⁴ Examples: test alarms test alarms step failures test alarms long clear auto-page test alarms long failures			

1. If **auto-page** option is not specified, the screen does not refresh once filled, and testing stops until the user presses PAGE (continue) or CANCEL (halts testing).

2. Press CANCEL to abort the command, ENTER to test the currently displayed alarm, NEXT ALARM (function key) to move to the next alarm, and PREV ALARM (function key) to move to the previous alarm without testing the currently displayed alarm. If this option is entered, then the NEXT ALARM (function key) or PREV ALARM (function key) can be pressed at any time during the command, even during test results. If NEXT ALARM or PREV ALARM is pressed during a test, the test is aborted, testing of the current alarm stops, and the next or previous alarm displays. If the first alarm is displayed and PREV ALARM is pressed, then the last alarm is displayed. If the last alarm is currently displayed and the NEXT ALARM is requested, then the first alarm displays. The only way to terminate this command is to press CANCEL.

3. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNINGS BELOW.

4. Refer to the Report Scheduler and System Printer feature specification for more details.

WARNING:
Executing a clear with short option may not clear all alarms, even if all tests pass.

WARNING:
Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Feature Interactions

With the enhancement of multiple maintenance users, there may be a possibility of two users attempting to test the same physical hardware (for example, one using the **test alarms** command and another using the **test board** command). If this command attempts to test a board that is currently being tested by another user, a error message displays.

Options form

After entering the **test alarms** command, you are presented with an options form for alarm selection.

```
test alarms repeat 1

HARDWARE TEST ALARM QUERY

The following options control which alarms will be tested.

ALARM TYPES
Major? y_      Minor? y_      Warning? y_

      Extension:  __
      Trunk ( group/member ):  __/__
```

Field descriptions (Hardware Test Alarm Query)

Alarm Types	The type of alarm to be tested: put y or n in the field(s) to selects one or a combination of alarms.
Interval	Tests alarms for the last hour (h), last day (d), last week (w) or all (a) [default].
From	Test alarm from the specified time specified (<i>mm/dd/hh/mm</i>). If no from date is entered, then no checking is done and the alarms active since a month prior to the current time are reported.
To	Test alarms associated with records to the specified time specified (<i>mm/dd/hh/mm</i>). If no to date is entered, any alarm active after the from date is selected.
Equipment Type	The technician can choose between five different equipment types. If there is no input to any of these fields, the system defaults to all the equipment. The user can select one of the following fields: ■ Cabinet: tests alarms associated with a particular cabinet (1-3). ■ Port Network: tests all alarms associated with a particular port network (1-3). ■ Board Number: tests all alarms associated with a particular circuit pack (PCss, default cabinet = 1). ■ Port: tests all alarms associated with a particular port on a circuit pack (PCsspp, default cabinet = 1). ■ Category: Alarms for a particular equipment category ■ Extension: Alarms associated with an extension number ■ Trunk (group/member): tests all alarms associated with a particular trunk group or trunk group member, <i>XX/YY</i>, where the group identifier tests all alarms associated with a trunk group (<i>XX/</i>__), and the group identifier <i>and</i> member identifier are both entered to test all alarms associated with a specific trunk group member (<i>XX/YY</i>).

Output

The following example shows the output from the **test alarms** command (query form left empty by pressing ENTER). The responses display on a test-by-test basis with one line of data for each test result.

test alarms

press CANCEL to quit -- press NEXT PAGE to continue

Field descriptions

When encountering errors in preparing a particular object to be tested (not inserted, contention, etc.), an error message display in the TEST RESULTS section of the output form.

ALARM ENTRY section	
Port	Port location of alarmed object (cabinet-carrier-slot-circuit); same identifier as alarm log
Maintenance Name	The name of the maintenance object
On Board	Fault detected is on the associated circuit pack (y) or off board (o).
Alt Name	Terminal extension numbers or trunk group numbers
Alarm Type	Major, Minor, or Warning
Service State	Current service state of the station and trunk ports: RDY (ready for service), OUT (out of service), or IN (in service).
Ack	Whether alarm has been acknowledged by the first and second OSS telephone numbers, respectively.
Date Alarmed	Day, hour, and minute of alarm.
Alarm Count	Count of the current alarm entry versus the total number of alarms to be tested.

Test results section	
Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	The name of maintenance object
Alt. Name	Alternate way to identify maintenance objects.
If the Object is The field contains	
station	extension
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
private CO line	P/xxx (where xxx = private CO line group number)
Test No	The test being executed
Result	Test result: Fail, Pass, Abort, or No Board. If this field has conflict, another user may be testing this hardware. If this field has epn-down, the epn is inaccessible at this time.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test analog-testcall

The test analog-testcall command performs facility diagnostic tests on an entire trunk group, an individual trunk group member, an individual trunk port or on all trunks on a board, depending on the options entered. The type of test call, the far-end test line number, and the various other parameters must be administered on the trunk group form before executing the command. Normally, the user should only invoke the full or supervision test. The other options are provided primarily for testing when setting up an ATMS schedule.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test analog-testcall	full	Executes the most comprehensive test call available using the administered test set type.	init inads craft cust	Test sequence = long; repeat = 1	See below
	no supervision	Executes a supervision-only test call (approx. 10 sec.) and confirms the presence of the test set at the far end.			
	no-selftest	Executes the "full" test (skips any self-test sequences), saving about 20 seconds on the type 105 transmission test and has no effect on type 100 or 102 transmission tests.			
	no-return-loss	Executes the "full" test (skips any return loss sequences), saving about 20 seconds on the type 105 transmission test and does not have any effect on type 100 or 102 transmission tests.			
	no-st-or-rl	Executes the "full" test (skips all self test and return loss sequences), saving about 40 seconds on the type 105 transmission test and does not have any effect on type 100 or 102 transmission tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: test analog-testcall trunk 78 f test analog-testcall trunk 78 f schedule test analog-testcall trunk 80/1 s r 2 test analog-testcall trunk 80/1 s r 2 schedule test analog-testcall trunk 78/2 no-selftest r 10 test analog-testcall trunk 78/2 no-selftest r 10 schedule test analog-testcall trunk 78 r 4 test analog-testcall trunk 78 r 4 schedule test analog-testcall port 2a1505 no-st-or-rl r 4 test analog-testcall port 2a1505 no-st-or-rl r 4 schedule test analog-testcall board 2a15 test analog-testcall board 2a15 schedule test analog-testcall port 2a1505 no-return-loss test analog-testcall port 2a1505 no-return-loss schedule te an t 80 te an t 80 schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

- Additional data is available after running a test. See the [“list measurements”](#) command with the **test-call** option for details on how to access the additional data.
- If the trunk is in use by call processing, the test aborts.
- If the trunk is in use by maintenance, the test queues and runs when the current maintenance activity finishes.

Output

The following example shows the output for the **test analog-testcall trunk 78** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test analog-testcall trunk 78
```

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01C1505	CO-TRK	78/1	845	PASS	
01C1507	CO-TRK	78/2	845	PASS	

Command Successfully Completed

Field descriptions

Port	The port address (cabinet-carrier-slot-circuit) of the maintenance object that is being tested.				
Maintenance Name	The type of maintenance object that is being tested.				
Alt. Name	Alternate way to identify maintenance objects. <table><tr><th>If the Object is</th><th>The field contains</th></tr><tr><td>trunk</td><td>xxx/yyy (where xxx = trunk group number and yyy = member number)</td></tr></table>	If the Object is	The field contains	trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)
If the Object is	The field contains				
trunk	xxx/yyy (where xxx = trunk group number and yyy = member number)				
Test No.	The test being executed				
Result	Test result: Pass, Fail, Abort, Disabled, No Board, or Extra Board.				
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.				

test board

This command performs a set of hardware diagnostic tests on a specified circuit pack. The system first validates that the board exists at the specified location. Then, based on the logical type of board (for example, Analog, Digital, Hybrid, and others), a series of tests perform diagnostics on the board and then returns results of the test along with any possible error codes. Some of the tests can be disabled by administering forms on the administration terminal.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test board	location	Physical location of the board PCSS	init inads craft nms	Test sequence = short; repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (includes a destructive test)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test board 01c11 l test board 01c11 l schedule test board 02e15 sh r 2 test board 01c08 test board 02d12 r 4 test board 02d12 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

Destructive long tests on a Switch Node Interface (SNI) board are not allowed unless the board has first been busied out.

Output

The following example shows the output from the **test board 1c07 short** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test board 01C07 short

test card-mem

This command executes a sequence of tests on the memory card in the specified switch processor element. The test sequences in order for both long and short options are listed in the following table:

Test	Short	Long
12 Volt Power Supply Test (#701)	X	X
Memory Card Insertion Test (#695)	X	X
Memory Card Format and Read Test (#696)	X	X
Memory Card Match Test (#697)	X	X
Memory Card Write-Protected Test (#698)	X	X
Memory Card Directory Recovery Test (#699)	X	X
Memory Card Translation Data Integrity Test (#694)		X
Memory Card Erase/Write/Read Test (#693)		X
Memory Card Capacity Test (#1014)		X
Flash Data Consistency Test (#421)		X ¹

1. The “Flash Data Consistency Test” is not executed in simplex systems.

These tests verify the sanity of the memory card device, the basic read/erase/write operations to the memory card, the integrity of the translation data stored in the memory card, the function of 12 volt power supply in TN777B NETCON circuit pack used for memory card erase/write operations, the translation capacity of the memory card, and the consistency of data stored in both memory cards in a High or Critical Reliability system. This command can also help troubleshoot the following hardware errors: CARD-MEM, 12V-PWR, CAP-MEM, and FL-DATA.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test card-mem	location	Carrier location where memory card resides: High or Critical Reliability (a or b) ¹ ; duplicated (a , A , b , or B)	init inads craft	Test sequence = short; repeat = 1	See below
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (includes a destructive test)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ²			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ³ Examples: test card-mem test card-mem a l test card-mem b sh r 2 test card-mem a sch test card-mem a c			

1. Carrier location required on command line
2. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
3. Refer to the Report Scheduler and System Printer feature specification for more details.

WARNING:
Since the “clear long” option clears all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Feature Interactions

The **test card-mem long** command invokes the Memory Card Erase/Write/Read Test. This means that the **save translation** and **save announcement** commands are rejected while the write-to-memory-card operation is active. This test also

invokes the Memory Card Capacity Test which determines whether the memory card is more than 98% full. This test is also invoked after the **save translation** command.

In a High or Critical Reliability System, running **test card-mem** command for a memory card in the standby SPE means that the standby SPE is put into the maintenance mode and no SPE interchange is allowed through the **reset system interchange** command or scheduled SPE interchange.

Output

The following example shows the output from the **test card-mem a long** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test card-mem a long                                SPE A

TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01A       12V-PWR              701        PASS
01A       CARD-MEM              695        PASS
01A       CARD-MEM              696        PASS
01A       CARD-MEM              697        PASS
01A       CARD-MEM              698        PASS
01A       CARD-MEM              699        PASS
01A       CARD-MEM              694        PASS
01A       CARD-MEM              693        PASS
01A       CAP-MEM              1014       PASS
01A       FL-DATA              421        PASS

Command successfully completed
```

Field descriptions

Port Port address (cabinet-carrier-slot-circuit): cabinet 1, carrier is **A** (control carrier A in a simplex system) and either **A** or **B** (control carriers A and B in a duplex system). The slot and circuit fields in the port address for the 12V-PWR, CAP-MEM, and CARD-MEM maintenance objects are always blank. The port address for maintenance object FL-DATA is blank.

Maintenance Name	The name of maintenance object being tested: ■ CARD-MEM for the memory card ■ 12V-PWR for 12-volt power supply in TN777B NETCON board ■ CAP-MEM for memory card capacity ■ FL-DATA for the data consistency stored in memory cards (duplicated switch)
Test No	The test being executed
Result	Test result: Pass, Fail, or Abort
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test cdr-link

This command first validates that the Call Detail Recording (CDR) link has been administered and exists in the switch. Then individual diagnostic tests run on the link and return results of the test along with any possible error codes. For information on what a CDR link is and does, see the description in [“status cdr-link”](#) section of this manual.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test cdr-link	<i>link-id</i>	Link-id = primary or secondary	init inads craft	Test sequence = short; repeat = 1	none
	<i>short</i>	Option for a brief series of nondestructive diagnostic tests.			
	<i>long</i>	Option for a longer, more comprehensive test series (includes a destructive test)			
	<i>repeat number</i>	How many times each test in the sequence is repeated (1-100)			
	<i>clear</i>	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	<i>schedule</i>	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test cdr-link primary l test cdr-link secondary sh r 2 test cdr-link primary test cdr-link secondary test cdr-link secondary c test cdr-link primary schedule			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output for the **test cdr-link primary** command. The responses display on a test-by-test basis with one line of data for each test result.

test cdr-link primary short

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
	PRI-CDR		215	PASS	

Command Successfully Completed

Field descriptions

Port	Not applicable (always blank)
Maintenance Name	The type of MO being tested: primary cdr-link= PRI-CDR; secondary cdr-link = SEC-CDR
Alt. Name	Not applicable (always blank)
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, Disabled
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test customer-alarm

This command performs hardware diagnostic tests on the leads of the Processor and EPN maintenance circuit packs, used for customer-provided alarms by closing the appropriate relay for 1 minute. Failure is verified by checking the customer alarm attached to the specified circuit pack.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test customer-alarm	location	Extension of the data module or data channel to be tested (per dial-plan)	init inads craft	See below	none
	short	Runs test number 115			
	long	Runs test number 115 (same as short test option)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test customer-alarm test customer-alarm schedule test customer-alarm 02 r 2 test customer-alarm 01b r 25 test customer-alarm 01b r 25 schedule test customer-alarm 2a test customer-alarm 2a sh test customer-alarm 01b l schedule test customer-alarm 3 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Defaults

The default cabinet is cabinet 1. The default carrier is carrier “a,” except for SPE duplex system PPNs. In this case the carrier has no default and either “a” or “b” must be entered. The default for the remaining parameter is a repeat of 1.

Output

The following example shows the output from the **test customer-alarm 02a** command.

```
test customer-alarm 02A

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
02A       CUST-ALM           115       PASS

Command Successfully Completed
```

Field Definitions

Port	The port address (cabinet-carrier-slot)
Maintenance Name	The maintenance name (always CUST-ALM)
Alt. Name	Not applicable
Test No.	The test number (always 115)
Result	Test result: Pass, Abort, or Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test data-module

This command performs hardware diagnostic tests on a data module or data channel. Test results are determined by the interface to the digital switch-data line port, digital line port, or network control data channel.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test data-module	extension	Extension of the data module or data channel to be tested (per dial-plan)	init inads craft cust nms	Test sequence = short; repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (includes a destructive test)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test data-module 30000 I test data-module 30000 test data-module 32000 sh r 2 test data-module 33000 I r 25 test data-module 33000 I r 25 schedule test data-module 30000 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

WARNING:
Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following example shows the output from the **test data-module 300** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test data-module 300

                                TEST RESULTS

test ds1-loop

This command validates that the board exists at the specified location and that the board is a TN464F or TN767E or later suffix DS1 Interface board. Long-duration loopback tests execute for an extended period of time until manually terminated. Short-duration loopback tests return the result of the test to the screen after executing. The **list measurements ds1 summary** command can be used to monitor the status of a long-duration loopback/span test.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test ds1-loop	<i>location</i>	Physical location of board (PcSS)	init inads craft super-user other ³	ds1/csu- loopbac k-tests	See below
	<i>cpe-loopback-jack-test-begin</i>	Long-duration loopback test setup through the Customer Premises Equipment (CPE) Loopback Jack. Allows user to specify a loop-up code for the CPE loopback jack if it differs from the default (0x47F). The loop-up code is entered by specifying the number of bits in the loop-up code as well as the actual hexadecimal bit-pattern. ¹			
	<i>far-csu-loopback - test-begin</i>	Long-duration loopback test tsetup through the far-end Channel Service Unit (CSU)			
	<i>one-way-span-test-begin</i>	Long-duration one-way span test			
	<i>end-loopback/ span-test</i>	Terminates long-duration one-way span and loopback testing			
	<i>inject-single-bit-error</i>	Single bit error sent within an active framed 3-in-24 test pattern used in long-duration loopback and span testing			
	<i>ds1/csu-loopback-tests</i>	Sequentially executes the following loopback tests: DS1 Board LoopBack, CSU Module Equipment LoopBack, and CSU Module Repeater LoopBack. ² Examples: test ds1-loop 01c08 test ds1-loop 1-3c03 cpe-loopback-jack test ds1-loop 1-3c03 cpe test ds1-loop 10c03 end test ds1-loop 02d12 fa test ds1-loop 02d12 inj			

1. For TN464F or TN767E or later suffix DS1 boards only. The test aborts if the board has not been taken out of service with the **busyout** command.

2. For TN464F or TN767E or later suffix DS1 boards

3. Logins with Maintain Switch Circuit Packs permissions enabled.

Feature Interactions

- Loopback or span tests are not allowed on DS1 boards unless the board has been busied out.
- Only one of the CPE Loopback Jack, far-end CSU, one-way span, or DS1/CSU loopback tests may be active at any given time on a DS1 span.

Output

The following example shows the output for the **test ds1-loop 1c07** command, and assumes that the board in cabinet 1, carrier c, slot 7 is a TN767E DS1 board. The responses display on a test-by-test basis with one line of data for each test result.

```
test ds1-loop 01C07 ds1/csu-loopback-tests

test duplication-interface

This command performs hardware diagnostic tests on the indicated duplication interface circuit pack, under the control of the active SPE that tests the SHDW-CIR, SPE-SELECT, and DUPINT maintenance objects.

- SHDW-CIR is associated with that portion of the duplication interface circuit pack that handles memory shadowing from the active to the standby SPE
- SPE-SELECT is associated with the SPE Select switch located on the front of the circuit pack

- DUPINT is associated with the duplication interface circuit packs other functions, including SPE-to-SPE communication, SAT connection, and environmental maintenance leads.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test duplication-interface	location	SPE location of the duplication interface circuit pack (1a, 1b, a, or b)	init inads craft	Text sequence = short; repeat = 1	Duplication-interface failures may prevent SPE switching.
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (includes a destructive test)			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test duplication-interface a test duplication-interface b sh test duplication-interface a l r 25 test duplication-interface 1b l r 25 schedule test duplication-interface 1a l c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output from the **test duplication-interface 1A** command, where A is the active carrier in an SPE duplex system. The responses display on a test-by-test basis with one line of data for each test result.

```
test duplication-interface a long                SPE A

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
1A        SHDW-CIR          285        PASS
1A        SHDW-CIR          283        PASS
1A        SHDW-CIR          284        PASS
1A        SPE-SELE          278        PASS
1A        DUPINT            315        PASS
1A        DUPINT            275        PASS
1A        DUPINT            276        PASS
1A        DUPINT            280        PASS

1A        DUPINT            277        PASS
1A        DUPINT            272        PASS
1A        DUPINT            274        PASS
1A        DUPINT            273        PASS
```

Command Successfully Completed

Field Definitions

Port	The port address (cabinet-carrier); always 01A or 01B
Maintenance Name	Always SHDW-CIR, SPE-SELE, or DUPINT.
Alt. Name	Not applicable
Test No.	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, or Disabled
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test eda-external-device-alm

This command performs a hardware diagnostic test on all or specific port's administered external device alarms. The test **PASSES** if the external device *is not* reporting an external device alarm and **FAILS** if the external device *is*

reporting an external device alarm. If you are entering a specific port, it must already be administered as an external device alarm port on a maintenance or an analog line port carrier board.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test eda-external-device-alm	physical location	In addition to the word physical , you must enter the physical location (PCSSpp for an administered external device alarm analog line port). ¹	init inads craft	Repeat = 1	none
	all	Tests all administered external device alarm ports on analog line and maintenance boards.			
	repeat	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ²			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ³ Examples: test eda-external-device-alm all test eda-external-device-alm all schedule test eda-external-device-alm physical 1major r 10 test eda-external-device-alm physical 2c1101 c			

1. Since the "maintenance board" alarm connections connect to control carrier boards that are in unnumbered slots, the standard port format cannot be used to designate these alarm connections. The special ports **Pmajor** and **Pminor** are used designate the major or minor maintenance board alarm connection for cabinet **P**. The major/minor designation specifies the pair of wires, *not* the alarm level associated with the connection (the "major" port can be administered as a major, minor or warning alarm and the "minor" port can be administered as a major, minor or warning alarm).

2. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.

3. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output for the **test external-device-alarm all** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test eda-external-device-alm all

Field definitions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	The name of maintenance object
Alt. Name	The alternate means of identifying the maintenance object, in this case, the administered (descriptive) name of the external device alarm.
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, or Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test environment

This command performs hardware diagnostic tests of the environment monitoring and control, and emergency transfer functions of both Processor Port Network (PPN) cabinets and Expansion Port Network (EPN) cabinets. Circuit packs involved are the Processor circuit pack (PPN simplex systems), the Duplication Interface circuit pack (PPN duplex systems), and EPN Maintenance circuit packs. The tone/clock circuit pack is involved in tests of the ring generator.

There are 8 Maintenance Objects involved in this testing:

1. DC-POWER tests power availability, battery charging and temperature functions in SCC cabinets only.
2. EMG-XFER tests emergency transfer status
3. EXT-DEV tests external (AUDIX, for example) alarm status for both the SCC and MCC cabinet systems.
4. POWER tests battery backup
5. AC-POWER tests AC power availability
6. CARR_POW tests carrier DC power availability. The long test of CARR_POW includes a power recycle test for non-Processor Element (SPE) carriers and is destructive. There is one instance of CARR_POW for each carrier in the cabinet.
7. CABINET tests air flow and temperature
8. RING_GEN tests ringing voltage are tested in MCC cabinets only.

NOTE:

The processor carrier and its duplicate if present as well as any EPN control carrier or an SCC carrier is not recycled. All port carriers are recycled, and service is interrupted for each port carrier. If a carrier containing an active EI is recycled, communications with that cabinet is disrupted. If a carrier containing an active tone-clock board is recycled, all ports in the cabinet or port network are service disrupted.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test environment	location	Cabinet (1-3); 1 = PPN, 2-3 = optional EPN.	init inads craft	Cabinet = 1; test sequence = short; repeat = 1	See below
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test environment test environment schedule test environment 1 sh test environment 1 l r 25 test environment 01 l r 25 test environment 01 l r 25 schedule test environment 2 l c test environment 3 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The long test recycles power in some specified cabinet on non-SPE and maintenance board carriers and is destructive. Specifically, the 'a' carrier of PPNs and EPNs does not have power recycled. In PPNs containing duplicated SPEs the 'b' carrier also does not have power recycled. All port carriers are recycled, and service is interrupted for each port carrier. If a carrier containing an active EI is recycled, communication with that cabinet is disrupted. If a carrier containing an active tone-clock board is recycled, all ports in the cabinet or port network are service disrupted.

Output

The following example shows the output for the **test environment 1** command to test a MCC/PPN cabinet. The responses display on a test-by-test basis with one line of data for each test result.

```
test environment 1

                                TEST RESULTS

test hardware-group

This command allows a user to perform a set of hardware diagnostic tests on the whole system, a carrier, cabinet, spe, or board. The tests vary according to the configuration of the system and the specified command options.

This command runs a series of tests on all the hardware on the entire system, an individual carrier, cabinet, spe, or board. The tests vary depending on options chosen and board types. Each test exercises diagnostics on all the hardware in the specified hardware group and reports results of the test along with any possible error codes. Concurrent testing is done to enhance performance, therefore, test results display on the SAT in the order they are received. Consequently, test results of one maintenance object may be intermixed with test results of other maintenance objects.

Because the tests for this command are not destructive, the tests performed on a particular maintenance object with either the **short** or the long **option** may not be the same as the corresponding demand tests.

A hardware-group command executing in the foreground may be cancelled by either pressing the CANCEL key or by entering the **cancel hardware-group** command at a different SAT. However, if the technician wants to cancel a **test hardware-group** command running in the background, the **cancel hardware-group** command can be entered on any SAT. A canceled **test hardware-group** command can be resumed at the point it left off by entering the **resume hardware-group** command. Restarts are not allowed for **test hardware-group** commands entered with either the **all-ports** option or the **spe-interchange** option.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test hardware-group	system	System-wide test of all hardware-groups	init inads	Test sequence = short; repeat = 1	See below
	carrier location	Carrier address: cabinet (1-3), carrier (A-E) ¹			
	cabinet location	Cabinet address (1-3) ²			
	board location	Board address in PCSS format ³			
	print	Output sent to printer			
	schedule	Command validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ⁴ Examples: test hardware-group system test hardware-group system print test hardware-group carrier 1a test hardware-group carrier 1a schedule test hardware-group cabinet 2 test hardware-group board 01c07 test hardware-group board 01c07 schedule test hardware-group spe test hardware-group spe print test hardware-group spe schedule			

1. The type of carrier may be port, or processor. In the case of a port carrier, all universal port and tone-clock boards (see reference 4) and its affiliated MOs residing in the specified carrier are tested. For a processor carrier, all SPE complex and tone-clock boards and its affiliated MOs are tested.
2. All PN and PNC related MOs plus cabinet specific MOs, including maintenance boards and environment (ring generator, battery, power, emergency transfer, external alarms, fans, and temperature) are tested if they reside in the specified 'cabinet location'.
3. All MOs on the specified 'board location' including ports are tested.
4. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

test hardware-group

Only one test hardware-group command can be active at any given time.

TTI	If the test hardware-group command is issued with the all-ports option when the TTI background task is active, some unadministered ports may not be tested. In addition, active alarms on line ports may be cleared by this task. The status tti command can be used to determine the state of the TTI background task.
Add Station	If a add station command is entered for an untranslated port at the same time as it is being tested as part of the test hardware-group command with the all-ports option, the error message, Object in use; please try later displays, and the request fails.
Trunk administration	If an attempt is made to add an unadministered trunk port to a trunk group at the same time as it is being tested as part of the test hardware-group with the all-ports option, the error message, Object in use; please try later displays, and the request fails.
Save translation	If the test hardware-group with the all-ports option while a translation save operation is active, some unadministered ports may not be tested. All other hardware are tested normally.
Hardware alarms	When a hardware error is detected by the test hardware-group command, the hardware goes through the standard escalation strategy. Alarms are raised on hardware that manifest 'hard' errors. This alarming strategy is the same, regardless of whether the ports are translated or not.
System interaction	The performance of test hardware-group is affected by call processing traffic, administration activity, choice of the short or long option, whether the all-ports option is chosen, whether the spe-interchange option is chosen, and other demand maintenance activity.
Scheduled and periodic maintenance	While executing the test hardware-group command, all scheduled background maintenance, periodic background maintenance, and data audits activity is suspended until the command completes. When the test hardware-group command is canceled or completes, all suspended periodic, scheduled, and data audits background maintenance activity are restarted where it left off.

Setting the Test Parameters

Once the user has entered the desired action (**test hardware-group**) and the object (board, carrier, etc.), then an options form displays.

test hardware-group systemPage 1 of 1

TEST HARDWARE-GROUP SELECTIONS

Select the desired options for the specified test.

Test sequence: short

Test repetition: repeat count: 1

Output OPTIONS: HARDWARE OPTIONS:

Auto-page? n All-ports? n

Background? n SPE-interchange? n

Failures? n

Field descriptions

Test sequence	Short (nondestructive) or long (more comprehensive, still nondestructive) test sequence
Test Repetition	repeat - (1-99) each test is executed the number of times specified on each physical object. continuously -all tests on all the specified hardware run until cancelled by either pressing the CANCEL key or by executing the cancel hardware-group command.
count :	Repeat test sequence value (1-99). If the Test sequence field is set to continuously , then this field disappears from the screen; if this field is set to repeat , then the field appears.
Auto-page?	Provides a new screen every time the SAT screen fills with test results. (n / y). The screen does not scroll to accommodate new results; instead a new screen is provided after the current screen fills up. If the auto-page option is not selected, the SAT screen does not refresh once it is filled, and testing stops until the user enters the PAGE key to continue or the CANCEL key to cancel the testing. This option is not allowed if the background option is selected.
Background?	Run the command in the background, thus freeing the SAT (n / y). The error results are tabulated in the error log, but no results display on the terminal. This option cannot be used if either the continuously or the auto-page options are selected.
Failures?	Only failing test results display (n / y). Test results that pass or abort are not displayed. The failures option has no effect if entered with the background option.
All-ports?	Tests all customer translated line and trunk ports as well as a set of untranslated line and trunk ports for boards listed in Table 8-7 (n / y).

Table 8-7. Test of ‘all ports’ option for the following boards:

Board Number	Description	Board Number	Description
TN413	Digital Line	TN746	16 port Analog Line
TN417	Auxiliary Trunk	TN747B	Central Office Trunk

SPE-interchange? Allow for planned interchange of duplicated SPEs and subsequent testing of both the active and standby SPEs.

Output

The following example shows the output for the **test hardware-group system** command and assumes that the board in port network 1, carrier c, slot 7 is an analog board with three administered ports and test sequence repeat = 3. Responses to this command running in the foreground display on a test-by-test basis with one line of data for each test result.

test hardware-group system

TEST RESULTS

The following example shows the output for the **test hardware-group system** with the **background** option selected.

test hardware-group system

Command started in background mode

test inads-link

This command attempts to make a call over the inads port on the maintenance board to verify the INADS alarm notification process. In the default settings, the system test the link to the first OSS telephone number. If there is an alarm pending to be reported or the call is in progress or up, then the test aborts. If the alarm origination to the OSS telephone number to be tested is disabled, then the test generates an informative error and the test continues. The test waits 2 minutes before dialing the call to allow the remote maintenance technician to logoff, thus freeing the line. A *local* SAT user entering the **test inads-link** command does not need to log off for the system to place the call, but the two-minute delay still exists.

Once the call is answered by INADS, the system sends a message with a test alarm type. INADS acknowledges receipt of the message and creates a trouble ticket. The trouble ticket is closed immediately and has a "INADS LINK TEST" message entered in the description field. If an alarm is raised while the test call is up, the system does not send an alarm message over the existing link. The normal retry mechanism is followed, which means an attempt to make a call to INADS to report the error takes place 7 minutes later. An INADS trouble ticket is created only if the connection is successfully established and a message is sent to the system acknowledging that INADS received the system message.

The Maintain Process Circuit Packs field must be set to **yes** on the inads and technician permission forms. This provides permissions to execute the **test inads-link** command. This field can be changed by executing a **change permission login** command.

No alarms are raised on the system and attendant alarm and acknowledgment lamp states are not changed as a result of the **test inads-link** command. The test does not run during periodic or scheduled maintenance.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test inads-link	1	First OSS telephone number	init inads craft nms	1st OSS number	none
	2	Second OSS telephone number Examples: test inads-link test inads-link 1 test inads-link 2			

Output

Command successfully completed Test passed

Command failed Link was up, there was an active alarm that the switch needs to report, or there was a problem with the call.

 **NOTE:**
An entry is made in the error log describing why the inads-link test failed.

test interface

This command performs hardware diagnostic tests on the specified processor interface circuit pack. In addition to testing the PI board, the tests examine the protocol and link interface that is transmitted over the board.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test interface	location	Location (cabinet-carrier-position) of the processor interface (position 1 = first processor interface in the carrier, 2 = second)	init inads craft nms	Test sequence = short; repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test interface 01a1 l test interface 01b2 s r 2 test interface 01b2 s r 2 schedule test interface b1 l r 25 test interface a2			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following example shows the output for the **test interface a1** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test interface a1

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01A1      PI-SCI              231        PASS
01A1      PI-BD                  52        PASS

Command Successfully Completed
```

Field descriptions

Port	Port address: cabinet-carrier-slot (the carrier associated with the particular processor interface board)
Maintenance Name	The name of maintenance object
Alt. Name	Not applicable.
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, or Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test isdn-testcall

This command starts an outgoing, asynchronous ISDN-PRI test call in the asynchronous method from a specified trunk. If the test results are PASS, the test call is started. A test result of ABORT means that a resource wasn't available, for example, B-channel or a Maintenance/Test circuit pack. A test result of FAIL denotes that the outgoing ISDN-PRI test call was not established.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test isdn-testcall	group number	The administered group number associated with each trunk group	init inads craft	duration = 8.4 or 9.6 sec	See below
	member number	The administered member number identifying a particular trunk within a trunk group.			
	minute number	Duration of the test call in minutes (1-120)			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: test isdn-testcall 80/1 test isdn-testcall 80/1 schedule test isdn-testcall 78/2 minutes 10 test isdn-testcall 78/3 minutes 100 schedule			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

- Use the **status isdn-testcall** command for details on how to access the additional data available after running the test.
- Only one ISDN trunk can be tested per port network at a time. Once testing is completed, another ISDN trunk can be tested in that port network.
- The maximum number of asynchronous outgoing test calls running depends upon the number of Maintenance/Test circuit packs in the system.

Output

The following example shows the output for the test **isdn-testcall 80/1** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test isdn-testcall 77/1                                SPE A

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01B1501   ISDN-TRK                077/001    258       PASS

Command Successfully Completed
```

Field descriptions

Port	Port address: cabinet-carrier-slot-circuit
Maintenance Name	The name of the maintenance object being tested.
Alt. Name	Alternate means of identifying the maintenance object: trunk object xxx/yyy, where xxx = trunk group number, yyy = member number
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, or Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test journal-printer

This command performs hardware diagnostics on the link between the switch and one of the specified journal printer links. There are two types of journal printer links: pms-log and wakeup-log. For general information on journal printer links, see the second paragraph in the “Description” section of the “busyout pms-link” manual pages. For information on what a journal printer is and does, see the second paragraph in the [“Output”](#) section of the [“status journal-link”](#) manual pages.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test journal-printer	pms-log	Tests the link to the pms logging printer (maintenance name = PMS-PRNT)	init inads craft	Test sequence = short; repeat = 1	See below
	wakeup-log	Tests the link to the wakeup logging printer (maintenance name = JNL-PRNT)			
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test journal-printer pms-log l test journal-printer pms-log l schedule test journal-printer wakeup-log r 2 test journal-printer wakeup-log r 2 schedule test journ pm r 3 test journ pm r 3 schedule			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The maintenance of a particular component on a link sometimes interferes with the maintenance of the link itself. Maintenance can put a link component in a busy state causing link set-up to fail. Frequent attempts at re-setup of a link may delay the recovery of a faulty component due to the maintenance test of a component only taking place when the component is idle. Therefore, the

technician needs to be able to disable the attempted re-setup of a link. Use of the busyout command causes the link to be torn down. If the link is already down, the busyout command stops periodic re-setup tries on the link.

Output

The following example shows the output for the **test journal-printer pms-log** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test journal-printer pms-log short

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
JRNL-LINK                215        PASS

Command Successfully Completed
```

Field descriptions

Port	Not applicable (always blank)
Maintenance Name	The name of maintenance object being tested: PMS-PRINT for testing the pms-log printer link JNL-PRNT for testing the wakeup-log printer link
Alt. Name	Not applicable (always blank)
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, Disabled
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test led

This command performs a test on all the LEDs in a specified cabinet. Once the cabinet is validated and the range of circuit packs determined, the **test led** command turns on all LEDs on the circuit packs contained in each carrier until all affected carriers are lit. Once all the LEDs are on, there is a 2-second pause, and then all the LEDs are turned off in the same order. Once all of the repeat cycles are completed, all affected LEDs are restored to the current status.

On a duplex PPN, only the long option tests the leds in the standby SPE. When executing the **test led long** command, the standby Processor, Memory, and Packet Control circuit pack LEDs can take up to 20 seconds to light.

The following LEDs are NOT lighted by the **test led** command:

- SPE Select LEDs on the Duplication Interface Circuit Packs
- Power Unit LEDs
- Yellow (amber) LED on the tape drive

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test led	all	All LEDs in all carriers are tested	init inads craft	all; repeat = 1; test sequence = short in a duplex system	none
	cabinet number	Cabinet number (each carrier tested sequentially)			
	short	Simplex: short and long option are identical and turn on and off all leds in the specified port network. Duplex: short option does <i>not</i> affect the leds in the standby SPE carrier in the PPN.			
	long	Simplex: short and long option are identical and turn on and off all leds in the specified port network. Duplex: long option <i>does</i> affects the leds in the standby SPE carrier in the PPN.			
	repeat number	Number of times each test in the sequence is repeated (1-100) Examples: test led test led all r 2 test led cabinet 1 test led c 1 test led 1 long			

Output

If the command is successful, Command successfully completed displays.

test link

This command validates that a specified link is administered and then performs a set of hardware diagnostic tests on the link.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test link	link-id	Link number (1-8; assigned via the communication-interface links form)	init inads craft	Test sequence = short; repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test link 1 test link 1 schedule test link 3 l test link 2 sh test link 2 r 2 test link 2 l c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following example shows the output for the test link 1 long command. The responses display on a test-by-test basis with one line of data for each test result.

test link 1 long

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01AXX01	PI-LINK		182	PASS	
01AXX01	PI-LINK		183	PASS	
01AXX01	PI-LINK		234	PASS	
01AXX01	PI-LINK		233	PASS	

Command Successfully Completed

Field descriptions

Port	Port address on the Processor Interface board associated with the link-id being tested.
Maintenance Name	The name of maintenance object being tested
Alt. Name	Not applicable.
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test maintenance

This command tests the EPN maintenance circuit pack in any Expansion Port Network control carrier. Specifying cabinets 2 - 3 allows testing of any connected EPN maintenance circuit packs. The test sequence checks the SAT interface, EI

link, reset, and sanity functions on the EPN maintenance circuit pack. The long test resets the EPN maintenance circuit pack, causing the EPNSAT link to be dropped and is destructive.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test maintenance	location	Physical location of the maintenance circuit pack: (2-3)	init inads craft	Test sequence = short; repeat = 1	See below
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test maintenance 2 test maintenance 3 schedule test maintenance 2 sh test maintenance 2 l c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The last test in the long test sequence on EPN maintenance circuit packs drops the EPNSAT link.

Output

The following example shows the output for the **test maintenance 2** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test maintenance 2

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
02A       MAINT              106        PASS
02A       MAINT              229        PASS
02A       MAINT              303        PASS
02A       MAINT              337        PASS

Command Successfully Completed
```

Field descriptions

Port	The port address (cabinet-carrier) of the maintenance object that is being tested. For this maintenance object, only the cabinet and carrier values display.
Maintenance Name	The maintenance name (always MAINT)
Alt. Name	Not applicable.
Test No.	The test being executed
Result	The result of the individual test: Pass, Abort, Fail, Disabled
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test memory

This command performs hardware diagnostic tests on any or all memory circuit packs in the specified carrier. Both short and the long test are nondestructive when testing memory.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test memory	location	Physical location of the memory circuit pack: cabinet number (optional, but always 1 if entered) and carrier letter (either a or b for duplex, a for simplex)	init inads craft nms	See below	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive test series (all nondestructive for this command).			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test memory test memory a test memory a schedule test memory 1a2 test memory b1 sh test memory b l r 25 test memory a l c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Defaults

The cabinet default is always 1. For SPE simplex systems, the default carrier is the “a” carrier; for SPE duplex systems, there is no default carrier. The defaults for the remaining parameters are short with a repeat of 1.

Output

The following example show the output for the **test memory 1b** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test memory 1b

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01B       MEM-BD           87         PASS
01B       MEM-BD           631        PASS

Command Successfully Completed
```

Field descriptions

Port	The port address (cabinet-carrier)
Maintenance Name	The name of maintenance object being tested is MEMORY.
Alt. Name	Not applicable.
Test No.	The test being executed
Result	The result of the test: Pass, Abort, or Fail
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test modem-pool

This command performs hardware diagnostic tests on the specified modem pool group or an individual member of a specified group (Combined or Integrated). A Combined modem-pool group consists of pairs of Analog and Digital Line ports. One pair of Analog and Digital Line ports used for modem-pooling is called a conversion resource. An Integrated group consists of modem-pool circuit packs, each containing two conversion resources. Therefore, when a member number is specified for a Combined modem-pool group, one conversion resource is tested, and when a member number is specified for an Integrated modem-pool group, two conversion resources are tested.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test modem-pool	group number	The administered group number (1-5)	init inads craft	Test Sequence = short; repeat = 1	none
	member number	The administered member number (1-32). A member is a pair of analog and digital line ports (two pair for the Integrated modem-pool).			
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test modem-pool 1 test modem-pool 1 schedule test modem-pool 1/3 l r 2 test modem-pool 1/3 l r 2 schedule test modem-pool 2 r 2 test modem-pool 2 l			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following example shows the output for the test modem-pool 1/3 command. The responses display on a test-by-test basis with one line of data for each test result.

```
test modem-pool 1/3 short                                SPE B

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01C0701   MODEM-PT              98         PASS
01C0701   MODEM-PT              99         PASS

Command Successfully Completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	The name of maintenance object (always MODEM-PT)
Alt. Name	Not applicable
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test network-control

This command performs hardware diagnostic tests on a specified network control circuit pack.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test network-control	location	Network control board carrier location in a High or Critical Reliability System (a or b).	init inads craft	Cabinet 1, carrier a, test sequence repeat = 1.	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	Number of times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test network-control test network-control a l test network-control b sh r 2 test network-control b l r 25 test network-control a test network-control a c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following example shows the output from the **test network-control a** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test network-control a
```

TEST RESULTS					
Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01A	DATA-BD		52	PASS	
01AXX01	DATA-CHL	4001	109	PASS	
01AXX01	DATA-CHL	4001	110	PASS	
01AXX01	DATA-CHL	4001	111	PASS	
01A	SW-CTL		95	PASS	
01A	SW-CTL		92	PASS	
01A	SW-CTL		94	PASS	
01A	SW-CTL		324	PASS	
01A	12V-PWR		701	PASS	
01A	CARD-MEM		695	PASS	
01A	CARD-MEM		696	PASS	
01A	CARD-MEM		697	PASS	
01A	CARD-MEM		698	PASS	
01A	CARD-MEM		699	PASS

Field descriptions

Port	Port address: cabinet (always 1)-carrier-slot-circuit. For the DATA-BD, SW-CTL, 12V-PWR, and CARD-MEM maintenance objects, the slot and circuit fields of port address are blank. DATA-CHL (administered data channel) uses XX as the slot address and has a circuit number between 01 and 04. The carrier field has a value A for the control carrier A in a simplex system, and A or B for control carriers A and B in a duplex system.
Maintenance Name	The name of the maintenance object: ■ DATA-BD for Network Control board ■ SW-CTL for Switch Control Archangel ■ DATA-CHL for administered data channel ■ 12V-PWR for 12 volt power supply unit on the Network Control board ■ CARD-MEM for flash memory card on Network Control board ■ 12V-PWR and CARD-MEM (shown only when the Network Control board is TN777B)

Alt. Name	Extension number of the DATA-CHL, if administered. For other maintenance objects, this field is not applicable and, therefore, empty.
Test No	The test being executed.
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test packet-control

This command performs hardware diagnostic tests on the specified packet-control circuit pack.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test packet-control	location	Applies only to duplicated configurations: if simplex, parameter is not used and thus is not valid; if duplicated, "location" represents the carrier in which the packet-control resides (1A or 1B).	init inads craft nms	Simplex: location optional, cabinet=1, carrier A. Duplex: cabinet=1, no default for the carrier.	See below
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test packet-control test packet-control A test packet-control B test packet-control 1A test packet-control 1B test packet-control a short test packet-control a s repeat 5 test packet-control b s r 5 test packet-control b long clear test packet-control b l r 25			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.

2. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The reset packet-control test (#586) does not run on the active packet-control. This test is part of the standby packet-control test sequence, illustrated in the screen output section below.

Output

The following example is the screen output for the **test packet-control 1B long** command. Note that carrier B is the active carrier in this example.

```
test packet-control 1B l
```

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01B	PKT-CTRL		583	PASS	
01B	PKT-CTRL		584	PASS	
01B	PKT-CTRL		585	PASS	

Command successfully completed

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	The name of maintenance object.
Alt. Name	Not applicable
Test No.	The test number run on the packet-control.
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test pkt

The test pkt runs a series of tests on the Packet bus of the specified PPN or EPN.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test pkt port-network	pn number	The Packet bus to be tested: <i>nn</i> (1-3)	init inads craft	Test Sequence = short; Repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ²			
		Examples: test pkt port-network 1 l test pkt port-network 2 sh r 2 test pkt port-network 2 sh schedule test pkt port-network 1 l r 25 test pkt port-network 2 test pkt port-network 1 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The *long clear* option forces a clear of all alarms if no errors are encountered during testing. The *short clear* option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following example is the output for the test pkt port-network 1 command. The responses display on a test-by-test basis with one line of data for each test result.

test pkt port-network 1

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
PN 01	PKT-BUS		571	PASS	
PN 01	PKT-BUS		572	PASS	
PN 01	PKT-BUS		573	PASS	

Command successfully completed

Field descriptions

Port	A port network number (1-3).
Maintenance Name	The name of maintenance object being tested.
Alt. Name	Not applicable.
Test No	The test being executed.
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test pms-link

This command performs the specified property management system link tests on the specified pms link by checking to see if the link is accessible and then performing a reset on the link (long test only). For general information on PMS

links, refer to the description of the [“busyout pms-link”](#) command. For information on what a PMS is and does, refer to the description of the [“status pms-link”](#) command.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test pms-link	short	Option for a brief series of nondestructive diagnostic tests.	init inads craft	Test Sequence = short; Repeat = 1	See below
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test pms-link sh r 5 test pms-link l test pms-link test pms-link c test pms-link c sch			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Feature Interactions

The maintenance of a particular component on a link may interfere with the maintenance of the link itself. Maintenance can put a link component in a busy state causing link set-up to fail. Frequent attempts at re-setup of a link may delay the recovery of a faulty component due to the maintenance test of a component only taking place when the component is idle. Therefore, the technician needs to be able to disable the attempted re-setup of a link. The **busyout** command is used to do this and causes the link to be torn down. If the link is already down, the **busyout** command stops periodic re-setup tries on the link.

Output

The following example shows the output for the **test pms-link long** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test pms-link long

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
PMS-LINK                214        PASS

Command Successfully Completed
```

Field descriptions

Port	Always blank
Maintenance Name	Always PMS-LINK
Alt. Name	Not applicable.
Test No	The test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test port

This command performs hardware diagnostic tests on an individual port circuit. In most cases, tests are performed on hardware connected to the port.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test port	location	PCSSpp	init inads craft	Test Sequence = short; Repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test port 01c1101 l test port 01c1101 l schedule test port 02e1502 sh r 2 test port 02d1201 r 4 test port 01c1101 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following example is the output for the **test port** command and assumes that the port in cabinet 1, carrier c, slot 7, circuit 1 is an analog port. The responses display on a test-by-test basis with one line of data for each test result.

```
test port 01c0701 short

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
01C0701   ANL-LINE           35         PASS
01C0701   ANL-LINE           48         PASS
01C0701   ANL-LINE           36         PASS

Command Successfully Completed
```

Field descriptions

Port	Port address (cabinet-carrier-slot-circuit)
Maintenance Name	The name of maintenance object.
Alt. Name	The alternate means of identifying the maintenance object.
If the Object is a The field contains	
	station extension
	trunk xxx/yyy (xxx = trunk group number and yyy = member number)
	private CO line P/xxx (xxx = private CO line group number)

Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test pri-endpoint

This command performs hardware diagnostic tests on all port circuits (B-channels) that are associated with the PRI endpoint extension.

The test pri-endpoint command performs hardware diagnostic tests on all port circuits (B-channels) that are associated with the specified PRI endpoint.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test pri-endpoint	extension	PRI endpoint extension to be tested (must conform to dial-plan)	init inads craft nms	Test Sequence = short; Repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test pri-endpoint 25012 test pri-endpoint 45002 sh test pri-endpoint 45892 l test pri-endpoint 24389 sh r 4 test pri-endpoint 34899 l r 6 test pri-endpoint 34912 l r 5 schedule test pri-endpoint 93483 r 2 test pri-endpoint 10022 c test pri-endpoint 92349 schedule			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following output example is for the test pri-endpoint 22501 command and assumes that the PRI endpoint ports for extension 22501 are in cabinet 1, carrier B, slot 20, circuits 1 to 3. The responses display on a port-by-port and test-by-test basis with one line of data for each test result.

test pri-endpoint 22501 short

page 1 of 1

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01B2001	PE-BCHL	22501	36	PASS	
01B2001	PE-BCHL	22501	255	PASS

01B2003	PE-BCHL	22501	256	PASS	
01B2003	PE-BCHL	22501	257	PASS	

Command Successfully Completed

Field descriptions

Port	The port address (cabinet-carrier-slot-circuit) of the maintenance object that is being tested.
Maintenance Name	The maintenance object name for the PRI endpoint port is PE-BCHL.
Alt. Name	The specified extension number of the PRI endpoint.
Test No	The actual test being executed.
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test processor

This command performs hardware diagnostic tests on a specified processor circuit pack.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test processor	location	Cabinet number (optional for simplex) and carrier letter (optional a for simplex; a or b for duplex).	init inads craft	See below	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test processor test processor schedule test processor a test processor 1a test processor b sh test processor a l c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Defaults

For SPE simplex systems, the location is optional and defaults to cabinet 1, carrier a. For SPE duplex systems, the cabinet default is again cabinet 1, but there is no default for the carrier. Defaults for the remaining parameters are short with a repeat of 1.

Output

The following output example is for the test processor a command. The responses display on a test-by-test basis with one line of data for each test result.

test processor aSPE B

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01A	PROCR		77	PASS

01A	PR-MAINT		102	ABORT	1018
01A	PR-MAINT		103	ABORT	1018
01A	PR-MAINT		106	PASS	
01A	PR-MAINT		228	PASS	
01A	PR-MAINT		229	ABORT	1018
01A	MEMORY		87	PASS	
01A	MEMORY		631	PASS	

Command successfully completed

Field descriptions

Port	The port address (cabinet-carrier) of the maintenance object that is being tested.
Maintenance Name	Maintenance object being tested is MEMORY.
Alt. Name	Not applicable.
Test No.	Test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test shadow-link

This command performs hardware diagnostics for the shadow link between the two duplication-interface circuit packs. This command works only with High or Critical Reliability systems. Refer to [Chapter 6, "Reliability Systems: A Maintenance Aid"](#) for more details.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test shadow-link	short long	Both the short and long test sequence execute only Test #318.	init inads craft	Test Sequence = short; Repeat = 1	none
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test shadow-link l test shadow-link sh r 2 test shadow-link sh r 2 schedule test shadow-link c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The *long clear* option forces a clear of all alarms if no errors are encountered during testing. The *short clear* option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following output example is for the **test shadow-link** command. The responses display on a test-by-test basis with one line of data for each test result.

test shadow-link

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
	SHDW-LNK		318	PASS	

Command Successfully Completed

Field descriptions

Port	The port address is always blank.
Maintenance Name	The maintenance name is always SHDW-LNK for this command.
Alt. Name	Not applicable.
Test No	The test number is always 318.
Result	Test result: Pass, Abort, Fail, Disabled
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test signaling-group

This command validates that the specified signaling group is administered and runs a series of diagnostic tests that return results of the test along with possible error codes. A signaling group is a collection of B-channels signaled for by a designated single D-channel or set of D-channels over an ISDN-PRI.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test signaling-group	group identifier	The station extension (must conform to dial-plan)	init inads craft	Test Sequence = short; Repeat = 1	See below
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test signaling-group 1 test signaling-group 1 repeat 10 test signaling-group 2 short test signaling-group 4 long test signaling-group 4 long clear test signaling-group 2 schedule			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Feature Interactions

Additional data is available after running a test. See the **status signaling-group** command for how to access the additional data.

Output

The following output example is for the **test signaling-group 1** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test signaling-group 1                                SPE A

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
1          ISDN-SGR                636       PASS
1          ISDN-SGR                639       PASS
1          ISDN-SGR                637       PASS

Command Successfully Completed
```

Field descriptions

Port	The signaling group number (1-8) of the signaling group that is being tested.
Maintenance Name	The type of maintenance object that is being tested.
Alt. Name	Not Applicable.
Test No	Test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test sp-link

The test sp-link command validates that the system printer link is administered and runs a series of diagnostic tests that return results of the test along with possible error codes.

The system printer link is a link from the switch to an external printer over which jobs can be printed. This link is created by administering the system printer extension and setting up a call to the system printer.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test sp-link	short	Option for a brief series of nondestructive diagnostic tests.	init inads craft	short	none
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹ Examples: test sp-link test sp-link sh test sp-link l test sp-link schedule test sp-link sh sch			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following output example is for the **test sp-link** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test sp-link                                SPE A

                                     TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
SYS-PRNT                215      PASS
SYS-PRNT                213      PASS

Command Successfully Completed
```

Field descriptions

Port	Not applicable. Always blank.
Maintenance Name	The name of maintenance object.
Alt. Name	Alternate means of identifying the maintenance object. This field contains the extension when the object is a data module.
Test No	Test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test spe-standby

This command allows the technician to perform hardware diagnostic tests on the standby Switch Processing Element (SPE) in a duplex SPE system. This command tests all MOs in the standby MO. The STBY-SPE MO itself does not have any defined tests. Instead, tests are run on the following MOs when the **test spe-standby** command is run.

MEMORY	DUPINT	PROCR	FL-DATA
SHDW-LNK	DATA-BD	PR-MAINT	PI-BD
SHDW-CIR	DATA-CHL	12V-PWR	PI-PT
SPE_SELEC	SW-CTL	CARD-MEM	PKT-CTRL

Refer to these MOs for more details. This command is only for a High or Critical Reliability systems.

Action/Object	Qualifiers	Qualifier Description	Permissions	Defaults	Feature Interactions
test spe-standby	short	Option for a brief series of nondestructive diagnostic tests.	init inads craft	Test Sequence = short; Repeat = 1	See below
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹ Examples: test spe-standby long test spe-standby l test spe-standby s r 2 test spe-standby c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The *long clear* option forces a clear of all alarms if no errors are encountered during testing. The *short clear* option only clears alarms pertinent to tests in the short sequence.

Feature Interactions

Testing the standby SPE maintenance object makes the standby SPE unavailable to take over for the active SPE.

Output

The following output example for the **test spe-standby** command assumes that the standby SPE is located in carrier B. The responses display on a test-by-test basis with one line of data for each test result.

test spe-standby

SPE A

TEST RESULTS					
Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01B	SHDW-CIR		285		PASS
01B	SHDW-CIR		284		PASS
01B	SPE-SELECT		278		PASS
01B	DUPINT		315		PASS
.	.		.		.
.	.		.		.
.	.		.		.

Command Successfully Completed

Field descriptions

Port	The port address: cabinet-carrier-slot-circuit
Maintenance Name	The type of maintenance object that is being tested.
Alt. Name	Alternate means of identifying the maintenance object. This field contains the extension when the object is a data module.
Test No	Test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test station

This command performs hardware diagnostic tests on an individual port circuit assigned to that extension. The technician must specify the extension and a translation is automatically done to the physical port location.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test station	extension	The station extension (must conform to dial-plan)	init inads craft cust nms	Test Sequence = short; Repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test station 81709 l test station 85136 s r 2 test station 85036 l r 25 test station 85036 l r 25 schedule test station 84297 r 4 test station 81709 c			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence. SEE WARNING BELOW.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

 **WARNING:**

Since the “clear long” options clear all counters if tests pass, it is possible for firmware counters to be cleared even when a problem exists. In some cases customer service might degrade since calls may be routed over defective equipment.

Output

The following screen is an example of the output from the **test station 81902 short** command with the assumptions that port in cabinet 1, carrier c, slot 7, circuit 1 is an analog port and extension 81902 is connected to that port. The responses display on a test-by-test basis with one line of data for each test result.

test station 81902 short

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01C0701	ANL-LINE		35	PASS	
01C0701	ANL-LINE		48	PASS	
01C0701	ANL-LINE		36	PASS	

Command Successfully Completed

Field descriptions

Port	The port address: cabinet-carrier-slot-circuit
Maintenance Name	The type of maintenance object that is being tested.
Alt. Name	Alternate means of identifying the maintenance object. This field contains the extension when the object is a station.
Test No	Test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test synchronization

This command updates all the boards with the correct synchronization source and parameters. The system sends a downlink message to the tone clock, DS1, and Expansion Interface boards to place them in the correct synchronization configuration, providing error-free digital communication between the switch and other PBXs, COs, or customer premise equipment.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test synch	short	Option for a brief series of nondestructive diagnostic tests.	init inads craft	Test Sequence = short; Repeat = 1	none
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedul e	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test synchronization r 3 test synchronization sh r 1 test synchronization sh r 1 schedule test synchronization l			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The responses display on a test-by-test basis with one line of data displayed for each test result. The following screen is an example of the output for the **test synchronization short** command.

test synchronization short

PN 01A	TDM-BUS		297	PASS	
PN 01B	TDM-BUS		294	PASS	
PN 01B	TDM-BUS		296	PASS	
PN 01B	TDM-BUS		297	PASS	

Command Successfully Completed

Field descriptions

Port	For TDM-BUS maintenance object the port network number and the bus (A or B) is displayed.
Maintenance Name	Maintenance object name
Alt. Name	Not applicable.
Test No	Test being executed
Result	Test result: Pass, Abort, Fail, No Board, Disabled, Extra Bd.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test tone-clock

The test tone/clock command performs hardware diagnostic tests on a technician-specified tone or clock circuit pack.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test tone-clock	location	PCSS	init inads craft	Test Sequence = short; Repeat = 1	none
	short	Option for a brief series of nondestructive diagnostic tests.			
	long	Option for a longer, more comprehensive series of both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ² Examples: test tone-clock 01a l test tone-clock 01b l schedule			

1. If no alarms are registered against the maintenance object then the test sequence is run only once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The responses display on a test-by-test basis with one line of data for each test result. The following is the output for the **test tone-clock 1a** command.

test tone-clock 1a

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01A	TONE-BD		46	PASS	
01A	TONE-BD		52	PASS	
01A	TONE-PT		40	PASS	
01A	TONE-PT		41	PASS	
01A	TDM-CLK		148	PASS	
01A	TDM-CLK		149	PASS	
01A	TDM-CLK		150	PASS	
01A	TDM-CLK		151	PASS	
01A	TDM-CLK		574	PASS	

Command Successfully Completed

Field descriptions

Port	The port address: cabinet-carrier-slot-circuit
Maintenance Name	Maintenance object name: TONE-BD, TONE-PT, and TDM-CLK.
Alt. Name	Not applicable.
Test No	Test being executed
Result	Test result: PASS, ABORT, FAIL, NO BOARD, DISABLED, EXTRA BD.
Error Code	Numeric code explaining why the release failed or aborted. Refer to the detailed list of the codes by test number for each MO.

test trunk

This command performs hardware diagnostic tests on an entire trunk group or an individual trunk group member, depending on the options entered.

Action/ Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test trunk	group number	Administered group number (1-99)	init inads craft cust	Test Seq. = short; Repeat = 1	none
	member number	Administered number identifying a particular trunk within a trunk group (1-99).			
	short	Command executes a series of nondestructive diagnostic tests.			
	long	Command executes a more comprehensive and longer version of the both destructive and nondestructive diagnostic tests.			
	repeat number	How many times each test in the sequence is repeated (1-100)			
	clear	This option causes the test sequence (short or long) to repeat until the alarm (if any) is cleared or a single test in the sequence fails. ¹			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ²			
		Examples: test trunk 78 l test trunk 80/1 sh r 2 test trunk 78/2 l r 25 test trunk 78/2 l r 25 schedule test trunk 80 test trunk 80 schedule test trunk 78 r 4 test trunk 78 c			

1. If no alarms are registered against the maintenance object then the test sequence exercises once. The **long clear** option forces a clear of all alarms if no errors are encountered during testing. The **short clear** option only clears alarms pertinent to tests in the short sequence.
2. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The responses display on a test-by-test basis with one line of data for each test result. The following screen is an example of the output for the **test trunk 78** command.

test trunk 78

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
01C1505	CO-TRK	078/001	3	PASS	
01C1505	CO-TRK	078/001	36	PASS	

Command Successfully Completed

Field descriptions

Port	The port address: cabinet-carrier-slot-circuit
Maintenance Name	The name of maintenance object being tested.
Alt. Name	The alternate means of identifying the maintenance object. If the object is a trunk, the field contains xxx/yyy (where xxx = trunk group number, yyy = member number). If the object is a private CO line, the field contains P/xxx (where xxx = private CO line group number).
Test No	The test number being executed
Result	The result of the individual test: PASS, ABORT, FAIL, NO BOARD, DISABLED, and EXTRA BD.
Error Code	A system-generated number indicating the reason that the test for the named MO failed or aborted.

test tsc-administered

This command submits a switched services request to run the Temporary Signaling Connection’s heartbeat test for all administered TSCs on a signaling group.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
test tsc-administered	signaling group number/	Signaling group number (1–8)	init inads craft	repeat = 1	Additional data available after running the test. See status tsc-administered for how to access additional data.
	tsc index	The number associated with each TSC in a signaling group.			
	repeat number	The number of times each test in sequence is repeated.			
	schedule	Command is validated and then a scheduling form displays to schedule execution of the command. The command is then placed in the command queue and is executed at the specified time. The information displayed by the command is sent to the system printer instead of the screen. ¹			

1. Refer to the Report Scheduler and System Printer feature specification for more details.

Output

The following is an example of the output from the **test tsc-administered 1/1** command. The responses display on a test-by-test basis with one line of data for each test result.

```
test tsc-administered 1/1

                                TEST RESULTS

Port      Maintenance Name  Alt. Name  Test No.  Result      Error Code
1/1       TSC-ADM              604       PASS

Command Successfully Completed
```

Field descriptions

- Port

Port address of the administered temporary signaling connection
(format = *signaling group no./tsc index*)
- Maintenance Name

The name of the maintenance object
- Alt. Name

Not applicable
- Test No.

The test number being executed

Result

Test result: Pass, Abort, Fail, No Board, Disabled, or Extra Bd.

Error Code

A system-generated number indicating the reason that the test for the named MO failed or aborted.

upgrade software

This command upgrades the software text image, the flash component of the LMM firmware, the MTP firmware, the Packet Control (PACCON), and the Processor Interface (PI) firmwares. Depending on whether the system is simplex (Standard reliability) or Duplex (High or Critical reliability), the processes for the upgrade are different:

System	Description of Upgrade
Simplex (Standard reliability)	The command verifies that a software card-mem is present and then, if present, proceeds to reprogram the flash memory and perform a level-4 restart. During the restart of the system, the system technician is prompted to replace the software card-mem with the translation card-mem. Service is provided upon completion of the system restart. Service down time is 5-12 minutes.
Duplex (High or Critical reliability)	The command verifies that a software card-mem is present in the standby SPE, programs the flash memory, resets the standby SPE, and prompts the system technician to replace the software card-mem with the translation card-mem. An interchange of SPEs is performed upon completion of a successful standby upgrade. At the same time, the old active SPE is upgraded automatically with the new software through similar swapping of card-mems. The service disruption time is 1-4 minutes.

 **WARNING:**

Be sure to save translations before this executing this command. It may also be helpful to read the Feature Interactions for this command before upgrading the system software.

Action/Object	Qualifier	Qualifier Description	Permissions	Defaults	Feature Interactions
upgrade software	none		init inads craft	none	See below

Feature Interactions

System Restarts

An upgrade causes a system restart: simplex systems perform a Level-4 restart, and duplex systems perform a Level-2 SPE-interchange after the standby is upgraded through a Level-4 restart.

Initcauses

Executing **display initcauses** shows the software upgrade and the system reset level.

Multi-User Contention

When this command is executing, all other maintenance commands are blocked. Exceptions to these are most of the status or display commands. All administration commands are not blocked. It is the user's responsibility to make sure that no new translations are added between the last **save translation** operation and the completion of the **upgrade software** command.

Recent Change History Log

The **upgrade software** command does not log for both simplex and duplex systems. This is due to the clearing of memory during the level 4 reset.

Periodic and Scheduled Maintenance

Periodic and scheduled maintenance is suspended during the upgrade.

Error and Alarm Log

Error and alarm logs before the software upgrade are lost.

Demand Busyout Objects

Maintenance objects that have been demand busyout are released when the processor reboots or interchanges during the software upgrade. If the command is cancelled before the actual reboot or interchange starts, then all demand busyout objects status are preserved.

Data Consistency between SPEs

Data consistency alarms are generated if the software in the active and standby SPE are not consistent.

Disabled Objects

All disabled objects retain their “disabled” status after a software upgrade according to the status recorded in the last **save translation** command.

Output

The following is the output from the **upgrade software** command and a successful simplex upgrade.

```
INITIATING SOFTWARE UPGRADE
MEM-CARD CHECKSUM          PASSED
REPROGRAMMING MTP          PASSED
ERASING MEMORY             PASSED
REPROGRAMMING SPE          PASSED
FLASH TEXT CHECKSUM        PASSED
UPGRADE COMPLETE
<beep>
REPLACE SOFTWARE MEM-CARD WITH TRANSLATION MEM-CARD
<beep>
```

Explanations and error recoveries to the above steps follow:

INITIATING SOFTWARE UPGRADE:	The system is upgrading the software.
MEM-CARD CHECKSUM:	If the card-mem checksum fails, the system reboots without performing the upgrade. Retry the command with another software card-mem.
REPROGRAMMING MTP:	If the MTP programming fails, the Manager I does not function anymore, meaning that the rest of the upgrade (if it occurs) are not visible and the MTP will not be present to monitor the health of the processor. The only recovery procedure is to power down and power up the system, since the presence of a software card-mem will cause a software upgrade.
ERASING MEMORY:	The rest of the memory is being erased.
REPROGRAMMING SPE:	This shows the status of the reprogramming. A total of 7 Mbytes has to be reprogrammed. If the reprogramming fails in the midst of upgrade, it will take the system into <i>SPE-down</i> mode. In this mode, the system technician can only reset the system or display alarms. The system should be reset and another upgrade attempted due to the detection of a software card-mem in the system.

FLASH TEXT CHECKSUM:	If the checksum fails, the software may or may not be healthy, but it will try to run for as long as it can until further system reset through system technician intervention.
REPLACE SOFTWARE MEM-CARD WITH TRANSLATION MEM-CARD:	The system technician is prompted by a beep and this text string on the Manager I to replace the software card-mem with the translation card-mem. The system boots without translation if the replacement is not done within 2 minutes. The only way to recover from this is to replace the card-mem and issue a <i>reset system 3</i> to read in the translations again.
UPGRADE COMPLETE:	The software upgrade is complete.

Packet Bus Fault Isolation and Correction

9

General

This chapter describes the fault isolation/correction procedures for the Packet Bus and for the various MOs that use the Packet Bus. Because the Packet Bus is shared by all circuit packs that must communicate on it, a faulty circuit pack can disrupt communication over the Packet Bus. In addition, a circuit pack that does not use the Packet Bus can cause service disruptions if the physical configuration of the switch is being modified (this is discussed in more detail later). For these reasons, isolating the cause of Packet Bus failure can be complicated. In this chapter, a flowchart is provided to aid in this isolation effort, as are detailed discussions of the tools and procedures used in the fault isolation and correction.

This chapter is organized into several sections that provide introductory information, as well as packet bus fault isolation and correction procedures. The sections of the chapter are as follows:

- [“Remote Maintenance versus On-Site Maintenance”](#) discusses the strategy and the requirements for performing remote maintenance and on-site maintenance for the Packet Bus.
- [“Tools for Packet Bus Fault Isolation and Correction”](#) discusses the tools that are needed to isolate and correct Packet Bus faults.
- [“Packet Bus”](#) describes the Packet Bus, its use, and the types of faults that can occur on the Packet Bus. A diagram that shows the physical and logical connections between circuit packs connected to the Packet Bus is also included.

- [“Circuit Packs That Use the Packet Bus”](#) describes the various circuit packs, ports, and endpoints that use the Packet Bus. The section discusses how these maintenance objects interact, how a failure of one maintenance object can affect another, and also the failure symptoms of these maintenance objects.
- [“Maintenance of the Packet Bus”](#) describes the Packet Bus maintenance software strategy. Similarities and differences between the Packet Bus and the TDM Bus are discussed. An overview of the Fault Isolation and Correction Procedures is also presented.
- [“The Maintenance/Test Circuit Pack \(TN771D\)”](#) discusses the use of the Maintenance/Test circuit pack in normal switch maintenance, as well as its role in Packet Bus fault isolation. The standalone mode of the Maintenance/Test (which is used to perform the Packet Bus Fault Isolation and Correction procedures on-site) is discussed in detail.
- [“Packet Bus Fault Isolation Flowchart”](#) presents a flowchart that is used to isolate a Packet Bus problem. This flowchart is the starting point for this process, and it is used to determine if a failure of service is caused by the Packet Bus itself or by another maintenance object on the Packet Bus.
- [“Packet Bus Fault Correction”](#) presents the procedures required to correct either a problem with the Packet Bus itself or one that is caused by a circuit pack connected to the Packet Bus.

The Packet Bus Fault Isolation Flowchart is intended to be the normal starting point for isolating and resolving Packet Bus problems. However, anyone who is unfamiliar with Packet Bus maintenance should read the introductory sections to gain a good understanding of the Packet Bus maintenance and the procedures involved.

Remote Maintenance versus On-Site Maintenance

Most packet bus fault isolation and repair procedures require a technician to be on-site. This is true because a packet bus failure is caused by a hardware failure of the packet bus itself or by a circuit pack that is connected to it. However, initial diagnoses can be made via use of the flowchart presented in the [“Packet Bus Fault Isolation Flowchart”](#) section of this chapter. However, before implementing the Maintenance/Test Standalone Mode Procedure (described later) and the Packet Bus Fault Correction Procedure, a technician must be on-site.

The flowchart as presented refers to the repair procedures in [Chapter 10, “Maintenance Object Repair Procedures”](#), for various MOs. When one of the decision points is reached, a remote technician can refer to the appropriate section and attempt to resolve any fault conditions. In addition, the remote technician can examine some of the other MOs on the flowchart. Keep in mind that if an MO that appears early on the flowchart fails, this failure can cause alarms with MOs that appear later in the flowchart.

The Maintenance/Test Packet Bus port (described in detail later in this chapter) can give the remote technician information about the state of the packet bus. This information can be obtained via the **status system** command and via the PKT-BUS test sequence. As described later, the Maintenance/Test circuit pack may or may not be present at a customer site, depending on system configuration. If a Maintenance/Test circuit pack is not present, one must be taken to the customer site.

In a high or critical reliability system, a Processor Interchange may resolve the packet bus problem. This operation can be done remotely, and is discussed in the [“Packet Bus Fault Correction”](#) section in this chapter.

Tools for Packet Bus Fault Isolation and Correction

The following list discusses several tools that are (or may be) required to perform Packet Bus Fault Isolation and Correction. The technician should be provided with these tools at the customer site:

- TN771 Maintenance/Test circuit pack for use in standalone mode, as well as the required connectors and cables. (Refer to the [“The Maintenance/Test Circuit Pack \(TN771D\)”](#) section in this chapter.)
- Replacement TN771 Maintenance/Test circuit pack may be needed. Conditions for requirement, and the relevant implementation steps are documented in the [“Special Precaution Concerning the TN771”](#) section in this chapter.
- Backplane pin-replacement kit may be required in the procedures described in the [“Packet Bus Fault Correction”](#) section of this chapter. If the kit is not available, replacement of a carrier may be required.

Packet Bus

Each port network has its own packet bus, and, accordingly, there is one packet bus MO in each port network. The packet bus is not duplicated, as is the TDM Bus. However, there are several spare leads on the packet bus and, in high and critical reliability systems, these spare leads are used to recover from some failures on the packet bus.

Packet Bus Usage

The packet bus carries ISDN-BRI signaling information for ISDN-BRI stations and data modules and for ASAI adjunct connections. The TN556 ISDN-BRI circuit pack is used for these connections. The SPE interface to the packet bus is the TN778 Packet Control (in high and critical reliability systems, there is one TN778 in each SPE). For systems with multiple port networks, the TN570 Expansion Interface is used to pass messages from the packet bus in one port network to

the packet bus in its neighbor. The TN771 Maintenance/Test Circuit Pack (discussed in detail later) provides packet bus maintenance testing and reconfiguration capabilities.

Packet Bus Faults

Two types of packet bus failures can occur:

- **Shorts.** A short occurs when leads on the packet bus become connected together. Such a connection can occur due to component failures on the packet bus interface of a circuit pack, a failure of the cables between carriers or the TDM/LAN terminators, or by pins being bent together on the backplane. Usually, a failure that occurs during normal operation is caused by a circuit pack failure. However, if the system configuration is being modified (for example, circuit packs are being moved), the cause of a subsequent packet bus failure is probably bent pins.
- **Opens.** An open occurs when there is a break on the packet bus such that the electrical path to the termination resistors is broken. Usually, this break is caused by a failed TDM/LAN cable or by a failed TDM/LAN terminator. The break can also be caused by a failure in the backplane of a carrier, although this is unlikely.

Shorts on the packet bus occur much more often than do opens. This is because the incorrect insertion of a circuit pack can cause leads to be shorted together. It is possible for a circuit pack to be the cause of a packet bus fault but still exhibit trouble-free operation. For example, the insertion of a TDM-only circuit pack (TN754B Digital Line) could bend the packet bus pins on the backplane. However, since the circuit pack does not communicate on the packet bus, the pack is not affected by the problem.

Packet bus faults do not necessarily cause service interruptions. However, most packet bus shorts do cause these interruptions. Depending on what leads are defective, the system may be able to recover and continue to communicate. This can be detrimental because it makes isolating the fault difficult. The Maintenance/Test circuit pack provides the capability to detect, and, in some cases, correct packet bus faults.

Packet Bus Connectivity

Various circuit packs communicate on the packet bus (see next section).

For details on ISDN-BRI and ASAI connectivity, refer to “BRI-PORT” and “BRI-SET/ASAI-ADJ” in [Chapter 10, “Maintenance Object Repair Procedures”](#). For details on Expansion Interface connectivity, refer to “EXP-INTF”.

Circuit Packs That Use the Packet Bus

Four circuit packs can use the packet bus. The following list identifies and discusses each circuit pack. An explanation of how each circuit pack assists in packet bus maintenance is also included.

⇒ NOTE:

The MOs involved with each circuit pack are listed in brackets. Documentation for each maintenance object is provided in [Chapter 10, "Maintenance Object Repair Procedures"](#).

- **TN778 Packet Control** [PKT-CTRL] provides the SPE interface to the packet bus, just as the TN777 Network Control does to the TDM Bus. All traffic on the packet bus passes through the packet control.

The packet control can detect failures of certain control leads on the bus. Such failures are indicated by an inability to transmit data. The packet control can also detect data errors on the packet bus.
- **TN570 Expansion Interface** [EXP-INTF] is used to connect the PNs in the system. For systems that use the packet bus, all Port Network connections must be made with TN570 circuit packs. All packet traffic between PNs passes through a pair of TN570s (one in each port network).

The Expansion Interface can detect a subset of control lead failures (though not as many as the packet control), and it can detect many data lead failures via parity errors on received data.
- **TN556, TN2198 and TN2208 ISDN-BRI circuit packs** [BRI-BD, BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, ASAI-ADJ] provides connections for ISDN-BRI station sets and data modules and for ASAI adjuncts. The Packet Bus is used to carry signaling information for sets and data modules. The Packet Bus passes signaling information and ASAI messages between the SPE and the ASAI adjunct. The ISDN-BRI circuit pack has the same fault detection capabilities as the TN570 Expansion Interface.
- **TN771D (or later) Maintenance/Test circuit pack** is the workhorse of packet bus maintenance. This circuit pack can detect all packet bus failures for the PN in which it resides. In High and Critical Reliability systems, the circuit pack enables the reconfiguring of the packet bus around a small number of failed leads. The TN771D circuit pack provides a standalone mode (that is, one that does not involve communication with the SPE) for inspecting the packet bus for faults. This is a critical tool for the packet bus fault correction procedures, which are described later.

Effect of Circuit Pack Failures on the Packet Bus

A failure of any of the circuit packs described in the previous section can disrupt traffic on the Packet Bus. Some failures cause actual Packet Bus failures with corresponding alarms, while others cause service outages without alarming the Packet Bus (although the failed circuit pack(s) should be alarmed).

The following list discusses the effects on the Packet Bus of a failure on each circuit pack that uses the Packet Bus.

- **TN778 Packet Control.** A failure of the Packet Control typically causes all Packet traffic in the system to fail. As a result, ISDN-BRI sets are not able to make or receive calls, and communication with an ASAI adjunct fails. A failure of the Packet Control may also cause a failure of the Packet Bus itself if the failure is on the interface circuitry. Otherwise, only the Packet Control is alarmed.

In a High or Critical Reliability system, there is one TN778 Packet Control in each SPE. If a Packet Control failure in the active SPE causes a Packet Bus disruption, performing an SPE interchange may restore service. In some cases, circuit pack failures may require that the circuit pack be replaced before service is restored.

- **TN570 Expansion Interface.** A failure of the Expansion Interface typically causes all Packet traffic in the connected EPN to fail. If the failure is on the Packet Bus interface, the Packet Bus may be alarmed as well.

In a High or Critical Reliability system, there is one EPN link in each control carrier for each EPN. If an active Expansion Interface failure causes a Packet Bus disruption, performing an Expansion Link switch may restore service. In some cases, circuit pack failures may require that the circuit pack be replaced before service is restored.

- **TN556 ISDN-BRI Circuit Pack.** A failure of the ISDN-BRI circuit pack typically causes some or all ISDN-BRI sets and data modules and/or an ASAI adjunct connected to the circuit pack to fail to function. If the failure is on the Packet Bus interface, the Packet Bus may be alarmed as well.
- **TN771 Maintenance/Test.** A failure of the Maintenance/Test may cause an incorrect indication of a packet bus failure or the inability to detect such a failure. A failure of the packet bus interface of the circuit pack may cause the packet bus to be alarmed.

A failure of the packet bus interface on any of the circuit packs discussed can cause the packet bus to be alarmed. This is true because such a failure may result in shorting packet bus leads together. This typically disrupts ALL packet bus traffic in the affected port network. A failure of the packet bus in the PPN affects packet traffic in the EPNs as well. Also, packet bus failures that do not affect all endpoints on that packet bus may occur. Therefore, a packet bus failure should not be ruled out even if some packet service is still present.

A circuit pack can fail in a manner such that it transmits bad data on the Packet Bus. If the Packet Control fails in such a fashion, all Packet traffic is disrupted (because all traffic requires the Packet Control). Likewise, such a failure on the Expansion Interface may disrupt all Packet traffic in that port network.

However, if an ISDN-BRI circuit pack fails such that it transmits bad data, all devices connected to the circuit pack fail to function. This failure may also disrupt the entire Packet Bus whenever the circuit pack tries to transmit data. Such a disruption may be indicated by Packet Bus alarms that occur and go away, intermittent failures of other Packet circuit packs, and/or interference with other connected endpoints. The failures mentioned are difficult to isolate because of their intermittent nature. In most cases, the failed circuit pack is usually alarmed, and all connected endpoints on the circuit pack are out of service until the circuit pack is replaced. These symptoms help in isolating the fault.

Maintenance of the Packet Bus

The following topics are discussed:

- Comparison between the Packet Bus and the TDM Bus
- Packet Bus Maintenance Software
- Overview of Fault Correction Procedures

Packet Bus and TDM Bus: a Comparison

Although the Packet Bus is similar to the TDM Bus in many ways, there are some important differences. For example, there are two physical TDM Busses in the switch (refer to the TDM-BUS section in [Chapter 10, "Maintenance Object Repair Procedures"](#), for more information), and one of these busses can fail without affecting the other (although half of the call-carrying capacity is lost in this case). On the other hand, there is only a single Packet Bus in the switch, and a failure of that bus can disrupt all traffic on the Packet Bus.

In High or Critical Reliability systems, the Maintenance/Test circuit pack provides Packet Bus reconfiguration capabilities. This allows the Packet Bus to remain in service with up to three lead failures. There is no corresponding facility on the TDM Bus, where the second physical TDM Bus continues to carry traffic until repairs are completed.

In addition, the system response varies according to the type of bus failure. Specifically, a catastrophic TDM Bus failure (one that affects both TDM Buses) disables ALL traffic in the system, while a catastrophic Packet Bus failure affects only Packet traffic. This means that all TDM traffic is unaffected, while all BRI and ASAI traffic does not work. The significance of this distinction depends on the customer's application. (For example, a customer whose primary application requires ASAI would consider the switch to be out of service, while a customer

with a large number of Digital/Analog/Hybrid sets and a small number of ISDN-BRI sets would probably not consider the Packet Bus failure a catastrophic problem.) The only way a Packet Bus failure can affect TDM traffic is via possible impact on system response time in a large switch due to ISDN-BRI endpoint maintenance running. This should rarely happen because the Packet Bus maintenance software is able to prevent this impact for most Packet Bus faults (see the next section).

**CAUTION:**

Since the correction procedures and some of the fault isolation procedures for the Packet Bus are highly destructive to service throughout the system (inasmuch as the procedures primarily involve removing circuit packs), particular attention must be paid to nondestructive fault isolation. Also, for the same reason, the time taken with destructive procedures must be minimized. This is the major reason that maintenance of the Packet Bus and of the Packet maintenance objects is described in such detail.

Packet Bus Maintenance Software

Packet Bus maintenance software involves the traditional set of error conditions, tests, and alarms relevant to Packet Bus faults. These are described in the PKT-BUS section in [Chapter 10, “Maintenance Object Repair Procedures”](#), and they are similar in design to the maintenance strategy for most maintenance objects.

In addition, because a Packet Bus failure can cause all BRI/ASAI endpoints in the affected Port Network (and their associated ports and circuit packs) to report failures, special care must be taken to ensure that the flood of error messages from the affected maintenance objects does not overload the system and interfere with TDM Bus traffic. When such a failure occurs, maintenance of Packet circuit packs is affected in the following manner:

- ISDN-BRI circuit pack (BRI-BD) in-line errors indicating possible Packet Bus failures are placed into the error log, but are not acted upon.
- ISDN-BRI port (BRI-PORT, ABRI-PORT) in-line errors indicating possible Packet Bus failures **are neither placed into the error log nor acted upon.**
- ISDN-BRI endpoint (BRI-SET, BRI-DAT, ASAI-ADJ) in-line error **are neither placed into the error log nor acted upon.**
- Circuit pack and port in-line errors that are not related to the Packet Bus, or that indicate a circuit pack failure, are acted upon in the normal fashion.
- Normal background maintenance (periodic and scheduled) is not affected.
- Foreground maintenance (for example, commands executed on the Manager I terminal) are not affected.

These interactions allow normal, non-Packet, system traffic to continue unaffected, and they reduce the number of extraneous entries into the Error/Alarm Logs. If the Packet Bus failure is caused by a failed circuit pack, the circuit pack should appear in the Error/Alarm Logs, which aids in fault isolation.

The following events indicate a Packet Bus failure that requires the actions in the previous paragraph to occur:

- In-line errors that indicate a possible Packet Bus failure reported by two or more Packet circuit packs
- Packet Bus Uncorrectable report from the Maintenance/Test Packet Bus port (M/T-PKT)
- Packet Bus Interface Failure from the Packet Control (PKT-CTRL)

If such a failure occurs, this information will be available in an Error Log entry for PKT-BUS. Refer to the PKT-BUS section in [Chapter 10, "Maintenance Object Repair Procedures"](#), for more detailed information.

Overview of Fault Correction Procedures

This section gives an overview of the procedures used to (1) isolate the cause of Packet Bus faults and to (2) correct the Packet Bus faults. These procedures are applicable to High and Critical Reliability systems, and they are detailed fully later in this chapter:

1. The first procedure attempts to determine if a circuit pack that interfaces to the Packet Bus is the cause of the Packet Bus problem. The error and alarm logs are examined for entries for these circuit packs, and the normal maintenance procedures for those circuit packs are attempted.
2. If the Packet Bus problem still exists, port circuit packs (those in the purple slots) are removed to look for circuit pack(s) that have failed and/or have damaged the Packet Bus pins (a diagram of the backplane pins is provided later).
3. If the Packet Bus problem is still not resolved, the same procedure is attempted for the control complex circuit packs.
4. If the problem is still not resolved, or if the Packet Bus faults are known to have open leads, a procedure is undertaken in which the bus terminators and cables are replaced. If this does not resolve the problem, the carrier connectivity of the port network is reconfigured to attempt to isolate a faulty carrier.

The Maintenance/Test Circuit Pack (TN771D)

Description

Packet bus reconfiguration is available only in high and critical reliability systems. In such systems that use the packet bus, a Maintenance/Test is required in each port network. In other configurations (for example, Standard Systems, no packet bus use), the circuit pack is optional.

CAUTION:

All TN771 circuit packs must be of TN771D vintage or later.

Normal Packet Functionality

The Maintenance/Test Packet Bus Port provides the packet bus testing and reconfiguration capabilities. When the port is in service, the port continuously monitors the packet bus for faults (or recovery from faults), and it reports this information to packet bus maintenance.

The yellow LED on the TN771D Maintenance/Test circuit pack provides a visual indication of the state of the packet bus, as follows:

- **Blinking** at a rate of 1 per sec — the Maintenance/Test Packet Bus port cannot swap leads to correct a Packet Bus fault (that is, there are too many faults). **The Packet Bus may be unusable.** If the failures detected by the Maintenance/Test Packet Bus port are open lead failures, the Packet Bus may still be operating.
- **On steady** — the Maintenance/Test Packet Bus port has swapped leads on the Packet Bus. **The Packet Bus is still operating.**

NOTE:

Because the yellow LED on the Maintenance/Test circuit pack can also be on steady when the other ports on the circuit pack are in use, the ports on the Maintenance/Test circuit pack used for ISDN-PRI trunk testing must be busied out before the Maintenance/Test circuit pack is used to help resolve Packet Bus faults. This is done via the **busyout port PCSS02** and **busyout port PCSS03** commands.

Also, be sure to release these ports when the process is completed.

- **Off** — there is no Packet Bus fault present.

NOTE:

It takes 5 to 10 seconds for the LED to respond to a change in the state of the Packet Bus.

In normal switch operation, the Maintenance/Test provides the visual feedback of the Packet Bus state. When standalone mode (described in the next section) is in effect, these visual indications are still provided; however, the Packet Bus is never reconfigured, and, as a result, the yellow LED either blinks or is off.

Standalone Mode

The TN771D Maintenance/Test provides a standalone mode for detecting Packet Bus faults. In the standalone mode, a terminal is connected to the Maintenance/Test circuit pack via the Amphenol™ connector on the back of the cabinet. This setup allows the System Technician to determine the state of the Packet Bus without having to access the Manager I terminal to provide these functions, even if the switch is not in service. Note that the Maintenance/Test does not reconfigure the Packet Bus when it is operating in standalone mode.

Standalone mode is used in the Packet Bus Fault Correction procedures. As a result, **a TN771 and a corresponding terminal must be available to the technician who is to perform such procedures.** A High or Critical Reliability system has a TN771 in each port network. However, the customer of a system that does not have High or Critical Reliability may have purchased a TN771 for ISDN-PRI trunk testing, or to increase the system's ability to detect Packet Bus failures.

The **list configuration** command is used to check for the presence of a circuit pack in the system. If a circuit pack is not present in the system, one must be taken to the customer site. The [“Special Precaution Concerning the TN771”](#) section in this chapter discusses the special cases when a spare TN771 must be taken to the customer site.

NOTE:

When in standalone mode, the yellow LED on the TN771 blinks if there is a Packet Bus fault. If there is no such fault, the yellow LED is off. This is true because Packet Bus reconfiguration cannot occur in standalone mode.

Required Hardware for Standalone Mode

In addition to the TN771, the following equipment is required to use the standalone mode:

1. Terminal or PC with terminal-emulation software. The EIA-232 (RS-232) port should be configured at 1200 baud, no parity, 8 data bits, and one stop bit. This is **not** the same configuration as for the Manager I terminal. Therefore, if the Manager I can be used for this operation (and this depends on the switch configuration and on customer requirements), remember to restore the original communication parameters before returning the Manager I to service.
2. 355A EIA-232 Adapter (COMCODE 105 012 637).
3. 258B Six-Port Male Amphenol Adapter (COMCODE 103 923 025).

4. D8W 8-wire modular cable of an appropriate length to connect the 258A on the back of the cabinet to the 355A adapter. The relevant COMCODE is determined by the length of the cable, as follows:
 - 103 786 786 (7 feet)
 - 103 786 802 (14 feet)
 - 103 786 828 (25 feet)
 - 103 866 109 (50 feet)

Slot Selection for Standalone Mode

When selecting a carrier slot to use for standalone mode in a port network that does not already contain a TN771, keep the following points in mind:

- A port circuit slot (indicated by a purple label) should be used.
- -5 volt power supply must be available in the carrier. This section describes the power supply configurations that provide this power supply.
- It is preferable that the slot chosen is in the A carrier if a free slot that matches the criteria presented in the first two items of information in this list is available.

Entering and Exiting Standalone Mode

NOTE:

When in standalone mode, the red LED on the TN771 is lit. This function is correct, and it serves as a reminder to remove the TN771 from standalone mode.

CAUTION:

The TN771 in standalone must be the ONLY TN771 in the port network. If a TN771 is already in the port network, place that TN771 in standalone mode. Do not insert a second TN771 into standalone mode. System behavior is rendered as undefined if this is done. In addition, the system is not able to detect the extra circuit pack in this case because a TN771 in standalone mode is invisible to the SPE.

CAUTION:

If the TN771 Packet Bus port has reconfigured the Packet Bus in a switch with a High or Critical Reliability system, (indicated by error type 2049 against PKT-BUS), placing the Maintenance/Test in standalone mode causes a loss of service to the Packet Bus. This is true because reconfiguration is not performed in standalone mode. Therefore, this procedure should be considered a service-disrupting procedure.

If the system has a TN771 installed in the Port Network to be examined, use the following steps to enter the standalone mode:

1. Ensure that Alarm Origination is suppressed either at login time or via the Maintenance-Related System Parameters form.
2. Attach the 258B Six-Port Male Amphenol Adapter to the Amphenol connector for the TN771's slot. Connect one end of a D8W 8-wire modular cable to port 1 of the 258B. Connect the other end of the cable to a 355A EIA-232 Adapter. Plug the EIA-232 Adapter into the terminal to be used, and turn the terminal on.
3. Reseat the TN771 circuit pack.

 NOTE:

In a High or Critical Reliability system, this causes a Minor, Off-board alarm to be raised against the Packet Bus. This alarm is not resolved until the TN771 (in particular, the Packet Bus port is returned to service. To ensure that Packet Bus alarms have been cleared, it may be necessary to restore the TN771 to normal mode.

If there is no TN771 in the Port Network, use the following steps to enter the standalone mode:

1. Attach the 258A Six-Port Male Amphenol Adapter to the Amphenol connector for the slot into which the TN771 is to be inserted. Connect one end of a D8W 8-wire modular cable to port 1 of the 258A. Connect the other end of the cable to a 355A EIA-232 Adapter. Plug the EIA-232 Adapter into the terminal to be used, and turn the terminal on.
2. Insert the TN771 circuit pack into the slot. The system does not recognize the presence of the circuit pack.

If the standalone mode is entered successfully, the following is displayed on the connected terminal:

Figure 9-1. Normal Standalone Mode Display

CAUTION:

If the display in [Figure 9-1](#) does not appear, be sure to check the wiring between the terminal and the TN771, and also the terminal parameters. If these are correct, the TN771 may be defective. In such a case, follow the procedures to exit standalone mode (described in the next paragraph). Then test the Maintenance/Test circuit pack.

NOTE:

If the TN771 fails while in standalone mode, the message TN771 circuit pack failed is displayed, and no further input is accepted on the terminal. The circuit pack must be replaced.

Use the following procedures to exit standalone mode:

1. Remove the 258A Adapter from the Amphenol connector.
2. If the TN771 was installed for this procedure, remove it. Otherwise, reseal the TN771.
3. Be sure that alarm origination is re-enabled on the Maintenance-Related System Parameters form if it was disabled there (if it was disabled at login, it is automatically re-enabled at logoff).

Using Standalone Mode in Packet Bus Fault Isolation and Correction

When the TN771 is in standalone mode, three commands can be used at the terminal:

- **ds** displays the current state of the Packet Bus leads.
- **dsa** toggles auto-report mode on and off. In auto-report mode, the state of the Packet Bus leads are displayed and the terminal beeps whenever a change occurs.
- **?** displays the available commands.

[Figure 9-2](#) presents an example of a standalone mode display. In the display, an 'S' indicates a shorted lead, an 'O' indicates an open lead, and a blank indicates no fault.

L	L	L	L	L	L	L	L	L	L	H	H	H	H	H	H	H	H	H	S	S	S	L	
P	0	1	2	3	4	5	6	7	8	P	0	1	2	3	4	5	6	7	8	S	F	B	F
S	S																O						

Command:

Figure 9-2. Example Standalone Mode Display

The information within a standalone mode display is used in the Packet Bus Fault Correction procedures that follow. The TN771 display indicates the specific leads on the backplane to examine for bent or damaged pins. [Figure 9-3](#) shows the location of the packet bus leads on the backplane as viewed from the front of the carrier, while [Figure 9-4](#) shows the same slot as viewed from the back of the carrier.

 **NOTE:**
This information is available only from the standalone mode and with an on-site connected terminal. This information is not available from the Manager I, and, thus, it is not available remotely. This is not a concern, inasmuch as this information cannot be used effectively if testing is not on site.

Figure 9-3. Packet Bus Leads on the Backplane - Front View

Figure 9-4. Packet Bus Leads on the Backplane - Back View

Special Precaution Concerning the TN771

⇒ NOTE:

A new TN771 Maintenance/Test circuit pack must be taken to the customer site whenever the following is true:

- Maintenance/Test Packet Bus port indicates that a Packet Bus fault is present.

⇒ NOTE:

Such a fault is indicated by a Major or Minor alarm against the Packet Bus. A Major alarm is indicated in the error log by Error Type 513, while a Minor alarm is indicated by Error Type 2049.

- Test #572 of the PKT-BUS test sequence is the only test that fails.

This precaution is taken because certain failures of the Maintenance/Test circuit pack can appear as Packet Bus failures. To ensure that the problem is indeed with the Packet Bus, implement the following steps:

1. Refer to the M/T-PKT Maintenance documentation in [Chapter 10, "Maintenance Object Repair Procedures"](#). Correct any problems with the TN771 Maintenance/Test Packet Bus port as described in that section. If the TN771 Maintenance/Test circuit pack is replaced during the correction process, enter the **test pkt P long** command to determine if the Packet Bus faults have been resolved. If there are still Packet Bus problems, correct them by using the procedures in the sections that follow.
2. If the Maintenance/Test circuit pack was not replaced, enter the **test pkt P** command. Record the results (PASS/FAIL/ABORT) and error codes for Test #572.
3. Enter the **status system P** command. Record the information listed for the Packet Bus.
4. Busyout the Maintenance/Test circuit pack by entering the **busyout board PCSS** command.
5. Replace the Maintenance/Test circuit pack with the new circuit pack.
6. Release the Maintenance/Test circuit pack by entering the **release board PCSS** command.
7. Enter the **test pkt P** and **status system P** commands as described in Steps 2 and 3.

8. If the data matches the previously recorded data, a Packet Bus problem exists. The original TN771 Maintenance/Test circuit pack is not defective, and it does not need to be returned to the factory. Replace the original TN771, then correct the Packet Bus problem by using the procedures in the sections that follow.
9. If the data does *not* match the previously recorded data, *the original TN771 Maintenance/Test circuit pack is defective*. If there are still indications of Packet Bus problems, correct them by using the procedures in the sections that follow.

Packet Bus Fault Isolation Flowchart

The flowchart in this section presents the steps to be taken for isolating and resolving Packet Bus problems. The order in which the maintenance objects should be examined can be determined by assessing how wide-spread the failure is. For example, since all ISDN-BRI devices communicate with the TN778 Packet Control circuit pack, this MO should be examined early in the sequence. On the other hand, a failure of a TN570 circuit pack in an EPN may cause ISDN-BRI failure in an EPN, but it could not be the cause of a failure in the PPN.

Whenever the flowchart refers to the Maintenance documentation for a specific MO, keep in mind that the repair procedure for that MO may in turn refer to another MO's repair procedure. The flowchart tries to coordinate these procedures so that a logical flow is maintained if the Packet Bus problems are not resolved via the first set of repair procedures. However, a Packet Bus failure can lead to a somewhat haphazard referencing of various MO procedures that may result in your implementing steps that either have already been completed or are not necessary. If this occurs, return to the flowchart at the step that follows the reference to [Chapter 10, "Maintenance Object Repair Procedures"](#), and then continue.

NOTE:

The following **status** commands can also help diagnose Packet Bus problems:

- **status system**
- **status packet-control**
- **status bri-port**
- **status station**
- **status data-module**

For a description of these commands, refer to the "Status Commands" section in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#). The commands provide information about the service state of various Packet maintenance objects. This information can be useful for remote maintenance, inasmuch it can explain the impact of the failure(s) on the system.

The Packet Bus Fault Isolation Flowchart appears on the following two pages.

NOTE:
See the “[Flowchart Description and Supplement](#)” section following the flowchart for a description of the flowchart as well as for supplementary information, the availability of which is indicated by the uppercase letters that appear in the flowchart.

Figure 9-5. Processing of Packet Bus Problems (Page 1 of 2)

Figure 9-6. Processing of Packet Bus Problems (Page 2 of 2)

Flowchart Description and Supplement

An uppercase letter in bold (for example, **A**, **B**, **C**, etc.) indicates that there is supplemental information with details about the relevant process that could not fit into the appropriate box or diamond.

⇒ NOTE:

Due to space restrictions, individual error codes and alarms are not detailed on the flowchart. The maintenance object descriptions in [Chapter 10, "Maintenance Object Repair Procedures"](#), discuss which errors and alarms could cause or be indicative of Packet Bus problems. In general, unless an error, alarm, or test refers explicitly to the TDM Bus, the error, alarm, or test should be considered a possible cause of Packet Bus problems.

The following paragraphs supplement the corresponding letter in the flowchart.

- a. Problems with the system clock (TDM-CLK) can cause service disruptions on the Packet Bus as well as on the TDM Bus. Therefore, if there are alarms active against TDM-CLK, these alarms should be resolved before any other Packet Bus fault isolation is attempted.

⇒ NOTE:

All TDM-CLK problems should be resolved before the process is continued, even if the problems refer only to the TDM Bus. (This is an exception to the previous note.) This is recommended because a Packet Bus problem cannot cause a TDM-CLK problem, while a TDM-CLK problem can cause a Packet Bus problem.

- b. The question "Are the Packet Bus problems resolved?" appears several times on the flowchart. This is a general question that can involve several checks. The basic question is "Are the problems that caused you to use this flowchart resolved?" Some of the more specific questions might be:

- Are all Packet Bus alarms resolved?
- Are all Packet circuit pack (port, endpoint) alarms resolved?

⇒ NOTE:

If all alarms are resolved, issue the **clear pkt** command. This command attempts to put the switch back into the service state by resolving any BRI problems that exist. Refer to [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#), for more information.

- Are all ISDN-BRI stations/data modules and/or ASAI adjuncts in service?
- Does the Maintenance/Test Packet Bus port (in normal or standalone mode) still indicate a Packet Bus fault?

- c. If only a single EPN is affected, the Packet Control is probably not the source of the problem. However, if all of the ISDN-BRI circuit packs are located in a single EPN, assume that the answer to this question is "No," and check the Packet Control.
- d. A Packet problem that affects more than one port network is probably caused by either a Packet Control failure or a PPN Packet Bus failure. The Packet Control is checked before the Packet Bus Fault Correction procedures are implemented.
- e. Because the Packet Bus in each port network is physically separate, each affected port network must be checked individually. The PPN should be checked first, however, since any EPN Packet problems are usually resolved once the PPN Packet problem is resolved. After resolving the problem in one port network, be sure to check if the problems in other port networks have also been resolved.
- f. This step applies only when an attempt to resolve an EPN Packet Bus problem is made. When checking the Expansion Interfaces in an EPN, be sure to check the corresponding ones in the PPN. Also, recall that all Expansion Interfaces in 286 systems, 386 systems, or later systems that are using the Packet Bus must be TN570s. Using TN776s results in an EPN where TDM traffic works but Packet traffic does not work.
- g. If a TN771 is not present, one must be installed to accommodate the standalone mode, which is discussed earlier in this chapter.
- h. If a TN771 is present, it can fail in such a fashion that it eventually disrupts the Packet Bus or misinterprets a Packet Bus problem.
- i. If work is being done on-site, follow the procedures described earlier in this chapter for placing the TN771 into standalone mode. If work is not being done on-site, go to the next step.
- j. The answer is "Yes" if the TN771 in standalone mode indicates any faulty leads. The answer is also "Yes" if Test #572 in the PKT-BUS test sequence fails, and/or if the **status system** display indicates that faulty leads are present and the TN771 in the port network is known to be functioning correctly.
- k. If the non-functional endpoints are isolated to a single circuit pack, the circuit pack is probably the cause of the problem.
- l. The procedures that must be executed are determined by which maintenance objects on the circuit packs are alarmed. Start with the procedures for the circuit pack errors/alarms, then continue with those for the port. Finally, execute the procedures for the endpoint.
- m. Follow the procedures outlined later in this chapter.

Packet Bus Fault Correction

Using and Interpreting Results from the Status System Command

The **status system** command can be issued to retrieve information about the Packet Bus. This command is described fully in the "Status Commands" section in [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

The **status system** command provides the service state, alarm status, and (if the Maintenance/Test Packet Bus port is activated) the number of faulty and open leads. This information can be used to determine the urgency of the repair. In general, a service state of "out" indicates extreme urgency, while a service state of "reconfig" indicates moderate urgency.

CAUTION:

Ultimately, the urgency of a repair is determined by the customer's requirements. A customer who uses ISDN-BRI for station sets probably considers a Packet Bus failure critical. However, a customer with only a small percentage of ISDN-BRI service may consider even an uncorrectable Packet Bus fault to be of minor importance and may prefer to delay performing repairs, due to their destructive nature.

NOTE:

If maintenance is actively running on the Packet Bus at the time the **status system** command is issued, the data reported for the Packet Bus may be inconsistent. The reason is that this data is updated by the maintenance tests that are running. If the data seems inconsistent, enter the command again.

If test results or the results of the **status system** command indicate that there are 24 faults on the Packet Bus, the problem is probably caused by faulty cables between carriers, or by defective bus terminators. However, before proceeding, make sure that the report is not being falsely given by the Maintenance/Test Packet Bus port. Accordingly, look for an M/T-PKT error in the error log. Then test the Maintenance/Test Packet Bus port by entering the **test port** command. Refer to the ["Special Precaution Concerning the TN771"](#) section earlier in this chapter if any problems are suspected.

If the carrier into which a TN771 Maintenance/Test circuit pack is installed does not have a -5 volt power supply, the Maintenance/Test Packet Bus port reports 24 open leads on the Packet Bus (via the **status system** command and via Test #572 of the PKT-BUS test sequence). No failure of the TN771 is indicated in this case because the TN771 is not defective. Refer to CARR-POW maintenance in [Chapter 10, "Maintenance Object Repair Procedures"](#), and ensure that a -5 volt power supply is available.

Considerations for High and Critical Reliability Systems

If a High or Critical Reliability system is involved, special considerations involving the features of this type of system must be kept in mind. In particular, if a Packet Bus problem is caused by a duplicated component, switching to the standby component may both alleviate the problem and isolate the faulty circuit pack. Therefore, the commands in the following list should be executed first in a High or Critical reliability system. For more information on these commands, refer to [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#).

- **reset system interchange** If this command resolves the Packet Bus problem, the problem is with the Packet Control in the (new) standby SPE. Refer to PKT-CTRL maintenance in [Chapter 10, "Maintenance Object Repair Procedures"](#).
- **set exp-link** If this command resolves the Packet Bus problem, the problem is with either the (new) standby EI Link or the EIs at either end. Refer to EXP-INTF maintenance in [Chapter 10, "Maintenance Object Repair Procedures"](#).
- **set tone-clock** If this command resolves the Packet Bus problem, the problem is with the (new) standby Tone-Clock. Refer to TDM-CLK maintenance in [Chapter 10, "Maintenance Object Repair Procedures"](#).

NOTE:

Keep in mind that, even though the steps discussed in the previous list may fail to resolve the problem, the steps are not necessarily fault-proof. Continue with the procedures in the next section.

Troubleshooting Procedures

As we discussed earlier in this chapter, Packet Bus faults are usually caused by a defective circuit pack connected to the backplane, by bent pins on the backplane, or by defective cables/terminators that make up the Packet Bus. The first two faults cause shorts, while the third fault causes either shorts or opens.

There are four procedures for correcting Packet Bus faults. The number of procedures that are to be used to correct faults depends upon a number of factors relevant to system performance and to the content of the procedures themselves. For example, if the Maintenance/Test Packet Bus port is activated, and if there is an indication of open leads on the Packet Bus (either via the **status system** command or via Test #572 failure), **go directly to Procedure 4**. The reason for this is that Procedures 1 through 3 try to locate faulty circuit packs or bent pins behind circuit packs. Since these types of failures can never cause open faults, Procedures 1 through 3 need not be implemented in this case. However, if there are both shorts and opens, execute Procedure 4, then return to Procedure 1 if there are still shorts after the open lead problems are resolved.

CAUTION:

Since Packet Bus fault isolation procedures involve removing circuit packs and possibly disconnecting entire carriers, these procedure have a profound effect on service. Therefore, if possible, implement these procedures after hours or during hours of minimum system use.

NOTE:

Each of these procedures contains one or more steps that require a determination as to whether the Packet Bus problem has been resolved. Accordingly, several condition checks must be performed. We can present each such check in the form of a question, as follows:

- Did the Maintenance/Test circuit pack standalone mode initially indicate the existence of faulty leads, and are these leads no longer indicated?
- Have all alarms against the Packet Bus and Packet circuit packs been resolved?

NOTE:

If all alarms are resolved, issue the **clear pkt** command. This command attempts to put the switch back into the service state by resolving any BRI problems that exist. Refer to [Chapter 8, "Maintenance Commands and Trouble-Clearing Aids"](#), for more information.

- Are all ISDN-BRI stations and data modules as well as any relevant ASAI adjuncts in service?

Note that if one of these conditions is not yet met, the others need not be checked.

The following sections discuss the four procedures for correcting Packet Bus faults.

Procedure 1

Procedure 1 determines if any circuit packs that use the Packet Bus have faults. For each circuit pack type (see [Table 9-1](#)), perform the following steps:

NOTE:

The circuit packs need not be checked in the order presented *if the flowchart in this chapter has been followed*. However, if newly added circuit packs are involved, check these packs first, inasmuch as the packs are most likely to have caused a problem.

1. Display the Error and Alarm Logs for the circuit pack via the **display errors** and **display alarms** commands.

2. If there are errors for the circuit pack, refer to the appropriate maintenance documentation in [Chapter 10, “Maintenance Object Repair Procedures”](#), and follow the recommended maintenance procedure to resolve the errors. Note that some of these procedures may refer to PKT-BUS maintenance as the cause of the fault; if so, implement these Packet Bus Fault Correction procedures at that point.
3. After implementing the repair procedure for the circuit pack (and regardless of whether this procedure succeeds or fails), determine if the Packet Bus fault is still present.
4. If the Packet Bus fault is still present, implement Procedure 1 for the next circuit pack.
5. If there are no more circuit packs in the list, go to Procedure 2.
6. If the Packet Bus fault has been resolved, the procedures are completed.

Table 9-1. Packet Circuit Packs

Circuit Pack Name	Circuit Pack Code	Associated Maintenance Objects
ISDN-BRI	TN556	BRI-BD, BRI-PORT, ABRI-PORT, BRI-SET, BRI-DAT, ASAI-ADJ
Maintenance/Test	TN771	M/T-BD, M/T-PKT
Packet Control	TN778	PKT-CTRL
Expansion Interface	TN570	EXP-INTF

Procedure 2

Procedure 2 removes and reinserts port circuit packs (those in the purple slots) one or several at a time. Use Procedure 2 for each port circuit pack in the port network until either (1) the problem is resolved or (2) there are no more circuit packs in the port network.

 **NOTE:**
This procedure should also be used for the TN570 Expansion Interface circuit pack in a standard system. For a High or Critical Reliability system, refer to Procedure 3 for the Expansion Interface circuit pack. Also, refer to Procedure 3 for the TN768 or TN780 Tone-Clock circuit pack in a switch with a High or Critical Reliability system.

 **CAUTION:**
The Expansion Interface circuit pack should be the last one checked in this procedure, since removing this circuit pack disconnects its EPN. The Tone-Clock circuit pack should be the next-to-last one checked. In addition, the TN771 must be reseated after the Tone-Clock is reinstalled.

If the Packet Bus problem is present when the circuit pack is inserted, but is resolved when the circuit pack is removed, either the circuit pack or the backplane pins in that slot caused the problem. If the backplane pins are intact, replace the circuit pack.

➤ NOTE:

In a multiple failure situation, the circuit pack could be one cause of the Packet Bus problem. However, there could also be other failures that are causing Packet Bus faults.

In Procedure 2, an option of working either with one circuit pack at a time or with multiple circuit packs simultaneously is available. In view of this, determine the level of service interruption to be allowed during this procedure. If causing a disruption to all users in the port network is deemed permissible, large groups of circuit packs should be worked with. This option allows faster job completion. *However, if large service disruptions are to be avoided, work with one circuit pack at a time.* This option is slower, but it disrupts only the users of a single circuit pack.

**CAUTION:**

If the TN771 Standalone mode does NOT indicate Packet Bus faults, perform Procedure 2 for ONLY the port (purple) slot Packet circuit packs listed in [Table 9-1](#). Also, problems with the backplane pins need not be checked for. Determining if the problem is resolved by removing circuit packs is sufficient.

Steps for Procedure 2:

1. Remove one or several circuit packs as appropriate, according to the considerations presented in the previous paragraphs. Any circuit pack(s) (whether Packet or non-Packet) that have been recently inserted should be checked first. It is likely that such a circuit pack caused a new problem. Keep in mind that Packet circuit packs should be checked before non-Packet circuit packs.

If the decision is made to remove multiple circuit packs, consider working with an entire carrier at a time to ensure a good granularity.

2. Determine if the Packet Bus fault is still present.
3. If the Packet Bus fault is still present:
 - Determine if the backplane pins in the removed circuit pack's slot are bent. Use the output from the Maintenance/Test standalone mode and [Figure 9-3](#) and [Figure 9-4](#).
 - If the backplane pins are bent, power down the carrier (refer to the "Removing Power" section in [Chapter 5, "Routine Maintenance Procedures"](#), straighten or replace the pins, reinsert the circuit pack, restore power (refer to the ["Restoring Power"](#) section in [Chapter 5](#), and repeat Procedure 2, beginning with Step 2, for the same circuit pack.

WARNING:

If this is a High or Critical Reliability system, and if the slot is in the Active control carrier, perform an SPE interchange before changing the circuit pack. Follow the procedures presented in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#).

- If the backplane pins are not bent, reinsert the circuit pack(s), and perform Procedure 2 for the next set of circuit packs.
4. If the Packet Bus fault is not present, do the following:
- Reinsert a circuit pack. If multiple circuit packs have been removed, reinsert the circuit packs **one at a time**, and repeat the following substeps until all of the circuit packs have been reinserted.
 - Determine if the Packet Bus fault has returned.
 - If the Packet Bus fault has returned, the reinserted circuit pack is defective. Replace the circuit pack and then continue.
 - If the Packet Bus fault does not return when all of the circuit packs have been reinserted, the procedure is completed.

Continue with Procedure 3 if all the port circuit packs have been checked, but the Packet Bus fault is still not resolved.

Procedure 3

Procedure 3 removes and reinserts control carrier circuit packs one at a time. The Packet Control, Tone-Clock, and Expansion Interface circuit packs are the only processor complex circuit packs that communicate on the Packet Bus. In addition, the Memory 1 and EPN Maintenance Board circuit packs are connected to the Packet Bus in the backplane (while the Memory 2 circuit pack is not). Therefore, these are the only processor complex circuit packs that are likely to cause a Packet Bus problem in a stable system. As a result, Procedure 3 should be performed only on the Packet Control, Memory 1, and EPN Maintenance Board circuit packs in all systems, and on the Expansion Interface and Tone-Clock circuit packs in High and Critical Reliability systems.

CAUTION:

If the TN771 Standalone mode does NOT indicate Packet Bus faults, perform Procedure 3 for ONLY the Packet Control, Expansion Interface, and Tone-Clock circuit packs. Also, problems with the backplane pins need not be checked for. Determining if the problem is resolved by removing circuit packs is sufficient.

In a system without High or Critical Reliability, do the following:

1. Power down the control carrier. Refer to the ["Removing Power"](#) section in [Chapter 5, "Routine Maintenance Procedures"](#).

2. Remove the suspect circuit pack.
3. As in Procedure 2, determine if the backplane pins in the removed circuit pack's slot are bent.
4. If the backplane pins are bent, do the following:
 - a. Straighten or replace the pins
 - b. Insert the same circuit pack
5. If the backplane pins are not bent, replace the circuit pack (reinsert the circuit pack if a replacement is not available).
6. Turn the power back on to reboot the system. Refer to the ["Restoring Power"](#) section in [Chapter 5, "Routine Maintenance Procedures"](#).
7. Determine if the Packet Bus fault is still present.
8. If the Packet Bus fault is still present, do the following:
 - a. If the circuit pack was reinserted in Step 5, replace the circuit pack, and repeat Procedure 3.
 - b. If the circuit pack was replaced in Step 5, repeat Procedure 3 for the next processor complex circuit pack.
9. If the Packet Bus fault does not recur, the procedure is completed.

If Procedure 3 fails to identify the cause of the problem, go to Procedure 4.

In a High or Critical Reliability System, do the following:

1. If the circuit pack to be replaced is in the SPE, perform an SPE interchange by entering the **reset system interchange** command. For an Expansion Interface circuit pack, enter the **set exp-link** command to switch to the standby expansion link. For a Tone-Clock circuit pack, enter the **set tone-clock** command to switch to the standby Tone-Clock circuit pack.
2. Remove the newly-inactive suspect circuit pack. For a circuit pack in the processor complex, use the procedures in [Chapter 6, "Reliability Systems: A Maintenance Aid"](#).
3. As in Procedure 2, determine if the backplane pins in the removed circuit pack's slot are bent.
4. If the pins are bent, do the following:
 - a. Power down the carrier. Refer to the ["Removing Power"](#) section in [Chapter 5, "Routine Maintenance Procedures"](#).
 - b. Straighten or replace the pins.
 - c. Insert the same circuit pack.
 - d. Restore power to the carrier. Refer to the ["Restoring Power"](#) section in [Chapter 5, "Routine Maintenance Procedures"](#).
5. If the backplane pins are not bent, insert or replace the circuit pack.

6. Determine if the Packet Bus fault is still present.
7. If the Packet Bus fault is still present, do the following:
 - a. If the circuit pack was reinserted in Step 5, replace the circuit pack. Then repeat Procedure 3, starting at Step 2.
 - b. If the circuit pack was replaced in Step 5, continue with Step 9.
8. If the Packet Bus fault does not recur, then the procedure is completed.
9. If the suspect circuit pack has been tested in the other control carrier, go to Step 10. Otherwise, implement Step 1, then Steps 2 through 8.
10. Repeat the procedure in the previous step for the next suspect circuit pack.

If all processor complex circuit packs have been checked and the problem is not resolved, continue with Procedure 4.

Procedure 4

Procedure 4 tries to isolate the failure to a particular set of carriers. Only the circuit packs in those carriers are checked. Procedure 4 is used if the preceding procedures fail, because it can help locate multiple circuit pack failures as well as failures of the carrier hardware. The procedure is also used if there are open leads on the Packet Bus. (The faults detected by Procedures 1 through 3 cannot cause open leads.)

In Procedure 4, the TDM/LAN Cable Assemblies and TDM/LAN termination resistor packs are replaced. If this action does not resolve the Packet Bus fault, the carriers are reconfigured by moving the termination resistor packs in such a manner that certain carriers are disconnected from the bus. This is done by moving the termination resistors on the carrier backplanes. To terminate the Packet Bus at the end of a particular carrier, first unplug the cable that connects the carrier to the next carrier and then replace the cable with a termination resistor (see [Figure 9-6](#)). When the length of the Packet Bus is modified via this procedure, circuit packs that are essential to system operation (for example, Processor Complex, Tone-Clock) must still be connected to the new "shortened" Packet (and TDM) Bus. In addition, the Maintenance/Test circuit pack (in standalone mode) must be connected to the "shortened" bus.

WARNING:

Power must be removed from the entire port network before any cables or terminators are removed. Failure to do so can cause damage to circuit packs and power supplies and can be hazardous to the technician. After cabling changes are made and verified, power must be restored to the port network. Use the TN771 Standalone mode to determine if the Packet Bus fault is resolved.

**CAUTION:**

Circuit packs in carriers that are not part of the shortened bus are not inserted. As a result, these circuit packs are not alarmed. Ignore these alarms for now. All alarms should be resolved when the cabinet is restored to its original configuration.

**Figure 9-7. Carrier Rewiring Example**

Procedure 4 is organized into two parts, as follows:

Part 1:

1. Power down the PN. See [“Removing Power”](#) section in [Chapter 5, “Routine Maintenance Procedures”](#).
2. Replace all of the TDM/LAN cables and both TDM/LAN terminators.
3. Restore power to the PN. See [“Restoring Power”](#) section in [Chapter 5, “Routine Maintenance Procedures”](#).
4. Determine if the packet bus fault is still present.
5. If the fault is present, go to Part 2.

Part 2:

Processor Port Network:

1. Terminate the Packet Bus so that it extends only from the Active control carrier (that is, the carrier that contains the Active SPE) to the carrier that contains the Maintenance/Test circuit pack. To allow this procedure to isolate the failure to the smallest possible number of carriers, place the Maintenance/Test circuit pack into a carrier that contains a processor complex, if possible.
2. Determine if the Packet Bus fault is still present. If so, and if there are shorts on the Packet Bus, perform Procedure 2 and/or Procedure 3 for only the circuit packs in those carriers that are connected to the "shortened" Packet Bus. (Procedure 2 is performed for port circuit packs, and Procedure 3 is performed for processor complex circuit packs.)
3. If the Packet Bus fault is not present, extend the Packet Bus to another carrier, and repeat the procedure in the previous step. When a carrier that causes the fault to recur is added, and if there are shorts, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.
4. If the Packet Bus fault recurs as the Packet Bus is extended, and if Procedures 2 and 3 (if performed) do not resolve the problem, the added carrier(s) that caused the problem to recur are defective and must be replaced.

Other Port Networks:

1. Terminate the Packet Bus so that it extends only from the carrier that contains the Active Expansion Interface to the nearest carrier that contains the Maintenance/Test circuit pack. Place the Maintenance/Test circuit pack into a carrier that contains an Expansion Interface circuit pack in order to allow the procedure to isolate the failure to the smallest possible number of carriers.
2. Determine if the Packet Bus fault is still present. If so, and if there are shorts on the Packet Bus, perform Procedure 2 and/or Procedure 3 for only the circuit packs in those carriers that are connected to the "shortened" Packet Bus.
3. If the Packet Bus fault is not present, extend the Packet Bus to another carrier, and repeat the procedure in the previous step. When a carrier that causes the fault to recur is added, and if there are shorts, perform Procedure 2 and/or Procedure 3 for only the circuit packs in that carrier.
4. If the packet bus fault recurs as the packet bus is extended, and if Procedures 2 and 3 (if performed) do not resolve the problem, the added carrier(s) that caused the problem to recur are defective and must be replaced.

Maintenance Object Repair Procedures

10

For Maintenance Objects on the DEFINITY Wireless Business System (DWBS), refer to the appropriate documentation that accompanies the DWBS.

Trouble-clearing is based on the type of indication received, system-alarmed troubles, or user-reported troubles. When viewing the Alarm Log, all major alarms display first, followed by minor alarms, and warning alarms. Resolve the first alarmed entry first because it may affect the rest of the alarmed entries. System-alarmed and user-reported troubles may exist at the same time. Always clear the alarmed troubles first. This often clears the user-reported faults without additional maintenance.

Escalation Procedures

This document is not intended to solve all troubles. When the limits of these procedures are reached and the problem is not resolved, it is the technician's responsibility to escalate to a higher level of technical support. Escalation must conform to the procedures in the *Technical and Administration Plan*.

Cabling Precautions

CAUTION:

Do not cut or bend fiber optic cables. Doing so may adversely affect communication between the EPN and the PP N cabinets.

CAUTION:

To avoid damaging the cable-to-connector interface when removing any Inter-Carrier Cable, grasp the cable connector, not the cable itself.

12V-PWR (12 Volt Power Supply)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
12V-PWR	MINOR	test card-mem sh	12 Volt Power Supply
12V-PWR	WARNING	test card-mem sh	12 Volt Power Supply

The 12 Volt Power Supply unit in the TN777B NETCON circuit pack is required for programming flash memory devices in circuit packs such as the TN786B or TN790 Processor circuit pack and the removable translation card. During the erase and write operations of a flash memory or translation card, the 12 volt power supply must be turned on under the instruction of software. For the read-only operation, the 12 volt power supply is not required.

If the 12-volt power supply cannot be turned on, all the erase and write operations to a flash device fail. Features such as "save translation," "save announcements," "system upgrade," "hard patching," and "core dump" always fail in this case.

Error Log Entries and Test to Clear Values

Table 10-1. 12 Volt Power Supply Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test card-mem
1 ²	Any	12 Volt Power Supply Test (#701)	MINOR	ON	test card-mem
257 ³	Any	12 Volt Power Supply Test (#701)	WARNING	ON	test card-mem

- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- Software cannot turn on the 12 volt power supply to provide 12 volt power to the flash memory or to the translation card.
- Software can turn on the 12 volt power supply, and 12 volt power is available. However, the software cannot turn the power supply off after operations are completed. The 12 volt power remains on. This error does not affect the normal operations involved in accessing the memory or the translation card.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following table. By clearing error codes associated with the *12 Volt Power Supply Test* for example, you may also clear errors generated from other tests in the testing sequence. The 12 Volt Power Supply Test can be initiated via either the **test card-mem** command or the **test network-control** command.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND ¹
12 Volt Power Supply Test (#701)	X	X		ND
Memory Card Insertion Test (#695) ²	X	X		ND
Memory Card Format and Read Test (#696) (a)	X	X		ND
Memory Card Match Test (#697) ²	X	X		ND
Memory Card Write-Protected Test (#698) ²	X	X		ND
Memory Card Directory Recovery Test (#699) ²	X	X		ND
Memory Card Translation Data Integrity Test (#694) ²		X		ND
Memory Card Erase/Write/Read Test (#693) ²		X		ND

1. D = Destructive; ND = Nondestructive
2. Refer to "CARD-MEM (Memory Card)" information for a description of this test.

12 Volt Power Supply Test (#701)

This test is nondestructive.

The purpose of the test is to diagnose the 12 volt power supply unit in the TN777B NETCON circuit pack. No erase and write-to-memory operations are started or verified during the test. The contents of flash memory and of the memory card should not be changed.

The test turns on the power supply, and it verifies that 12 volt power appears by reading the control register in the TN777B NETCON circuit pack. After the power supply is turned on, the maintenance software waits for three seconds before verifying the appearance of 12 volt power. After the 12 volt power supply can be turned on and verified, the test turns the power supply off and then verifies that the power is off. The control register in the TN777B NETCON circuit pack is read again for the verification.

If, while this test is running, an application attempts to erase or write a flash memory or a memory card, this test remains active, and the application is barred.

Table 10-2. 12 Volt Power Supply Test

Error Code	Test Result	Description/Recommendation
1192	ABORT	12 volt power supply is being used by other applications or by maintenance. 1. The 12 volt power supply is in use. Retry the test card-mem command after the maintenance operation application is completed.
2106 2114	ABORT	Internal system error 1. Retry the command at one minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
109	FAIL	The 12 volt power supply unit in the TN777B NETCON circuit pack cannot be turned on by the software. 1. Retry the test card-mem command one more time to verify the operation of the 12 volt power supply in the TN777B NETCON circuit pack. 2. If the failure indicated by Error Code 109 persists, the TN777B NETCON circuit pack must be replaced with a new circuit pack. Follow the standard procedure for replacing the NETCON circuit pack from the SPE control carrier. 3. After the new TN777B circuit pack is inserted, enter the test card-mem command to verify the operations of the 12 volt power supply in the TN777B NETCON circuit pack. The alarm is resolved after the test passes twice.
110	FAIL	The 12 volt power supply unit in the TN777B NETCON circuit pack cannot be turned off by the software. 1. Retry the test card-mem command one more time to verify the operation of the 12 volt power supply in the TN777B NETCON circuit pack. 2. If the failure indicated by Error Code 110 persists, the TN777B NETCON circuit pack should be scheduled for replacement during the next regular maintenance visit. This failure does not cause any service disruption.
	PASS	The 12 volt power supply unit in the TN777B NETCON circuit pack is functioning correctly.

ABRI-PORT (ASAI ISDN-BRI Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ABRI-PORT ²	MAJOR(b)	test port PCSSpp l	ASAI ISDN-BRI Port
ABRI-PORT	MINOR	test port PCSSpp l	ASAI ISDN-BRI Port

1.

Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., and so forth); and pp is the 2-digit port number (for example, 01).
2.

The alarm level for ABRI ports may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to MAJOR for all ABRI ports in the system.

 **NOTE:**

Refer to "BRI-PORT (ISDN-BRI Port), ABRI-PORT (ASAI ISDN-BRI Port)" for repair procedures.

AC-POWER

AC Power for AC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
AC-POWER	WARNING	test environment P	AC Power

1. Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

NOTE:
For environment maintenance, PPN or EPN cabinet configuration aspects in a high or critical reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Also refer to the DC-POWER (DC Power) for environment maintenance strategy.

The AC Power MO represents the AC power provided to the system from a wall outlet. The AC power comes from the wall outlet, through the Power Distribution Unit (PDU), if installed, and is then distributed to the various cabinets. The battery charger monitors AC power via fuse F3. See Figure 10-1. If no PDU is installed, the power is supplied directly to each cabinet from each individual wall outlets.

When the system loses power (for example, a power outage in the building), a Major alarm is logged against AC Power and the system goes on battery backup, which is known as Nominal Power Holdover (NPH). If power is restored before the NPH time expires, the alarm is resolved. Each basic control cabinet has separate batteries for NPH. The nominal power holdover provided is as follows:

- The batteries power the system for 10 seconds in a PPN cabinet, for 15 seconds in an EPN cabinet, and for 10 minutes in the control carrier in a standard reliability system.
- The batteries also provide system power for five minutes in the control carrier in high and critical reliability systems.

WARNING:
Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the "DEFINITY AUDIX System Power Procedures" in Chapter 5, "Routine Maintenance Procedures", on the circuit pack, and in DEFINITY AUDIX documentation.

Figure 10-1. Small Cabinet Environment Components (AC-POWER)

Error Log Entries and Test to Clear Values

Table 10-3. AC Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test environment P sh r 1
513	Any	AC Power Query Test (#78)	WARNING	OFF	test environment P sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence.

Refer to the appropriate test description and follow the recommended procedures.

AC Power Query Test (#78)

Table 10-4. TEST #78 AC Power Query Test

Error Code	Test Result	Description / Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier (PPN or EPN). Resolve all DC-POWER alarms. Then, repeat the test. 3. If the test continues to ABORT with a 2000 Error Code, resolve all DUPINT (Duplication Interface) errors in a high or critical reliability system PPN, PR-MAINT (Maintenance/Tape Processor) errors in a standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Repeat the test.
2029	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-4. TEST #78 AC Power Query Test — Continued

Error Code	Test Result	Description / Recommendation
1	FAIL	 NOTE: For a Global AC MCC (J58890CH) use the procedures outlined in step 2. The switch is currently without AC power.  WARNING: <i>Turn off power to the 397C Battery Charger before removing Fuse F5.</i> 1. Check for AC at the wall outlet. a. If there is no AC power at the wall outlet, then the problem is not with the system itself. Power must be restored to the wall outlet. b. If there is AC power at the wall outlet, then there could be a problem with the Battery or Battery chargers. Resolve all alarms logged against POWER (Battery & Battery Charger), and rerun the test. If the test still fails, the fuse F5 may have opened. Replace fuse F5 and rerun the test. If the test still fails, then the PR-MAINT (Maintenance/Tape Processor) in a PPN in a system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a high or critical reliability system PPN, or the EPN MAINT (Maintenance) circuit pack in an EPN multicarrier cabinet system may be incorrectly reporting the problem. c. alarms against these MOs, and rerun the test. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that are not detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.

Continued on next page

Table 10-4. TEST #78 AC Power Query Test — Continued

Error Code	Test Result	Description / Recommendation
1 (cont'd.)	FAIL (cont'd.)	2. Procedures for a Global MCC (J58890CH): a. For a nominal holdover system if there is no AC power at the wall outlet, then the problem is not with the system itself. Power must be restored to the wall outlet. b. If there is AC power at the wall outlet, then there could be a problem with the Rectifiers (RM850), Battery Interface Unit, or battery. Resolve all alarms logged against the POWER Maintenance Object, and rerun the test. If the test still fails, the BIU may be defective. Check to see if the BOD alarm LED is “on”, on the BIU. If the BOD LED is “on” replace the Battery Interface Unit (BIU). If the BOD LED is “off” and the BOK LED is “on” then the SYSAM or the EPN Maintenance circuit pack may be incorrectly reporting the problem. Resolve all alarms against these Maintenance Objects and rerun the test.
100	FAIL	The switch is currently without AC power, and AC Power maintenance is in the middle of timing the NPH interval. 1. Follow the repair steps outlined above for Error Code 1.
	PASS	The PR-MAINT (Maintenance/Tape Processor) in a PPN in a system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a High or Critical Reliability system PPN, or the EPN MAINT (Maintenance) circuit pack in an EPN multicarrier cabinet system has reported that the switch has AC power. If there is no AC power at the wall outlet, then look for and resolve all alarms against the appropriate MO listed.

AC Power for DC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
AC-POWER	WARNING	test environment P	AC Power

1. Where P is an appropriate port network number determined via the PORT field from the Alarm or Error Log.

 **NOTE:**
For environment maintenance, the PPN or EPN cabinet configuration aspects in a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Refer to the "DC-POWER (Single-Carrier Cabinet Power)" information for environment maintenance strategy.

In a DC-powered multicarrier cabinet system, the AC-POWER maintenance object still exists, but serves no functional purpose. Because the system cannot determine the type of powering provided, all AC-POWER tests should always either pass or abort.

Error Log Entries and Test to Clear Values

Table 10-5. AC Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test environment P sh r 1
513	Any	AC Power Query Test (#78)	WARNING	OFF	test environment P sh r 1

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following table. By clearing error codes associated with the *AC Power Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-6. System Technician-Demanded Tests: AC-Power

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78)	X	X	ND
Power Unit Query Test (carrier E) (#127) (b)	X	X	ND
Power Unit Query Test (carrier D) (#127) (b)	X	X	ND
Power Unit Query Test (carrier A) (#127) (b)	X	X	ND
Power Unit Query Test (carrier B) (#127) (b)	X	X	ND

Table 10-6. System Technician-Demanded Tests: AC-Power — Continued

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Power Unit Query Test (carrier C) (#127) (b)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Temperature Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive, ND = Non-destructive

- Notes:
- a. Refer to "POWER" for a description of this test.
 - b. Refer to "CARR-POW" for a description of this test.
 - c. Refer to "EMG-XFER" for a description of this test.
 - d. Refer to "CABINET" for a description of this test.
 - e. Refer to "EXT-DEV ADMIN? N" or "EXT-DEV ADMIN? Y" for a description of this test.
 - f. Refer to "RING-GEN" for a description of this test.

AC Power Query Test (#78)

This test queries the Maintenance/Tape Processor in a PPN in a system without High or Critical Reliability, the Duplication Interface circuit pack in a High or Critical Reliability system PPN, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of AC power to the switch. In a DC-powered system, this test should never fail.

Table 10-7. TEST #78 AC Power Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2029	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
any	FAIL	The Maintenance/Tape Processor in a PPN in a system without High or Critical Reliability, the Duplication Interface circuit pack in a High or Critical Reliability system PPN, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system is incorrectly reporting a problem with AC power. If this test fails, the problem is with the circuit pack and not with AC-POWER. The suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.
	PASS	All that can be inferred is that the PR-MAINT (Maintenance/Tape Processor) in a PPN in a system without High or Critical Reliability, the DUPINT (Duplication Interface) circuit pack in a High or Critical Reliability system PPN, or the EPN MAINT (Maintenance) circuit pack in an EPN multicarrier cabinet system is working properly.

ADM-CONN (Administered Connection)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ADM-CONN	MAJOR	status administered-connection N	Administered Connection
ADM-CONN	MINOR	status administered-connection N	Administered Connection
ADM-CONN	WARNING	status administered-connection N	Administered Connection

1. Where N is an appropriate Administered Connection number determined via the PORT field from the Alarm or Error Log.

An Administered Connection provides an end-to-end connection between two access endpoints or data modules. This connection is automatically established when the administered connection is administered and is due to be active. An error is logged when an administered connection cannot be established or when an established administered connection fails. An alarm is logged when a connection cannot initially be established or fails and cannot be reestablished. An alarming strategy is supported on a per administered connection basis. An alarm is raised for a connection when either the number of consecutive failed attempts to establish the connection reaches the alarm threshold or it can be determined that a failed attempt to establish was due to an administered error. The alarm raised ("major," "minor," "warning," or "none") is specified in the "Alarm Type" field of the Administered Connection Administration Form.

Continued on next page

Table 10-8. Administered Connection Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
111 (a)(b)(c)(q)	Any	None	Any	OFF	None
127 (a)(b)(c)(g)	Any	None	Any	OFF	None

Notes:

- a. These errors have no specific test associated with them. Refer to Notes b through p for an explanation and appropriate action.
- b. These errors are valid only for administered connection established over ISDN facilities; only error 127 is valid for administered connection established over non-ISDN facilities (or between two endpoints on the same switch).
 - Aux Data 1—Administered connection establishment failed
 - Aux Data 2—Active administered connection failed; attempting reestablishment via auto restoration
 - Aux Data 3—Auto restoration failed
 - Aux Data 4—Active administered connection failed; attempting reestablishment via fast retry
 - Aux Data 5—Fast retry failed
- c. These errors are typically associated with administrative problems and are not expected to be of a temporary nature. Therefore, the administered connection is not retried and the failure is alarmed immediately (the alarm threshold specified by the customer is ignored).
- d. The address of the destination endpoint is: an unassigned number (1); has an invalid number format (28); or is restricted form terminating calls ("Access Denied") [due to COR (Class of Restriction)]. Verify that the destination address is correct and that the destination endpoint is administered. The destination endpoint is not administered on the switch where this error is logged.
- e. A request has been made to use a transit network or common carrier that cannot be accessed. Check the routing pattern used by this Administered Connection and verify that the inter-exchange carrier specified is correct.
- f. The exact failure cause is unknown or has been mapped to one of these values. If this is not a temporary condition, try reversing the direction of the Administered Connection (that is, originate the Administered Connection from the destination switch). This may yield another failure cause.

- g. The destination endpoint is not available. Check the status of the destination endpoint (using **status access-endpoint** or **status data-module**) and verify that the endpoint is not busy or otherwise unavailable (for example, out-of-service). The status for the destination endpoint is not available on the switch where this error is logged.
 - h. This switch sent an ISDN message to another switch, which either did not respond (18) or did not respond within the allotted time (102). This could be due to link failure or congestion or outage at the other switch.
 - i. The address of the destination endpoint has changed. Verify that the new address is correct and change the Administered Connection accordingly. The destination endpoint is not administered on the switch logging this error.
 - j. Indicate that a resource (for example, a circuit or bearer capability) required by the administered cConnection is not presently available.
 - k. A network failure (38) or temporary failure (41) has occurred. Error Log entries for other maintenance objects (for example, DS1-BD or ISDN-LNK) may indicate a local problem.
 - l. A request to use a network service has been denied because the service has not been purchased. Check the routing pattern used by this Administered Connection and verify that the service type is correct. If the service type appears correct, check with the customer or network provider or both to determine what services have been purchased by the customer.
 - m. Indicate that outgoing calls may be barred on the originating switch (52) or that incoming calls may be barred on the destination switch (54). To restore an administered connection failure, issue the **status administered connection** command for current administered connection state (observe the retry count). If the administered connection state is "failed," then verify and correct the Administered Connection Administration Form.
 - n. The requested bearer capability (65), channel type (66), or facility (69) is not implemented or is unknown to the network. Check the address of the destination endpoint and the routing pattern used by this Administered Connection, and verify that they are correct and available.
 - o. These errors indicate that an ISDN protocol error has occurred.
 - p. The destination endpoint (or some intermediate facility) is not compatible with the originating endpoint. Check the BCC fields of the routing pattern used by this Administered Connection. Also, check if the originating and destination endpoints are compatible (for example, the originating access endpoint is voice-grade data, and the destination access endpoint is 64k data).
-

ADX8D-BD (AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run ¹	Full Name of MO
ADX8D-BD	MINOR or WARNINGS	test board PCSS sh	AUDIX Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

The ADX8D-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack (sometimes called Embedded AUDIX) operating in digital-port (DP) mode. For circuit pack problems, see “XXX-BD (Common Port Circuit Pack)”. Port level problems are covered by ADX8D-PT.

DEFINITY AUDIX consists of two circuit packs that occupy 5 slots on a port cabinet. The tests described in this manual apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

ADX8D-PT (AUDIX Digital Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run ¹	Full Name of MO
ADX8D-PT	MINOR	test port PCSSpp l	AUDIX Digital Port
ADX8D-PT	WARNING	test port PCSSpp sh	AUDIX Digital Port

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

The ADX8D-PT maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack (sometimes called Embedded AUDIX) operating in digital-port (DP) mode. The maintenance strategy for ports on the TN566 operating in control-link mode is described in ADX16A-PT.

The tests described in this section apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction Board (MFB) and the TN2169 Alarm Board (ALB). Because of its size this combination occupies 5 slots, but only 1 slot is functional as far as the switch is concerned. The other 4 slots are seen by the switch as “AUDIX-reserved” slots (or ADXDP-RS/ADX8D-RS.)

In DP mode the TN566 pack supports up to 8 voice ports, each with a primary information channel and a secondary information channel. Ports are administered in increments of two. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, DEFINITY AUDIX is not an adjunct.

 **CAUTION:**

Never do any of the following without first shutting down AUDIX. Follow instructions on the TN566/TN2169 faceplate:

- Remove DEFINITY AUDIX circuit packs
- Cycle power to a carrier containing DEFINITY AUDIX circuit packs
- Remove power to a carrier containing DEFINITY AUDIX circuit packs

Error Log Entries and Test to Clear Values

Table 10-9. DEFINITY AUDIX Digital Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1(a)	40987	None	WARNING	OFF	
1(b)	1 to 20	None	WARNING	OFF	
15(c)	Any	None			
18(d)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
23(e)	0	None	WARNING	OFF	
130(f)		None	WARNING	ON	test port PCSSpp sh
257(g)	40971	None			
513(h)	Any	None			
1537(i)	40968	None	WARNING	OFF	
1793		Voice & Ctrl. Local Loop Test (#13)	MIN/WRN ²	ON	test port PCSSpp l r 3
2049		NPE Crosstalk Test (#9)	MIN/WRN ²	ON	test port PCSSpp l r 3
2305(j)	40967	None			
3840(k)	40965	None			
3840(l)	41029	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

- Notes:
- a. The user may experience a noisy port or link. This is an off-board problem that is detected by the port circuit. If this problem exists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a predetermined time.
- b. At least 15 off-board problems have been detected with the link to the voice port. When an error with the link is detected, an on-board counter is incremented. Also see Note (a).
- c. This is an internal type error that occurs when an audit request fails.
- d. The port is busied-out by command. You can release the port via the **release port PCSSpp** command.

- e. The circuit pack is administered but not physically installed. The alarm will clear when a circuit pack is inserted.
- f. The circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the AUDIX circuit pack (see precaution at the beginning of this section).
- g. Something is interfering with transmitting to the voice port. This is usually an on-board problem and can be ignored if no user complaints are received.
- h. AUDIX is not available to the switch, possibly due to a busyout on the AUDIX system. Check out the AUDIX system referring *DEFINITY AUDIX System Maintenance*, 585-300-110, if necessary.
- i. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice port. This can be ignored if no user complaints are received. If the problem persists, replace the circuit pack (see precaution at the beginning of this section). Once the problem is resolved, the alarm is retired after a certain period of time.
- j. The link between the circuit pack and the voice port is successfully reset. No craft action is necessary.
- k. No voice ports are connected to the DEFINITY AUDIX circuit pack. No maintenance action is required.
- l. The message buffer in the circuit pack is full.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when you are inspecting errors in the system. By clearing error codes associated with the *Voice and Control Channel Local Loop Around Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Voice and Control Channel Local Loop Around Test (#13)		X	ND
NPE Crosstalk Test (#9)		X	ND

1. D = Destructive; ND = Nondestructive

NO-OP Tests

The maintenance strategy for DEFINITY AUDIX emulates the one for DIG-LINE. The tests listed below apply only to DIG-LINE and not to DEFINITY AUDIX. These are referred to as *NO-OP* tests, and they always return PASS.

- Electronic Power Feed Test (#11)
- Station Lamp Updates Test (#16)
- Station (Digital) Audits Test (#17)

NPE Crosstalk Test (#9)

This test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence, and it takes about 20 to 30 seconds to complete.

Crosstalk testing is performed on both the primary information channel (voice) and on the secondary information channel (data) associated with each DEFINITY AUDIX port. If this test fails on either channel, the voice port is taken out-of-service.

Table 10-10. TEST #9 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. Also, the port may have been busy during the test. 1. Check the port status. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle. When the port is idle, try (a).
2	ABORT	System resources may not have been available, or the port may have been busy during the test. Try (a).
1000	ABORT	System resources required to run this test are not available. The port may be in use. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle before retesting. Try (a).
1001	ABORT	System resources required to run this test are not available. Try (a).
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS" to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors, and if it is not handling heavy traffic, try (a).

Table 10-10. TEST #9 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors. 2. Resolve any "TONE-PT" errors. Try (a).
1004	ABORT	The port was put in use during the test. The test has been aborted. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the port is in use, wait until the port is idle before testing.
1020	ABORT	Test disabled by background testing. Use the status station command to determine when the voice port is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. Try (a).
1 2	FAIL	The NPE of the tested port is transmitting in error. This causes noisy and unreliable connections. Failure code 1 indicates that the Crosstalk test failed on the primary channel. Failure code 2 indicates that the Crosstalk test failed on the secondary channel. 1. Replace the circuit pack .
	PASS	The port is using its allocated time slots correctly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist, examine the connections.

Note:

a. Retry the command at 1-minute intervals a maximum of 5 times.

Voice and Control Channel Local Loop Test (#13)

This test checks the information and control channels between the Switch Processing Element (SPE) and the DEFINITY AUDIX port circuit. First, the primary information (voice) channel loop back test is run.

While the primary information channel is still looped around, the Control Channel Loop Around Test is performed. The Loop Around Test for the secondary information (data) channel is then performed. This test is the same as the primary information channel loop around test.

Next, a Conference Test is implemented for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of the four tests run. If any test fails or aborts, the sequence is stopped.

Table 10-11. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal System Error. Try (a).
1000	ABORT	System resources required to run this test are not available. The port may be in use. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle before retesting. Try (a).
1001	ABORT	System resources required for this test are not available. Try (a).
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or may have time slots that are out-of-service due to TDM-BUS errors. Refer to "TDM-BUS" to diagnose TDM-BUS errors. 1. If the system has no TDM-BUS errors, and is not handling heavy traffic, try (a).
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present, or some Tone Detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors. 2. Resolve any "TONE-PT" errors. 3. If neither condition exists, try (a).
1004	ABORT	The port was put in use during the test. Use the display port PCSSpp to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, you must wait until the port is idle before retesting. Try (a).
2000	ABORT	Response to the test was not received within the allowable time period. Try (a).
2100	ABORT	Could not allocate the necessary system resources for this test. Try (a).

Continued on next page

Table 10-11. TEST #13 Voice and Control Channel Local Loop Test — Continued

Error Code	Test Result	Description/Recommendation
7	FAIL	Conference Test failed on the primary channel. Some users may not notice a disruption in service. In extreme cases, the conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
15	FAIL	The control channel between the processor and DEFINITY AUDIX circuit pack is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port. This failure could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
None	FAIL	The test failed for reasons external to the DEFINITY AUDIX circuit pack. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack by using the test board PCSS s command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and if the test still fails, replace the AUDIX circuit pack (see precaution at the beginning of this section).
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to 10 times and see if it continues to pass. 2. If complaints still exist, examine the connections.

ADX16D-B (16 Port AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run ¹	Full Name of MO
ADX16D-B	MINOR	test board PCSS sh	AUDIX Circuit Pack
ADX16D-B	WARNING	test board PCSS sh	AUDIX Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

The ADX16D-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack combination operating in 16 port mode digital (DP). For circuit-pack-level problems, see “XXX-BD (Common Port Circuit Pack)”. Port-level maintenance is covered by ADX16D-PT.

DEFINITY AUDIX consists of 2 circuit packs that occupy 5 slots on a port carrier. The tests described in this manual apply  to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy of its own that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

ADX16A-BD (AUDIX Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run ¹	Full Name of MO
ADXCL-BD or VADX16A-BD	MINOR, or WARNINGS	test board PCSS sh	AUDIX Circuit Pack

1. *UU* is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21).

The ADX16A-BD maintenance object represents a TN566/TN2169 DEFINITY AUDIX circuit pack combination operating in control-link (CL) mode. For circuit-pack-level problems, see “XXX-BD (Common Port Circuit Pack)”. Port-level maintenance is covered by ADX16A-PT.

DEFINITY AUDIX consists of 2 circuit packs that occupy 5 slots on a port carrier. The tests described in this manual apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

ADX16D-P (16-Port AUDIX Digital Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run ¹	Full Name of MO
ADX16D-P	MINOR or WARNINGS	test port PCSSpp I	AUDIX Digital Port

1. *UU* is the universal cabinet number (1 for PPN, 2-44 for EPNs). *C* is the carrier designation (A, B, C, D, or E). *SS* is the number of the slot in which the circuit pack resides (01 to 21). *pp* is the two digit port number (01, 02, ...).

CAUTION:

Never do any of the following without first shutting down AUDIX. Follow the instructions on the TN566/TN2169 faceplate:

- *Remove DEFINITY AUDIX circuit packs*
- *Cycle power to a carrier containing DEFINITY AUDIX circuit packs*
- *Remove power to a carrier or cabinet containing DEFINITY AUDIX circuit pack.*

The ADX16D-P maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack operating in digital-port (DP) mode. The maintenance strategy for ports on the TN566 operating in control-link mode is described in ADX16A-PT.

The tests described in this section apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction Board (MFB) and the TN2169 Alarm Board (ALB). Because of its size this combination occupies 5 slots, but only 1 slot is functional as far as the system is concerned. The other 4 slots are seen by the switch as “AUDIX-reserved” slots (or ADX16-RES/ADX16D-RS).

In 16 Port DP mode, the TN566 pack supports up to 16 voice ports, each with a primary information channel and a secondary information channel. Ports are administered in increments of two. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, DEFINITY AUDIX is not an adjunct.

Error Log Entries and Test to Clear Values

Table 10-12. DEFINITY AUDIX Digital Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1(a)	40987	None	WARNING	OFF	
1(b)	1 to 20	None	WARNING	OFF	
15(c)	Any	None			
18(d)	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
23(e)	0	None	WARNING	OFF	
130(f)		None	WARNING	ON	test port PCSSpp sh
257(g)	40971	None			
513(h)	Any	None			
1537(i)	40968	None	WARNING	OFF	
1793		Voice and Control Local Loop TEST (#13)	MIN/ WRN ²	ON	test port PCSSpp l r 3
2049		NPE Crosstalk Test (#9)	MIN/ WRN ²	ON	test port PCSSpp l r 3
2305(j)	40967	None			
3840(k)	40965	None			
3840(l)	41029	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. The user may experience a noisy port or link. This is an off-board problem that is detected by the port circuit. If this problem exists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a predetermined time.
- b. At least 15 off-board problems have been detected with the link to the voice port. When an error with the link is detected, an on-board counter is incremented. Also see Note a, above.
- c. This is an internal type error that occurs when an audit request fails.
- d. The port is busied-out by command. Release the port with the **release port PCSSpp** command.
- e. The circuit pack is administered but not physically installed. The alarm will clear when a circuit pack is inserted.

- f. The circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reseal or replace the AUDIX circuit pack (see caution at the beginning of this section).
- g. Something is interfering with transmitting to the voice port. This is usually an on-board problem and can be ignored if no user complaints are received.
- h. AUDIX is not available to the switch, possibly due to a busyout on the AUDIX system. Refer to *DEFINITY AUDIX System Maintenance*, 585-300-110, if necessary.
- i. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice port. This can be ignored if no user complaints are received. If the problem persists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a certain period of time.
- j. The link between the circuit pack and the voice port is successfully reset. No craft action is necessary.
- k. No voice ports are connected to the DEFINITY AUDIX circuit pack. No maintenance action is required.
- l. The message buffer in the circuit pack is full.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Voice and Control Channel Local Loop Around Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Voice and Control Channel Local Loop Around Test (#13)		X	ND
NPE Crosstalk Test (#9)		X	ND

1. D = Destructive; ND = Nondestructive

NO-OP Tests

The maintenance strategy for DEFINITY AUDIX emulates the one for DIG-LINE. The tests listed below apply only to DIG-LINE and not to DEFINITY AUDIX. These tests always return PASS.

- Electronic Power Feed Test (#11)
- Station Lamp Updates Test (#16)

- Station (Digital) Audits Test (#17)
- Digital Terminal Remote Loop Around Test (1201)

NPE Crosstalk Test (#9)

This test verifies that this port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence, and it takes about 20 to 30 seconds to complete.

Crosstalk testing is performed on both the primary information channel (voice) and on the secondary information channel (data) associated with each DEFINITY AUDIX port. If this test fails on either channel, the voice port is taken out-of-service.

Table 10-13. TEST #9 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. Also, the port may have been busy during the test. 1. Check the port status. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for this test. Wait until the port is idle (a).
2	ABORT	System resources may not have been available, or the port may have been busy during the test. 1. Check if port is being used try (a)
1000	ABORT	System resources required to run this test are not available. The port may be in use. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Refer to "Status" commands in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states. Wait until the port is idle before testing. 1. If the port status is idle, try (a)
1001	ABORT	System resources required to run this test are not available. Try (a)
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS" to diagnose TDM-BUS errors. 1. If system has no TDM-BUS errors, and if it is not handling heavy traffic, try (a)

Table 10-13. TEST #9 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors in the Error Log. 2. Resolve any "TONE-PT" errors in the Error Log.
1004	ABORT	The port was put in use during the test. The test has been aborted. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Refer to "Status" commands in Chapter 8 for explanations of all possible states. Wait until the port is idle before testing.
1020	ABORT	Test disabled via background testing. Use the status station command to determine when the voice port is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period (a).
1 2	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. Failure code 1 indicates that the Crosstalk test failed on the primary channel. Failure code 2 indicates that the Crosstalk test failed on the secondary channel. 1. Replace the circuit pack (see caution at the beginning of this section).
	PASS	The port is using its allocated time slots correctly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist, examine the connections.

Note:

a. Retry the command at 1-minute intervals a maximum of 5 times.

Voice and Control Channel Local Loop Test (#13)

This test checks the information and control channels between the Switch Processing Element (SPE) and the DEFINITY AUDIX port circuit. The SPE sends a message to loop around both the information and control channels for the port. First, the primary information (voice) channel loop back test is run.

While the primary information channel is still looped around, the Control Channel Loop Around Test is performed. The Loop Around Test for the secondary

information (data) channel is then performed. This test is the same as the primary information channel loop around test.

Next, a Conference Test is implemented for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of the four tests run. If any test fails or aborts, the sequence is stopped.

Table 10-14. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal System Error (a)
1000	ABORT	System resources required to run this test are not available. The port may be in use. Use the display port PCSSpp command to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Refer to "Status" commands in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids" for explanations of all possible states. Wait until the port is idle before retesting, then try (a).
1001	ABORT	System resources required to run this test are not available; try (a).
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots that are out-of-service due to TDM-BUS errors. Refer to "TDM-BUS" to diagnose TDM-BUS errors. 1. If the system has no TDM-BUS errors and if it is not handling heavy traffic, try (a).
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present, or some tone detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors. 2. Resolve any "TONE-PT" errors. Try (a).
1004	ABORT	The port was put in use during the test. The test has been aborted. Use the display port PCSSpp to determine the voice port extension of the port. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Wait until the port is idle before retesting. Try (a).
2000	ABORT	Response to the test request was not received within the allowable time period. Try (a).
2100	ABORT	Could not allocate the necessary system resources for this test. Try (a).

Continued on next page

Table 10-14. TEST #13 Voice and Control Channel Local Loop Test — Continued

Error Code	Test Result	Description/Recommendation
7	FAIL	Conference Test failed on the primary channel. In some cases, users may not notice a disruption in service. In extreme cases, the conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
15	FAIL	The control channel between the processor and AUDIX is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port. This failure could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from no noticeable effect to loss of use of this port.
None	FAIL	The test failed for reasons external to the AUDIX. 1. Run circuit pack tests to check the tone generator circuit pack and the tone detector circuit pack by using the test board PCSS s command. 2. Resolve any problems detected on the tone generator circuit pack or tone detector circuit pack. 3. If the tone generator and tone detector circuit packs are functioning properly, and if the test still fails, replace the AUDIX (see caution at the beginning of this section).
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to 10 times and see if it continues to pass. 2. If complaints still exist, examine the connections.

- Notes:
- a. Retry the command at 1-minute intervals a maximum of 5 times.

ADX16A-PT (AUDIX Analog Line/Control Link)

MO Name (in Alarm Log)	Alarm Level	Initial Command To Run ¹	Full Name of MO
ADXCL-PT or ADX16A-PT	MINOR	test port PCSSpp l	AUDIX Analog Line/ Control Link
ADXCL-PT or ADX16A-PT	WARNING	test port PCSSpp sh	AUDIX Analog Line/ Control Link

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21). pp is the two digit port number (01, 02, ...).

CAUTION:

Never do any of the following without first shutting down AUDIX. Follow the instructions on the TN566/TN2169 faceplate:

- Remove DEFINITY AUDIX circuit packs
- Cycle power to a carrier containing DEFINITY AUDIX circuit packs
- Remove power to a carrier containing DEFINITY AUDIX circuit packs

The ADX16A-PT maintenance object represents a port on a TN566/TN2169 DEFINITY AUDIX circuit pack that is operating in control-link (CL) mode. For circuit-pack-level problems (ADX16A-BD or ANL-16-BD), see “XXX-BD (Common Port Circuit Pack)”. For port-level problems with AUDIX operating in digital-port mode, see ADXDP-PT/ADX8D-PT.

The tests described in this section apply only to switch-side maintenance which tests circuit pack components related to the TDM bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY AUDIX System Maintenance*, 585-300-110.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction Board (MFB) and the TN2169 Alarm Board (ALB). Because of its size this combination occupies 5 slots, but only 1 slot is functional as far as the switch is concerned. The other 4 slots are seen by the switch as “AUDIX-reserved” slots.

In CL mode the TN566 pack supports up to 16 voice ports. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, DEFINITY AUDIX is not an adjunct.

Error Log Entries and Test to Clear Values

Table 10-15. DEFINITY AUDIX Analog Line/Control Link Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1(a)	40977	None			
18	0	busyout station <extension>	WRN	ON	release station <i>extension</i>
23(b)	0	None	WRN	OFF	
130(c)		None	WRN	ON	test port PCSSpp sh
257(d)	40973	None			
513(e)	Any	None			
1025(f)		Loop Around Test (#161)	MIN/ WRN ²	ON	test port <i>PCSSpp l r 2</i>
1281		Conference Test (#7)	MIN/ WRN ²	ON	test port <i>PCSSpp l r 2</i>
1537		NPE Crosstalk Test (#6)	MIN/ WRN ²	ON	test port <i>PCSSpp l r 2</i>

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. This is an in-line error and can only be resolved over time. This indicates that no terminal equipment was present when ringing was attempted. Execute the short **test port PCSSpp** command.
- b. The circuit pack has been logically administered but not physically installed. The alarm will be cleared when the circuit pack is installed.
- c. The circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reseal or replace the circuit pack.
- d. This is an in-line error and can only be resolved over time. This error indicates that ringing voltage is absent. If only one analog circuit pack in the system has this problem, then replace the circuit pack. If only analog circuit packs on a particular carrier have this error, then the ringing generator may not be connected to this carrier. If analog circuit packs on many carriers have this error, check the ringing generator.
- e. AUDIX is not available to the switch. Check the AUDIX system, referring to *DEFINITY AUDIX System Maintenance*, 585-300-110.

f. The TDM bus is out of service. See the “TDM-BUS” section.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Loop Around Test #161* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Loop Around Test (#161)		X	ND
Conference Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND

1. D = Destructive; ND = Nondestructive

NO-OP Tests

The maintenance strategy for DEFINITY AUDIX emulates the one for ANL-16-L. The tests listed below apply only to ANL-16-L and not to DEFINITY AUDIX. These tests always return PASS.

- Battery Feed Test (#35)
- Audits and Updates Test (#36)
- Station Present Test (#48)

Tests 36 and 48 ABORT when AUDIX is not running.

NPE Crosstalk Test (#6)

This test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the long test sequence and takes about 25 seconds to complete.

Table 10-16. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources for this test. Try (a).

Table 10-16. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Wait until the port is idle before testing. Try (a).
1001	ABORT	Could not allocate the necessary system resources to run this test. Try (a).
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, then try (a).
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors. 2. Resolve any "TONE-PT" errors. Then, try (a).
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the port is in use, it is unavailable for certain tests. Wait until the port is idle before testing. Try (a).
1005	ABORT	This condition indicates that the test is not applicable when the analog port is used in a combined modem pool. This error can be ignored.
1018	ABORT	Test disabled via administration. 1. To enable the test for the particular analog station being tested, enter the change station <extension> command and change the "Test?" field on the Station Form from "n" to "y."
2000	ABORT	Response to the test request was not received within the allowable time period.
2012	ABORT	System could not respond to this request.
2100	ABORT	Could not allocate the necessary system resources for this test. Try (a).
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.

Continued on next page

Table 10-16. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

- Note:
- a. Retry the command at 1-minute intervals a maximum of 5 times

Conference Circuit Test (#7)

This test verifies that the NPE channel for the port being tested can correctly perform the conferencing function.

Table 10-17. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. (a)
1000	ABORT	System resources required to run test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the port is in use, wait until it is idle before retesting.(a)
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the port is in use, wait until it is idle before testing. Try (a).
1018	ABORT	Test disabled by administration. This only applies to analog stations. 1. To enable the test for the analog station being tested, enter the change station <extension> command and change the "Test?" field on the Station Form from "n" to "y."
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources for this test. Try (a).

Continued on next page

Table 10-17. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/Recommendation
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Note:

- a. Retry the command at 1-minute intervals a maximum of 5 times.

Loop Around Test (#161)

This test is designed to check the on-board transmission capabilities of the NPE on the analog port.

Table 10-18. TEST #161 Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources for this test. Try (a).
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the port is in use, wait until it is idle before testing. 1. If the port status is idle, try (a).
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS" to diagnose TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, try (a).

Continued on next page

Table 10-18. TEST #161 Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors. 2. Resolve any "TONE-PT" errors. 3. If neither condition exists, try (a).
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the port is in use, wait until the port is idle before testing. Try (a).
1018	ABORT	Test disabled by administration. To enable the test for the particular analog station being tested, enter the change station <extension> command and change the "Test?" field on the Station Form from "n" to "y."
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources for this test. Try (a).
	FAIL	The reflective Loop Around Test failed. This causes noisy or unreliable connections or other users calling this port may hear an echo. 1. Replace the circuit pack.
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

Note:

a. Retry the command at 1-minute intervals a maximum of 5 times.

ALARM-PT (ALARM PORT)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ALARM-PT	MIN	test port PCSSpp l	Alarm-Port
ALARM-PT	WRN	test port PCSSpp sh	Alarm-Port

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The Alarm Port Maintenance Object provides on-board maintenance for an analog line port that is administered as an external device alarm port. Tests are provided to verify the analog line port's ability to detect an external device alarm. The External Device Alarm (EXT-DEV) Maintenance Object is used for the off-board external device alarm.

ANL-16-L (16-Port Neon Analog Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ANL-16-L	MIN	test port PCSSpp l	16-Port Neon Analog Line
ANL-16-L	WRN	test port PCSSpp sh release station <ext>	16-Port Neon Analog Line

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The following are 16-Port Analog Line circuit packs:

TN746	TN746B
TN468 [G3iV2-386]	TN749 [G3iV2-386]
TN468B [G3iV2-386]	TN2135 [G3iV2-386]
TN2144 [G3iV2-386]	TN2149 [G3iV2-386]

These circuit packs provide 16 ports for analog voice terminals. The TN746, TN468, and TN749 support only single-line, on-premises/in-building, analog voice terminals, and not off-premises stations, since these circuit packs are not equipped with lightning protection. The TN746B, TN2144, TN2149, and TN468B support both on-premises and off-premises (that is, out-of-building) analog voice terminals. The TN468, TN468B, TN479, TN2135, TN2144, and TN2149 do NOT support the neon message waiting feature.

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled via the **change station <extension>** command. However, on some releases of the software, this action disables Tests #6, #7, #161, and #35 as well as Test #48.

No maintenance of the terminal connected to the 16-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the neon message waiting lamp power and the common ringing application circuitry are reported as part of the Common Port Circuit Pack errors (see errors 1281 and 1793 in the XXX-BD (Common Port Circuit Pack) Maintenance documentation).

Hardware Error Log Entries and Test to Clear Values

Table 10-19. 16-Port Neon Analog Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	40960 40977	none			
15 (b)	Any	Audits and Updates Test (#36)			
18	0	busyout station <extension>	WRN	ON	release station <extension>
130 (c)		None	WRN	ON	test port PCSSpp sh
257 (d)	40973	none			
513 (e)		Station Present Test (#48)	WRN	OFF	test port PCSSpp sh r 2
769		Battery Feed Test (#35)	MIN/WRN ²	ON	test port PCSSpp sh r 2
1025		Loop Around Test (#161)	MIN/WRN ²	ON	test port PCSSpp l r 2
1281		Conference Test (#7)	MIN/WRN ²	ON	test port PCSSpp l r 2
1537		NPE Crosstalk Test (#6)	MIN/WRN ²	ON	test port PCSSpp l r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. This is an in-line error and can only be resolved over time. This indicates that no terminal equipment was present when ringing was attempted. Execute the short **test port PCSSpp** command, and follow the procedure for the results of Test #48.

■

40960—indicates that too many simultaneous incoming ringing attempts were made on this board. Only four ports on a board may be ringing simultaneously. A fifth incoming call will cause an inline error from the board.

- 40977—indicates that no terminal equipment was connected when ringing was attempted. Run the short Test via the **test port PCSSpp** command, and follow the procedure for the results of Test #48.
- b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).
- c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- d. This is an in-line error and can only be resolved over time. This error indicates that ringing voltage is absent. If only one Analog circuit pack in the system has this problem, then replace the circuit pack. If only Analog circuit packs on a particular carrier have this error, then the ringing generator may not be connected to this carrier. If Analog circuit packs on many carriers have this error, then it is probably a problem with the ringing generator.
- e. Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled using the **change station <extension>** command. However, on some releases of the software, this action disables Tests #6, #7, #161, and #35 as well as Test #48.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following table when inspecting errors in the system. By clearing error codes associated with the *Battery Feed Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Battery Feed Test (#35)	X	X	ND
Station Present Test (#48)	X	X	ND
Loop Around Test (#161)		X	ND
Conference Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-20. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at one-minute intervals a maximum of five times.
1001	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS (TDM Bus)" Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times.

Continued on next page

Table 10-20. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to "TTR-LEV (TTR Level)" Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to "TTR-LEV (TTR Level)" Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold).
1018	ABORT	The test has been disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station being tested, enter change station extension and set the 'Test?' field on the station from 'n' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-20. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is

instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 10-21. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold).
1018	ABORT	The test has been disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for the particular analog station being tested, enter change station extension and set the 'Test?' field on the station from 'n' to 'y.'

Table 10-21. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. 1. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT Maintenance documentation. 2. If there are no TONE-PT errors in the error log, retry the test at 1-minute intervals for a maximum of 5 times.
Any	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Issue the display port and the status station commands to determine if the station is idle. If the station is found to be idle, issue the test port command for this port. 2. If the test continues to fail, issue the busyout port and the release port commands, and then retest the port. 3. If the test still fails, replace the board.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery, and by trying to detect a current.

⇒ NOTE:
For the TN746B 16-Port Neon Analog Line circuit pack, Test #35 always "passes." No actual testing is performed on the TN746B while the test is running. Test #35 operates in the normal manner for TN746.

Table 10-22. TEST #35 Battery Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold).

Table 10-22. TEST #35 Battery Feed Test — Continued

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test has been disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for the particular analog station being tested, enter change station extension and set the 'Test?' field on the station from 'n' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
	FAIL	The port's battery feed chip is unable to supply sufficient power to the terminal equipment. This could be a marginal test, and the terminal equipment may be operating satisfactorily. 1. Retry the test at 1-minute intervals for a maximum of 5 times. 2. If the test continues to fail, determine whether the customer is experiencing problems on this line. Replace the circuit pack only if the customer is experiencing problems.
	PASS	The port's battery feed chip is able to provide power to the station equipment to detect on-/off-hook, but may not be able to supply power for touch-tones. If touch-tones are inoperative on this station, then replace the circuit pack because this port is inoperative. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Station Status and Translation Audits and Updates Test (#36)

This test updates the Analog port's message lamp state (if it has one) and translations (such as station type, dial type, network connection) with information kept in the software. The software is updated with the switchhook state reported by the port processor. When the ringer is in the off state, this test also turns off the station's ringer to prevent constant ringing caused by defective hardware.

Table 10-23. TEST #36 Station Status and Translation Audits and Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold).
1006	ABORT	This port has been busied out by command, or taken out-of-service by the failure of the NPE Crosstalk Test. 1. Look in the error log for error type 18 (port busied out) for this port. If this error is present, release the port with the release station extension command, and run the test again. 2. Look in the error log for error type 1025 (NPE crosstalk test failed) for this port. If this error is present, investigate the errors associated with the NPE Crosstalk Test 6. 3. Make sure that the terminal is connected and in service, and then retest.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.

Table 10-23. TEST #36 Station Status and Translation Audits and Updates Test — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL	This does not indicate a hardware problem. The switchhook audit failed. The other updates were not performed because of this failure. This may occur when the audit is performed at the same time that the terminal equipment goes off-hook. Use the status station command to determine when the port is available for testing. 1. When the port becomes available for testing, retry the command at one-minute intervals a maximum of five times.
5	FAIL	This does not indicate a hardware problem. However, there may be an internal software error. The message waiting lamp update failed. The translation and ringer updates were not performed because of this failure.
7	FAIL	The translation update failed. This does not indicate a hardware problem. However, there may be an internal software error. The ringer update was not performed because of this failure.
8	FAIL	This does not indicate a hardware problem. However, there may be an internal software error. The ringer update failed. 1. Retry the command at one-minute intervals a maximum of five times.
	PASS	The software and the port processor have the same status. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Station Present Test (also called Ringing Application Test) (#48)

This test provides a burst of ringing current to the terminal equipment and detects that current flows. This test ascertains whether terminal equipment is connected to the port.

This test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled using the Tests field of the station administration screen form. However, on some releases of the software, this action disables Tests #6, #7, #161, and #35 as well as Test #48.

Table 10-24. TEST #48 Station Present Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold).
1008	ABORT	Could not allocate a ringing circuit. Either all the ringing circuits are in use or the ringing generator is defective or it is not wired correctly. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or is not wired correctly (see errors for RING-GEN). If it doesn't occur on other ports, then all four ring phases are in use.

Table 10-24. TEST #48 Station Present Test — Continued

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test has been disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the brief ringing disturbance that this test may cause). 1. To enable the test for the particular analog station being tested, enter change station extension and set the 'Test?' field on the station from 'n' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
	FAIL	The terminal equipment is not connected to the circuit pack. Some terminal equipment such as modems may fail even when connected properly. 1. Remotely test the equipment. 2. If the test fails again, look for RING-GEN errors in the error log. If present, refer to the RING-GEN (analog ring generator) Maintenance documentation. 3. Check all of the wiring between the station equipment and the switch. Then, run the test again. 4. If the test still fails, the set may be defective. Check the set, and replace it, if necessary. 5. Some terminal equipment could fail even when it is connected properly. If this is the case, disable the test using the change station extension command (enter 'n' into the Test field). Note that this action also disables tests 6, 7, 161, and 35 on this port.
	PASS	The station is connected properly to the switch. This test may also pass if no terminal equipment is connected and the terminal is located very far from the switch. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

Continued on next page

Table 10-24. TEST #48 Station Present Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Loop Around Test (#161)

Each Analog port consists of:

- an NPE for port connectivity and gain, and conferencing functionality
- a code that converts the digital signals of the TDM Bus to analog signals
- a battery feed chip that provides power to the telephone set for signaling, dial pulsing, transmission, and balance

This test is designed to check the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the analog port. A Tone Detector and a Tone Generator talk and listen on the same pair of time slots as the Analog Port. The Analog Port is then instructed to go into loop around mode (see the following below). The test passes if the signal measured by the Tone Detector is within acceptable limits.

Figure 10-2. Analog Loop Around Test

Table 10-25. TEST #161 Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 25-1. TEST #161 Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS (TDM Bus)" Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to the "TTR-LEV (TTR Level)" Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to the "TONE-PT (Tone Generator)" Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test is not run because the port is administered as either an External Alert or Announcement port.

Continued on next page

Table 10-25. TEST #161 Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test has been disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for the particular analog station being tested, enter change station extension and set the 'Test?' field on the station from 'n' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The reflective loop around test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board, as described below. 1. Since the test may be affected by a line seizure, repeat the test at 1-minute intervals for a maximum of 5 times. 2. Run circuit pack tests to check the tone generator circuit pack and the tone detector circuit pack by using the test board PCSS short command. 3. Resolve any problems that are detected on the tone generator circuit pack or the tone detector circuit pack. 4. If the tone generator and tone detector circuit packs are functioning properly and the test still fails and a voice terminal is connected and wired properly, replace the analog line circuit pack.
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, or by examining the station.

Continued on next page

Table 10-25. TEST #161 Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

ANL-BD (Analog Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ANL-BD	MIN	test board PCSS sh	8-Port Analog Line Circuit Pack
ANL-BD	WRN	test board PCSS sh	8-Port Analog Line Circuit Pack
ANL-BD	MIN	test board PCSS sh	8-Port Neon Analog Line Circuit Pack
ANL-BD	WRN	test board PCSS sh	8-Port Neon Analog Line Circuit Pack
ANL-BD	MIN	test board PCSS sh	16-Port Neon Analog Line Circuit Pack
ANL-BD	WRN	test board PCSS sh	16-Port Neon Analog Line Circuit Pack

1. Where P is the port network number (1 for PPN and 2 or [G.1] 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to "XXX-BD (Common Port Circuit Pack)" Maintenance documentation for circuit pack level errors. See also "ANL-LINE (8-Port Analog Line), ANL-NE-L (8-Port Neon Analog Line)", and "ANL-16-L (16-Port Neon Analog Line)" Maintenance documentation for related line information.

ANL-LINE (8-Port Analog Line), ANL-NE-L (8-Port Neon Analog Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ANL-LINE	MIN	test port PCSSpp l	8-Port Analog Line
ANL-LINE	WRN	test port PCSSpp sh	8-Port Analog Line
ANL-NE-L	MIN	test port PCSSpp l	8-Port Neon Analog Line
ANL-NE-L	WRN	test port PCSSpp sh	8-Port Neon Analog Line

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

The 8-Port Analog Line circuit packs are:

- TN742 TN431 [G3iV2-386]
- TN769 TN443 [G3iV2-386]
- TN712 TN467 [G3iV2-386]
- TN411 [G3iV2-386]

These circuit packs provide eight ports for single line on-premises or off-premises analog endpoints such as analog voice terminals, queue warning level lamps, recorded announcements, dictation machines, PagePac™ paging equipment, external alerting devices, modems, facsimile machines, and AUDIX voice ports. The TN769 supports a neon message waiting lamp. The other eight-port analog lines do not support the lamp.

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled using the Tests field of the station administration screen. However, on some releases of the software, this action disables Tests #6, #47, and #35 as well as Test #48. Test #47 may cause a false alarm when the port is connected to off-premises equipment, some non-voice terminal equipment, and some loop equipment. If this is the case, then the test should be disabled using the Tests field of the **change station <extension>** command.

No maintenance of the terminal connected to the 8-Port Analog Line circuit pack or 8-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the neon message waiting lamp power (for ANL-NE-L only) and the common ringing application circuitry are reported as part of the Common Port Circuit Pack errors (see errors 1281 and 1793 in the XXX-BD (Common Port Circuit Pack) Maintenance documentation).

Hardware Error Log Entries and Test to Clear Values

Table 10-26. 8-Port Analog Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	40960 40975 40977	None			
15 (b)	Any	Audits and Updates Test (#36)			
18	0	busyout station <extension>	WRN	OFF	release station <extension>
130(c)		None	WRN	ON	test port PCSSpp sh
257 (d)		Station Present Test (#48)	WRN	OFF	test port PCSSpp sh r 3
513		Battery Feed Test (#35)	MIN/ WRN ²	ON	test port PCSSpp sh r 2
769 (e)		Loop Around and Conference Test(#47)			test port PCSSpp l r 3
1025		NPE Crosstalk Test (#6)	MIN/WR N ²	ON	test port PCSSpp l r 3
1281 (f)					
1793 (f)					

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Major or Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. These are in-line errors and can only be resolved over time.
- 40960—indicates that too many simultaneous incoming ringing attempts were made on this board. Only four ports on a board may be ringing simultaneously. A fifth incoming call will cause an inline error from the board.

■ 40975—indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance. Call the terminal equipment and verify that the terminal

rings. If the terminal doesn't ring, then replace it. Otherwise, issue the **test port PCSSpp** command, and follow the procedure for Test #48.

- 40977—indicates that no terminal equipment was connected when ringing was attempted. Run the Short Test via the **test port PCSSpp** command, and follow the procedure for the results of Test #48.
- b. This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate errors (if any).
- c. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- d. Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled via the **change station <extension>** command. However, on some releases of the software, this disables Tests #6, #47, and #35 as well as Test #48.
- e. Test #47 may cause a false alarm when the port is connected to off-premises equipment, some non-voice terminal equipment, and some loop equipment. If this causes a false alarm, then disable the test by changing the Tests field of the **change station** command to "no."
- f. Refer to "XXX-BD (Common Port Circuit Pack)" Maintenance documentation.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery Feed Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Battery Feed Test (#35)	X	X	ND
Station Present Test (#48)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Loop Around and Conference Test (#47)		X	ND
Station Status and Translation Audits and Updates Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-27. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS (TDM Bus)" Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to "TTR-LEV (TTR Level)" Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to "TONE-PT (Tone Generator)" Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times.

Table 10-27. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1018	ABORT	Test disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter change station extension and set the 'Test?' field on the 'Station Form' to 'y.'
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-27. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises.  NOTE: This test always passes for Analog circuit packs TN712 prior to Vintage 14 and TN742 prior to Vintage 4.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Battery Feed Test (also called Port Diagnostic Test) (#35)

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switchhook capabilities of the battery feed chip by terminating the port, applying battery, and trying to detect a current.

Table 10-28. TEST #35 Battery Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times.
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5

Table 10-28. TEST #35 Battery Feed Test — Continued

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Test disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter change station extension and set the 'Test?' field on the 'Station Form' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The port's battery feed chip is unable to supply sufficient power to the terminal equipment. This may occur when the test is performed at the same time that the terminal equipment goes off-hook. 1. Use status station to determine when the port is available for testing. When the port becomes available for testing, retry the command at 1-minute intervals a minimum of five times. 2. If the test continues to fail, determine whether the customer is experiencing problems on this line. Replace the circuit pack only if the customer is experiencing problems.
	PASS	The port's battery feed chip is able to provide power to the station equipment to detect on-/off-hook. However, the battery feed chip may still be unable to provide power for touch-tones. If tones are heard when buttons are pressed, then the battery feed chip is functioning correctly; otherwise, replace the circuit pack because this port is defective. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises.  NOTE: This test always passes for TN712 Analog circuit packs prior to Vintage 14 and TN742 prior to Vintage 6.

Continued on next page

Table 10-28. TEST #35 Battery Feed Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Station Status and Translation Audits and Updates Test (#36)

This test updates the analog port's message lamp state (if it has one) and translations (such as station type, dial type, network connection) with information kept in the software. The software is updated with the switchhook state reported by the port processor. When the ringer is in the off state, this test also turns off the station's ringer to prevent constant ringing caused by defective hardware.

Table 10-29. TEST #36 Station Status and Translation Audits and Updates Test

Error Code	Test Result	Description/ Recommendation
1004	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1006	ABORT	This port has been busied out by command or taken out-of-service by the failure of the NPE Crosstalk Test. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error is present, then release the port with the release station extension command and run the test again. 2. Look in the Error Log for Error Type 1025 (NPE Crosstalk Test failed) for this port. If this error is present, then investigate the errors associated with the NPE Crosstalk Test (#6) first. 3. Make sure that the terminal is connected and in service, and then retest.
2000	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.

Table 10-29. TEST #36 Station Status and Translation Audits and Updates Test — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL	This does not indicate a hardware problem. The switchhook audit failed, and the other updates were not performed because of this failure. This condition may occur when the audit is performed at the same time that the terminal equipment goes off-hook. Use the status station command to determine when the port is available for testing. 1. When the port becomes available for testing, retry the command at one-minute intervals a maximum of five times.
5	FAIL	This does not indicate a hardware problem but may indicate an internal software error. The message waiting lamp update failed. The translation and ringer updates were not performed because of this failure.
7	FAIL	The translation update failed. The ringer update was not performed because of this failure. This does not indicate a hardware problem but may be an internal software error.
8	FAIL	This does not indicate a hardware problem but may be an internal software error. The ringer update failed. 1. Retry the command at one-minute intervals a maximum of five times.
	PASS	The software and the port processor have the same status. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises.  NOTE: This test always passes for TN712 Analog circuit packs prior to Vintage 14 and TN742 circuit packs prior to Vintage 6.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Loop Around and Conference Test (#47)

Each Analog Port consists of:

- an NPE for port connectivity and gain, and conferencing functionality
- a code that converts the digital signals of the TDM Bus to analog signals
- a battery feed chip that provides power to the telephone set for signaling, dial pulsing, transmission, and balance.

This test is designed to check the on-board transmission capabilities of the NPE, the code, and the battery feed chip of the Analog Port. A Tone Detector and a Tone Generator talk and listen on the same pair of time slots as the Analog Port. The Analog Port is then instructed to go into loop around mode (see Figure 10-2). The test passes if the signal measured by the Tone Detector is within acceptable limits.

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. As part of Test #47, the operation of the port conference circuits in the NPE for three and four parties is also tested. In addition, a test is run to measure noise. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

The noise test is performed by filtering out the tone, and then measuring inherent port noise.

NOTE:

This Loop Around Test is sensitive to the length of the loop, the equipment in the loop, or the equipment terminating the loop, such as off-premises stations. If this test is causing a false alarm, then disable the test by changing the Tests field to "no" using the **change station** command for this station.

Figure 10-3. Analog Loop Around and Conference Test

Table 10-30. TEST #47 Loop Around and Conference Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
7	ABORT	The port was seized by a user for a valid call. 1. Enter display port PCSSpp to determine the station's extension. Enter status station extension to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port is idle, retry the command at 1-minute intervals up to 5 times.

Continued on next page

Table 10-30. TEST #47 Loop Around and Conference Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. (This could be a Music-on-Hold port.) 1. Enter display port PCSSpp to determine the station's extension. Enter status station extension to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 2. If the port is idle, retry the command at 1-minute intervals up to 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS (TDM Bus)" Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to "TTR-LEV (TTR Level)" Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to "TONE-PT (Tone Generator)" Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times.
1004	ABORT	The port has been seized for a valid call during the conference or noise test. Use the status station command to determine when the port is available for testing. 1. If the circuit pack is a TN742 with vintage 10 or less, this test is not valid. Otherwise, proceed with #2. 2. When the port is available for testing, retry the command at 1-minute intervals, a maximum of 5 times. 3. If the test continues to abort and the port is not in use, escalate the problem.

Continued on next page

Table 10-30. TEST #47 Loop Around and Conference Test — Continued

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1018	ABORT	Test disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter change station extension and set the 'Test?' field on the 'Station Form' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals a maximum of 5 times.
7	FAIL	The conference test or the noise test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board, as described below.
13		The reflective loop around with gain set to low and the 600-ohm balance failed. This will cause noisy or unreliable connections.
14		The reflective loop around test (with the gain set to high, using RC balance) failed. This could cause noisy or unreliable connections. The problem can also be off-board, as described below.
15		The nonreflective loop around test failed. This could cause noisy or unreliable connections, or users calling this port may hear an echo. The problem can also be off-board, as described below. <i>More information continues on the next page.</i>

Continued on next page

Table 10-30. TEST #47 Loop Around and Conference Test — Continued

Error Code	Test Result	Description/ Recommendation
7 13 14 15 (cont'd.)	FAIL (cont'd.)	1. Disconnect the terminal equipment from the circuit pack at the cross-connect and run the test again. 2. If the test fails again, replace the circuit pack and reconnect the terminal equipment. If the test passes the second time, then the test results were affected by the terminal equipment connected to the port; in this case, ignore the results of this test if all other tests pass or abort and the station is operating properly. Failure of test 47 does not cause an alarm. If there are failures of other tests, then investigate those errors. User reported troubles with this port should be investigated by using other port tests, by examining station wiring, and by examining the station to ensure that it is correctly translated as off-premises or on-premises. ➡ NOTE: If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test.
	PASS	The port is able to provide an analog transmission path to the station equipment. User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises. ➡ NOTE: This test always passes for TN712 Analog circuit packs prior to Vintage 14 and TN742 circuit packs prior to Vintage 6.

Table 10-30. TEST #47 Loop Around and Conference Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

Station Present Test (also called Ringing Application Test) (#48)

This test provides a burst of ringing current to the terminal equipment and detects that current flows. This test is to ascertain whether or not terminal equipment is connected to the port.

This test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled using the Tests field of the station administration screen. However, on some releases of the software, this action disables Tests #6, #47, and #35 as well as Test #48.

Table 10-31. TEST #48 Station Present Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 10-31. TEST #48 Station Present Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp to determine the station's extension. Enter status station extension to determine the service state of the port. If the port is in use, it will be unavailable for certain tests. Wait until the port is idle before retesting. 1. If the port is idle, retry the command at 1-minute intervals up to 5 times. 2. Check for phone left off-hook or for wiring problems.
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The test was aborted due to a configuration problem. This code will result under either of the following conditions: 1. This test may not be applicable, or it may be disruptive to terminal equipment other than a voice terminal (for example, the modem pool member or music on hold). 2. The circuit pack is one of the following: — TN742 vintages 13,14 and 15 — TN769 vintages 3,4 and 5
1008	ABORT	Could not allocate a ringing circuit for one of the following reasons: ■ All the ringing circuits are in use, or ■ The ringing generator is defective, or ■ It is not wired correctly. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, look for RING-GEN errors in the Error Log. If an ABORT 1008 occurs for Test #48 on other circuit packs as well, then the ringing generator may be defective or not wired correctly. If it does not occur on other ports, then that circuit pack is currently using all four ringing phases.

Table 10-31. TEST #48 Station Present Test — Continued

Error Code	Test Result	Description/ Recommendation
1018	ABORT	The test was disabled via administration. The default for the 'Test' field on the 'Station' form is 'y'; thus, you may want to determine why this field has been set to 'n' on this station (this may be due to the ringing application test 48, which can be customer or terminal disturbing). 1. To enable the test for a particular station, enter change station extension and set the 'Test?' field on the 'Station Form' to 'y.'
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required to run this test are not available. Either a system allocation to get information about the port or to put the port into a service state failed or the attempt to put the port in connection with a tone source failed (this could be a tone-clock problem). The tone-clock and tone detectors could be having a communication problem, for example, the companding modes could be out of synchronization. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The terminal equipment is not connected to the circuit pack or the ringing generator may have failed. 1. Remotely test the equipment. 2. If the test fails again, look for RING-GEN errors in the error log. If present, refer to the RING-GEN (analog ring generator) Maintenance documentation. 3. Check all of the wiring between the station equipment and the switch. Then, run the test again. 4. If the test still fails, the set may be defective. Check the set, and replace it, if necessary. 5. Some terminal equipment (such as a modem) could fail even when it is connected properly. If this is the case, disable the test using the change station extension command (enter 'n' into the 'Test' field). Note that this action also disables tests 6, 7, 161, and 35 on this port.
	PASS	The station is connected properly to the switch. This test may also pass if no terminal equipment is connected and the terminal is located far from the switch (that is, it is off-premises). User-reported troubles on this port should be investigated by using other port tests, by examining station wiring, by examining the station, and by ensuring that the terminal is correctly translated as off-premises or on-premises.  NOTE: This test always passes for TN712 Analog circuit packs prior to Vintage 14 and TN742 circuit packs prior to Vintage 6.

Table 10-31. TEST #48 Station Present Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.

ANN-BD (Announcement Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ANN-BD	MINOR	test board PCSS I	Announcement Circuit Pack
ANN-BD	WRN	test board PCSS I	Announcement Circuit Pack

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The TN750 Announcement circuit pack is a service circuit which provides a DEFINITY Generic 3 customer with an integrated means for recording announcements that can be played back on demand by call processing as part of a calling feature (for example, announcements on hunt group calls). There are 16 Announcement Ports on the Announcement circuit pack. Each port can play any integrated announcement, independently of the other ports. In addition to the 16 Announcement Ports, the Announcement circuit pack also has one Data Line Circuit Port (port 17). The Data Line Circuit Port is used for uploading/downloading the announcement memory to/from the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2]. If there are any errors associated with port 17, refer to "DAT-LINE (Data Line)" Maintenance documentation. If there are any errors associated with any other port, refer to "ANN-PT (Announcement Port)" Maintenance documentation.

 **NOTE:**

TN750C is required if your system will have multiple announcement boards. To use multiple announcement boards, you must have G3V4 software, and at least one TN750C (up to ten are allowed). Only one TN750A/B may be present in the system when a TN750C is used. The announcements from a TN750A/B can be saved and restored to a TN750C — but once the announcements are recorded onto a TN750C, they are not backward compatible with the TN750A/B.

The Announcement circuit pack has two processors on it. The first processor, or Angel, controls the circuit pack and communicates with the switch via the control channel on the TDM Bus. The second processor, or Speech Processor (SP), controls the speech memory and announcements. Digital speech is converted from its TDM Bus form to an internal storage form (for recording) and vice versa (for playbacks) by the 140AY device on the circuit pack, which has 16 channels (one for each Announcement Port).

General Notes

Here are a few **very important** general notes that apply to any problem on the Announcement circuit pack. The user should read this before attempting to work on the TN750 Announcement circuit pack or Announcement Ports, **especially if the circuit pack needs to be replaced.**

1. The Announcement circuit pack retains all integrated announcements *as long as the circuit pack has power*. For this reason, whenever there is a problem with either the Announcement circuit pack or an Announcement Port that may require the circuit pack to be reset, it is always best to try to reset the circuit pack via the **reset board PCSS** command first. If that does not work, replace the circuit pack. **Announcements are preserved through a software reset, but they are lost when the circuit pack is reseated.**
2. **If a customer has announcements on the Announcement circuit pack that cannot be rerecorded easily, then announcements must be saved on the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2] to ensure that they are not lost.** This should be done as soon as the announcements are recorded on the circuit pack (or whenever they are changed), assuming that the circuit pack is in proper working order (see Note).

NOTE:

Unlike translations, announcements are NEVER automatically saved to the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2].

3. The administration terminal **save announcements** command replaces the announcement file on the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2] the Announcement circuit pack speech memory. Care must be taken not to mistakenly enter this command and, as a result, destroy a valid file on the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2].
4. The **restore announcements** command replaces the Announcement circuit pack speech memory with the announcement file on the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2]. Care must be taken not to mistakenly enter this command, destroying valid speech memory (especially if the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2] does not have a valid announcement file on it).
5. Whenever the Announcement circuit pack is replaced, announcements must always be rerecorded or downloaded to the new circuit pack. Otherwise, call processing is not able to use the pack.
6. If announcement speech memory is corrupted, announcements should not be saved [that is, if the Announcement Checksum Test (#209) fails, or if the speech sounds corrupted on playback]. This can ruin a good announcement file on the system tape [G3iV1.1-286] or memory card

[G3sV2, G3iV2-386, G3vsV2] and potentially cause errors/alarms on any circuit pack to which the new file is downloaded. However, if the customer does not have a valid announcement file on the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2], announcements can be saved in an effort to try to retain some of them (all of the announcements recorded may not be corrupted).

7. Due to a hardware fault in the TN750 announcement board, the following sequence of events may cause the announcement file to become corrupted and unusable:
 - Fill the board with recorded announcements.
 - Delete the last few announcements recorded.
 - Re-record the announcements deleted.

If the announcement file becomes corrupted, the only solution is to re-record all announcements. To do this, follow these steps:

- a. Remove the announcement board.
- b. Remove the tape cartridge from the tape drive. Do this so that announcements are not automatically restored from tape.
- c. Re-insert the announcement board.
- d. Re-record all announcements.
- e. Insert the tape cartridge in the tape drive.
- f. Issue the save announcements command to save all the announcements on the tape.

This hardware fault is fixed in the TN750B announcement board. However, the TN750B board will not automatically correct an announcement file which has previously been corrupted by a TN750 board. The only way to correct an announcement file corrupted by the TN750 board is to follow the steps above.

Announcement Administration

A brief description of the integrated announcement administration is given here to aid in troubleshooting the Announcement circuit pack and its ports. In many cases, it is necessary to record, play back, and/or delete announcements to resolve an alarm. It may also be necessary to save and restore announcements as part of the maintenance procedures. For a complete description of integrated announcement administration, please refer to the following manuals:

1. *DEFINITY Communications System Generic 3 Implementation*, 555-230-653
2. *DEFINITY Communications System Generic 1 and Generic 3 System Management*, 555-230-500

3. *DEFINITY Communications System Generic 3 V2 Traffic Reports*, 555-230-511
4. *DEFINITY Communications System Generic 1 and Generic 3 Voice Terminal Operations*, 555-230-701

Announcement Session

Announcements can be recorded, played back, and deleted from an announcement session. A station's COS needs to include console permissions in order for that station to be able to enter an announcement session. To enter an announcement session, go off-hook on a station that has console permissions and enter the appropriate Feature Access Code (FAC), administered as Announcement access code on the FACs form. Dial tone should be returned at this point. Enter the extension of the announcement that needs to be recorded, deleted, or played back. Again, dial tone should be heard. To record an announcement, press station keypad digit 1, record after the tone, and hang up when done. To play back an announcement, press 2. To delete an announcement, press 3 (confirmation tone is given if the delete worked). Announcements can also be played back by simply calling the announcement extension associated with them.

Uploading/Downloading Announcements

Integrated announcements on the TN750 Announcement circuit pack can be uploaded to the system tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2] with the administration terminal **save announcements** command. Likewise, integrated announcements can be downloaded to the Announcement circuit pack with the **restore announcements** command. Both of these commands require a free data module of NETCON type to be administered, a data module of announcement type (on the Announcement circuit pack) to be administered, and a tape cartridge to be in the system's tape drive (must not be write-protected) or a memory card (must not be write-protected). These commands are useful in maintaining the customer's recorded announcements. Depending on system traffic, announcement uploads and/or downloads take between 30 and 45 minutes.

The system **automatically** tries to download the Announcement circuit pack five minutes after it is inserted. This automatic download procedure is aborted if:

1. An announcement is recorded within 10 minutes of circuit pack insertion.
2. An announcement download is invoked sooner with the administration terminal **restore announcements** command.
3. No announcement and/or NETCON data module is administered.
4. Either the announcement data module is busy or all the administered NETCON data modules are busy.

5. No tape [G3iV1.1-286] or memory card [G3sV2, G3iV2-386, G3vsV2] is in the system.
6. The tape or memory card in the system does not have a valid announcement file saved on it.

 **NOTE:**

Unlike translations, there is no provision in the Generic 3 system for automatically saving announcements to the system tape or memory card.

Hardware Error Log Entries and Test to Clear Values

Table 10-32. Announcement Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level (See WARNING message below)	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test board PCSS sh r 1
1(a)	0	Circuit pack removed or SAKI Test (#53)	MINOR	ON	
2(p)		None			
14(b)	1 to 64	Announcement Checksum Test (#209)			
18	0	busyout board PCSS	WARNING	OFF	release board PCSS
23(c)	0	None	WARNING	OFF

3840(n)	Any	None			
3999(o)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

WARNING:
All alarms are upgraded to MAJOR when the BASE Tone Generator is set to 12. (France).

Notes:

- a. Error Type 1— This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

 NOTE:

The alarm is logged about 11 minutes after the circuit pack has been removed and/or SAKI Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, follow the instructions for "Red (alarm)" in the "Control and Port Circuit Pack Status LEDs" section in Chapter 7, "LED Interpretation".

 NOTE:

The alarm is logged about 11 minutes after the circuit pack has been removed and/or SAKI Test (#53) fails.

 WARNING:

Reseating and/or replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.

- b. Error Type 14—Whenever the Announcement Checksum Test (#209) fails, this error is logged. The Aux Data indicates the number of the first defective announcement found. This number corresponds to the announcement numbers on the announcement form. The extension relating to the announcement can be determined by the **display announcement** command. This error only appears in the Error Log in conjunction with Error Type 2817. Follow the procedures for Error Type 2817 to troubleshoot Error Type 14.
 - c. Error Type 23—The circuit pack has been logically administered but not physically installed. The alarm is cleared when the circuit pack is installed.
 - d. Error Type 125—A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use the **change circuit-pack** command to readminister this slot to match the circuit pack inserted.
-  Error Type 170—Announcement board is not allowed in slot A03 for a system with Enhanced SCC cabinet. The red led of announcement board is turned on and the error message "Announcement board is not allowed in slot A03" is shown on SAT when **test/busyout/release board A03** commands are entered. The announcement board must be removed and inserted into a different slot.
- f. Error Type 217 and 267—Indicate that there is more than one TN750 Announcement circuit pack inserted in the system. Remove the alarmed circuit pack..
 - g. Error Type 257—This error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.

- h. Error Type 513—This error, when reported with Aux Data in the range of 4352 to 4358, indicates the circuit pack has reported a hardware failure on the circuit pack. The circuit pack should be replaced.

WARNING:

Replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.

- i. Error Type 1025—This error is not service-affecting and no action is required.
- j. Error Type 1281—The SP found a fault in the speech main memory (SMM) (that is, it found one or more faulty memory locations). Whenever this error is logged, error 2817 is also logged [see Note (k)], which causes the maintenance system to run the Announcement Checksum Test (#209) to determine if the bad memory location was being used by an announcement.
- k. Error Type 1538—The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
 - 1. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
 - 2. A busyout/release of the circuit pack has no effect on test results.
 - 3. A **list configuration** command shows that the circuit pack and ports are properly installed.

The system tries to restore the circuit pack within 15 minutes. If the error recurs after 15 minutes, replace the circuit pack. (Refer to Chapter 5, "Routine Maintenance Procedures".)

- l. Error Type 2049 and 2817—These errors are logged in conjunction with Error Type 1281, Aux Data 17699. Since that error [see Note (j)] means that a defective speech memory location was found, the announcement checksum error is also logged. This causes the Announcement Checksum Test (#209) to run, which determines if the defective memory location has corrupted any recorded announcements. If the Checksum Test passes, the faulty memory location is currently not being used, and the SP marks the location as faulty to ensure that future announcements do not attempt to use it.

NOTE:

As memory locations are marked faulty, the amount of available memory decreases, which decreases the total amount of announcement time available on the circuit pack.

- m. Error Type 2049—A transient error that does not cause an alarm can occasionally occur during a SPE, TDM BUS, or Tone Clock interchange. It is possible for a marginal Tone-Clock circuit pack to cause this error

against the ANN-BD without alarming the TONE-BD. If this error occurs again, replacing the Tone-Clock circuit pack may clear up this error. See the FAIL case in the Clock Match Inquiry Test (#212).

- n. Error Type 3840— This error is not service-affecting and no action is required.
- o. Error type 3999— Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.
- p. Error Type 2—Check the Class of Restriction (COR) administered for the Data Line extension assigned to the TN750 for uploading and downloading announcements. The extension can be found by using **list data-module**.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in [Table 10-33](#) when inspecting errors in the system. By clearing error codes associated with the *Control Channel Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-33. System Technician-Demanded Tests: ANN-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND ¹
Control Channel Loop Around Test (#52) (a)		X		ND
Angel-Speech Processor (SP) Handshake Test (#208)		X		ND
Clock Match Inquiry (#212)	X	X		ND
Super Frame Match Inquiry (#211)	X	X		ND
140AY Loop Around Test (#210)	X	X		ND
Announcement Checksum Test (#209)	X	X		ND
Network Processor Element (NPE) Audit Test (#50) (a)		X		ND

Table 10-33. System Technician-Demanded Tests: ANN-BD — Continued

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND ¹
SAKI Test (#53) (a)			X	D

1. D = Destructive, ND = Non-destructive

Note:

a. For a complete description of these tests, refer to the "XXX-BD (Common Port Circuit Pack)" Maintenance documentation.

Angel-Speech Processor (SP) Handshake Test (#208)

This test checks the integrity of the communication link between the two processors on the Announcement circuit pack. Failure of this test indicates that the Speech Processor is insane and **results in the loss of all integrated announcements on the circuit pack.**

Table 10-34. TEST #208 Angel-Speech Processor (SP) Handshake Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 10-34. TEST #208 Angel-Speech Processor (SP) Handshake Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed. Circuit pack cannot be used. Announcement speech memory is cleared when this test fails. Therefore, when the problem has been resolved, announcements must be rerecorded or downloaded to the circuit pack. Refer to "General Notes" near the beginning of this Maintenance documentation. 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, replace the circuit pack and then run this test again. 2. If there are recurring alarms on this circuit pack caused by this test failing, replace the circuit pack even if Step 1 works.  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance documentation.</i>
	PASS	The communications link between the two processors on the Announcement circuit pack is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to "ANN-PT (Announcement Port)" Maintenance documentation for a description of the port tests.

Announcement Checksum Test (#209)

Associated with every recorded announcement is a checksum. In this test, the SP checks a stored global checksum covering all recorded announcements against a calculated one and returns the results to the maintenance system. If the global checksum failed, maintenance requests the SP to check each individual announcement's checksum.

If the test fails, then it returns the total number of defective announcements found. In addition, associated with each failure is an error in the Error Log (Error Type 14). The Aux Data indicates the number of the first defective announcement found. This number corresponds to the announcement numbers on the announcement form. The extension relating to the announcement can be determined by the **display announcement** command.

Table 10-35. TEST #209 Announcement Checksum Test

Error Code	Test Result	Description/ Recommendation
0	ABORT	An error code of 0 indicates that the announcement file has been corrupted due to a hardware fault in the TN750 board. Follow step #7 under "General Notes" at the beginning of this section.
1023	ABORT	There are no announcements currently recorded on the circuit pack.
1024	ABORT	This abort code is given for the following reasons: 1. An announcement upload or download is in progress. 2. An announcement upload or download is requested when this test is running. 3. A record is in progress. 4. A record request comes in when this test is running. If an announcement upload or download is in progress, a status data-module <announcement data extension> command should show that the announcement data port is connected to a NETCON data channel, and [for G3iV1.1-286] the tape drive should be active or [for G3sV2, G3iV2-386, or G3vsV2] the "card-in-use" amber LED for the memory card is on (to determine the extension of the announcement data module, use the list data-module command). See Note (a) at end of table for more information. 1. Wait until the blocking event is finished, and then run this test again. An upload or download could take up to 45 minutes to complete, and a recording session is finished as soon as the station that was making the recording is placed on-hook. 2. If the test continues to abort, and a record or upload/download is not in progress, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT ABORT	Could not allocate the necessary system resources to run this test. Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 10-35. TEST #209 Announcement Checksum Test — Continued

Error Code	Test Result	Description/ Recommendation
0-256	FAIL	Test failed. The error code indicates the total number of defective announcements that were found. When TEST #209 fails with error code 0, the Global Checksum failed on the board, but no individual Checksum failed.  NOTE: Since the announcements are recorded digitally, it is possible for the Announcement Checksum Test to <i>fail</i> but still have all the announcements sound uncorrupted. When an individual announcement fails the Checksum Test, always listen to the announcement first before taking any action (an announcement can be played back by dialing the announcement extension associated with the announcement number). If the announcement sounds corrupted, then rerecord it or delete it.  1. Look in the Error Log to determine the number of the first defective announcement. Play back the announcement. If the announcement sounds defective, rerecord it or delete it. If the error code was greater than one (indicating that there is more than one defective announcement), run this test again and repeat this step. 2. If after deleting and rerecording all defective announcements, the checksum test still fails, reset the circuit pack using the reset board PCSS command and run this test again. 3. If the test still continues to fail, reseal the circuit pack and restore all announcements with an appropriate time estimate (for example, 40 minutes.) Then rerecord the lost announcements (that is, those recorded since the last save operation) and run this test again. 4. If the test still continues to fail, replace the circuit pack, and run this test again.  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.</i>
	PASS	All recorded announcements checksum correctly, indicating that the speech main memory is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to "ANN-PT (Announcement Port)" Maintenance documentation for a description of the port tests.

Notes:

- a. The Announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the Announcement Ports on the circuit pack will be unusable by software, one of which is the record port. Also, **save/restore announcements** will not work, since the record port looks busy to the circuit pack. Note that software does not have any way of knowing this, and attempts to use the ports.

If the circuit pack is locked into this state, the following symptoms are observed:

1. When attempting to record an announcement, users hear the proper record tone, but the announcement do not record (they do not know it until the announcement is played back).
2. Performing a **test board long** when the circuit pack is in this state yield the following abort codes:
 - Ports 1 AND 9 abort Test #206 with code 1024
 - Ports 1 AND 9 abort Test #205 with code 2000
 - Board level Tests #209 and #210 abort with code 1024
3. The **save/restore announcements** command times out with:
Error encountered, can't complete request

The Announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack:

- **busyout board PCSS** (this command drops all calls in progress on the Announcement circuit pack)
- reset circuit pack using the **reset board PCSS** command
- release circuit pack using the **release board PCSS** command

140AY Loop Around Test (#210)

This test checks the integrity of the record channel on the Announcement circuit pack (Announcement Port 1). The main function of the 140AY device is to accept Pulse Code Modulation (PCM)/Adaptive Differential Pulse Code Modulation (ADPCM) samples and compress/expand the samples using ADPCM. This test connects a Tone Generator to one port (Announcement Port 1, the recording port), and a Tone Detector to another port (Announcement Port 9). A tone is generated by the Tone Generator on the first port and looped through the 140AY device to the second port. The Tone Detector then responds with a tone present/absent message. The 140AY Loop Around Test is repeated at three different speech compression rates.

Since this test involves sending a tone through two different ports, the Playback Speech Memory Array (PSMA) Test (#206) [see ANN-PT (Announcement Port) Maintenance documentation for a description of this test] is run on the two ports first to make sure that they are working properly.

Table 10-36. TEST #210 140AY Loop Around Test

Error Code	Test Result	Description/ Recommendation
1-3	ABORT	Response to the test request was not received within the allowable time period. The error code indicates at which speech compression rate the test aborted (one being the first rate tested, three being the last). 1. Retry the command at one-minute intervals a maximum of five times.
10	ABORT	The PSMA Test (#206) failed on Announcement Port 1.
90	ABORT	The PSMA Test (#206) failed on Announcement Port 9. 1. Refer to"ANN-PT (Announcement Port)" Maintenance documentation, Test #206.
1000	ABORT	System resources required to run this test are not available. This test needs Announcement Ports 1 and 9 to run. One of the ports may be in use on a valid call. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and Ports 1 and 9 are not in use, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS (TDM Bus)" Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to the "TTR-LEV (TTR Level)" Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to the "TONE-PT (Tone Generator)" Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times.

Continued on next page

Table 10-36. TEST #210 140AY Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1007	ABORT	The Announcement circuit pack thinks that Port 1 or Port 9 is busy. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow the Announcement Port maintenance procedures for Ports 1 and 9. 3. If the Announcement Ports pass all their tests, escalate the problem.
1024	ABORT	Announcement circuit pack blocked the test because an announcement download is in progress. If an announcement download is in progress, a status data-module &ltannouncement data extension> command should show that the announcement data port is connected to a NETCON data channel, and [for G3iV1.1-286] the tape drive should be active or [for G3sV2, G3iV2-386, or G3vsV2] the "card-in-use" amber LED for the memory card should be on (to determine the extension of the announcement data module, use the list data-module command). See Note (a) at end of table for more information. 1. Wait until download is finished (can take up to 45 minutes), and then run the test again. 2. If the test continues to abort and there is no download in progress, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this error type. 1. Retry the command at one minute intervals a maximum of 5 times.
2007	ABORT	The Announcement circuit pack thinks that Port 1 or Port 9 is busy. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, follow the Announcement Port maintenance procedures for Ports 1 and 9. 3. If the Announcement ports pass all their tests, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 10-36. TEST #210 140AY Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1-3	FAIL	Test failed. The error code indicates at which speech compression rate the test actually failed (one being the first rate tested, three being the last). 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test still fails, replace the circuit pack (see Warning) and run this test again. 2. If there are recurring alarms on this circuit pack caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.</i>
	PASS	The record channel on the Announcement circuit pack is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to "ANN-PT (Announcement Port)" Maintenance documentation for a description of the port tests.

Notes:

- a. The Announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the Announcement Ports on the circuit pack will be unusable by software, one of which is the record port. Also, **save/restore announcements** will not work since the record port looks busy to the circuit pack. Note that software does not have any way of knowing this, and attempts to use the ports.

If the circuit pack is locked into this state, the following symptoms are observed:

- 1. When attempting to record an announcement, users hear the proper record tone, but the announcement does not record (they do not know it until the announcement is played back).
- 2. Performing a **test board long** when the circuit pack is in this state yields the following abort codes:
 - Ports 1 AND 9 abort Test #206 with code 1024
 - Ports 1 AND 9 abort Test #205 with code 2000
 - Board level Tests #209 and #210 abort with code 1024
- 3. The **save/restore announcements** command times out with:

Error encountered, can't complete request

The Announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack:

- **busyout board PCSS** (this command drops all calls in progress on the Announcement circuit pack)
- reset circuit pack using the **reset board PCSS** command
- release circuit pack using the **release board PCSS** command

Super Frame Match Inquiry Test (#211)

The super frame is a means by which the SP synchronizes with the 140AY device on the Announcement circuit pack. If the super frame is not synchronized, the SP is not able to properly process record/playback requests. Both the SP and the hardware generate a super frame pulse. When these two pulses are out of synch, the SP sets a flag to indicate the mismatch. When this test is run, the state of this flag is returned.

Table 10-37. TEST #211 Super Frame Match Inquiry

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 10-37. TEST #211 Super Frame Match Inquiry — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed. Announcement playbacks should sound corrupted. 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this circuit pack caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.</i>
	PASS	The SP can properly process record/playback requests. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to "ANN-PT (Announcement Port)" Maintenance documentation for a description of the port tests.

Clock Match Inquiry Test (#212)

This test is supported to determine the state of the clock generation circuitry on the Announcement circuit pack. This circuitry is used for controlling various pieces of the hardware, like the 140AY device. It is also used to synchronize the Announcement circuit pack with the clock that is on the backplane.

Table 10-38. TEST #212 Clock Match Inquiry Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period. If Error Type 1538 is present in the Error Log, follow the maintenance strategy recommended for this Error Type.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times.

Continued on next page

Table 10-38. TEST #212 Clock Match Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed. Announcements recorded or played back while the clock circuitry is not functioning properly sound distorted. The ANN-BD may be defective or the Active Tone-Clock circuit pack (TONE-BD) in the same Port Network as the ANN-BD may be marginal and is causing this test to fail. 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, proceed to Step 2 or 3 as applicable. 2. If this is a High or Critical Reliability system, determine the Active TONE-BD in this Port Network via the status system command and make the Standby Tone-Clock circuit pack active via the set tone-clock PCSS command. Rerun the test. If the test passes, then replace the now Standby Tone-Clock circuit pack. If the test continues to fail, replace the ANN-BD circuit pack.  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.</i>

Continued on next page

Table 10-38. TEST #212 Clock Match Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL (cont'd.)	3. If this is a Standard system (that is, not a High or Critical Reliability system), replace the ANN-BD. Rerun the test. If the test continues to fail, replace the Tone-Clock circuit pack located in the same Port Network as the ANN-BD.  WARNING: <i>Replacing the Tone-Clock circuit pack causes a standard system PPN to perform a COLD 2 reset or an EPN to reset. See the "How to Replace a Tone-Clock Circuit Pack" section in the "TONE-BD (Tone-Clock Circuit Pack)" Maintenance documentation. Replacing the ANN-BD results in loss of integrated announcements. See "General Notes" near the beginning of this Maintenance procedure.</i> 4. If there are recurring alarms on this circuit pack caused by this test failing, replace the ANN-BD even if the previous steps were successful.  WARNING: <i>Replacing the TONE-BD causes a standard system PPN to perform a COLD 2 reset or an EPN to reset. Replacing the ANN-BD results in loss of integrated announcements. See the "General Notes" section near the beginning of this Maintenance procedure.</i>
	PASS	Announcement record/playbacks should have clear sound quality. User-reported troubles on this circuit pack should be investigated using other circuit packs and port tests. Refer to "ANN-PT (Announcement Port)" Maintenance documentation for a description of the port tests.

ANN-PT (Announcement Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ANN-PT	MINOR	test port PCSSpp l	Announcement Port
ANN-PT	WRN	test port PCSSpp l	Announcement Port

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The TN750 Announcement circuit pack is a service circuit pack that provides a customer with an integrated means for recording announcements that can be played back on demand by call processing as part of a calling feature (that is, announcements on hunt group calls). There are 16 Announcement Ports on the Announcement circuit pack. Each port can play any integrated announcement, independently of the other ports. In addition to the 16 Announcement Ports, the Announcement circuit pack also has one Data Line Circuit Port (Port 17). The Data Line Circuit Port is used for uploading/downloading the announcement memory to/from the system tape. If there are any errors associated with Port 17, refer to "DAT-LINE (Data Line)" Maintenance documentation. If there are any errors associated with the circuit pack, refer to "ANN-BD (Announcement Circuit Pack)" Maintenance documentation.

The Announcement circuit pack has two processors on it. The first processor, or Angel, controls the circuit pack, and communicates with the switch via the control channel on the TDM Bus. The second processor, or SP, controls the speech memory and announcements. Digital speech is converted from its TDM Bus form to an internal storage form (for recording) and vice versa (for playbacks) by the 140AY device on the circuit pack, which has 16 channels (one for each Announcement Port).

General Notes

Here are a few **very important** general notes that apply to any problem on the Announcement circuit pack. The user should read this before attempting to work on the TN750 Announcement circuit pack or Announcement Ports, **especially if the circuit pack needs to be replaced.**

1. The Announcement circuit pack retains all integrated announcements *as long as the circuit pack has power*. For this reason, whenever there is a problem with either the Announcement circuit pack or an Announcement Port that may require the circuit pack to be reset, it is always better to try to reset the circuit pack via the **reset board PCSS** command first and, if that does not work, then try to reseat it. **Announcements are preserved through a software reset, but they are lost when the circuit pack is resealed.**

2. **If a customer has announcements on the Announcement circuit pack that cannot be re-recorded easily, then announcements must be saved on the system tape to ensure that they are not lost.** This should be done as soon as the announcements are recorded on the circuit pack (or whenever they are changed), assuming that the pack is in proper working order (see Note).

This should be done as soon as the announcements are recorded on the circuit pack (or whenever they are changed), assuming that the pack is in proper working order (see Note).

 NOTE:

Unlike translations, announcements are NEVER automatically saved to the system tape.

3. The administration terminal **save announcements** command replaces the announcement file on tape with the Announcement circuit pack speech memory. Care must be taken not to mistakenly enter this command, thereby destroying a valid file on tape.
4. The terminal **restore announcements** command replaces the Announcement circuit pack speech memory with the announcement file on the system tape. Care must be taken not to mistakenly enter this command, thereby destroying valid speech memory (especially if the system tape does not have a valid announcement file on it).
5. Whenever the Announcement circuit pack is replaced, announcements must always be re-recorded or downloaded to the new circuit pack. Otherwise, call processing is not able to use the circuit pack.
6. If announcement speech memory is corrupted, **announcements should not be saved**, that is, if the Announcement Checksum Test (#209) fails or if the speech sounds corrupted on playback. This can ruin a good announcement file on tape and potentially cause errors/alarms on any circuit pack to which the new file is downloaded. However, if the customer does not have a valid announcement file on tape, then announcements can be saved in an effort to try to retain some of them (all of the announcements recorded may not be corrupted).
7. Although Announcement Port 5 and Data Line Circuit Port 17 on the Announcement circuit pack are logically two separate ports, they are physically the same port. Therefore, if one of the ports is in use, the other one will be busy. Also, if Announcement Port 5 is out-of-service, the Data Line Circuit Port is taken out-of-service. However, if the Data Line Circuit Port is out-of-service, the Announcement Port remains in-service.

Announcement Administration

A brief description of the integrated announcement administration is given here to aid in the troubleshooting of the Announcement circuit pack and its ports. In many cases, it is necessary to record, play back, and/or delete announcements

to resolve an alarm. It may also be necessary to save and restore announcements as part of the maintenance procedures. For a complete description of integrated announcement administration, please refer to the following manuals:

1. *DEFINITY Communications System Generic 3 Implementation*, 555-230-653
2. *DEFINITY Communications System Generic 1 and Generic 3 Voice Terminal Operations*, 555-230-701
3. *DEFINITY Communications System Generic 1 and Generic 3 System Management*, 555-230-500
4. *DEFINITY Communications System Generic 3 V2 Traffic Reports*, 555-230-511

Announcement Session

Announcements can be recorded, played back, and deleted from an announcement session. A station's COS needs to include console permissions in order for that station to be able to enter an announcement session. To enter an announcement session, go off-hook on a station that has console permissions and enter the appropriate FAC (administered as Announcement access code on the FACs form). Dial tone should be returned at this point. Enter the extension of the announcement that needs to be recorded, deleted or played back. Again, dial tone should be heard. To record an announcement, press station keypad digit 1, record after the tone, and hang up when done. To play back an announcement, press station keypad digit 2. To delete an announcement, press station keypad digit 3 (confirmation tone is given if the delete worked). Announcements can also be played back by simply calling the announcement extension associated with them.

Uploading/Downloading Announcements

Integrated announcements on the TN750 Announcement circuit pack can be uploaded to the system tape with the administration terminal **save announcements** commands. Similarly, integrated announcements can be downloaded to the Announcement circuit pack with the administration terminal **restore announcements** command. Both of these commands require a free data module of NETCON type to be administered, a data module of announcement type (on the Announcement circuit pack) to be administered, and a tape cartridge to be in the system's tape drive (must not be write-protected). These commands are useful in maintaining the customer's recorded announcements. Depending on system traffic, announcement uploads/downloads take between 30 and 45 minutes.

The system **automatically** tries to download the Announcement circuit pack five minutes after it is inserted. This automatic download procedure is aborted if:

1. An announcement is recorded within 10 minutes of circuit pack insertion.

2. An announcement download is invoked sooner with the administration terminal **restore announcements** command.
3. There is no announcement and/or NETCON data module administered.
4. Either the announcement data module is busy or all the administered NETCON data modules are busy.
5. There is no tape in the system.
6. The tape in the system does not have a valid announcement file saved on it.

 **NOTE:**

Unlike translations, there is no provision in the system for automatically saving announcements to the system tape.

Hardware Error Log Entries and Test to Clear Values

Table 10-39. Announcement Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1		Playback Speech Memory Array (PSMA) Test (#206)	MINOR	ON	test port PCSSpp sh r 3
18	0	The port was busied out	WARNING	OFF	release port PCSSpp
130 (a)		None	WARNING	ON	test port PCSSpp sh
257		Channel Administration Memory Array (CAMA) Test (#205)	MINOR	ON	test port PCSSpp l r 3
	17667	In-line error			
513		140AY Channel Sanity Inquiry Test (#222)	MINOR	ON	test port PCSSpp sh r 3
	17684	In-line error			
769 (b)		None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

 **Notes:**

a. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

- b. This error is logged and the port is alarmed when an alarm is raised on the Announcement circuit pack because of a faulty condition with a common circuit pack resource. Any one of the following alarmed errors on the Announcement circuit pack causes this error to be logged against the Announcement Port: 1793, 2049, 2305, 2561. Follow the ANN-BD (Announcement Circuit Pack) Maintenance documentation to resolve these alarms. When the corresponding circuit pack alarm is cleared, this alarm clears.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Channel Administration Memory Array (CAMA) Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Channel Administration Memory Array (CAMA) Test (#205)		X	ND
Playback Speech Memory Array (PSMA) Test (#206)	X	X	ND
140AY Channel Sanity Inquiry Test (#222)	X	X	ND

1. D = Destructive; ND = Nondestructive

Channel Administration Memory Array (CAMA)
Test (#205)

This test is a memory device that stores information used to control the 140AY device. The Angel asynchronously feeds the CAMA with the control information. During the CAMA test, the Angel writes patterns into the CAMA, reads them back, and verifies that they match. If the patterns do not match, the test fails. This test is run periodically by the switch maintenance and by the Announcement circuit pack in the background.

Table 10-40. TEST #205 Channel Administration Memory Array (CAMA)
Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the circuit pack is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. See Note (a) at end of table for more information.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-40. TEST #205 Channel Administration Memory Array (CAMA)
Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed. Announcements played back on this port may sound corrupted. 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. Refer to "General Notes" near the beginning of this Maintenance procedure.</i>
	PASS	This test verifies that the Angel processor can properly set up this port for playbacks. User-reported troubles on this circuit pack should be investigated using other port and circuit pack tests. (Refer to "ANN-BD (Announcement Circuit Pack)" Maintenance documentation for a description of the circuit pack tests.)

Notes:

- a. The Announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the Announcement Ports on the circuit pack (one of which is the record port) will be unusable by software. Also, **save/restore announcements** will not work since the record port looks busy to the circuit pack. Note that software does not have any way of knowing this and attempts to use the ports.

If the circuit pack is locked into this state, the following symptoms are observed:

1. When attempting to record an announcement, users hear the proper record tone, but the announcement does not record (they do not know it until the announcement is played back).
2. Performing a **test board long** when the circuit pack is in this state yields the following abort codes:
 - Ports 1 AND 9 abort Test #206 with code 1024
 - Ports 1 AND 9 abort Test #205 with code 2000
 - Board level Tests #209 and #210 abort with code 1024
3. The **save/restore announcements** command times out with:

Error encountered, can't complete request

The Announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack:

- **busyout board PCSS** (this command drops all calls in progress on the Announcement circuit pack)
- reset circuit pack using the **reset board PCSS** command
- release circuit pack using the **release board PCSS** command

Playback Speech Memory Array (PSMA) Test (#206)

The PSMA test checks the integrity of a playback channel's interface to the speech memory and the TDM Bus. The SP has an internal buffer that contains a specific 256-byte sequence. During this test, the byte sequence is "played" through the 140AY device onto the TDM Bus. A General Purpose Tone Detector is used to confirm that the proper sequence was played. **This test is very important.** It is the only test that actually checks an Announcement Port's ability to play back an announcement on the TDM Bus. If the test fails, the Tone Detector returns the number of bytes that did not match the expected sequence. The larger the number, the more severe the problem with that port. If this test fails, announcements played over this port should sound corrupted.

It is the only test that actually checks an Announcement Port's ability to play back an announcement on the TDM Bus. If the test fails, the Tone Detector returns the number of bytes that did not match the expected sequence. The larger the number, the more severe the problem with that port. If this test fails, announcements played over this port should sound corrupted.

Table 10-41. TEST #206 Playback Speech Memory Array (PSMA) Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the pack is not in use, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS (TDM Bus)" Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat the test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to "TTR-LEV (TTR Level)" Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to "TONE-PT (Tone Generator)" Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-41. TEST #206 Playback Speech Memory Array (PSMA) Test —
Continued

Error Code	Test Result	Description/ Recommendation
1024	ABORT	Announcement circuit pack blocked the test because an announcement download is in progress. If an announcement download is in progress, a status data-module <announcement data extension> command should show that the announcement data port is connected to a NETCON data channel, and the tape drive should be active. (To determine the extension of the announcement data module, use the list data-module command.) See Note (a) at end of table for more information. 1. Wait until download is finished (could take a maximum of 45 minutes), and then run the test again. 2. If the test continues to abort and there is no download in progress, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-41. TEST #206 Playback Speech Memory Array (PSMA) Test —
Continued

Error Code	Test Result	Description/ Recommendation
1 to 254	FAIL	Test failed. The error code indicates the number of byte count errors found by the Tone Detector. 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. Refer to "General Notes" near the beginning of this Maintenance procedure.</i>
255	FAIL	Test failed. The Announcement Port and the Tone Detector never synchronized. Check for active GPTD-PT errors, and refer to "GPTD-PT [General Purpose Tone Detector Port (CPTR)]" Maintenance documentation to diagnose them first. 1. If there are no active GPTD-PT errors, reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. Refer to "General Notes" near the beginning of this Maintenance procedure.</i>

Table 10-41. TEST #206 Playback Speech Memory Array (PSMA) Test —
Continued

Error Code	Test Result	Description/ Recommendation
	PASS	This port can cleanly play announcements. User-reported troubles on this pack should be investigated using other port and circuit pack tests. Refer to "ANN-BD (Announcement Circuit Pack)" Maintenance documentation for a description of the circuit pack tests.

Notes:

- a. The Announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the Announcement Ports on the circuit pack (one of which is the record port) will be unusable by software. Also, **save/restore announcements** will not work, since the record port looks busy to the circuit pack. Note that software does not have any way of knowing this and attempts to use the ports.

If the circuit pack is locked into this state, the following symptoms are observed:

- 1. When attempting to record an announcement, users hear the proper record tone, but the announcement does not record (they do not know it until the announcement is played back).
- 2. Performing a **test board long** when the circuit pack is in this state yields the following abort codes:
 - Ports 1 and 9 abort Test #206 with code 1024
 - Ports 1 and 9 abort Test #205 with code 2000
 - Board level Tests #209 and #210 abort with code 1024
- 3. The **save/restore announcements** command times out with:

Error encountered, can't complete request

The Announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack:

- **busyout board PCSS** (this command drops all calls in progress on the Announcement circuit pack)
- reset circuit pack using the **reset board PCSS** command

- release circuit pack using the **release board PCSS** command

140AY Channel Sanity Inquiry Test (#222)

The Angel keeps a sanity status bit for each of the 16 channels on the 140AY device. This test queries the Angel to determine the status for a particular channel. If a channel is insane, that implies that announcements cannot be played back on that channel.

Table 10-42. TEST #222 140AY Channel Sanity Inquiry Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Test failed. Announcements cannot be played back over this port. 1. Reset the circuit pack via the reset board PCSS command and then run this test again. If the test continues to fail, replace the circuit pack (see Warning). 2. If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).  WARNING: <i>Replacing the circuit pack results in loss of integrated announcements. Refer to "General Notes" near the beginning of this Maintenance procedure.</i>

Error Code	Test Result	Description/ Recommendation
	PASS	Announcements can be played back over this port. User-reported troubles on this pack should be investigated using other port and circuit pack tests. Refer to the "ANN-BD (Announcement Circuit Pack)" Maintenance documentation for a description of the circuit pack tests.

ANNOUNCE (Announce)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ANNOUNCE	none	none	ANNOUNCEMENT

The ANNOUNCE MO logs an error in the hardware error log if at least one of the following is true:

- The **save announcements** or **restore announcements** command does not complete successfully, or the
- System fails to restore announcements from the memory card [386 system] or tape [286 system] at boot time.

Figure 10-4 shows the connection of the Announcement Circuit Pack to the system. To save or restore announcements, an ANNOUNCEMENT Data Extension must be administered, and at least one DATA-CHL (Network Control Data Channel) must be in the in-service/idle state.

Figure 10-4. Connection of Announcement Circuit Pack to the System

Hardware Error Log Entries

ANNOUNCE Error Log Entries					
Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1(a)(f)	any	None			
257(b)(f)	any	None			
513(c)(f)	0	None			
769(d)(f)	0	None			
1025(e)(f)	any	None			

- Notes:
- a. Error occurred while saving announcements. (See Table 10-42 in the next section for an explanation of Aux Data and for recommended repair actions.)
 - b. Error occurred while saving announcements to the standby SPE. (See Table 10-42 in the next section for an explanation of Aux Data and for recommended repair actions.)
 - c. User pressed cancel while announcements were being saved by the active PE.
 - d. User pressed cancel while announcements were being saved by the standby PE.
 - e. Error occurred while restoring announcements. (See Table 10-42 in the next section for an explanation of Aux Data and for recommended repair actions.)
 - f. The port field for this error contained the active PE complex when the error occurred.

Aux Data Error Codes and Recommended Repair Procedures

Table 10-43. Aux Data Error Codes and Recommended Repair Procedures

Aux Data	Description/ Recommendation
9000 through 9031	CARD-MEM [386 systems] errors. Check and resolve CARD-MEM [386 systems] errors and alarms.
30001 through 30054	Tape [286 systems] errors. Check and resolve TAPE [286 systems] errors and alarms.
32001	Internal system error. 1. Check other ANNOUNCE errors and take corrective action. If there are no other ANNOUNCE errors, do the following: 2. Retry the command at two minute intervals a maximum of three times. 3. If the save/restore announcements command fails, escalate the problem.
32002	Announcement circuit pack is in use. 1. Retry the command at two minute intervals a maximum of three times. 2. If the save/restore announcements command fails, escalate the problem.
32003	Announcement port is in use. 1. Wait for all Announcement ports to become available. 2. Enter the save/restore announcements command.
32004	There are no announcements recorded on the Announcement Circuit Pack. The save announcements command is not allowed to prevent the destroying of the announcement file on tape [286 systems] or on the memory card [386 systems].

Continued on next page

Table 10-43. Aux Data Error Codes and Recommended Repair Procedures —
Continued

Aux Data	Description/ Recommendation
32005	Integrated announcement circuit pack is not present. The Announcement Circuit Pack is not inserted, or it is defective. 1. Enter the list config command to check for the presence of the circuit pack in the system. 2. If the Announcement Circuit Pack is present, use the test board PCSS command to check the status of the Announcement Circuit Pack.
32006	Announcement Data Module not available. 1. Use the status command to check the status of the Announcement Data Module.
32007	Announcement Data Module out of service. 1. Use the status command to check the status of the Announcement Data Module.
32008	Announcement data is being saved or loaded. 1. Retry the command at two minute intervals a maximum of three times. 2. If the save/restore announcements command fails, escalate the problem.
32009	Required DATA-CHL is not administered or out of service. (A DATA-CHL is required to save or restore announcements.) 1. Add a DATA-CHL if none is administered. 2. If a DATA-CHL is administered, use the status command to check the status of all DATA-CHLs. At least one DATA-CHL should be in the in-service/idle state.
32010 32013	DATA-CHL is not administered, or it is unavailable. (A DATA-CHL is required to save or restore announcements.) 1. Add a DATA-CHL if none is administered. 2. If a DATA-CHL is administered, use the status command to check the status of all DATA-CHLs. At least one DATA-CHL should be in the in-service/idle state.
32012	Required Announcement Data Module is not administered. 1. Add an Announcement Data Module and repeat the command.

Continued on next page

Table 10-43. Aux Data Error Codes and Recommended Repair Procedures —
Continued

Aux Data	Description/ Recommendation
32014	Command timed out on the standby processor [286 systems]. This could present problems. 1. Check the error and alarm logs for errors and alarms that are logged against the STBY-SPE (Standby SPE) [286 systems].
32015	Time of day not set. 1. Set the time of day, and reenter the save/restore announcements command.
32016	Internal System errors. Check for any other ANNOUNCE errors and take corrective action.If there are no other announcements errors, do the following: 1. Retry the command at two minute intervals a maximum of three times. 2. If the save/restore announcements command fails, escalate the problem.

ASAI-BD (Multi-Application Platform Board)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ASAI-BD	MIN	test board PCSS sh	ASAI-BD
ASAI-BD	WRN	test board PCSS sh	ASAI-BD

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth).

Maintenance testing of the common circuit pack is handled by on-board firmware and SPE-controlled tests. Maintenance software queries the firmware for error and alarm information, status, and test results. Firmware automatically reports error conditions that result in SPE-controlled testing.

For MAPD board insertion, the switch makes an additional board query if any of the following circuit packs are inserted:

Circuit Pack	Vintage
TN754	49
TN556	49, 80 or greater
TN800	any

For any of the above initial board uplinks, the switch queries the board for administration data, as well as reporting the switch software release and the system type.

For the native mode, the response to the board query downlink messages consists of several CCMS uplink messages that identify the true board code, vintage, suffix, emulation type, and number of reserved slots needed.

 **NOTE:**

Refer to LAN-BD Maintenance documentation for circuit pack level errors. See also ASAI-PT/ASAI-EPT (BRI Line) maintenance documentation for related line information. See the following exceptions listed below:

- **Hyperactivity:** currently, the common circuit pack is considered "hyperactive" if the Service Dispatcher receives 200 uplink messages from the circuit pack in a 10-second period. Since MAPD has 32 ports, the hyperactivity limit increases to 500 uplink

messages per 10 seconds. The switch issues an alarm when the limit reaches 400; when it reaches 500 up-link messages in 10 seconds, the board is taken out of service.

- LED use: the LED Control Message 038x requests the Angel to drive the red, yellow, and green LEDs on the face plate of a typical port board on or off. On the MAPD, only the red LED is controlled by this message. Yellow and green change requests received from the switch by the MAPD drive LCD behavior rather than LED behavior. The DEFINITY switch continues to send the same LED control messages to the MAPD that the DEFINITY switch currently sends to all other port boards. The MAPD handles proper interpretation of these messages. You should note that the PC on the MAPD and the switch itself control the LEDs and the LCD on the MAPD.
- Port Administration: in Administration Without Hardware (AWOH), the switch allows administration of up to 8 ports in any of the first 12 ports. If the port type later reported by the board does not match the existing type, the switch assumes it to be a MAPD board with a different configuration and rejects the board.

NOTE:

Refer to the LAN-BD documentation for circuit pack level errors. For related information, see ASAI-PT and ASAI-EPT maintenance documentation.

ASAI-EPT

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-EPT	MAJOR ¹	test station extension	ASAI-Adjunct

1. The alarm level for ASAI adjuncts is administered using the **set options** command. The alarm level can be set independently for off-board and on-board alarms to WARNING, MINOR, or MAJOR for all ASAI adjuncts in the system.

The maintenance strategy for this endpoint MO is built on maintenance facilities offered in the Lucent ISDN-BRI protocol and in the ASAI adjuncts. Currently there are no facilities in the protocol that provide for maintenance of set data features.

The TN800 is a PC-based platform that allows interaction of multiple applications with DEFINITY at any time. DEFINITY Release 5 software (Native mode) supports emulation of three types of port MOs on this board. The type of ports to be emulated is defined by the applications running on the TN800.

 **NOTE:**
If the TN800 is emulating BRI, the software/firmware supports a maximum of 12 ports, but only 8 of the 12 ports can be administered at any one time.

Error Log Entries and Test to Clear Values

Table 10-44. ASAI-EPT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level ASAI-EPT	On/ Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test ASAI-ADJ

Error Type	Aux Data	Associated Test	Alarm Level ASAI-EPT	On/ Off Board	Test to Clear Value
2567 (h)	0	None			
2568 (i)	0	None			
3329 (j)	Any	Signaling Link Status (626)	MAJ/WNG [†]	OFF	
3584-3839 (k)	0, 1	None			
3841 (l) 4095	0	None			

-
1.

Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2.

Major alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a.
- Errors of this type indicate violations of the ISDN-BRI signaling protocol. Timers associated with certain Layer 3 messages have expired before a required response was received. In the following table, the aux data column indicates which timer has just expired. For more information, refer to the Lucent ISDN-BRI Specification.

Aux Data	Timer Type
2	First T303 (SETUP timer)
3	Second T303 (SETUP timer)
4	T305 (DISConnect timer)
5	First T308 (RELease timer)
6	Second T308 (RELease timer)
10	T316 (REStart timer)
12	T309 (Layer 2 Failure timer)
16	TM100 (Management Information Message timer 1)
17	TM200 (Management Information Message timer 2)
102	TASAI (ASAI Routing Timer)

The switch sent a message to an endpoint that did not respond in the allotted time. This may be due to failure of the point-to-point signaling link or because of a problem in the ASAI adjunct. To repair:

- Execute the **test station extension** command and perform the associated repair procedures for those tests.
- b. An endpoint is not responding to the service state query message sent to the adjunct or to the endpoint. This error causes an alarm to be raised. The alarm is retired when the switch receives a response to the service state query to the endpoint or to the adjunct.

When this error occurs for an ASAI adjunct, the Aux Data field indicates the state of the ASAI link and whether an invalid response or no response was received to the query from the switch, as shown in the following table:

Aux Data	ASAI Link State	Error
102	13-restarting	No response to RESTART message
104	13-restarting	Invalid response to RESTART message
152	13-restarted	No response to Layer 3 query
154	13-restarted	Invalid response to Layer 3 query
202	13-established	No response to Layer 3 query
204	13-established	Invalid response to Layer 3 query

See "status bri-port" in Chapter 8 for an explanation of the ASAI link states.

For ASAI or Lucent adjuncts, the switch queries the adjunct every two minutes. The Layer 3 Query Test is not executed for ASAI or Lucent adjuncts through a command issued from the management terminal. While alarmed for this error, the switch takes the associated port out-of-service for five seconds every 15 minutes. This action attempts to stimulate recovery actions to be taken by the adjunct.

When this error occurs for an ASAI or Lucent adjunct, the service technician should:

1. Execute the **test station extension** command and perform the associated repair procedures for those tests.
 2. Check the health of the adjunct by following the recommended repair procedures of the manufacturer of the adjunct if the preceding step does not resolve the problem.
- c. This error and associated warning alarm are logged against an ASAI endpoint when the adjunct has asked the switch to suspend maintenance on the ASAI endpoint. Busying out and releasing the ASAI station clears this alarm.
 - d. This error occurs when the endpoint sends more messages than the switch can handle. The switch suspends the reception of messages from the endpoint for a short period of time. There is no repair procedure for this error. If the condition persists, replace the endpoint.
 - e. This error occurs when the signaling link associated with the ASAI endpoint has too much link-establishment related traffic. This occurs if the signaling link is alternating between assigned and established states. If this problem persists, replace the endpoint.

- f. This error occurs when the ASAI-EPT message is not transmitted because the PKT-CTRL (packet control circuit pack) transmit buffers are exhausted. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI adjunct. Resolve the problem by following the repair procedures for the PKT-CTRL. If these attempts fail, re-engineering the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.
- g. The ASAI message is not transmitted because the transmit buffer for the ASAI link is full, causing the link to be flow-controlled. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI adjunct. Resolve the problem by following the repair procedures issued by the manufacturer of the adjunct. If these attempts fail, re-engineering of the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.
- h. This version of ASAI is not supported. Check the software version that is running on the ASAI adjunct.
- i. The adjunct identification is invalid. Check the vendor ID or software running on the ASAI adjunct.
- j. This occurs when the point-to-point signaling link to the endpoint goes down, except when the link goes down because either a system technician has busied out the PKT-CTRL or the PKT-BUS, or they have failed. This error raises an alarm against the endpoint or adjunct. Execute the **test station extension short** command and note the results of the Signaling Link Status Test (#626). If this test fails, follow the repair procedure for Test #626. The alarm is retired when the signaling link is re-established to the endpoint or adjunct.
- k. The switch software logs certain ASAI cause values. The cause value is determined from the following formulas:
 - If the error type is greater than 3712, then the ASAI cause value is equal to the error type minus 3712. The switch sent this value to the adjunct.
 - If the error type is less than 3712, then the ASAI cause value is equal to the error type minus 3584. The switch sent this value to the adjunct.

Table 10-44 contains a description of the various ASAI cause values and recommended system technician actions associated with the cause value. The ISDN-BRI Specification (AT&T PUB 801-802-100) contains further information. In addition, the Aux Data field of the Error Log entry contains additional diagnostic information.

- l. The switch software logs certain ASAI cause values. The cause value is determined from the following formula:
 - If the error type is greater than 3968, then the ASAI cause value is equal to the error type minus 3968. The switch sent this value to the endpoint.

- If the error type is less than 3968, then the ASAI cause code is equal to the error type minus 3840. The switch sent this value to the endpoint.

Table 10-45. ASAI Cause Values

Code	Explanation	Recommendation
0	Unrecognized ASAI Protocol Operation.	Requested ASAI protocol is not implemented by switch or adjunct. Aux data field of error log entry contains protocol identifier for unrecognized operation. 1. Consult switch and adjunct documentation to determine which set of operations is supported by switch and the adjunct. Adjunct administration turning off operations not implemented by the switch may resolve the problem.
34	No circuit or channel available	A resource on the switch is unavailable for a call. For BRI endpoints, this cause value is not logged. For ASAI, this condition means that there are no available trunks for an outgoing call request. 1. Verify that the adjunct is administered to support the trunk capabilities of the switch. 2. Investigate trunk group status by issuing the status trunk command from the SAT or by requesting trunk group query(ies) from the adjunct. 3. Perform trunk diagnostic procedures outlined in this manual.
40	Resources not available.	No available internal resources to service switch or adjunct request. Exceeds system transaction capacity for adjunct or switch. 1. May require re-engineering of adjunct services.
50	Requested facility not subscribed	Requested facility is implemented, but not administered. Potential administration problem with endpoint or adjunct. For BRI endpoints: 1. Verify the switch administration of endpoint using either the display station or display data-module commands. 2. If Step 1 does not resolve the problem, refer to the endpoint's service manual and verify administration on the endpoint. For ASAI adjuncts: 1. Display the Customer Optional Features Form (administration screen) on the switch to determine which ASAI capabilities are turned on in the switch. 2. Verify that the adjunct is administered to support the identical capabilities as the switch. If there is a mismatch in the administered capabilities, then readminister the switch and/or the adjunct to establish a consistent set of desired capabilities on both the switch and the adjunct.

Table 10-45. ASAI Cause Values — Continued

Code	Explanation	Recommendation
58	Bearer capability not presently available	Requested bearer capability is implemented, but not administered. No B-channel administered. See code 50 above.
63	Service or option not available	Requested ASAI capability or resource is not available on the switch or adjunct. More than one adjunct may be contending for the same switch resource. Potential administration mismatch between the resource domains administered on the switch and those administered on the adjunct. 1. Verify that no overlapping administration of switch resources (for example, requesting notifications on a single domain by multiple adjuncts attempting to control a single call) exists across all adjuncts connected to the switch. If overlaps exist, then re-administer the adjuncts to ensure that each adjunct is associated with a unique set of switch resources.
65	Bearer service not implemented	Requested service not implemented in switch or endpoint.
69	Requested facility not implemented	Requested service not supported in switch or endpoint. 1. Consult switch and endpoint documentation to determine service support.
79	Service or option not implemented	Requested service or option (or combination of selected options) is not supported (implemented) in switch or the adjunct. 1. Consult switch and adjunct documentation to determine ASAI service and options supported by both switch and adjunct. Re-administration of the switch-administered capabilities (see Customer Optional Feature Form) or those of the adjunct may be necessary to correct the problem.
81	Invalid CRV	An invalid CRV was sent by the adjunct. 1. This may indicate a CRV inconsistency between the switch and the adjunct. See the CallVisor protocol reference manual.
87	Internal switch audit	There is an inconsistency in switch data records. 1. There is no action needed, since the switch has corrected the data inconsistency.

System Technician-Demanded Tests:
Descriptions and Error Codes

When inspecting errors in the system, always investigate errors associated with the circuit pack and port first. Clearing these error codes first may also clear errors generated against the endpoint. When all circuit pack and port errors have been cleared, but errors still exist against the endpoint, investigate errors in the table below. By clearing error codes associated with the Signaling Link Status Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Signaling Link Status Test (#626)	X	X	ND

1. D = Destructive; ND = Nondestructive

BRI Layer 3 Query Test (#629)

This test is not used by the ASAI-ADJ maintenance object. For information about this test, see BRI-SET in the maintenance documentation.

Signaling Link Status Test (#626)

This test determines the current status of the signaling link. This test passes if the link is "bound" to an endpoint and fails if the link is "not bound."

The definition of the term "bound" for a link depends upon the type of endpoint and may depend on the successful completion of procedures at both Layers 2 and 3 of the protocol. The definition of "bound" for ASAI type of endpoint is:

- ASAI adjuncts and BRI endpoints not administered for MIM initialization (point-to-point):

For endpoints of this type, the signaling link is "bound" when the link is connected at Layer 2 (L2 established).

Table 10-46. TEST #626 Signaling Link Status Test

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.

Table 10-46. TEST #626 Signaling Link Status Test — Continued

Error Code	Test Result	Description/ Recommendation
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL maintenance documentation.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. Execute the test port long PCSSpp command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1113	FAIL	The signaling link is not "bound" to the adjunct. For ASAI adjuncts this error indicates that the link is disconnected at Layer 2. Since the signaling link associated with the endpoint has been identified by administration, the link is only "unbound" from the endpoint when it is disconnected. 1. Execute the status bri-port PCSSpp command and refer to the associated procedures for this command contained in "BRI-PORT".
	PASS	The signaling link is connected at Layer 2 and "bound" to the ASAI adjunct.

ASAI-PT

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
ASAI-PT	MAJOR ^{2,3}	test port PCSSpp I	ASAI ISDN BRI Port
ASAI-PT	WARNING	test port PCSSpp I	ASAI ISDN BRI Port

- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, or D); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., and so forth).
- The alarm level for ASAI adjunct ports may be administered using the **set options** command. The alarm level can be set independently for off-board and on-board alarms to WARNING, MINOR, or MAJOR for all ASAI adjunct ports in the system.
- All alarming for an ASAI adjunct and off-board alarming for an ASAI port is disabled if the ASAI adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm is logged against the ASAI adjunct. Check the Hardware Error and Alarm Logs to see if the adjunct has disabled alarming.

Unless otherwise stated, all maintenance actions contained in this section apply to ASAI-PT and ISDN-BRI ports connected to ASAI adjuncts. This port type is administered as an ASAI-BD on the TN800 circuit pack.

The TN800 circuit pack is a PC-based platform that allows interaction of multiple applications with DEFINITY at any time. DEFINITY Release 5 software (Native mode) will support emulation of three types of port MOs on this board. The type of ports to be emulated are defined by the applications running on the TN800. The TN800 can support a maximum of 32 ports (time slots) at a time.

The TN800 connects to the switch through a single slot in the backplane, however its width is not limited to one slot. The number of slots occupied by the TN800 is supplied by the board during its insertion. The TN800 in Release 5 is 3 slots wide. The blank (reserve) slots are to the left of the functional slot.

In non-native mode the TN800 is recognized as TN556, TN2181, TN754, or TN746 based on the switch software and the application running on the TN800. In non-native mode only one type of port MOs will run at any time, and the port type depends on the application running on the TN800. If the TN800 fails diagnostics in non-native mode, the system's alarm and error logs would show a failure for the board type the TN800 is emulating.

Error Log Entries and Test to Clear Values

Table 10-47. ASAI-PT Port Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level ASAI-PORT	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	(a)	Level 1 Status Inquiry (#621)	MAJ ²	OFF	test port PCSSpp sh r 2
513 (b)	0	none	(b)	ON	
1537 (c)	46210	CRC Error Counter (#623)	MAJ ²	OFF	
3841 (d)	46208	None			
3844 (e)	46223	None			
3845 (f)		None			
3846 (g)	TEI	None			

1.

Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2.

Major and Minor alarms may be downgraded to warning alarms based on the value used in the **set options** command.

Notes:

- a. This error occurs when the Level 1 Status Inquiry fails or when the BRI circuit pack detects that Level 1 has been deactivated on the port. The aux data field contains one of the following values:

- Blank

This indicates that the Level 1 Status Inquiry failed.
- 32773

This is a message from the ASAI-Line circuit pack indicating Level 1 has been deactivated.

Refer to the repair procedures for Test #621.

- b. The circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signalling information over D-channel. This error occurs when the Packet Bus transmit FIFO buffer overflows. This condition probably indicates a hardware problem as well. The ASAI-PORT alarm level is MAJOR with aux data 0. Use troubleshooting procedures for both on-board hardware problems and potential off-board Packet Bus problems.

- c. The port received an invalid frame over the D-channel. When the Cyclical Redundancy Check (CRC) errors exceed 5 within 15 minutes, the port is taken out of service for 5 seconds. If 5 more CRC errors are received within 15 minutes of the first set of 5 errors, the port is taken out of service for one minute. If 5 more CRC errors are received within 15 minutes of the last 5, the port is taken out of service for 15 minutes.
- This error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.
- Check the wiring to the endpoints or the adjunct.
 - If the problem persists, replace the endpoints or adjuncts.
- d. This error occurs when a Layer 1 Transmission error is detected for the port. Run the Long Test Sequence and note the results of the Layer 1 Transmission Error Counter Test (#624).
- e. This error occurs when the circuit pack detects an overflow of its receive buffers. Run the Long Test Sequence and note the results of the Receive FIFO Overflow Counter Test (#625).
- f. This error occurs when the BRI Port Local LAN Looparound Test (#618) fails. Run the Long Test Sequence and note the results of Test (#618).
- g. The Terminal Endpoint Identifier (TEI) administered for the ASAI endpoint most likely does not match the TEI administered in the ASAI adjunct. Check the switch administration of the TEI against that of the adjunct, and make sure that both are using the same TEI.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. For example, by clearing error codes associated with the NPE Crosstalk Test, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
ASAI Port Local LAN Looparound Test (#618)		X	D
Level 1 Status Inquiry Test (#621)	X	X	ND
CRC Error Counter Test (#623)		X	ND
Layer 1 Transmission Error Counter Test (#624)		X	ND
Receive FIFO Overflow Error Counter Test (#625)		X	ND
Clear Error Counters (#270)	X	X	ND

1. D = Destructive; ND = Nondestructive

BRI Port Local LAN Looparound Test (#618)

This test is destructive.

This test verifies the connectivity of a BRI port across the LAN Bus and executes only if the port is out-of-service. The test aborts if calls associated with the port are in-progress. Failures of this test indicate either on-board faults associated with the ASAI-PT hardware on the circuit pack or problems with the LAN Bus, which is used to form connectivity between the switch and the ASAI-PT.

The dotted lines in Figure 10-5 show how a Looparound Test is performed across the Packet Bus for the D-channel.

Figure 10-5. BRI Port Local LAN Looparound Path

Table 10-48. TEST #618 BRI Port Local LAN Looparound

Error Code	Test Result	Description/Recommendation
1015	ABORT	The port is not in the out-of-service state. 1. Display the Port Status form using the status bri-port PCSSpp command to determine which stations or adjuncts are on this port. 2. Use the extension shown on this form in the status station command to determine if the station or adjunct is in use. 3. If the port is in use, wait until it is idle, and use the busyout port PCSSpp command to place it in the out-of-service state and repeat this test.  WARNING: <i>Since the "busyout" command is destructive, using this command prior to the port being idle causes all transactions associated with the ASAI on the port to be torn down. Note that third party calls established by an ASAI adjunct remain connected even though the port is taken out-of-service.</i>
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Follow the repair procedures for the PKT-CTRL. 2. Issue the test port long PCSSpp command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. Issue the test port long PCSSpp command and review the results of the BRI Port Local LAN Looparound Test to verify the repair.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-48. TEST #618 BRI Port Local LAN Looparound — Continued

Error Code	Test Result	Description/Recommendation
	FAIL	The Looparound test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use. Reset the circuit pack by issuing the busyout board PCSS and the reset board PCSS commands. 2. If the test fails again, execute test pkt P on the management terminal. If this fails, follow the failure procedures the in PKT-BUS section. 3. If the tests executed in Step 2 pass, the problem is local to the BRI board. Replace the circuit pack.
	PASS	The BRI Port Local LAN Looparound test has passed.

Level 1 Status Inquiry Test (#621)

This test determines the state of the transmission facility of a BRI port at the Level 1 (L1) or physical layer. L1 can be in one of two possible states: Activated or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state the Level 1 interface can communicate with the BRI endpoint or ASAI adjunct administered on this port. This test passes if the state of L1 is activated. This test also passes if software has taken this port out of service.

The Deactivated state indicates a problem with the ASAI circuit pack. When in this state, the Level 1 interface is idle and is not trying to communicate with the BRI endpoints or adjunct. When an ASAI port is placed in the out-of-service state, Level 1 is also put into the deactivated state. This could be due either to the system detecting a fault with the port or in response to a **busyout port PCSSpp** request.

Table 10-49. TEST #621 Level 1 Status Inquiry

Error Code	Test Result	Description/Recommendation
1187	ABORT	The board, port, or station may have been busied-out by a technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port and ASAI-BD (board busied out). If this error type is present for ASAI-PT only, then release the port using the release port pp command and run the test again. If the error is present for both ASAI-BD and ASAI-PT, then release the board with the release port PCSS command and run the test again.  NOTE: When you release a port, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack using the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
3	FAIL	Received a status of Level 1 Deactivated; the port is out-of-service. 1. Issue the status bri-port PCSSpp command to verify that the service state of the port is out-of-service. If the port is not out-of-service, proceed to Step 2. 2. If the port has been placed out-of-service using the busyout port PCSSpp command, try releasing the port by executing the release port PCSSpp command. Then issue the test port long PCSSpp command, and review the results of Level 1 Status Inquiry test. If this test is still failing, proceed to Step 3. 3. After executing the test port long PCSSpp command, review the results of all the tests. Follow the repair procedures for any tests that fail. Verify repair of the problem by executing the test port PCSSpp command and by determining that the Level 1 Status test passes.
	PASS	This test indicates that Level 1 is activated, or that software has taken the port out of service.

Layer 1 Transmission Error Counter Test (#624)

This test reads and clears the BRI port's Layer 1 Transmission error counter maintained on the ASAI circuit pack. This counter is incremented by the circuit pack when it detects a Layer 1 transmission problem. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error is most likely due to a problem with the wiring or adjunct (verify that the wiring meets the configuration rules defined in *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111). It does not indicate a problem with the TN800 circuit pack. This test is useful for verifying the repair of the problem

Table 10-50. TEST #624 Layer 1 Transmission Error Counter Test

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack using the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate necessary system resources to run test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The TN800 circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, review the results of other tests in the Long Test Sequence. Note the results of the Level 1 Status Inquiry test. Follow the repair procedures for any of the executed tests if they fail. Otherwise, go to the next step. 3. Replace the circuit pack.
	PASS	The Layer 1 Transmission error counter was read correctly and has a value of 0.

Receive FIFO Error Counter Test (#625)

This test reads and clears the BRI port's Receive FIFO error counter maintained on the TN800 circuit pack. This counter is incremented by the circuit pack when it detects an overflow of its receive buffers. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error can occur if signaling frames are being received from a Packet Bus at a rate sufficient to overflow the receive buffers on the circuit pack for a port or if hardware fault is causing the receive buffers not to be emptied properly. This test is useful for verifying the repair of the problem.

Table 10-51. TEST #625 Receive FIFO Error Counter Test

Error Code	Test Result	Description/Recommendation
2000	ABORT	Response was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of 5 times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal system error
2100	ABORT	Could not allocate necessary system resources to run test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The TN800 circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, review the results of other tests in the Long Test Sequence. Note the results of the Level 1 Status Inquiry test. Follow repair procedures for any of the tests that fail. Otherwise, go to the next step. 3. If the tests for the endpoints or adjunct pass and the Layer 1 Transmission Error Counter Test continues to fail, check the wiring to the endpoints or adjunct.
	PASS	The Layer 1 Transmission error counter was read correctly and has a value of 0.

Clear Error Counters Test (#270)

There are various error counters associated with each ASAI-PT. This test clears those counters and triggers the auditing of Layer 3 reinitialization. This test is used only to send messages to the ASAI-PT and, therefore, should neither abort nor fail. ASAI uses a fixed TEI value of 1.

Table 10-52. TEST #270 Clear Error Counters

Error Code	Test Result	Description/Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The message to clear the error counters of the ASAI-PT has been sent.

ASAI-RES/E-DIG-RES (TN800 reserve slot)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-RES	NONE	NONE	TN800 ASAI reserve slot
E-DIG-RES	NONE	NONE	TN800 DIG reserve slot

There are no tests associated with these MOs. Both the **test board** and **busy out board** commands abort when either is attempted on a reserved slot. An error message indicates the slot is associated with the circuit pack that the TN800 is emulating, but the requested operation is not valid.

The TN800 MAPD (Multi-Application Platform for DEFINITY) circuit pack connects to the switch through a single slot in the backplane. The number of slots occupied by the MAPD pack is supplied by the board when inserted. The TN800 in R5EM is 3 slots wide. The TN800 requires 2 reserve slots to its left. The reserve (blank) slots are to left of the functional slot and are place holders on the switch, and do not have any interaction with the switch.

Each instance of these MOs represents a reserve slot associated with respective circuit pack mode in which the MAPD is working.

BRI-BD/LGATE-BD (ISDN-BRI Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
BRI-BD	MAJOR	test board PCSS I	ISDN-BRI Line Circuit Pack
BRI-BD	MINOR	test board PCSS I	ISDN-BRI Line Circuit Pack
BRI-BD	WARNING	test board PCSS sh	ISDN-BRI Line Circuit Pack
LGATE-BD	MAJOR	test board PCSS I	DEFINITY Lan Gateway
LGATE-BD	MINOR	test board PCSS I	DEFINITY Lan Gateway
LGATE-BD	WARNING	test board PCSS sh	DEFINITY Lan Gateway

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.).

 **NOTE:**

Some of the information in this section is reserved for future use.

 **CAUTION:**

A detailed flowchart for isolating and resolving Packet Bus faults is included in Chapter 9, "Packet Bus Fault Isolation and Correction". This flowchart, along with the other information presented in the chapter, can help in resolving problems that involve more than a single station or circuit pack. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9, "Packet Bus Fault Isolation and Correction", in addition to the relevant MO documentation.

ISDN-BRI Line is a packet port circuit pack that provides access to ISDN-BRI endpoints. The ISDN-BRI Line circuit pack supports 12 ports, each of which provides access to ISDN stations. Voice and circuit-switched data from the ISDN stations are carried on the Time Division Multiplex (TDM) Bus. Signaling is carried over the Packet Bus.

LEDS

The ISDN-BRI Line circuit pack performs extensive initialization tests and lights both the red and green LEDS during the initialization testing. See Chapter 7, "LED Interpretation", for more details on circuit pack status LEDs.

Hardware Error Log Entries and Test to Clear Values

Table 10-53. BRI-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test board PCSS sh r 1
1(a)	Any	None	MINOR	ON	
18(b)	0	busyout board PCSS	WARNING	OFF	release board PCSS
23(c)	0	None	WARNING	OFF	
257(d)	65535	Control Channel Loop Test (#52)	MINOR	ON	test board PCSS r 20
513(e)	4352 to 4357				
769(f)	4358				
1025(g)	4363	NPE Audit Test (#50)			
1293 to 1294 (h)	46088 to 46096	SAKI Sanity Test (#534)	MINOR	ON	See footnote (h)
1537 to 1538 (i)	46082		MINOR	ON	
1793 (j)	46080		MINOR	ON	
1794 (j)	46094		MINOR	ON	
1795 (j)	46085		MINOR	ON	
2306 (j)		LANBIC Receive Parity Error Counter Test (#595)			
3330 (k)	46083		MINOR	OFF	
3840 (l)	4096 to 4101				
3843 (m)	46097				
3999 (n)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

NOTE:

The alarm is logged approximately 11 minutes after the circuit pack has been removed and/or SAKI Sanity Test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, then follow the instructions for "Red (alarm)" in the "Control and Port Circuit Pack Status LEDs" section in Chapter 7, "LED Interpretation". (Also, refer to the "Handling Control Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures".

- b. This circuit pack has been busied out via the **busyout board PCSS** command.
- c. Port(s) has(have) been administered on this circuit pack but the circuit pack is not physically present.
- d. This error indicates transient communication problems between the switch and this circuit pack. Execute the **test board PCSS** command and refer to the repair procedures for the Control Channel Loop Around Test (#52).
- e. An on-board hardware failure has been detected by the circuit pack.

The reported aux data values correspond to the following detected errors:

4352	External RAM error
4353	Internal RAM error
4355	ROM Checksum error
4357	Instruction set error

Reset the circuit pack by executing the **busyout board PCSS** and **reset board PCSS** commands. When it is reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one of these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedure in footnote (a) for error type 1.

- f. This error is reported by the circuit pack when it detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.
- g. This error is reported by the circuit pack when it cannot update NPE memory and read it back. This error type can be ignored, but may lead to errors of other types being reported against this circuit pack.
- h. A critical hardware failure has been detected on the circuit pack. Reset the circuit pack via the **busyout board PCSS** and **reset board PCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm via the **test board PCSS long clear** command. If the Circuit Pack Restart Test (#594) fails, replace the circuit pack.

The reported error types correspond to the following detected errors:

1293	On-board auxiliary processor insane
1294	Internal memory access error

i. These error types are reported when the following errors are detected:

1537	Frame overrun at Packet Bus interface. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those maintenance objects.
1538	Circuit packet is hyperactive; that is, it is flooding the switch with messages sent over the control channel. The circuit pack is taken out-of-service when a threshold number of these errors is reported to the switch. Clear the alarm via the following commands: busyout board PCSS, reset board PCSS, test board PCSS long clear, release board PCSS . If the error recurs within 10 minutes, then replace the circuit pack.

j. These errors indicate that the circuit pack is having problems transmitting data to the Packet Bus.

1793	Parity errors are detected when transmitting data to the Packet Bus.
1794	Overflow of Packet Bus transmit buffers has occurred.
1795	Circuit pack cannot find end of frame when transmitting to Packet Bus. Clear the alarm via the following commands: busyout board PCSS, reset board PCSS, test board PCSS long clear, release board PCSS . If the error recurs within 10 minutes, then replace the circuit pack.
2306	This error occurs when the circuit pack detects an error in a received frame from the packet bus. These errors are most likely caused by a packet bus problem, but may be due to a circuit pack fault. An invalid Link Access Procedure Data (LAPD) frame error occurs if the frame contains a bad Cyclical Redundancy Checking (CRC), is greater than the maximum length, or violates the link level protocol. When bus parity errors are reported, the LANBIC Receive Parity Error Counter Test (#595) should be performed to determine if the condition had cleared. Refer to the "PKT-BUS (Packet Bus)" Maintenance documentation to determine if the problem is isolated to this circuit pack or if the problem is caused by Packet Bus faults.

- k. A critical failure has been detected in the Packet Bus interface of the circuit pack. This failure may be due to either a Packet Bus fault or an on-board fault. If the Packet Bus is alarmed, refer to the "PKT-BUS (Packet Bus)" section and Chapter 9, "Packet Bus Fault Isolation and Correction" for recommended repair procedures. The probability of this error being related to Packet bus problems increases with the number of ISDN-BRI circuit packs displaying this error.

If the Packet Bus is not alarmed, reset the circuit pack via the **busyout board PCSS** and **reset board PCSS** commands. If the Circuit Pack Restart Test (#594) passes, then the on-board circuitry is healthy. Retire the alarm via the **test board PCSS long clear** command. If the Circuit Pack Restart Test (#594) fails, replace the circuit pack. If the problem persists after complying with the above instructions, then follow normal escalation procedures.

- l. These errors are not service-affecting. No action is required. These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

4096	Bad major heading
4097	Bad port number
4098	Bad data
4099	Bad sub-qualifier
4100	State inconsistency
4101	Inconsistent downlink message

- m. This error is not service-affecting. No action is required.

3843	Bad translation RAM detected, but call continues by using another translation location.

- n. Error type 3999— Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.
-

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Control Channel Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Control Channel Loop-Around Test (#52)	X	X	ND
NPE Audit Test (#50)		X	ND
LANBIC Receive Parity Error Counter Test (#595)		X	ND

1. D = Destructive; ND = Nondestructive

NPE Audit Test (#50)

Refer to the repair procedure described in the "XXX-BD (Common Port Circuit Pack)" Maintenance documentation as NPE Audit Test (#50).

Control Channel Loop Around Test (#52)

Refer to the repair procedure described in the "XXX-BD (Common Port Circuit Pack)" Maintenance documentation as Control Channel Loop Around Test (#52).

SAKI Sanity Test (#53)

Refer to the repair procedure described in the "XXX-BD (Common Port Circuit Pack)" Maintenance documentation as SAKI Sanity Test (#53).

LANBIC Receive Parity Error Counter Test (#595)

This test is destructive.

The test reads and clears the LANBIC Receive Parity Error Counter on the circuit pack. This counter is incremented by the circuit pack when it detects a parity error in data received from the Packet Bus.

These errors may be indicative of a circuit pack problem, Packet Bus problem, or a problem with another circuit pack on the bus. This test is useful for verifying the repair of the problem.

Table 10-54. TEST #595 LANBIC Receive Parity Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test.
2012	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
1-10	FAIL	The circuit pack is still detecting errors of this type. The error code indicates the value of the on-board error counter. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, verify the validity of the Packet Bus. Run the Packet Bus maintenance test with the test pkt P long command. If any Packet Bus tests fail, refer to the"PKT-BUS (Packet Bus)" Maintenance documentation for recommended repair procedures. 3. If the Packet Bus test passes, check the validity of the circuit pack. Execute a test that involves data transmission onto the Packet Bus. For example, the BRI may use the connectivity tests of the port-level maintenance object (BRI-PORT) by executing the test port PCSSpp command. Refer to the repair procedures for the executed test if it fails. Otherwise, proceed to the next step. 4. Other circuit packs on the Packet Bus may be the cause of the parity error. Use the display errors command to check the Error Log for other circuit packs that are alarmed. If any alarms are present for the other circuit packs, retire those alarms also. Then, rerun the LANBIC Receive Parity Error Counter Test (#595) on this circuit pack.
	PASS	No errors detected by circuit pack.

BRI-DAT (ISDN-BRI)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
BRI-DAT	WARNING ¹	test data-module	ISDN-BRI Standalone Data Module

1. The alarm level for ASAI adjuncts may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to WARNING, MINOR, or MAJOR for all ASAI adjuncts in the system.

Refer to BRI-SET (ISDN-BRI Set) Maintenance documentation.

BRI-PORT (ISDN-BRI Port), ABRI-PORT (ASAI ISDN-BRI Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
BRI-PORT	MINOR	test port PCSSpp l	ISDN-BRI Port
BRI-PORT	WARNING	test port PCSSpp sh	ISDN-BRI Port
ABRI-PORT	MAJOR ^{2, 3}	test port PCSSpp l	ASAI ISDN-BRI Port
ABRI-PORT	WARNING ^{2, 3}	test port PCSSpp l	ASAI ISDN-BRI Port
ATT-PORT	MAJOR ^{2, 3}	test port PCSSpp l	AT&T Adjunct ISDN-BRI Port
ATT-PORT	WARNING ^{2, 3}	test port PCSSpp l	AT&T Adjunct ISDN-BRI Port
LGATE-PORT	MAJOR ^{2, 3}	test port PCSSpp l	Ethernet ASAI Port
LGATE-PORT	WARNING ^{2, 3}	test port PCSSpp l	Ethernet ASAI Port
ATTE-PT	MAJOR ^{2, 3}	test port PCSSpp l	Ethernet AT&T Adjunct Port
ATTE-PT	WARNING ^{2, 3}	test port PCSSpp l	Ethernet AT&T Adjunct Port

- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).
- The alarm level for ASAI and AT&T adjunct ports may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to WARNING, MINOR, or MAJOR for all ASAI and AT&T adjunct ports in the system.
- All alarming for an ASAI and AT&T adjunct and OFF-BOARD alarming for an ASAI or AT&T port is disabled if the ASAI or AT&T adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm is logged against the ASAI or AT&T adjunct. The Hardware Error and Alarm Logs should be checked to see if the adjunct has disabled alarming.

NOTE:

Some of the information in this section is reserved for future use.

CAUTION:

A detailed flowchart for isolating and resolving Packet Bus faults is included in Chapter 9, "Packet Bus Fault Isolation and Correction". This flowchart, along with the other information presented in the chapter, can help in resolving problems that involve more than a single station or circuit pack. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9, "Packet Bus Fault Isolation and Correction" in addition to the relevant MO documentation.

**WARNING:**

If a significant Packet Bus failure occurs, errors and alarms may not be logged as expected for BRI-PORT/ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT. Conditions under which this occurs are detailed in the "Maintenance of the Packet Bus" section of Chapter 9, "Packet Bus Fault Isolation and Correction".

The TN2208 LGATE MFB provides DEFINITY with the interface to Adjunct-Switch Application Interface (ASAI) and AT&T adjuncts (for example, CONVERSANT[®]. Voice System). The circuit pack contains 12 ports of line circuit interface (although only 8 are usable by the switch), each of which operates with two B-channels (referred to as B1 and B2 throughout this section) and one D-channel as specified in the AT&T ISDN-BRI Specification. In this context, the term "ISDN-BRI port" is used to refer collectively to ports on the TN2208 circuit pack which are connected to ASAI or AT&T adjuncts.

The TN556 and TN2198 ISDN-BRI Line circuit packs provide DEFINITY with the interface to ISDN-BRI end points, Adjunct-Switch Application Interface (ASAI) and AT&T adjuncts (for example, CONVERSANT[®]. Voice System). The circuit packs contain 12 ports of line circuit interface, each of which operates with two B-channels (referred to as B1 and B2 throughout this section) and one D-channel as specified in the AT&T ISDN-BRI Specification. In this context, the term "ISDN-BRI port" is used to refer collectively to ports on the TN556 and TN2198 circuit packs which are connected to either BRI endpoints or ASAI or AT&T adjuncts.

For BRI endpoints, each B-channel may support voice or circuit-switched data and may be circuit-switched simultaneously. The B-channels are not used on ports connected to ASAI or AT&T adjuncts. The D-channel is used for conveying signaling between the switch and a BRI endpoint(s) or ASAI or AT&T adjunct. Each ISDN-BRI D-channel is connected to the switch processor and the ISDN-BRI port through the Packet Control circuit pack and the Packet Bus.

ISDN-BRI endpoints are available in various configurations. All endpoints require the D-channel to convey signaling information to the switch. Only one B-channel is required for a voice-only set or a stand-alone data module (BRI-DAT). A voice and data-capable set requires both B-channels (one for voice and one for data). Therefore, each TN556 or TN2198 port can support either two voice-only sets, two stand-alone data modules (BRI-DAT), or one voice and data-capable set. Only a single ASAI or AT&T adjunct may be connected to an ISDN-BRI port. Multiple adjuncts per line are not supported.

Figure 10-6 illustrates the physical connection (solid line) between an ISDN-BRI Port and its associated ISDN-BRI set(s). Each physical connection allows for two B-channels and one D-channel. Each ISDN-BRI circuit pack can support up to 12 of these *physical* connections to different voice and voice/data sets or ASAI or AT&T adjuncts. On a TN2198 each ISDN-BRI circuit pack can support up to 12 *physical* connections to a NT1, which, in turn, connects to 2 terminals.

This section covers the maintenance documentation for ISDN-BRI ports. Some of the results of maintenance testing of ISDN-BRI ports may be affected by the health of the ISDN-BRI Line circuit pack (BRI-BD), BRI endpoint (BRI-SET), or ASAI adjunct (ASAI-AJ/LGATE-AJ) or AT&T adjunct (ATT_AJ/ATTE-AJ). These interactions should be kept in mind when investigating the cause of ISDN-BRI port problems. For more information on the circuit pack and endpoints, refer to the BRI-BD (ISDN-BRI Line Circuit Pack) Maintenance documentation, the BRI-SET (ISDN-BRI Endpoint) Maintenance documentation, and ASAI-AJ (Adjunct-Switch Application Interface) Maintenance documentation, ATT-AJ (AT&T Adjunct) Maintenance documentation, LGATE-AJ (Ethernet Adjunct-Switch Application Interface) Maintenance documentation, and ATTE-AJ (Ethernet AT&T Adjunct) Maintenance documentation.

3842 (j)	0	None				
3843 (k)	0	None				
3844 (l)	46223	None				

Continued on next page

Table 10-55. ISDN-BRI Port Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level BRI-PORT	Alarm Level ABRI-PORT ATT-PORT LGATE-PORT ATTE-PT	On/ Off Board	Test to Clear Value
3845 (m)		None				
3846 (n)	TEI	None				
3847 (o)	0	None				

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description, and follow the recommended procedures.
2. Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.

Notes:

- a. This error occurs when the Level 1 Status Inquiry fails or when the BRI circuit pack detects that Level 1 has been deactivated on the port. The aux data field contains one of the following values:
 - blank - this indicates that the Level 1 Status Inquiry failed.
 - 32773 - this is a message from the BRI-LINE circuit pack indicating Level 1 has been deactivated.

Refer to the repair procedures for Test #621.

- b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.
- c. This error occurs when the EPF Status Inquiry fails due to an overcurrent condition or when the BRI-LINE circuit pack detects that the EPF is in an over current condition. The aux data field contains one of the following values:
 - blank - this indicates that the EPF Status Inquiry failed due to an overcurrent condition.
 - 40988 - this indicates that the BRI-LINE circuit pack has detected an overcurrent condition and has turned the EPF off.

Execute the Short Test Sequence and see the repair procedures for Test #622.

- d. This error indicates that the circuit pack is having problems transmitting data to the Packet Bus, thus affecting the conveyance of signaling information over the D-channel. With Aux Data 46222, this error occurs

when the Packet Bus transmit buffers overflow. This condition probably indicates a hardware problem. The BRI-PORT Alarm Level for the error with Aux Data 46222 is "MIN/WRN," and the ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT Alarm Level is "MAJ/MIN/WNR." With Aux Data 0, this error occurs whenever the Packet Bus transmit FIFO buffers overflow. This condition can be caused by an on-board hardware problem as well as by problems on the Packet Bus that disrupt the BRI circuit pack's ability to transmit data onto the Packet Bus. Use troubleshooting procedures for both on-board hardware problems and potential off-board Packet Bus problems. See the "PKT-BUS (Packet Bus)" Maintenance section in this chapter as well as Chapter 9, "Packet Bus Fault Isolation and Correction" for more details on Packet Bus troubleshooting procedures. The BRI-PORT Alarm Level for the error with Aux Data 0 is "MINOR," and the ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT Alarm Level is "MAJOR."

- e. This error occurs when the NPE Crosstalk Test (#617) fails. Run the Long Test Sequence, and pay particular attention to the results of Test #617.
- f. This error occurs when broadcast signaling links associated with this port have too much link establishment related traffic. This could occur if an endpoint on this port is sending link establishment traffic on a port level broadcast link, or if there are Level 1 problems on the port. Check the error logs for Level 1 errors. If Level 1 problems exist, follow the repair procedures listed for test #621. Software will suspend activity to this port for 75 minutes when the port is alarmed due to this error (note that service suspension does not occur if the port is an ABRI-PORT/LGATE-PT/ATTE-PT/ATT-PORT). If this problem persists, replace the endpoint or endpoints associated with this port. If replacing the endpoints does not fix the problem, follow normal escalation procedures.
- g. This error occurs when the port receives an invalid frame over the D-channel. When CRC errors exceed five within 15 minutes, the port is taken out of service for five seconds. If five more CRC errors are received within 15 minutes of the first set of five errors, the port is taken out of service for one minute. If five more CRC errors are received within 15 minutes of the last five, the port is taken out of service for 15 minutes.

This error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.

- Check the wiring to the endpoints or the adjunct.
 - If the problem persists, replace the endpoints or adjuncts, or escalate the problem.
- h. This error occurs when the BRI Port Local TDM Loop Around Test (#619) fails. Run the Long Test Sequence, and pay particular attention to the results of Test #619.

There are no Test to Clear Values for the following error types. The error types are simply provided as additional data that may prove useful while troubleshooting.

- i. This error occurs when a Layer 1 Transmission error is detected for the port. Run the Long Test Sequence, and pay particular attention to the results of the Layer 1 Transmission Error Counter Test (#624).
- j. A BRI port supports up to three Terminal Endpoint Identifiers (TEIs). This error occurs when the switch receives a request for a fourth TEI on a port. Check the number of endpoints administered for this port.
- k. This error occurs when an SPID initialization request is made from an endpoint and the switch determines that the SPID value is invalid or is a duplicate of another SPID that is already initialized at Layer 3 on the port. Check the administration of the endpoints.
- l. This error occurs when the circuit pack detects an overflow of its receive buffers. Run the Long Test Sequence, and pay particular attention to the results of the Receive First In First Out (FIFO) Overflow Error Counter Test (#625).
- m. This error occurs when the BRI Port Local LAN Loop Around Test (#618) fails. Run the Long Test Sequence, and pay particular attention to the results of Test #618.
- n. This error most likely occurs when the Terminal Endpoint Identifier (TEI) administered for the ASAI or AT&T endpoint does not match the TEI administered in the ASAI or AT&T adjunct. Check the switch administration of the TEI against that of the adjunct, and make sure that both are using the same TEI.
- o. Indicates that sets on the port do not support Layer 3 initialization. Consult the Service Set documentation.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#617)		X	D
BRI Port Local LAN Loop Around Test (#618)		X	D
BRI Port Local TDM Loop Around Test (#619)		X	D
Electronic Power Feed Restoral Test (#620)	X	X	ND
Level 1 Status Inquiry Test (#621)	X	X	ND
Electronic Power Feed Inquiry Test (#622)	X	X	ND
CRC Error Counter Test (#623)		X	ND
Layer 1 Transmission Error Counter Test (#624)		X	ND
Receive FIFO Overflow Error Counter Test (#625)		X	ND
Clear Error Counters (#270)	X	X	ND

1. D = Destructive; ND = Nondestructive

 **NOTE:**
The NPE Crosstalk Test and the BRI Port Local TDM Loop Around Test are not executed for ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT.

NPE Crosstalk Test (#617)

This test is destructive.

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes approximately 20 to 30 seconds to complete. Crosstalk testing is performed on both B-channels (B1 and B2) associated with a BRI port. If this test fails on either channel, any endpoints connected to the port are taken out-of-service.

This test is not executed for ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT because the B-channels associated with the port are not used by ASAI or AT&T adjuncts.

Table 10-56. TEST #161 Loop Around Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension or trunk group/member number of the port. Use the status bri-port PCSSpp command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) Wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the status station command for the station associated with this port and determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this type of translation. Ports administered as "ASAI" or "ADJK" can not run this test, because the B channels associated with the port are not used by ASAI or AT&T Adjunct Links. This is a normal condition.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1, 2	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. Error code 1 indicates that the NPE Crosstalk Test failed on Channel B1. Error code 2 indicates that the NPE Crosstalk Test failed on Channel B1. 1. Replace circuit pack.
	PASS	The port is correctly using its allocated time slots. 1. To be sure that this is not an intermittent problem, repeat this test a maximum of 10 times to make sure it continues to pass. 2. If complaints still exist, examine the station, connections, and wiring.

BRI Port Local LAN Loop Around Test (#618)

This test is destructive.

This test, which verifies the connectivity of a BRI port across the LAN Bus, executes only if the port is out-of-service. The test aborts if calls associated with the port are in-progress. Failures of this test indicate either on-board faults associated with the BRI-PORT hardware on the circuit pack or problems with the LAN Bus, which is used to form connectivity between the switch and the BRI-PORT.

The dotted lines in Figure 10-7 show how a Loop Around Test is performed across the Packet Bus for the D-channel.

Figure 10-7. Path of the BRI Port Local LAN Loop Around

Table 10-57. TEST #618 BRI Port Local LAN Loop Around

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The port is not in the out-of-service service state. 1. Display the BRI Port Status form via the status bri-port PCSSpp command to determine which stations or adjuncts are on this port. 2. Use the extension shown on this form in the status station command to determine if the station or adjunct is in use. 3. If it is in use, wait until it is idle, and then busyout the port (using the busyout port PCSSpp command) to place it in the out-of-service state and repeat this test.  WARNING: <i>Since the "busyout" command is destructive, execution of this command prior to the port being idle causes all calls associated with BRI endpoints and all transactions associated with ASAI or AT&T adjuncts on the port to be torn down. Note that third party calls established by an ASAI or AT&T adjunct remain connected even though the port is taken out-of-service.</i>
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Follow the repair procedures for the PKT-CTRL. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 10-57. TEST #618 BRI Port Local LAN Loop Around — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The Loop Around Test has failed. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the board are not in use. Reset the circuit pack by issuing the busyout board PCSS and the reset board PCSS commands. 2. If the test fails again, execute test pkt P on the G3MT terminal. If this fails, follow failure procedures in PKT-BUS section. 3. If tests executed in Step 2 pass, the problem is local to the BRI board. Replace the circuit pack.
	PASS	The BRI Port Local LAN Loop Around Test has passed.

BRI Port Local TDM Loop Around Test (#619)

This test is destructive.

This test verifies the connectivity of a BRI port across the TDM Bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

This Loop Around Test runs a series of individual tests on the two B-channels (B1 and B2) associated with the port. It is a collection of the following:

- A Loop Around Test across the TDM Bus for B1.
- A Conference Circuit Test for B1.
- A Loop Around Test across the TDM Bus for B2.
- A Conference Circuit Test for B2.

The tests are run in the above order. If one fails, the remaining tests in the sequence are not executed. An error code is returned at that point.

This test is not executed for ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT because the B-channels associated with the port are not used by ASAI or AT&T adjuncts.

The dotted lines in Figure 10-8 show how a Loop Around Test is performed for the B-channels. The figure shows a terminal connected to a BRI line board using a TN556. If a TN2198 is used, the terminal would be connected to a NT1, and the NT1 to the BRI board.

Figure 10-8. Path of the BRI Port Local TDM Loop Around

Table 10-58. TEST #619 BRI Port Local TDM Loop Around

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The system resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension or trunk group/member number of the port. Use the status bri-port PCSSpp command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) Wait until the port is idle before retesting. 1. If the port is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-58. TEST #619 BRI Port Local TDM Loop Around — Continued

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM Bus errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the status station command for the station associated with this port and determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	This test is not valid for this type of translation. Ports administered as “ASAI” or “ADJK” can not run this test, because the B channels associated with the port are not used by ASAI or AT&T Adjunct Links. This is a normal condition.
2000	ABORT	Response to the test was not received from the BRI-LINE circuit pack within the allowable time period. 1. If this result occurs repeatedly, attempt to reset the circuit pack if the other ports are not in use. Reset the circuit pack by issuing the busyout board PCSS and the reset board PCSS commands. 2. If this result occurs again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 10-58. TEST #619 BRI Port Local TDM Loop Around — Continued

Error Code	Test Result	Description/ Recommendation
2103	ABORT	The system could not make the conference connection for the test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1, 2	FAIL	As stated previously, this test runs a TDM Loop Around Test on each B-channel. This indicates that the loop around failed on one of the channels. Error Code 1 indicates that the TDM Loop Around Test failed on B1. Error Code 2 indicates that the TDM Loop Around Test failed on B2.
7, 8	FAIL	As stated previously, this test runs a Conference Circuit Test on each B-channel. A failure here indicates that one of these conference tests failed; Error Code 7 means that the test failed on B1; Error Code 8 means that the test failed on B2. 1. If the test fails repeatedly, attempt to reset the circuit pack if the other ports on the circuit pack are not in use. Reset the circuit pack by issuing the busyout board PCSS and the reset board PCSS commands. 2. If the test fails again, replace the circuit pack.
	PASS	The BRI Port Local TDM Loop Around Test has passed.

Electronic Power Feed Restoral Test (#620)

This test attempts to restore the Electronic Power Feed (EPF) on an ISDN-BRI port twice. In this test, the processor requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit to the station or adjunct. If no current is being drawn by a station, this probably indicates that the station is not connected. No current being drawn by an adjunct is the normal condition. If an overcurrent condition is sensed (that is, too much current is being drawn), this condition may indicate a short in the wiring to the endpoint or adjunct. Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This response is reported by the Electronic Power Feed Inquiry (#622), which follows in the testing sequence. EPF Restoral is attempted again by this test five seconds later. This test always passes for the TN2198 because it has no EPF. This test will always abort when run on the TN2208.

Table 10-59. TEST #620 Electronic Power Feed Restoral

Error Code	Test Result	Description / Recommendation
1005	ABORT	This test is not valid for this port type. The TN2208 does not have an electronic power feed, and the test will abort.
2012	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	PASS	The EPF Test passed. The message to turn on the power feed to the station or the adjunct was successfully sent to the port. 1. Although this test should not return a fail result, after running this test, the Error Log should be checked for any entries with error type 257 to examine the real results of this test. 2. An error type of 257 in the Error Log indicates some problem with the power to the station or the adjunct. Check for a short in the wiring, a damaged jack, a defective voice terminal or adjunct, or an incorrect type of terminal.

Level 1 Status Inquiry Test (#621)

This test determines the state of the transmission facility of a BRI port at the physical layer (that is, Level 1). Level 1 can be in one of three possible states: Activated, Pending Activation, or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state the Level 1 interface can communicate with the BRI endpoint or ASAI or AT&T adjunct administered on this port. This test passes if the state of Level 1 (L1) is Activated. This test also passes if software has taken this port out of service. See the description of the Level 1 "Deactivated State" below for more details.

The Pending Activation state indicates a problem with the endpoints or adjunct, the wiring to the sets or adjunct, or the BRI-LINE circuit pack. When in this state, the Level 1 interface is either not receiving any L1 framing from the endpoint or adjunct (Endpoint Idle), or it is communicating with the endpoint or adjunct but cannot transition to the Activated state (Endpoint Active).

The Deactivated state indicates a problem with the BRI-LINE circuit pack. When in this state, the Level 1 interface is idle and is not trying to communicate with the BRI endpoints or adjunct. When an ISDN-BRI port is placed in the out-of-service state, Level 1 is also put into the Deactivated state. This could be due either to the system detecting a fault with the port or to a **busyout port PCSSpp** request.

Table 10-60. TEST #621 Level 1 Status Inquiry

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The board, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port and BRI-BD (board busied out). If this error type is present for BRI-PORT only, then release the port via the release port pp command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the board via the release port PCSS command and run the test again.  NOTE: When you release a port, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 2. Make sure the terminal is connected. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.

Continued on next page

Table 10-60. TEST #621 Level 1 Status Inquiry — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL	Received a status of Level 1 Pending Activation-Endpoint Idle which indicates a problem with the BRI endpoint or ASAI or AT&T adjunct, the wiring to the endpoint or adjunct, or the ISDN-BRI port. For the TN2198, received a status of Level 1 Pending Activation. U interface down, which indicates a problem with a connection between the switch and the NT1.  NOTE: An NT1 is a 2- to 4-wire converter that is used to connect 4-wire AT&T terminals to a 2-wire TN2198 circuit pack. The NT1 also has status lamps to determine the health of the unit. 1. For the TN556 or TN2208, verify that an endpoint is connected to the port. If an endpoint is connected to the port, then proceed to step 2. For the TN2198 verify that the connections are good between the switch and the NT1. Verify that the NT1 has power. 2. As necessary, check and repair the wiring between the circuit pack and the endpoint or adjunct. If a TN2198 is used, the set must have been plugged in for at least 15 seconds before it will stabilize. Execute the test port PCSSpp command, and review the results of the Level 1 Status Inquiry Test to verify the repair. If this test is still failing, proceed to Step 3. 3. For BRI endpoints, replace the BRI endpoint(s) connected to the port or the NT1 if a TN2198 is used. For ASAI or AT&T adjuncts, follow the recommended repair procedures of the manufacturer for link communication problems. For the NT1, follow the manufacturers repair procedures. Then execute the test port PCSSpp command and review the results of the Level 1 Status Inquiry Test to verify repair. If this test is still failing, proceed to Step 4. 4. Escalate the problem to the next tier.

Continued on next page

Table 10-60. TEST #621 Level 1 Status Inquiry — Continued

Error Code	Test Result	Description/ Recommendation
2	FAIL	For the TN556 or TN2208, received a status of Level 1 Pending Activation-Endpoint Active which indicates a problem with the BRI endpoint or ASAI or AT&T adjunct, the wiring to the endpoint or adjunct, or the ISDN-BRI port. For the TN2198, received a status of Level 1 Pending Activation. U interface up S/T interface down, which indicates a problem with the NT1 or the wiring between the NT1 and the BRI endpoint (S/T interface). 1. As necessary, check and repair the wiring between the circuit pack and the endpoint or adjunct. Execute the test port PCSSpp command, and review the results of the Level 1 Status Inquiry test to verify the repair. If this test is still failing, proceed to Step 2. 2. For BRI endpoints, try replacing the BRI endpoint(s) connected to the port. For ASAI or AT&T adjuncts, follow the recommended repair procedures of the manufacturer for link communication problems. For the NT1, follow the recommended repair procedures of the manufacturer. Then execute the test port PCSSpp command, and review the results of the Level 1 Status Inquiry test to verify repair. If this test is still failing, proceed to Step 3. 3. Escalate the problem to the next tier.
3	FAIL	Received a status of Level 1 Deactivated; the port is out-of-service. 1. Issue the status bri-port PCSSpp command to verify that the service state of the port is out-of-service. If the service state of the port is not out-of-service, escalate the problem to the next tier. Otherwise, proceed to Step 2. 2. If the port has been placed out-of-service via the busyout port PCSSpp command, try releasing the port by executing the release port PCSSpp command. Then issue the test port long PCSSpp command, and review the results of Level 1 Status Inquiry test. If this test is still failing, proceed to Step 3. 3. After executing the test port long PCSSpp command, review the results of all the tests. Follow the repair procedures for any tests that fail. Verify repair of the problem by executing the test port PCSSpp command and by determining that the Level 1 Status test passes. If the test continues to fail for this reason, proceed to Step 4. 4. Escalate the problem to the next tier.

Continued on next page

Table 10-60. TEST #621 Level 1 Status Inquiry — Continued

Error Code	Test Result	Description/ Recommendation
4	FAIL	For the TN2198 only: Received a status of Level 1 Pending Activation, the NT1 has a loss of power indicating a problem with the NT1. 1. For the NT1 follow the manufacturers recommended repair procedures. 2. Execute the test port PCSSpp command, and review the results of the Level 1 Status Inquiry test to verify the repair. If the test is still failing proceed to Step 3. 3. Escalate the problem to the next tier.
	PASS	This test indicates that Level 1 is activated, or that software has taken the port out of service.

Electronic Power Feed Inquiry (#622)

This test queries the BRI-LINE circuit pack for the status of the Electronic Power Feed (EPF) supplied to a BRI endpoint or an ASAI or AT&T adjunct. If the EPF is on and no overcurrent condition exists, this test passes. All other states are not normal and indicate a problem with the endpoint or adjunct, the wiring to the endpoint or adjunct, or the BRI-LINE circuit pack. This test is not run on the TN2208 circuit pack or the TN2198 and will always return a pass for a TN2198. The TN2208 has no power feeds.

Table 10-61. TEST #622 Electronic Power Feed Inquiry

Error Code	Test Result	Description/ Recommendation
1005	ABORT	This test is not valid for this port type. Ports on the TN2208 cannot run this test because this board does not have an electronic power feed.
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.

Table 10-61. TEST #622 Electronic Power Feed Inquiry — Continued

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1	FAIL	The BRI-LINE circuit pack reports that it has detected an overcurrent condition and has turned off the EPF. 1. As necessary, check and repair the wiring between the circuit pack and the endpoint or adjunct. Check the endpoints and replace one or both sets if the sets are drawing too much current. Execute the test port PCSSpp command and review the results of the EPF Inquiry Test to verify the repair. If this test is still failing, proceed to Step 2. 2. Execute the test port PCSSpp command, and review the results of the Level 1 Status Inquiry Test. If this test is also failing, then follow the repair procedure for the Level 1 Status Inquiry Test. Otherwise, escalate this problem to the next tier.
	PASS	The Electronic Power Feed Inquiry Test reports that the EPF is on.
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.

Layer 1 Transmission Error Counter Test (#624)

This test reads and clears the BRI port's Layer 1 Transmission error counter maintained on the BRI-LINE circuit pack. This counter is incremented by the circuit pack when it detects a Layer 1 transmission problem. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error is most likely due to a problem with the wiring or the endpoint or adjunct (verify that the wiring meets the configuration rules defined in *DEFINITY Communications System Generic 1 and Generic 3i Wiring*, 555-204-111). It does

not indicate a problem with the ISDN-BRI circuit pack. This test is useful for verifying the repair of the problem.

Table 10-62. TEST #624 Layer 1 Transmission Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate necessary system resources to run test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
value	FAIL	The BRI-LINE circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, review the results of other tests in the Long Test Sequence. Pay particular attention to the results of the Level 1 Status Inquiry test. Follow repair procedures for any of the executed tests if they fail. Otherwise, go to the next step. 3. If the tests for the endpoints or adjunct pass and the Layer 1 Transmission Error Counter Test continues to fail, check the wiring to the endpoints or adjunct. If the wiring appears to be fine, escalate the problem.
	PASS	The Layer 1 Transmission error counter was read correctly and has a value of 0.

Receive FIFO Overflow Error Counter Test (#625)

This test reads and clears the BRI port's Receive FIFO Overflow error counter maintained on the BRI-LINE circuit pack. This counter is incremented by the circuit pack when it detects an overflow of its receive buffers. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is non-zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error can occur if signaling frames are being received from the Packet Bus at a rate sufficient to overflow the receive buffers on the circuit pack for a port OR if a hardware fault is causing the receive buffers not to be emptied properly by the circuit pack. This test is useful for verifying the repair of the problem.

Table 10-63. TEST #625 Receive FIFO Overflow Error Counter Test

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received from the circuit pack within the allowable time period. 1. If the test aborts repeatedly a maximum of five times, reset the circuit pack via the busyout board PCSS and reset board PCSS commands. 2. If the test aborts again, replace the circuit pack.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
value	FAIL	The BRI-LINE circuit pack is still detecting errors of this type. The Error Code field contains the value of this counter. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, run the Long Test Sequence and pay particular attention to the Loop Around Tests (#618 and #619). See the repair procedures for the executed test if it fails. Otherwise, go to the next step. 3. Replace the circuit pack.
	PASS	The Receive FIFO Overflow error counter was read correctly and has a value of 0.

Clear Error Counters Test (#270)

This test is not an actual test in the strict sense of the word. There are various error counters associated with each BRI-PORT/ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT. This test clears those counters and triggers the auditing of Terminal Endpoint Identifier (TEI) values and layer 3 reinitialization. This test is used only to send messages to the BRI-PORT/ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT and, therefore, should neither abort nor fail.

Table 10-64. TEST #270 Clear Error Counters

Error Code	Test Result	Description/ Recommendation
Any	ABORT	This test should never abort.
Any	FAIL	This test should never fail. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to fail, escalate the problem.
	PASS	The message to clear the error counters of the BRI-Port/ABRI-Port/ATT-PORT/LGATE-PT/ATTE-PT has been sent.

BRI-DAT		test data-module	

- Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01). The alternate name field contains the extension of the endpoint. This field is used to distinguish between endpoints on the same port.
- The alarm level for ASAI and AT&T adjuncts may be administered using the **set options** command. The alarm level can be set independently for Off-Board and On-Board alarms to WARNING, MINOR, or MAJOR for all ASAI and AT&T adjuncts in the system.
- Alarming for an ASAI and AT&T adjuncts is disabled if the adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm are logged against the endpoint. Busing out and releasing the ASAI station or ADJLK station will clear the alarm.

 **CAUTION:**

A detailed flowchart for isolating and resolving Packet Bus faults is included in Chapter 9, "Packet Bus Fault Isolation and Correction". This flowchart, along with the other information presented in the chapter, can help in resolving problems that involve more than a single station or circuit pack. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to reference Chapter 9, "Packet Bus Fault Isolation and Correction" in addition to the relevant MO documentation.

**WARNING:**

If a significant Packet Bus failure occurs, errors and alarms may not be logged as expected for BRI-SET/BRI-DAT/ASAI-ADJ/ATT-ADJ/LGATE-AJ/ATTE-AJ. Conditions under which this occurs are detailed in the "Maintenance of the Packet Bus" section of Chapter 9, "Packet Bus Fault Isolation and Correction".

The TN2208 ESAI MFB provides DEFINITY with an Ethernet interface to Adjunct-Switch Application Interface (ASAI) and AT&T adjuncts (for example, CONVERSANT[®] Voice System). This circuit pack contains 8 ports of line circuit interface, each of which operates with two B-channels (referred to as B1 and B2 throughout this section) and one D-channel as specified in the AT&T ISDN-BRI Specification. In this context, the term "ISDN-BRI port" is used to refer collectively to ports on the TN2208 MFB circuit pack which is connected to ASAI or AT&T adjuncts. The TN2208 ESAI MFB is handled by switch software as it is an ISDN BRI compatible board and all maintenance actions referring to ASAI and AT&T Adjunct Links in this section apply.

In G3iV1.1-286 and G3iV2-386, two types of ISDN-BRI endpoints may be connected to ISDN-BRI (ISDN Basic Rate Interface Line) TN556 and TN2198 circuit packs: ISDN-BRI station endpoints, ASAI (Adjunct-Switch Application Interface) and AT&T adjuncts (for example CONVERSANT[®] Voice System). These circuit packs contain 12 ports of line circuit interfaces, each of which operates at 192 kilobits per second (kbps) with two B-channels and one D-channel as specified in the AT&T ISDN-BRI specification (PUB 801-802-100). For BRI endpoints, each B-channel may support voice or circuit-switched data and may be circuit-switched simultaneously. The B-channels are not used by ASAI or AT&T adjuncts. The D-channel is used for conveying signaling between the switch and a BRI endpoint(s) or ASAI or AT&T adjuncts. Each ISDN-BRI D-channel is connected to the switch processor and the ISDN-BRI port through the PKT-CTRL (Packet Control) and the PKT-BUS (Packet Bus).

ISDN-BRI endpoints come in a number of configurations. All endpoints require the D-channel to convey signaling information to the switch. A voice-only set requires only one B-channel. A voice and data-capable set requires both B-channels (one for voice and one for data). Therefore, each TN556 port can support either two voice-only sets or one voice and data-capable set. Only a single ASAI or AT&T adjunct may be connected to an ISDN-BRI port. Multiple adjuncts per line are not supported.

Figure 10-9 illustrates the physical connection (solid line) between an ISDN-BRI Circuit Pack and a voice or voice/data set. Each physical connection allows for two B-channels, as stated above, plus one D-channel. Each ISDN-BRI circuit pack can support up to 12 of these PHYSICAL connections to different voice and voice/data sets or ASAI and AT&T adjuncts.

Figure 10-9. ISDN-BRI Set Interactions

This section contains the ISDN-BRI Set, ASAI Adjunct, and AT&T Adjunct Maintenance documentation. Some of the results of maintenance testing of the ISDN-BRI Set or the ASAI and AT&T Adjunct may be affected by the health of the ISDN-BRI circuit pack and Port. These interactions should be kept in mind when investigating the cause of ISDN-BRI Set problems.

-
- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
 - Major alarms on this MO may be downgraded to Warning alarms based on the value used in the **set options** command.
-

Notes:

-
- Errors of this type indicate violations of the ISDN-BRI signaling protocol; timers associated with certain Layer 3 messages have expired before a required response was received. In the following table, the aux data field indicates which timer has just expired. (For more information, refer to the AT&T ISDN-BRI Specification.)
-

Aux Data	Timer Type
2	First T303 (SETUP timer)
3	Second T303 (SETUP timer)
4	T305 (DISConnect timer)
5	First T308 (RELease timer)
6	Second T308 (RELease timer)
10	T316 (REStart timer)

Aux Data	Timer Type
12	T309 (Layer 2 Failure timer)
16	TM100 (Management Information Message timer 1)
17	TM200 (Management Information Message timer 2)
102	TASAI (ASAI Routing Timer)

The switch sent a message to the endpoint which did not respond in the allotted time. This can happen occasionally due to failure of the point-to-point signaling link or because of a problem in the BRI endpoint or ASAI adjunct or AT&T adjunct. Execute the **test station extension sh** command and pay particular attention to the results of the BRI Layer 3 Query Test (#629). If this test fails, follow the repair procedure for Test #629.

- b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.
- c. This error occurs when the endpoint does not respond to the service state query message sent to the adjunct or the endpoint. This error causes an alarm to be raised. The alarm is retired when the switch receives a response to the service state query to the endpoint or the adjunct.

For BRI endpoints, the Aux Data field for this error contains "0." When it occurs, execute the **test station extension sh** command and pay particular attention to the results of the BRI Layer 3 Query Test (#629). If this test fails, follow the repair procedure for Test #629.

When this error occurs for an ASAI or AT&T adjunct, the Aux Data field indicates the state of the ASAI link or AT&T link and whether an invalid response or no response was received to the query from the switch, as shown in the following table:

Aux Data	ASAI Link State	Error
102	13-restarting	No response to RESTART message
104	13-restarting	Invalid response to RESTART message
152	13-restarted	No response to Layer 3 query
154	13-restarted	Invalid response to Layer 3 query
202	13-established	No response to Layer 3 query
204	13-established	Invalid response to Layer 3 query

(See "Status BRI-Port" in Chapter 8, "Maintenance Commands and Trouble-Clearing Aids" for an explanation of the ASAI link states.)

For ASAI or AT&T adjuncts, the switch automatically queries the adjunct every two minutes (and therefore the Layer 3 Query Test is not executed for ASAI or AT&T adjuncts via a command issued from the G3MT

terminal). While alarmed for this error, the switch momentarily (for five seconds) takes the associated port out-of-service every 15 minutes. This action is taken in an attempt to stimulate recovery actions to be taken by the adjunct.

When this error occurs for an ASAI or AT&T adjunct, the service technician should:

1. Execute the **test station extension** command, paying particular attention to any tests which fail, and perform the associated repair procedures for those tests.
 2. Check the health of the adjunct by following the recommended repair procedures of the manufacturer of the adjunct if the preceding step does not resolve the problem.
 3. The alarm condition persists and, if the above steps do not resolve the problem, follow normal escalation procedures.
- d. This error and associated WARNING alarm are logged against an ASAI or AT&T endpoint when the adjunct has asked the switch to suspend Maintenance on the ASAI or AT&T endpoint. Busying out and releasing the ASAI station or ADJLK station will clear this alarm.
- e. This error occurs when the endpoint sends more messages than the switch can handle. The switch suspends the reception of messages from the endpoint for a short period of time. There is no repair procedure for this error. If the condition persists, replace the endpoint.
- f. This error occurs when the signaling link associated with a BRI endpoint has too much link establishment related traffic. This could occur if the signaling link is bouncing between assigned and established states. Software will suspend activity to this endpoint for 75 minutes when the endpoint is alarmed due to this problem (note that service suspension does not occur if the endpoint is an ASAI or AT&T adjunct). If this problem persists, replace the endpoint. If replacing the endpoint does not fix the problem, follow normal escalation procedures.
- g. This error occurs when the ASAI-ADJ or ATT-ADJ or LGATE-AJ or ATTE-AJ message is not transmitted because the PKT-CTRL (Packet Control Circuit Pack) transmit buffers are exhausted. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI or AT&T adjunct. Attempt to resolve the problem by following the repair procedures for the PKT-CTRL. If these attempts fail, the problem should be escalated because re-engineering of the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.
- h. This error occurs when the ASAI message is not transmitted because the transmit buffer for the ASAI link is full, causing the link to be flow controlled. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the PKT-CTRL, the signaling link, or the ASAI or AT&T adjunct. Attempt to resolve the problem by following the repair procedures issued by the manufacturer of the

adjunct. If these attempts fail, the problem should be escalated because re-engineering of the traffic on the PKT-CTRL, signaling link, or adjunct may be necessary.

- i. This error indicates a problem with Layer 2 over the D-channel between the switch and the endpoint. When this error occurs, an alarm is raised against the station or adjunct. Execute the **test station extension short** command and pay particular attention to the results of the BRI XID Test (#628). If this test fails, follow the repair procedure for Test #628.
- j. This error indicates a problem with the B-channel connection between the switch and the endpoint. When this error occurs, a warning alarm is raised against the endpoint. Execute the **test station extension l** command, and pay particular attention to the results of the BRI Remote Loop Back Test (#627). If this test fails, follow the repair procedure for Test #627.
- k. This error occurs whenever the point-to-point signaling link to the endpoint goes down (except when it goes down because either the PKT-CTRL or the PKT-BUS has failed or has been busied out by system technician). When this error occurs, an alarm is raised against the endpoint or adjunct. Execute the **test station extension short** command and pay particular attention to the results of the Signaling Link Status Test (#626). If this test fails, follow the repair procedure for Test #626. The alarm is retired when the signaling link is reestablished to the endpoint or adjunct.
- l. Certain ASAI protocol-specific cause codes are logged by switch software. The cause code can be determined from the following formula:

If the error type is greater than 3712, then the ASAI cause code is equal to the error type minus 3712. This code was sent to the adjunct by the switch.

If the error type is less than 3712, then the ASAI cause code is equal to the error type minus 3584. This code was sent to the switch by the adjunct.

A description of the various ASAI cause values is contained in the Table 10-64. This table also contains recommended system technician actions associated with the cause value. Further information can also be found in the AT&T ASAI Specification (AT&T PUB 288-500-03). In addition, the Aux Data field of the Error Log entry contains additional diagnostic information.

Table 10-66. ASAI Cause Values

Code	Explanation	Recommendation
	Service or Option Not Available	

Continued on next page

Table 10-66. ASAI Cause Values — *Continued*

Code	Explanation	Recommendation
0	Unrecognized ASAIProtocol Operation	Requested ASAI protocol operation is not implemented by the switch or adjunct. Aux Data field of Error Log entry contains protocol identifier for unrecognized operation. 1. Consult switch and adjunct documentation to determine which set of operations is supported by the switch and the adjunct. Adjunct administration turning off operations not implemented by the switch may resolve the problem. 2. If Step 1 does not resolve the problem, escalate to the next tier.
40	Resources not available	No available internal resources to service switch or adjunct request. System transaction capacity for adjunct or switch is exceeded. 1. Re-engineering of adjunct services my be required. If problem persists, escalate problem to the next tier.
63	Service or Option Not Available	Requested ASAI capability or resource is not available on the switch or adjunct. More than one adjunct may be contending for the same switch resources. Potential administration mismatch between the resource domains administered on the switch and those administered on the adjunct. 1. Verify that no overlapping administration of switch resources (e.g., requesting notifications on a single domain by multiple adjuncts or multiple adjuncts attempting to control a single call) exists across all adjuncts connected to the switch. If overlaps exist, then readminister the adjuncts to guarantee that each adjunct is associated with a unique set of switch resources. 2. If Step 1 does not resolve the problem, escalate to the next tier.

Continued on next page

Table 10-66. ASAI Cause Values — Continued

Code	Explanation	Recommendation
	Service or Option Not Implemented	
79	Service or Option Not Implemented	Requested service or option (or combination of selected options) is not supported (implemented) in switch or the adjunct. 1. Consult switch and adjunct documentation to determine ASAI service and options supported by both switch and adjunct. Readministration of the switch-administered capabilities (see Customer Optional Feature Form) or those of the adjunct may be necessary to correct the problem. 2. If Step 1 does not provide the set of desired services due to deficient implementation, escalate the problem to the next tier.
	Switch Error Conditions	
87	Internal Switch Audit	There is an inconsistency in switch data records. 1. There is no action needed since the switch has corrected the data inconsistency. 2. If a number of these errors continue to occur, then escalate to next tier.

- m. Certain ISDN-BRI cause codes are logged by switch software. The cause code can be determined from the following formula:

If the error type is greater than 3968, then the ISDN-BRI cause code is equal to the error type minus 3968. This code was sent to the endpoint by the switch.

If the error type is less than 3968, then the ISDN-BRI cause code is equal to the error type minus 3840. This code was sent to the switch by the endpoint.

A description of the various ISDN-BRI cause values is contained in Table 10-65. This table also contains recommended system technician actions associated with the cause value. Further information can also be found in the AT&T ISDN-BRI Specification (AT&T PUB 801-802-100). In addition, the Aux Data field of the Error Log entry contains additional diagnostic information.

- n. Error 3847 indicates that sets on the port do not support level 3 initialization. Consult the Set Service documentation

- o. For the Error 2567 indicates that the version of ASAI is not supported, check version of the software running on the ASAI or AT&T adjunct.
- p. For Error 2568 indicates that the adjunct id is invalid, check the vender id or software running on the AT&T adjunct.

Table 10-67. ISDN-BRI Cause Values

Code	Explanation	Recommendation
1	Channel in Use	Requested channel is in use by another station on the BRI-PORT. (Not applicable for ASAI or AT&T adjuncts.) For BRI endpoints: 1. Try to originate a call to or from this port. 2. If the error persists, busy out and release the port. 3. If the problem still persists, replace stations on the port. 4. If the problem still persists, escalate to the next tier.
34	SWITCH RESOURCES NOT AVAILABLE No circuit or channel available	A resource on the switch is unavailable for a call. For BRI endpoints: This cause value is not logged. For ASAI or AT&T Adjuncts: This condition means that there are no available trunks for an outgoing call request. 1. Verify that the adjunct is administered to support the trunk capabilities of the switch. 2. Investigate trunk group status by issuing status trunk commands from the SAT or by requesting a trunk group query or queries from the adjunct. 3. Perform trunk diagnostic procedures outlined in this manual. 4. If step 3 does not resolve the problem, escalate to the next tier.

Continued on next page

Table 10-67. ISDN-BRI Cause Values — Continued

Code	Explanation	Recommendation
42	Switch Equipment Congestion	Switch takes control to limit received traffic. For BRI endpoints: This cause value is not logged. For ASAI or AT&T Adjuncts: 1. See CallVisor protocol reference manual. 2. If step 1 does not resolve the problem, escalate to the next tier.
	Service or Option Not Available	

Continued on next page

Table 10-67. ISDN-BRI Cause Values — Continued

Code	Explanation	Recommendation
50	Requested Facility Not Subscribed	Requested facility is implemented, but not administered. Potential administration problem with endpoint or adjunct. For BRI endpoints: 1. Verify the switch administration of endpoint using either the display station or display data-module commands. 2. If Step 1 does not resolve the problem, refer to the endpoint's service manual and verify administration on the endpoint. 3. If Step 2 does not resolve the problem, escalate to the next tier. For ASAI adjuncts: 1. Display the Customer Optional Features Form (administration screen) on the switch to determine which ASAI capabilities are turned on in the switch. 2. Verify that the adjunct is administered to support the identical capabilities as the switch. If there is a mismatch in the administered capabilities, then readminister the switch and/or the adjunct to establish a consistent set of desired capabilities on both the switch and the adjunct. 3. If Step 2 does not resolve the problem, escalate to the next tier. For AT&T adjuncts: 1. Display the Customer Optional Features Form (administration screen) on the switch to determine if the AT&T adjunct is set enabled on in the switch. 2. If error type 2567 or 2568, verify the AT&T adjunct version, and readminister if needed. 3. If step 2 does not fix the problem, escalate to the next tier of support.
58	Bearer Capability Not Presently Available Service or Option Not Implemented	Requested bearer capability is implemented, but not administered. No B-channel administered. See recommendation 50 above.

Table 10-67. ISDN-BRI Cause Values — Continued

Code	Explanation	Recommendation
65	Bearer Service Not Implemented	Requested service not implemented in switch or endpoint.
69	Requested Facility Not Implemented	Requested service not supported in switch or endpoint. 1. Consult switch and endpoint documentation to determine service support. 2. If Step 1 does not resolve the problem, escalate to the next tier.
ADJUNCT/SWITCH ERROR CONDITIONS		
81	Invalid CRV	An invalid CRV was sent by the adjunct. 1. This may indicate a CRV inconsistency between the switch and the adjunct. See the CallVisor protocol reference manual. 2. If step 1 does not resolve the problem, escalate to the next tier.

System Technician-Demanded Tests:
Descriptions and Error Codes

When inspecting errors in the system and deciding which ones to address, always investigate errors associated with the circuit pack and port first. Clearing these error codes first may also clear errors generated against the endpoint. When all circuit pack and port errors have been cleared, and errors still exist against the endpoint, always investigate errors in the order they are presented in the table below. By clearing error codes associated with the *Signaling Link Status Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-68. System Technician-Demanded Tests: BRI-SET

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Signaling Link Status Test (#626)	X	X	ND
BRI XID Test (#628)	X	X	ND
BRI Layer 3 Query (#629)	X (a)	X (a)	ND

Continued on next page

Table 10-68. System Technician-Demanded Tests: BRI-SET — Continued

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
BRI Remote Loop Back (#627)		X (a)	ND
BRI Set Audits (#630)	X (a)	X (a)	ND
BRI Vendor ID Test (#631)		X (a)	ND
BRI Model/Vintage ID Test (#632)		X (a)	ND

1. D = Destructive, ND = Non-destructive

Note:

- a. Will execute the **test port long PCSSpp** command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Signaling Link Status Test (#626)

This test determines the current status of the signaling link. This test passes if the link is "bound" to an endpoint and fails if the link is "not bound."

The definition of the term "bound" for a link depends upon the type of endpoint and may depend on the successful completion of procedures at both Layers 2 and 3 of the protocol. The definition of "bound" for each type of endpoint is as follows:

- **BRI endpoints administered for MIM (management information messages) initialization (multipoint):**

NOTE:

An MIM is a level 3 message that conveys management and maintenance information between a communications system and a BRI terminal.

For endpoints of this type, the signaling link is "bound" when the link is connected at Layer 2 and the link has been associated with an endpoint, [that is, the endpoint has completed SPID initialization (L3 established)].

- **ASAI adjuncts and BRI endpoints not administered for MIM initialization (point-to-point):**

For endpoints of this type, the signaling link is "bound" when the link is connected at Layer 2 (L2 established).

For all endpoint types, a signaling link becomes "unbound" when it is disconnected at Layer 2. For BRI endpoints supporting MIM initialization, a signaling link may also become "unbound" if a subsequent attempt to perform SPID initialization on a "bound" link fails, (that is, wrong SPID is entered into the endpoint by the user).

Table 10-69. TEST #626 Signaling Link Status Test

Error Code	Test Result	Description/ Recommendation
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Continued on next page

Table 10-69. TEST #626 Signaling Link Status Test — Continued

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. 2. If this error type is present for BRI-SET only, then release the station via the release station command. a. If this error type is present for BRI-PORT and BRI-SET, then release the port via the release port PCSSpp command and run the test again. b. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the release port PCSSpp command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the release port PPCSS command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the release board PPCSS command and run the test again.  NOTE: When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 3. Make sure the terminal is connected. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-69. TEST #626 Signaling Link Status Test — Continued

Error Code	Test Result	Description/ Recommendation
1113	FAIL	The signaling link is not "bound" to the adjunct or endpoint. For BRI endpoints supporting MIM initialization, this error indicates that the endpoint has not been bound to a signaling link (that is, SPID initialization has not been completed). Since the signaling link associated with the endpoint is not identified until SPID initialization completes, this error does not imply that the signaling link is connected or disconnected at Layer 2 nor does it provide the status of TEI assignment for the endpoint. For ASAI adjuncts and BRI endpoints not supporting MIM initialization, this error indicates that the link is disconnected at Layer 2. Since the signaling link associated with the endpoint has been identified via administration, the link is only "unbound" from the endpoint when it is disconnected. 1. Execute the status bri-port PCSSpp command and refer to the associated procedures for this command contained in the BRI-PORT (ISDN-BRI Port) Maintenance documentation. 2. If the test continues to fail, escalate the problem.
	PASS	The signaling link is connected at Layer 2 and "bound" to the BRI endpoint or ASAI adjunct.
1113	FAIL	The signaling link is not "bound" to the adjunct or endpoint. For BRI endpoints supporting MIM initialization, this error indicates that the endpoint has not been bound to a signaling link (that is, SPID initialization has not been completed). Since the signaling link associated with the endpoint is not identified until SPID initialization completes, this error does not imply that the signaling link is connected or disconnected at Layer 2 nor does it provide the status of TEI assignment for the endpoint. For ASAI adjuncts and BRI endpoints not supporting MIM initialization, this error indicates that the link is disconnected at Layer 2. Since the signaling link associated with the endpoint has been identified via administration, the link is only "unbound" from the endpoint when it is disconnected. 1. Execute the status bri-port PCSSpp command and refer to the associated procedures for this command contained in the BRI-PORT (ISDN-BRI Port) Maintenance documentation. 2. If the test continues to fail, escalate the problem.

BRI Remote Loop Back Test (#627)

This test checks the integrity of a circuit switched B-channel connection between the switch and the endpoint.

In this test, the endpoint is put in the "maintenance busy" state to prevent the switch from issuing calls to the endpoint during the test. An application message containing a loop back activate request for the appropriate B-channel is sent to

the endpoint. The endpoint responds with a loop back activated response. Maintenance then sends data to the endpoint over the B-channel under test. Since the B-channel is looped back at the endpoint, maintenance should receive the data that it sent. If no data is detected, the test fails. An application message containing a loop back deactivate request is then sent to the endpoint to terminate the remote loop back test. The endpoint responds with an MIM message containing a loop back deactivate response. Maintenance then releases the endpoint so that it is available to terminate calls.

This test is not executed for ASAI adjuncts because adjuncts do not support MIMs upon which this test is based.

Table 10-70. TEST #627 BRI Remote Loop Back

Error Code	Test Result	Description/ Recommendation
1000	ABORT	Could not seize the endpoint or B-channels for test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	The endpoint's MIMs Supported field is administered to "no." 1. Use the change station extension command to change parameter only if the endpoint documentation reflects support for ISDN-BRI Management and Maintenance Procedures.
1113	ABORT	The signaling link between the switch and the endpoint is down. 1. Use the test port PCSSpp long command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of the Signaling Link Status Test (#626) which is run as part of this command. If this test aborts or fails, follow the repair procedure for Test #626. 3. If the XID Test continues to abort, escalate the problem.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.

Table 10-70. TEST #627 BRI Remote Loop Back — Continued

Error Code	Test Result	Description/ Recommendation
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. 2. If this error type is present for BRI-SET only, then release the station via the release station command. a. If this error type is present for BRI-PORT and BRI-SET, then release the port via release port PCSSpp command and run the test again. b. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the release port PCSSpp command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the release board PPCSS command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the release port PPCSS command and run the test again.  NOTE: When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 3. Make sure the terminal is connected. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2068	ABORT	The endpoint has rejected the switch sent application message. This indicates that the endpoint does not support the ISDN-BRI Management and Maintenance Procedure for Loop Back Testing. 1. Use the change station extension command and change the MIMs Supported field to "no."

Table 10-70. TEST #627 BRI Remote Loop Back — Continued

Error Code	Test Result	Description/ Recommendation
2069	ABORT	The endpoint has returned an error response to the application message sent by the switch.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	FAIL	No loop back activation or deactivation response is received from the endpoint. 1. Consult the endpoint documentation to determine if ISDN-BRI Management and Maintenance Procedures are supported. If not supported, use change station extension command to change the MIMs Supported? field to "no." Use the busyout station extension and release station extension commands to busyout and release the endpoint to resolve any endpoint alarms resulting from failure of this test. 2. If the endpoint supports these procedures and the test continues to fail, assume the endpoint is defective and replace it.
2071	FAIL	No data is detected on Channel B1 during loop back.
2072	FAIL	No data is detected on Channel B2 during loop back. 1. Replace the endpoint and repeat test. 2. If test continues to fail, check the wiring between the endpoint and the switch and repeat the test. 3. If test continues to fail, escalate the problem.
	PASS	The endpoint has responded to the switch activate and deactivate loop back application messages. Data has been detected on the looped back channels.
1000	ABORT	Could not seize the endpoint or B-channels for test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

BRI XID Test (#628)

This test checks the D-channel connection between the SPE and the endpoint or adjunct.

In this test, a D-channel XID frame is sent to the endpoint or adjunct over the point-to-point signaling link. The test passes if the endpoint or adjunct responds with a Layer 2 XID-RESPONSE frame.

This test must be administered to not run in the station administration form for ports on a TN2208.

Table 10-71. TEST #628 BRI XID

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The BRI-SET, ASAI-ADJ, ATT-ADJ, LGATE-AJ, ATTE-AJ is busy. The test cannot be executed at this time: 1. Pause momentarily (30 seconds) and re-execute at this time. 2. If this problem persists, escalate this problem.  NOTE: A BRI-PORT can also be busy. When using this for BRI-PORT/ABRI-PORT tests, the words "BRI-SET, ASAI-ADJ, ATT-ADJ, " can be changed to "BRI-PORT, ABRI-PORT, ATT-ADJ."
1005	ABORT	The endpoint is not administered to support XID Testing. 1. If the endpoint documentation reflects support XID testing, use the change station extension command to change the XID Testing? field on the form to "yes."
1113	ABORT	The signaling link between the switch and the endpoint is down. 1. Use the test port PCSSpp I command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of the Signaling Link Status Test (#626) which is run as part of this command. If this test aborts or fails, follow the repair procedure for Test #626. 3. If the XID test continues to abort, escalate the problem.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.

Table 10-71. TEST #628 BRI XID — Continued

Error Code	Test Result	Description/ Recommendation
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. 2. If this error type is present for BRI-SET only, then release the station via the release station command. a. If this error type is present for BRI-PORT and BRI-SET, then release the port via release port PCSSpp command and run the test again. b. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the release port PCSSpp command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the release port PCSSpp command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the release board PPCSS command and run the test again.  NOTE: When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 3. Make sure the terminal is connected. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-71. TEST #628 BRI XID — Continued

Error Code	Test Result	Description/ Recommendation
2000	FAIL	The XID-RESPONSE message was not received from the endpoint. 1. Consult the endpoint documentation to determine if the Layer 2 XID and XID-RESPONSE messages are supported. If the documentation reflects no support for these messages, change XID Testing? field to "no" using the change station extension command. 2. If the endpoint supports these Layer 2 messages and the test continues to fail, assume the endpoint is defective and replace it. 3. If the test continues to fail, escalate the problem.
	PASS	The switch can successfully pass messages over the D-channel to the BRI endpoint.

BRI Layer 3 Query Test (#629)

This test is used to check the application layer communications between the switch and the endpoint or adjunct.

For BRI endpoints, an application message containing the appropriate endpoint service state is sent by the switch to the endpoint. The endpoint responds with an acknowledgment to the application message.

For ASAI and AT&T adjuncts, this test is not executed from the administration terminal. Rather, a query message is automatically sent by the switch every two minutes. Failure of the switch to receive a response to a query from the adjunct is logged in the Hardware Error Log.

Table 10-72. TEST #629 BRI Layer 3 Query

Error Code	Test Result	Description/ Recommendation
1005	ABORT	The endpoint's MIMs Supported? field is administered to "no." 1. Use the change station extension command to change the parameter only if the endpoint documentation reflects support for ISDN-BRI Management and Maintenance Procedures.

Continued on next page

Table 10-72. TEST #629 BRI Layer 3 Query — Continued

Error Code	Test Result	Description/ Recommendation
1113	ABORT	The signaling link between the switch and the endpoint or adjunct is down. 1. Use the test port PCSSpp long command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of Test #626, which is executed with the command. If this test aborts or fails, follow the repair procedure for the Signaling Link Status Test. 3. Escalate problem if BRI Layer 3 Query Test continues to abort.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Consult the repair procedure for PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Continued on next page

Table 10-72. TEST #629 BRI Layer 3 Query — Continued

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. 2. If this error type is present for BRI-SET only, then release the station via the release station command. a. If this error type is present for BRI-PORT and BRI-SET, then release the port via the release port PCSSpp command and run the test again. b. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the release port PCSSpp command and run the test again. If the error is present for BRI-SET only, then release the circuit pack via the release port PPCSS command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the release board PPCSS command and run the test again.  NOTE: When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 3. Make sure the terminal is connected. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-72. TEST #629 BRI Layer 3 Query — Continued

Error Code	Test Result	Description/ Recommendation
2068	ABORT	The endpoint has rejected the switch sent application message. This indicates that the endpoint does not support the ISDN-BRI Management and Maintenance Procedure for Endpoint Service Messages. 1. Use the change station extension command and change the MIMs Supported? field to "no."
2069	ABORT	The endpoint has returned an error response to the switch sent application message. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	FAIL	No response is received from the endpoint or the adjunct. For BRI endpoints: 1. Consult the endpoint documentation to determine if ISDN-BRI Management and Maintenance Procedures are supported. If not supported, use the change station extension command to change the "MIMs Supported?" field to "no." Use the busyout station extension and release station extension commands to busyout and release the endpoint to resolve any endpoint alarms resulting from failure of this test. 2. If the endpoint supports these procedures and the test continues to fail, assume the endpoint is defective and replace it.
	PASS	The endpoint has successfully responded to the switch's application message.

BRI Set Audits Test (#630)

This is a series of two tests which are classified as audits. The switch sends messages to the BRI endpoint to perform the following tests:

- Ringer Audit - This audit ensures that both the switch and the endpoint agree as to the current state of the endpoint's ringer.
- Lamps Audit - This audit ensures that both the switch and the endpoint agree as to the current state of the endpoint's lamps.
- Call Activity Audit - This audit ensures that the state of calls is consistent between the switch and the endpoint.

This test is not executed for ASAI or AT&T adjunct because adjuncts do not employ ringers or lamps, or establish calls on the B-channels associated with the BRI interface.

Table 10-73. TEST #630 BRI Set Audits

Error Code	Test Result	Description/ Recommendation
1113	ABORT	The signaling link between the switch and the endpoint is down. 1. Use the test port PCSSpp long command to clear any errors which prevent establishment of the signaling link. 2. Examine the results of the Signaling Link Status Test (#626) which is run as part of this command. If this test aborts or fails, follow the repair procedure for Test #626. 3. If the BRI Set Audits test continues to abort, escalate the problem.
1139	ABORT	The Packet Bus in the port network is out-of-service. 1. Follow the repair procedures for the Packet Bus. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.
1141	ABORT	The PKT-CTRL is out-of-service. 1. Refer to PKT-CTRL (Packet Control Circuit Pack) Maintenance documentation. 2. If Step 1 does not resolve the problem, escalate to the next tier.
1144	ABORT	The PPN Packet Bus is out-of-service. 1. Follow the repair procedures for the Packet Bus in the PPN. 2. After completing Step 1, execute the test port long PCSSpp command, and review the results of the BRI Port Local LAN Loop Around Test to verify the repair.

Table 10-73. TEST #630 BRI Set Audits — Continued

Error Code	Test Result	Description/ Recommendation
1187	ABORT	The circuit pack, port or station may have been busied out by a technician. 1. Look in the Error Log for Error Type 18 (busied out) for BRI-BD, BRI-PORT, or BRI-SET. 2. If this error type is present for BRI-SET only, then release the station via the release station command. a. If this error type is present for BRI-PORT and BRI-SET, then release the port via the release port PCSSpp command and run the test again. b. If the error is present for BRI-BD, BRI-PORT, and BRI-SET, then release the circuit pack via the release port PCSSpp command and run the test again. If the error is present for both BRI-BD and BRI-PORT, then release the circuit pack via the release board PPCSS command and run the test again.  NOTE: When you release the circuit pack, you release all ports associated with it. If certain ports still need to be busied out, use the release port PCSSpp command to busy them out. 3. Make sure the terminal is connected. 4. Retry the command at one-minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.
2012	ABORT	Internal System Error.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

SPID Facility Test

This test is used to verify the wiring and operation of the signaling link between the switch and a endpoint or adjunct on a BRI interface. **This test is not executed from the administration terminal, but rather is executed by using a BRI test set equipped with a display.** The test set may replace the BRI set, ASAI or AT&T adjunct under test by plugging it into the same jack or by bridging it onto the wiring at some point between the switch and the endpoint (or adjunct), thereby creating a pseudo-BRI multipoint configuration.

When plugged into the port in this manner, the test set establishes a signaling link connection with the switch and attempts to complete SPID initialization by using the Service SPID administered for the system (see the System Maintenance Administration Form). If the test set displays the correct administered port address for the endpoint or adjunct under test, the test passes (see Service SPID Display which follows). If after one-minute nothing is displayed on the test set, the test fails.

Table 10-74. SPID Facility Test

Test Result	Description/ Recommendation
FAIL	No response is received from the endpoint. 1. Check the physical wiring between the switch and the endpoint or adjunct. 2. If test continues to fail, escalate to the next tier.
FAIL	Display does not match administered port address for the endpoint or adjunct. 1. Change station administration for endpoint or adjunct to match displayed port address. 2. If test continues to fail, escalate the problem.
PASS	Display matches administered port address for the endpoint or adjunct. For BRI endpoints: 1. Verify that the SPID values administered in the switch and the endpoint are consistent. 2. If the SPID values are correct, replace the endpoint. 3. If test continues to fail, escalate the problem. For ASAI adjuncts: 1. Verify that the TEI values administered in the switch and the adjunct are consistent. 2. If the TEI values are correct, consult the recommended repair procedures of the manufacturer for the adjunct. 3. If test continues to fail, escalate the problem.

The abbreviations used in (Service SPID Display) have the following meanings:

- Pport network (1,2, ...)
- CCarrier (A,B,C, ...)
- SSSlot (01, 02, ...)
- ppport (01-12)
- extextension one and two (one through 99999)
- SPIDservice order profile identifier

CABINET (Cabinet Sensors)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CABINET	MAJOR	test environment P	Cabinet Sensors
CABINET	MINOR ²	test environment P	Cabinet Sensors

1. Where P is an appropriate port network number determined via the Port field from the Alarm or Error Log.
2. If a minor alarm occurs for a variable speed fan, the fan should be checked for a dirty filter. If the filter is not dirty, the fan should be replaced.

 **NOTE:**
CABINET is valid only in a multicarrier cabinet system. For information concerning single-carrier cabinet systems, refer to the DC-POWER (Single-Carrier Cabinet Power) Maintenance documentation.

Each multicarrier cabinet is equipped either with six non-variable speed fans or with six variable speed fans.

Non-Variable Speed (Standard) Fan Option. A non-variable speed (standard) fan is indicated by one of the following Product Codes: "ED67077 G1," "ED67077 G2," or "ED67077 G3." Multicarrier cabinets with non-variable speed fans contain a fan speed control unit known as the AHD1 circuit pack. This circuit pack is designed to keep the temperature within the cabinet below 65⁰ C (149⁰ F). Air is drawn in by the three fans located in the front of the cabinet. The air is channeled upwards through a filter, then through carriers A, B, and C and out the top of the cabinet. Air is drawn in by the three fans located in the back of the cabinet as well. The air is channeled down through a filter, then through carriers D and E and out the bottom of the cabinet. The AHD1 circuit pack monitors five of the six temperature sensors located throughout the multicarrier cabinet, and it uses the output of these sensors to adjust fan speed and to report air flow problems. The Maintenance/Tape Processor in a Standard system PPN, the Duplication Interface circuit pack, a PPN for a High or Critical Reliability system, and the EPN Maintenance circuit pack in an EPN multicarrier cabinet system directly monitor the sixth sensor (S1) to report temperature problems. The Cabinet Sensors maintenance object represents the air flow and temperature problems reported by the AHD1 circuit pack and by the Maintenance/Tape Processor, the Duplication Interface circuit pack, or the EPN Maintenance circuit pack in the multicarrier cabinet systems.

The fans and the AHD1 circuit pack obtain their power from the -48 volt DC power supply of the 631 DB DC power unit in the A carrier. In a PPN cabinet for a High or Critical Reliability system, the 631 DB DC power unit in the B carrier can also provide power to the fans. The power goes from the power unit(s) to the current limiter card (982LS), over a wiring harness from the A carrier to the back of the fan unit, through the AHD1 circuit pack, and then to the fans. The front fans

are wired in parallel with a rear fan. The repair scenarios that follow rely on the technician's ability to distinguish between high fan speed and low fan speed. The only way to distinguish between the fan speeds is by the sound of the fans. When operating at high speed, the fans make a higher pitched sound than when they run at low speed. The technician probably knows from prior experience what the fans sound like at low speed as well as at high speed.

Figure 10-10 shows a multicarrier cabinet system and the location of the temperature sensors S1 through S4 (there are actually two S3 sensors and two S4 sensors) as well as the location of the fans, the AHD1 circuit pack, and the filters. The figure also shows other environment-related components of a multicarrier cabinet system and can be ignored for this section on Cabinet Sensors.

**Figure 10-10. Multicarrier Cabinet Environment Components (CABINET)
[Non-Variable Speed Fan Option]**

Sensor S1 informs the Maintenance/Tape Processor, the Duplication Interface circuit pack, or the EPN Maintenance circuit pack when the temperature at the top of the cabinet reaches 65⁰ C (149⁰ F). Sensor S2 is not monitored by any circuit pack. However, when the temperature at the top of the cabinet reaches 70⁰ C (158⁰ F), this sensor causes the Power Distribution Unit to shut down power to the entire cabinet. At this point, Emergency Transfer is invoked, and no other system functions are provided.

The S3 and S4 sensors constantly report the temperature at the air exhaust in the cabinet (top and bottom S3 sensors) and at the air intake (S4 sensors). The AHD1 circuit pack uses this information to determine fan speed and air flow alarm state. If there is at least a 15 ⁰C (27 ⁰F) air temperature difference between

the air exhaust and air intake, **and** if the air exhaust temperature is greater than 50 °C (122 °F), all the fans are turned up to high speed. If this condition exists, the AHD1 circuit pack reports an air flow problem which results in a Minor alarm against the Cabinet Sensors.

Variable Speed Fan Option. A variable speed fan is indicated by the Product Code "ED67077 G'x," where 'x' is '4' or a number greater than '4.' A variable speed fan contains Thermal Speed Control and an alarm circuit. As a result, the AHD1 circuit pack is not required in this type of fan.

A variable speed fan has two connectors: a two pin connector for the -48 volt input power for backward compatibility, and the five pin Molex connector for speed control and alarm circuitry. The -48 volt power circuitry is isolated from the speed control and the alarm circuitry.

An alarm lead from all six variable speed fans is tied to a single lead leading to the processor circuit pack. Three fans on the front of the system are connected to an S3 sensor, which monitors the exhaust air temperature above carrier position "C." Three fans on the back of the system are connected to another S3 sensor, which monitors the exhaust air in the power distribution unit. The speed of the variable speed fans is determined by the temperature detected by the S3 sensors. Thus, the fans' speed changes continuously according to the temperature of the exhaust air. If the fan speed drops below the preset limit, or if the fan fails, the fan alarm circuit reports an air flow problem, which results in a minor alarm.

A multicarrier cabinet containing variable speed fans is presented in Figure 10-11. Note that the two S4 sensors that are included with non-variable speed fans are not required with variable speed fans.

 NOTE:

The new variable speed fans are backward compatible to the carriers for the non-variable speed fans. However, the carriers for the variable speed fans are not backward compatible to cabinets configured for the carriers for the non-variable speed fans. Finally, the carriers for the non-variable speed fans are not forward compatible to cabinets configured for the carriers for variable speed fans.

Figure 10-11. Multicarrier Cabinet Environment Components (CABINET) [Variable Speed Fan Option]

Replacement Procedures for AHD1 Fan Speed Controller Circuit Packs and Fans

AHD1 Fan Speed Controller Circuit Pack Replacement Procedure

NOTE:
The procedures in this section pertain only to non-variable speed (standard) fans.

1. Refer to Chapter 5, "Routine Maintenance Procedures", for details on removing power from the system.
2. Remove the fan assembly cover by pulling the cover outward.
3. Loosen and remove the retaining screw nearest the power plug on the front fan located to the extreme left.
4. Disconnect the power plug from the fan.
5. Loosen and remove the other retaining screw on the fan.
6. Remove the fan from the fan assembly.

CAUTION:

DO NOT TOUCH! Resistors on the circuit pack are hot.

7. Lift the latch on the AHD1 fan speed controller circuit pack.
8. Using the latch as a handle, pull the circuit pack up and out of its holder.
9. Insert a replacement AHD1 circuit pack, and push down on the latch until the latch snaps in place.
10. Position the fan, and reconnect the fan power plug.
11. Insert and tighten the retaining screws.
12. Replace the fan assembly cover.
13. Refer to Chapter 5, "Routine Maintenance Procedures", for details on restoring power to the switch.

Fan Replacement Procedure

NOTE:

The procedures in this section pertain to both non-variable speed (standard) fans and variable speed fans.

First, determine which fans are defective:

NOTE:

The following instructions are for servicing a Medium Cabinet. For a Small Cabinet (only two fans in the rear), follow Step 2A below, but start from the rear of the cabinet.

1. If any fan is **not** rotating, a more detailed inspection is required to determine why the fan has stopped operating. The fact that a fan is not spinning is not always proof that it is damaged. Since each front fan is electrically in parallel with a rear fan, an internal short circuit in a front fan prevents power from reaching the rear fan (and vice versa).

Remove the fan assembly cover by pulling the cover outward. Remove the power connector from each inoperative front fan.

2. The following must be done to determine if the front fan or the rear fan has failed:

a. Test the front fan:

Measure the input impedance between the (+) and (-) input terminals of the front fan with an ohmmeter. **IMPORTANT: Attach the "common" lead of the ohmmeter to the fan's (-) input terminal and the "ohms" or "+" lead of the ohmmeter to the fan's (+) input terminal.**

Follow the guidelines in the table below:

Input Impedance	Fan Analysis	Action	Next Step
2.0M < ohms < 20M	Good	None	Go to Step 2B
ohms < 2.0M	Short Circuit	Replace	Go to Step 3
ohms > 20M	Open Circuit	Replace	Go to Step 3

b. Test the "paired" rear fan:

From the front of the cabinet, use a voltmeter to measure the DC voltage across the two female contact pins in the connector housing of the fan wire harness removed from the inoperative front fan in Step 1. (This voltage is the same voltage seen across the input terminals of the paired fan in the rear of the assembly.)

Follow the guidelines in the table below:

Input Impedance	Fan Analysis	Action	Next Step
VDC > 25V	Good	(AHD1 or Front Fan failed)	
VDC < 25V	Short Circuit	Replace	Go to Step 3

3. To replace a fan located at the front of the switch cabinet, remove the fan assembly cover by pulling the cover outward. To replace a fan located at the rear of the switch cabinet, use a No. 10 slot screwdriver or 5/16-inch (8mm) wrench and remove the panel covering the fan assembly.
4. Loosen and remove the retaining screw nearest the power plug on the defective fan.

 **DANGER:**
48-volt power is present on the fan plug.

5. Disconnect the power plug from the defective fan.
6. Loosen and remove the other retaining screw on the fan.
7. Remove the fan from the fan assembly.
8. Position the replacement fan and reconnect the fan power plug.
9. Insert and tighten the retaining screws.

10. Replace the fan assembly cover or panel.

Hardware Error Log Entries and Test to Clear Values

Cabinet Sensors Error Log Entries					
Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test environment P sh r 1
1	Any	Cabinet Temperature Query Test (#122)	MINOR	ON	test environment P sh r 3
257	Any	Cabinet Temperature Query Test (#122)	MAJOR	ON	test environment P sh r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-75. System Technician-Demanded Tests: CABINET

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
Power Unit Query Test (carrier E) (#127) (c)	X	X	ND
Power Unit Query Test (carrier D) (#127) (c)	X	X	ND
Power Unit Query Test (carrier A) (#127) (c)	X	X	ND
Power Unit Query Test (carrier B) (#127) (c)	X	X	ND
Power Unit Query Test (carrier C) (#127) (c)	X	X	ND
Emergency Transfer Query Test (#124) (d)	X	X	ND
Cabinet Temperature Query Test (#122)	X	X	ND

Table 10-75. System Technician-Demanded Tests: CABINET — Continued

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive, ND = Non-destructive

Notes:

- a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.
- b. Refer to AC-POWER (AC-Power) Maintenance documentation for a description of this test.
- c. Refer to CARR-POW (Carrier Port Power Unit for AC- and DC-Powered Systems) Maintenance documentation for a description of this test.
- d. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.
- e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.
- f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test. This test shows up in the test sequence only if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Cabinet Temperature Query Test [for Non-Variable Speed Fans] (#122)

This test queries the Maintenance/Tape Processor in a Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN for the status of the cabinet sensors in the cabinet that contains non-variable speed fans.

➤ NOTE:

The descriptions for Error Codes 1 and 2 (FAIL) in the following table are reversed for Generic 1 systems that use a TN731B maintenance circuit pack . That is, Error Code 1 indicates an "over temperature" problem while Error Code 2 indicates and "air flow" problem. If you are servicing a Generic 1 system, be sure to follow the proper service strategy.

Table 10-76. TEST #122 Cabinet Temperature Query Test
[Non-Variable Speed Fans]

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a Error Code 2000, check for and resolve all DUPINT (Duplication Interface) errors in a Duplicated Option PPN, PR-MAINT (Maintenance/Tape Processor) errors in a standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test. 4. If the test continues to ABORT with a Error Code 2000, escalate the problem.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-76. TEST #122 Cabinet Temperature Query Test
[Non-Variable Speed Fans] — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL	The AHD1 circuit pack has reported an air flow problem. The temperature difference between the air intake and the air exhaust is at least 15⁰ C (27⁰ F) and the absolute temperature at the top of the cabinet is at least 50⁰ C (122⁰F) (referred to as the 15⁰ C/50⁰ C criteria). The fans should be running at high speed. - If none of the fans are running, then: - Look for and resolve all alarms against the CARR-POW (Carrier Port Power Unit). - Verify -48 volt DC power is available to the fan units. Check the fan unit wiring harness connector. Check that there is 48 volt DC between pins 3, 9, 11 and 2, 8, 10. - If there is -48 volt DC power at the connector, there should be power to the fans. If the fans are not running, replace the AHD1. If the fans still do not run, escalate the problem. - If there is no -48 volt DC power at the connector, then the current limiter card (982LS) is probably defective. Replace the current limiter card. If the fans still do not run, escalate the problem. - If only a few of the fans are not running, replace the defective fans. - If all the fans can be started, wait five minutes and rerun the test. If the test fails again, proceed to Step 4 or 5 as applicable.

Continued on next page

Table 10-76. TEST #122 Cabinet Temperature Query Test
[Non-Variable Speed Fans] — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL (cont'd.)	4. If the fans are not at high speed, measure the cabinet temperature at the air intake and the air exhaust at the top of the cabinet. a. If the 15⁰ C/50⁰ C criteria is met, there is a problem with either the AHD1 circuit pack or the fans that is preventing the fans from operating at high speed. Replace the AHD1 circuit pack and/or the fans. If this succeeds in getting the fans to run at high speed, wait five minutes to give the cabinet time to cool down and, rerun the test. If the problem persists, go to step 5. b. If the 15⁰ C/50⁰ C criteria is not met, the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack is incorrectly reporting this condition. Look for and resolve all errors on these maintenance objects first, then rerun the test. If the test still fails, escalate the problem. 5. If the fans are running at the high speed, check the items on list that follows. Any on of the items could be restricting or redirecting the flow of air within the cabinet. a. Check both filters. If a filter is dirty or clogged it should be cleaned or replaced. The filters can either be washed with soap and water or vacuumed. b. Make sure there is nothing (other than circuit packs) in the carrier slots that could be restricting the air flow. c. Make sure there are no missing (blank) circuit pack or carrier faceplates. Install and/or replace them as necessary. d. Make sure the cabinet door is properly closed. The door must be closed for the fans to be able to properly cool the cabinet. Wait five minutes to give the fans a chance to cool the cabinet. Rerun the test. If the tests still fails, proceed to Step 6.

Continued on next page

Table 10-76. TEST #122 Cabinet Temperature Query Test
[Non-Variable Speed Fans] — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL (cont'd.)	6. At this point, there should be nothing impeding the air flow, and the fans should be running at high speed. Check the temperatures for the 15⁰ C/50⁰ C criteria. a. If the 15⁰ C/50⁰ C criteria exists, a temperature problem exists, and the fans (at high speed) should cool down the switch. Wait five minutes and rerun the test. If the test still fails, the ambient room temperature is probably too high, and the room should be cooled. b. If the 15⁰ C/50⁰ C criteria does not exist, the AHD1 circuit pack, the fans, or the S3 or S4 sensors are defective. Replace these items one at a time (in the order listed). Rerun the test between each replacement. Failures can occur on the Maintenance/Tape Processor, the Duplication Interface, and the EPN Maintenance circuit pack that are not detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If this does not clear the problem, follow normal escalation procedures.
2	FAIL	The PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack has reported a temperature problem because the S1 sensor has detected a temperature of at least 65⁰ C (149⁰ F). The entire cabinet is in danger of being powered down if the temperature reaches 70⁰C (158⁰ F). 1. If none of the fans are running: a. Look for and resolve all alarms against the CARR-POW (Carrier Port Power Unit). b. Verify that 48 volt DC is available to the fan units. Check the fan unit wiring harness connector. Verify that there is 48 volt DC between pins (3, 9, 11 and 2, 8, 10). ■ If there is 48 volt DC at the connector, there should be power to the fans. If the fans are not running, replace the AHD1. If the fans still do not run, follow normal escalation procedures. ■ If there is not 48 volt DC at the connector, the current limiter card (982LS) is probably defective. Replace the current limiter card. If the fans still do not run, escalate the problem. 2. If only a few of the fans are not running, replace the defective fans. 3. If all the fans can be started, wait five minutes, and rerun the test.If the test fails again, proceed to Step

Table 10-76. TEST #122 Cabinet Temperature Query Test
[Non-Variable Speed Fans] — Continued

Error Code	Test Result	Description/ Recommendation
2	FAIL (cont'd.)	4. Check the temperature at the top of the cabinet. If the temperature is at least 65⁰ C (149⁰ F), the ambient room temperature is too high, and the fans cannot cool the system. Unless the room temperature is reduced, the system is going to shut down soon. If the temperature is less than 65⁰ C, then: a. The PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may be incorrectly reporting this condition. First, look for and resolve all errors on these MOs, then rerun the test. If this test fails again, return to Step 1. If there are no errors, continue. b. The sensor S1 may be incorrectly reporting the temperature at the top of the cabinet. Replace sensor S1, and rerun the test. If the test still fails, escalate the problem.
3	FAIL	The AHD1 circuit pack has reported both air flow and temperature problems. Resolve the airflow error first, then, correct the temperature error as described previously.
	PASS	The AHD1 circuit pack has not reported any temperature or air flow problems. The temperatures at the air exhaust at the top of the cabinet and the air intake at the bottom of the cabinet can be measured and the results compared against the criteria described previously. If a problem has been reported, troubleshoot this problem by using the procedures for the "FAIL" cases described previously.

CAP-MEM (Memory Card Capacity)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
CAP-MEM	MINOR/ WARNING ¹	test card-mem long	Memory Card Capacity

1. The WARNING alarm is generated when the alarm is downgraded by using the **set option** command.

Memory Card Capacity tracks the percentage of used translation storage space on the memory card. Whenever translation space usage on the memory card reaches 98% of capacity, an alarm is generated. This alarm serves to inform the user that a larger flash card may be required for the system.

Error Log Entries and Test to Clear Values

Table 10-77. Memory Card Capacity Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1 (a)	112	Memory Card Capacity Test (#1014)	MINOR/ WARNING (b)	OFF	test card-mem long

- Notes:
- a. The memory card translation storage space is at least or more than 98% full.

b. This alarm has been downgraded by the **set option** command.

System Technician-Demanded Tests: Descriptions and Error Codes

Always investigate tests in the order presented in the table that follows when you are inspecting errors in the system. By clearing error codes associated with the "Memory Card Capacity Test," for example, you may also clear errors generated from other tests in the testing sequence. The "Memory Card Capacity Test" can be initiated via either the **test card-mem long** command or after a **save translation** command.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
12 Volt Power Supply Test (#701) (a)	X	X	ND
Memory Card Insertion Test (#695) (b)	X	X	ND
Memory Card Format and Read Test (#696) (b)	X	X	ND
Memory Card Match Test (#697) (b)	X	X	ND
Memory Card Write-Protected Test (#698) (b)	X	X	ND
Memory Card Directory Recovery Test (#699) (b)	X	X	ND
Memory Card Translation Data Integrity Test (#694) (b)		X	ND
Memory Card Erase/Write/Read Test (#693) (b)		X	ND
Memory Card Capacity Test (#1014)		X	ND

1. D = Destructive; ND = Nondestructive

- Notes:
- a. Refer to 12V-PWR (12 Volt Power Supply) Maintenance documentation for a description of this test.
 - b. Refer to CARD-MEM (Memory Card) Maintenance documentation for a description of this test.

Memory Card Capacity Test (#1014)

This test is a nondestructive test. The purpose of the test is to verify that the percentage of translation storage space used in the memory card is less than 98%.

This test can be initiated through a system technician demanded **test card-mem long** command, or it can be executed as part of a maintenance test sequence after the **save translation** operation.

Table 10-78. TEST #1014 Memory Card Capacity Test

Error Code	Test Result	Description/ Recommendation
112	ABORT	The Memory Card Translation storage is at least 98% full. 1. Inform the user that it may be necessary to upgrade to a larger flash card. 2. Replace the memory card with a larger one, or downgrade the alarm to WARNING by using the set option command. 3. Rerun the test.
2012 2106 2114	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for repairing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem long command.
2110	ABORT	No Memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Rerun the test.
	PASS	The Memory Card Translation storage is less than 98% full.

CARD-MEM (Memory Card)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
CARD-MEM	MAJOR ¹		Memory Card
CARD-MEM	MINOR	test card-mem long	Memory Card
CARD-MEM	WARNING	test card-mem sh	Memory Card

1. The "MAJOR" alarm occurs only at power-up time or on a Reset System 3, 4, or 5 when the switch cannot load all translations from the memory card.

A memory card contains a set of flash EPROM memory devices. The data can be stored in a memory card and can remain nonvolatile, even when the power is off. The memory card is installed into the TN777B NETCON circuit pack to save the translations, announcements, and core dumps. During the system reboot or a system power down condition, the in-core system maintenance hardware error logs are temporarily saved in the memory card before the system goes down. When the system is restarted, the error logs file is read back from the memory card.

The Hard Patch feature also uses the memory card as temporary storage when LMM applies an update file to the in-core system software. The system software is stored in the "flash" section of main memory. The memory card used for saving translations doesn't contain a copy of the system software.

The recommended size of a memory card for each configuration is described in the following table.

Memory Card Size	Usage	File Names
1 Megabyte	Without Announcements	translation
4 Megabyte	With Announcements	translation announcements
10 Megabyte	With Announcements	translation announcements
10 Megabyte	Maintenance	translation announcements core_dump
10 Megabyte	System Upgrade	system_software

Customers can have either 1 MB, 4 MB, or 10 MB memory cards for the normal operations. 10 MB memory cards are also used for maintenance and software upgrades. The software upgrade memory card cannot be used for saving translations.

Always use 4 MB memory Cards, 10 MB memory cards should only be used when a 4MB card gives an error in the CAP-MEM Maintenance Object Test #1014 (Memory Card Capacity Test).

A memory card has a write-protection switch along its edge. If the write-protection switch is enabled, the memory card cannot be written to.

The 12 volt power supply unit located in TN777B NETCON circuit pack supports the erase and write operations of flash memory devices in the TN786B or TN790 Processor circuit pack. The unit also supports the memory card inserted in the TN777B NETCON circuit pack. If the 12 volt power supply unit cannot be turned on to supply 12 volts, all erase and write operations fail. Refer to 12V-PWR (12 volt power supply) Maintenance documentation for a detailed description.

To write data (for example, translations) onto a memory card, the system software first erases the memory card and then writes the data. An erased bit can be written again, but a written bit cannot be changed or written again until after the next erasure. Software erase and write operations on a memory card take longer as the card usage increases. A memory card that cannot be erased or written to by software should be replaced.

Removing A Memory Card From The Slot

A memory card can be removed from the slot at the TN777B NETCON circuit pack only when the fourth yellow LED with a label "card-in-use" is not glowing. Otherwise, the memory card operation might be interrupted abnormally, and the files stored in the memory card may become corrupted.

Resolving an Alarm Raised Against a Memory Card

The list that follows discusses the procedures for resolving an alarm that is raised against a memory card:

1. Remove the inserted memory card from the slot at the TN777B NETCON circuit pack while the "card-in-use" amber LED on TN777B is not glowing.
2. Insert the new formatted memory card firmly into the slot at the TN777B NETCON circuit pack.
3. Enter the **test card-mem** command to verify the new memory card.
4. If the alarm cannot be resolved by replacing the memory card, do the following:
 - a. Remove the memory card from the TN777B NETCON circuit pack.
 - b. Replace the TN777B NETCON circuit pack in the appropriate control carrier. Since the TN777B is in the SPE control complex, follow the standard procedures for replacing an SPE circuit pack.
 - c. Insert the memory card back into the slot at the TN777B circuit pack.
 - d. Enter the **test network-control [long]** command to verify the new TN777B and the memory card.

5. Once the alarm is resolved, enter the **save translation** command to store the current system translations to the memory card.
6. If applicable, enter the **save announcements** command to store the current announcements to the memory card.

Error Log Entries and Test to Clear Values

Table 10-79. Mrmory Card Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test card-mem
1(a)		Memory Card Insertion Test (#695)	MINOR	OFF	test card-mem
257(b)		Memory Card Format and Read Test (#696)	MINOR	OFF	test card-mem
513(c)	Any	Memory Card Match and Read Test (#697)	WARNING	OFF	test card-mem
769(d)		Memory Card Write-Protected Test (#698)	WARNING	OFF	test card-mem
1025(e)	104 105 106 107 108	Memory Card Dir. Recovery Test (#699)	MINOR	OFF	test card-mem
1281(f)	Any	Memory Card Translation Data Integrity Test (#694)	MINOR	OFF	test card-mem long
1537(g)	104 105 106 107 108	Memory Card Erase/Write/Read Test (#693)	MINOR	OFF	test card-mem long
3329(h)	any	None	MINOR/ MAJOR	OFF	
3841(i)	Any	Save Translation	MINOR	OFF	save translation
3843(j)	Any	Save Translation	MINOR	OFF	save translation

1. Run the Short Test sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. System detects that no memory card is inserted in the slot at the TN777B NETCON circuit pack. If a memory card is in place, the memory card may have a bad physical connection.
- b. System software cannot recognize the inserted memory card because the inserted memory card is not formatted or the directories in the memory card are corrupted. The system cannot use this memory card. The memory card must be replaced with a good memory card.
- c. The inserted memory card does not have enough storage space to support system operations, such as saving translations and, if applicable, announcements; or, the memory card is a system-upgrade memory card that cannot be used for saving translations. This hardware error raises a WARNING/OFF_BOARD alarm. The memory card should be replaced with one of the recommended size.

The "Aux Data" field contains the following error codes:

- 101: Inserted memory card is a system-upgrade memory card
 - 102: While the announcement feature is in use, no announcement file is available in the memory card
 - 103: The inserted memory card is a system-upgrade memory card, and, while the announcement feature is in use, no announcement file is available in the memory card.
 - 116: The capacity of the inserted memory card doesn't match the system configuration.
 - 118: While the announcement feature is in use, no announcement file is available in the memory card, and the capacity of the inserted memory card doesn't match the system configuration.
 - 132: System translation reaches a 98% capacity of the memory card reserved storage space.
 - 134: While the announcement feature is in use, no announcement file is available in the memory card, and system translation reaches a 98% capacity of the memory card reserved storage space.
 - 148: The capacity of the inserted memory card doesn't match the system configuration, and system translation reaches a 98% capacity of the memory card reserved storage space.
 - 150: While the announcement feature is in use, no announcement file is available in the memory card, and the capacity of the inserted memory card doesn't match the system configuration. Also, the system translation reaches a 98% capacity of the memory card reserved storage space.
- d. The write-protection switch of the memory card is in the "protected" position. A write-protected memory card can not be erased or written. Before entering the **test** command to resolve the alarm, follow the

standard procedure for taking the memory card out of the slot. Then, change the "write-protection" switch to the "not-protected" position. Finally, insert the memory card back into the slot.

- e. The memory card has been detected with a broken directory. A MINOR/OFF_BOARD alarm is raised when maintenance cannot restore the broken directory. The memory card must be replaced before the test to resolve the alarm is run.

The "Aux Data" field contains the following error codes:

- 104: Directories on the memory card are corrupted and cannot be recovered.
 - 105: "0" cannot be written into the memory card before an erase operation.
 - 106: Memory card cannot be erased.
 - 107: Data cannot be written into a memory card after an erasure.
 - 108: 12 volt power supply for directory recovery can't be turned on. The 12 volt power supply on TN777B NETCON circuit pack may be defective. Follow the standard procedure to replace the TN777B NETCON circuit pack.
- f. The translations file stored in the memory card is corrupted with a checksum error during the read operation. The memory card can no longer hold the written data. Enter the **save translation** command to restore the translations. Then, run the **test** command to clear the alarm. If the error occurs repeatedly, replace the memory card.
 - g. The maintenance test "Memory Card Erase/Write/Read Test" failed. Enter the **status card-mem** command to verify that a user's memory card is inserted and that the write-protection switch of the memory card is off. Rerun the **test card-mem** command to verify that the 12 volt power supply is functional.

Enter the **test card-mem long** command again to verify the test result of the "Memory Card Erase/Write/Read Test." If the test still fails, the memory card should be replaced. After the new memory card is inserted, enter the **test card-mem long** command again to resolve the alarm.

The "Aux Data" field contains the same error codes as for Error Type "1025." See Note (e).

- h. There was an error while translations were being loaded. The relevant alarm occurs at power-up or on a Reset System 3, 4, or 5 if the switch cannot load translations.

In a standard system, the alarm invokes Emergency Transfer. The repair procedure for a standard system is provided in the list that follows:

⇒ NOTE:
Follow this procedure **only** if there are no other memory card errors or alarms. If such errors or alarms exist, resolve them before trying to resolve this alarm.

1. After you resolve all other memory card problems, issue the **reset system 3** command.
2. After the system is restarted, issue the **status card-mem** command.
3. If the "translation" is not present, insert a backup memory card and then issue the **reset system 3** command.

⇒ NOTE:
In a High or Critical Reliability System where the problem is in the Standby SPE, use the procedure above substituting **reset spe-standby 3** and **status card-mem a/b** for the Standby SPE.

- i. The "save translation" operation failed. The reasons for failure are described in the "Aux Data" field and include the following:

Aux Data	Description
1	Directory file on the memory card failed the checksum test
2	NETCON is not a TN777B circuit pack
3	Too many commands are running
4	Command has been aborted
5	Command has collided with a current command
6	Software controller is idle
7	Memory card has been erased
8	Only one good directory is on the card
9	All directories are corrupted, and the memory card needs reformatting
10	Hard patch file is full
11	Hardware fault: data can't be written into the memory card
12	Software error: passed parameters were out of range
13	Command has been aborted
14	Magic number is illegal
15	Driver was trapped when reading the memory card
16	No memory card is inserted

17	Second directory in the memory card could not be found
18	File in the memory card is not available
19	Memory card does not match the system usage
20	Memory card is too small for the system usage
21	Broken directory couldn't be recovered
22	System upgrade card is inserted
23	Illegal write is requested
24	Generic software failure
25	Driver timed out
26	Driver is unable to program "O's" in the memory card
27	Memory card can't be erased
28	Memory card is write-protected
29	12 volt power supply could not be turned on
109	Standby SPE does not respond to the request from the Active SPE
124	Can't access Standby SPE for saving translation

A MINOR/OFF_BOARD alarm is raised when two consecutive "save translation" operations fail. The alarm is resolved only when the translation is saved onto the memory card successfully.

- j. The save translations failure is due to other hardware failures. Enter the **test card-mem long** command and resolve other card-mem failures first. After the all test card-mem pass message is received, use the **save translation** command to resolve this error.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *Memory Card Insertion Test* for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	D/ND ¹
12 Volt Power Supply Test (#701) (a)	X	X		ND
Memory Card Insertion Test (#695)	X	X		ND
Memory Card Format and Read Test (#696)	X	X		ND
Memory Card Match Test (#697)	X	X		ND
Memory Card Write-Protected Test (#698)	X	X		ND
Memory Card Directory Recovery Test (#699)	X	X		ND
Memory Card Translation Data Integrity Test (#694)		X		ND
Memory Card Erase/Write/Read Test (#693)		X		ND

1. D = Destructive; ND = Nondestructive

Note:

a. Refer to 12V-PWR (12 Volt Power Supply) Maintenance documentation for a description of this test.

Memory Card Erase/Write/Read Test (#693)

The purpose of this test, which is nondestructive, is to verify the erase, write, and read operations. The test erases the backup copy of the translation file stored in the memory card, and it verifies that the erase operation works. The test then writes the primary copy of the translation file from the same memory card to the erased flash segment, and it verifies that the translation file is written successfully.

This test can be initiated through a system technician demanded **test card-mem long** command, or it can be executed as part of a maintenance test sequence when the **save translation** and **save announcements** operations fail. The test and relevant applications (for example, saving translations, saving announcements) cannot be executed at the same time.

Table 10-80. TEST #693 Memory Card Erase/Write/Read Test

Error Code	Test Result	Description/ Recommendation
1192	ABORT	Applications are accessing the memory card. 1. Wait 10 minutes for the applications to complete. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
2110	ABORT	No memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2111	ABORT	Inserted memory card cannot be recognized. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2112	ABORT	Internal system error The inserted memory card is a "system-upgrade" memory card. 1. Replace the inserted memory card with a user's memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2115	ABORT	The memory card is write-protected. 1. Take the memory card out, and change the "write-protection" switch to the "not-protected" position. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2113	ABORT	The inserted memory card has only one directory file. 1. Enter the test card-mem command, and verify that the "Memory Card Directory Recovery Test" (#699) passes. If the directory file cannot be recovered, replace the memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-80. TEST #693 Memory Card Erase/Write/Read Test — Continued

Error Code	Test Result	Description/ Recommendation
2117	ABORT	No translation file has been saved onto the memory card. 1. Enter the save translation command, and verify that the translations are saved onto the memory card successfully. 2. Retry the command at 1-minute intervals a maximum of 5 times.
104	FAIL	Directories on the memory card are corrupted and cannot be recovered.
105	FAIL	"0" cannot be written into memory before an erase operation.
106	FAIL	Memory card cannot be erased.
107	FAIL	Data cannot be written onto a memory card after an erasure. 1. Replace the memory card and re-run the test.
108	FAIL	12 volt power supply for the Memory Card Erase/Write/Read Test can't be turned on. The 12 volt power supply on TN777B NETCON circuit pack may be defective. 1. Re-enter the test card-mem command, and verify the result of Test 701 for the 12 Volt Power Supply. 2. If Test 701 fails, follow the Standard Repair Procedure to replace the TN777B NETCON circuit pack with a new TN777B circuit pack. 3. Retry the command a 1-minute intervals a maximum of 5 times.

Memory Card Translation Data Integrity Test
(#694)

This test, which is nondestructive, verifies the integrity of the translation file stored in the memory card by reading (without any PREC updates) the translation file from the memory card and by then performing a checksum error checking. The calculated checksum value is compared with the recorded checksum value in the translation file. If these two values are different, this indicates that the translation file is corrupted.

Table 10-81. TEST #694 Memory Card Translation Data Integrity Test

Error Code	Test Result	Description/ Recommendation
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
2110	ABORT	No memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2111	ABORT	Inserted memory card cannot be recognized. 1. Insert a new formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2112	ABORT	Internal system error The inserted memory card is a "system-upgrade" memory card. 1. Replace the inserted memory card with a user's memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	A checksum error is detected in the translation file that is stored in the inserted memory card. 1. Enter the save translation command, and verify that translations can be successfully saved onto the memory card. 2. Rerun the test. 3. If the test fails again, replace the memory card, and repeat Steps 1 and 2.
	PASS	No checksum error is found in the translation file.

Memory Card Insertion Test (#695)

This test, which is nondestructive, verifies whether a memory card is inserted into the memory card slot at the TN777B NETCON circuit pack and also whether the system can detect its existence.

Table 10-82. TEST #695 Memory Card Insertion Test

Error Code	Test Result	Description/ Recommendation
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
	FAIL	No memory card is inserted in the TN777B NETCON circuit pack, or the inserted memory card has a bad connection. 1. Insert a memory card into the slot at the TN777B NETCON circuit pack. 2. If a memory card is already inserted, take the memory card out and examine the connectors of the memory card and the TN777B NETCON circuit pack. Insert the memory card into the slot again. 3. When a memory card is pushed into the slot, make sure that the memory card is inserted firmly into the slot. 4. Re-enter the test card-mem command. If the test still fails, replace the memory card, and then repeat this step one more time. 5. If the test still fails after you replace the memory card, replace the TN777B NETCON circuit pack. Follow the Standard Repair Procedures for a memory card.
	PASS	A memory card is inserted into the TN777B NETCON circuit pack, and the system can recognize its existence.

Memory Card Format and Read Test (#696)

This test is a nondestructive test. The memory card must be formatted before an application. The test reads the directory file from the memory card, and it verifies the integrity of the directory file.

Table 10-83. TEST #696 Memory Card Format and Read Test

Error Code	Test Result	Description/ Recommendation
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
2110	ABORT	No memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2113	ABORT	One of the two directories in the memory card is corrupted. 1. Re-enter the test card-mem command, and verify that Test #699 passes. 2. If the test is aborted again with this error code, replace the memory card.
	FAIL	System software cannot recognize the inserted memory card. The memory card is not formatted, or the directories of the memory card are corrupted. 1. Replace the memory card with a new formatted memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	System recognizes the inserted memory card, and it can read the directories from the memory card.

Memory Card Match Test (#697)

This test is a nondestructive test. The test verifies the inserted memory card for consistency with the system configuration. The test helps answer the following questions:

- Is the inserted memory card a system software upgrade card?
- Does the size of the inserted memory card match the capacity of the system configuration?

- Does the inserted memory card contain the Announcement file for a system with an Announcement circuit pack?
- Does the size of the translations in the system reach 98% of the reserved storage space on the memory card?

If the answer to any of these questions is "yes," maintenance raises a WARNING alarm for service attention. A new memory card is usually required.

Table 10-84. TEST #697 Memory Card Match Test

Error Code	Test Result	Description/ Recommendation
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
2110	ABORT	No memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Rerun the test.
2111	ABORT	Inserted memory card is not formatted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Rerun the test.
101	FAIL	The inserted memory card is a system-upgrade memory card. 1. Replace the memory card with a user's memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.
102	FAIL	The inserted memory card does not contain an Announcements file, and the system is configured with the Announcement feature. 1. Replace the memory card with a 10 MB memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-84. TEST #697 Memory Card Match Test — Continued

Error Code	Test Result	Description/ Recommendation
103	FAIL	The memory card is a system-upgrade memory card and, while the announcement feature is in use, no announcement file is available in the memory card. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.
116	FAIL	The capacity of the inserted memory card doesn't match the system configuration. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.
118	FAIL	While the announcement feature is in use, no announcement file is available in the memory card, and the capacity of the inserted memory card doesn't match the system configuration. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.
132	FAIL	Translation reaches 98% of the memory card reserved storage space. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.
134	FAIL	While the announcement feature is in use, no announcement file is available in the memory card, and system translation reaches a 98% capacity of the memory card reserved storage space. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.
148	FAIL	The capacity of the inserted memory card doesn't match the system configuration, and system translation reaches 98% of the memory card reserved storage space. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-84. TEST #697 Memory Card Match Test — Continued

Error Code	Test Result	Description/ Recommendation
150	FAIL	While the announcement feature is in use, no announcement file is available in the memory card, and the capacity of the inserted memory card doesn't match the system configuration. Also, system translation reaches a 98% capacity of the memory card reserved storage space. 1. Replace the memory card with one of a larger size. See the system configuration guidelines. 2. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The inserted memory card matches the system configuration, and the card has enough space for saving translations and (if applicable) announcements.

Memory Card Write-Protection Test (#698)

This test, which is nondestructive, verifies whether the write-protected switch on the memory card is turned on. The memory card cannot be erased or written to when the write-protected switch is on.

Table 10-85. TEST #698 Memory Card Write-Protected Test

Error Code	Test Result	Description/ Recommendation
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.

Continued on next page

Table 10-85. TEST #698 Memory Card Write-Protected Test — Continued

Error Code	Test Result	Description/ Recommendation
2110	ABORT	No memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2111	ABORT	Inserted memory card is not formatted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	The Write-Protect switch of the inserted memory card is set to the protect position. 1. Take the memory card out, and move the write-protect switch to the "not-protected" position. 2. Insert the memory card back into the slot. 3. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The inserted memory card is not write-protected.

Memory Card Directory Recovery Test (#699)

This test is a nondestructive test. All memory cards, except the memory card for system software upgrade, have two copies of both directory files and translation files to ensure that there is at least a good translation file in the memory card at any time, especially during the "save translation" operation.

If one of the two directory files (for example, the directory file) is missing or broken (for example, the directory file has a bad checksum), maintenance can build the directory file. The Memory Card Directory Recovery Test

- Verifies the integrity of both active and backup directory files in a memory card, and
- Requests a rebuilding of the directory file if the file is missing or corrupted.

When the test passes, both directories are sane. If the memory card is a system-upgrade memory card, the test is aborted. If the test fails, the broken or missing directory cannot be rebuilt. As a result, all subsequent "write-to-memory card" operations are blocked. When an alarm is raised and Error Type 1025 for "CARD-MEM" is active, replace the memory card.

Table 10-86. TEST #699 Memory Card Directory Recovery Test

Error Code	Test Result	Description/ Recommendation
1192	ABORT	Contention error. Applications are accessing the memory card. 1. Wait 10 minutes for the applications to complete. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2012 2106 2114	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
2013 2100 none	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2108	ABORT	The NETCON circuit pack is not a TN777B circuit pack. 1. Follow the Standard Repair Procedures for replacing the NETCON circuit pack with the TN777B circuit pack. 2. Re-enter the test card-mem command.
2110	ABORT	No memory card is inserted. 1. Insert a formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2111	ABORT	Inserted memory card cannot be recognized. 1. Insert a new formatted memory card into the slot at the TN777B NETCON circuit pack. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2112	ABORT	Internal system error The inserted memory card is a "system-upgrade" memory card. 1. Replace the inserted memory card with a user's memory card. 2. Retry the command at 1-minute intervals a maximum of 5 times.
2115	ABORT	The memory card is write-protected. 1. Take the memory card out, flip the "write-protection" switch to the "not-protected" position, and insert the memory card back into the slot. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-86. TEST #699 Memory Card Directory Recovery Test — Continued

Error Code	Test Result	Description/ Recommendation
104	FAIL	Directories in the memory card are corrupted and cannot be recovered.
105	FAIL	"0" cannot be written into memory before an erase operation.
106	FAIL	Memory card cannot be erased.
107	FAIL	Data cannot be written into a memory card after the erase operation. Maintenance cannot restore the missing or broken directory file in the inserted memory card. 1. Replace the memory card with a new, formatted one. 2. Retry the command at 1-minute intervals a maximum of 5 times.
108	FAIL	12 volt power supply for directory recovery can't be turned on. The 12 volt power supply on TN777B NETCON circuit pack may be defective.
		1. Re-enter the test card-mem command, and verify the result of Test 701 for 12 Volt Power Supply. 2. If Test 701 fails, follow the Standard Repair Procedure to replace the TN777B NETCON circuit pack with a new TN777B circuit pack. 3. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Both directory files in the inserted memory card are sane.

CARR-POW (Carrier Port Power Unit) for AC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CARR-POW	MAJOR	recycle carrier PC	Carrier Port Power Unit

1. Recycle the carrier indicated by the PORT field in the Alarm Log.

DEFINITY Generic 1 offers two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configurations may be powered by either an external AC or DC power source.

➤ NOTE:
For environment maintenance, the aspects of a PPN configuration for a High or Critical Reliability system or of an EPN cabinet configuration are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate MO section(s).

- For a single-carrier cabinet system, refer to the "DC-POWER" Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following Maintenance documentation sections: "AC-POWER", "CUST-ALM (Customer-Provided Alarming Device)", or "POWER (Battery & Battery Charger) for AC-Powered Systems".
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following Maintenance documentation sections: "AC-POWER (AC Power) for DC-Powered Systems", "CUST-ALM (Customer-Provided Alarming Device)", or "POWER (Battery & Battery Charger) for DC-Powered Systems".

Every carrier in the system must be supplied with +5 volt, -48 volt, and -5 volt DC power for the various circuit packs to operate properly. This power is supplied to the carriers as follows: AC from a wall outlet comes into the PDU, which distributes the power via a set of fuses (F1 to F7) to the power units. Each carrier in the system is equipped with two power units: the 631 DA AC power unit and the 631 DB AC power unit, which together supply the required voltages to the carrier. Figure 10-12 illustrates the position of the power unit and the power distribution unit (PDU) and shows which power unit each fuse controls (Figure 10-12 also shows other Environment maintenance-related items that can be ignored for this section on Carrier Port Power Unit). Figure 10-13 illustrates the position of the power unit and the PDU and shows which power unit each fuse

10 Maintenance Object Repair Procedures*CARR-POW (Carrier Port Power Unit) for AC-Powered Systems*

Page 10-246

controls in a small cabinet (from a System 75 R1V3 upgrade). Figure 10-14 shows the position of the fuses on the PDU and describes how to replace a fuse. The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins. For more information, refer to the "Troubleshooting Backplane Voltage Problems" section found in Chapter 5, "Routine Maintenance Procedures".

The power unit has two LEDs: if the yellow LED is lit it means the power unit is operating as normal; if the red LED is lit it means the power unit has a fault; and if neither is lit it LED means no external power is being supplied. The CARR-POW (Carrier Port Power Unit) MO represents the pair of power units that power each carrier in a multicarrier cabinet system. If a problem is reported by hardware for a power unit on a port carrier, the system can recycle the pair of power units in a port carrier; however, if the problem is reported on a control carrier, the system cannot recycle the pair of power units in a control carrier. In a standard multicarrier cabinet (PPN or EPN) carrier A is the control carrier, and carriers B, C, D, and E are the port carriers. In a High or Critical Reliability system multicarrier cabinet (PPN or EPN), carriers A and B are the control carriers, and carriers C, D, and E are the port carriers. However, carrier B can be recycled only if the Active Expansion Interface Link and Active Tone-Clock circuit pack are in the A carrier.

Loss of the 631 DB Carrier Port DC Power Unit in the active control carrier (the A carrier for a standard system and either the A or B carrier for a High or Critical Reliability system) causes loss of the administration terminal. In a High or Critical Reliability system, the Active SPE should switch to the Standby SPE if there is a CARR-POW alarm.

Recycling a carrier turns off the pair of power units, and turns them back on two seconds later.

**WARNING:**

Recycling carriers disrupts service for all circuit packs on the carrier.

The DEFINITY Generic 1 can also support neon message waiting lamps on analog telephones. If this is required, then the carrier(s) that contains the TN769 Analog Neon circuit packs must also be supplied with 165 volt to power the neon lights. The 165 volt can only be supplied by a TN752 or a TN755B power unit circuit pack. The following table lists all power unit and power-related circuit packs for the system and indicates the voltages they can supply. Figure 10-12 through Figure 10-17 show a schematic of each power unit type. The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages

on the backplane pins. Refer to Chapter 2 in *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test*, 555-230-104.

Power Supply	+5	-48V	-5V	165V	Cabinet Position
631 WA	yes	no	no	no	Left Side

Figure 10-17. 631DA or 631DB AC Power Unit

Power Unit Replacement Procedures

The procedures for replacing the various power units are given below:

Replacing a 631AR or 631BR AC Power Unit

If the power unit to be replaced is in a control carrier of a PPN system, refer to "Removing Power" and "Restoring Power" in Chapter 5, "Routine Maintenance Procedures", before replacing the power unit. To replace the power unit, implement the following steps:

1. Set the power switch to OFF, and unplug the power cord.
2. Move the locking slide on the power unit to its leftmost position and unlatch the locking lever.
3. Remove the power unit from the carrier.

4. Before installing the replacement power unit in the carrier, turn the power unit on its side and operate rocker switches 1 through 4 on the dip switch as follows:

Switch	631AR Position	631BR Position
1	open	open
2	closed	closed
3	open	open
4	closed	open

 **NOTE:**
In the open position, the rocker is down on the side opposite the number. In the closed position, the rocker is down on the side adjacent to the number.

5. Move the locking slide on the replacement power unit to the extreme left position and open the locking lever.
6. Insert the power unit into the carrier until some resistance is felt.
7. Lift the locking lever upward until it latches.
8. Move the locking lever slide on the power unit to the extreme right position.
9. Connect the power cord and set the power switch to ON.

Replacing a 631DA or 631DB AC Power Unit

If the power unit to be replaced is in a control carrier of a PPN system, refer to "Removing Power" and "Restoring Power" in Chapter 5, "Routine Maintenance Procedures" before replacing the power unit. To replace the power unit, follow the procedure below:

1. Unplug the power cord.
2. Move the locking slide on the power unit to the extreme left position and unlatch the locking lever.
3. Remove the power unit from the carrier.
4. Move the locking slide on the replacement power unit to the extreme left position and open the locking lever.
5. Insert the power unit into the carrier until some resistance is felt.
6. Lift the locking lever upward until it latches.
7. Move the locking lever slide on the power unit to the extreme right position.
8. Connect the power cord and set the power switch to ON.

Replacing a TN736 or TN752 Power Unit Circuit Pack

If the TN736 or TN752 power unit circuit pack is in a control carrier of a PPN system, then refer to the "Handling Control Circuit Packs" section in Chapter 5, "Routine Maintenance Procedures". Replacing either power unit interrupts the -5 volt supply to the carrier. This causes all the analog circuit packs in the carrier to fail their Loop Around Tests and may cause failures in circuit packs in the control complex. After the power unit has been replaced, look for alarms against these maintenance objects. If ANL-LINE alarms exist, refer to Test #47 (Loop Around and Conference Test) in ANL-LINE Maintenance documentation. For CO-TRK alarms, refer to Test #33 (Loop Around and Conference Test) in CO-TRK Maintenance documentation.

Hardware Error Log Entries and Test to Clear Values

Carrier Port Power Unit Error Log Entries					
Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test environment P Sh r 1
1(a)(b)	0 or 1	Power Unit Query Test (#127)	MAJOR	ON	test environment P r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. Where P is an appropriate port network number taken for the PORT field of the Error Log.
- b. Run the Power Unit Query Test (#127) first using the **test environment P r 2** command. Then, if a carrier must be recycled to clear the CARR-POW alarm, use the **recycle carrier PC** command to run the Power Unit Recycle Test (#126). The Power Unit Recycle Test (#126) is not included in either the long or Short Test Sequences.

WARNING:
The Power Unit Recycle Test (#126) is destructive. For more information, refer to the description of this test.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
Power Unit Query Test (carrier E) (#127)	X	X	ND
Power Unit Query Test (carrier D) (#127)	X	X	ND
Power Unit Query Test (carrier A) (#127)	X	X	ND
Power Unit Query Test (carrier B) (#127)	X	X	ND
Power Unit Query Test (carrier C) (#127)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Temperature Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.
- b. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.
- c. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.
- d. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.
- e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.
- f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test. This test only shows up in the test sequence if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Power Unit Recycle Test (#126)

This test is destructive.

This test is destructive because it requires all circuit packs in the recycled carrier to be removed and inserted. These actions cause all calls originating or terminating on circuit packs in this carrier to be dropped. The pair of power units in the specified carrier is recycled. Both power units in the carrier are turned off for two seconds and then back on again. After the power units have been turned back on, the test queries the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a system with High or Critical Reliability, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of pair of power units in the specified carrier. If both power units are on and functioning, then the test passes. If both power units are not on and functioning, the test fails, and BOTH power units are turned off.

Table 10-87. TEST #126 Power Unit Recycle Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1129	ABORT	Only occurs when recycling carrier 2B. Indicates that the Active Tone-Clock for the EPN is in carrier 2B. 1. Issue the set tone-clock 2A command. 2. Rerun the test.
1130	ABORT	Only occurs when recycling carrier 2B. Indicates that the Active Expansion Interface Link for the EPN is in carrier 2B. 1. Issue the set expansion-link A01 command. 2. Rerun the test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-87. TEST #126 Power Unit Recycle Test — Continued

Error Code	Test Result	Description/ Recommendation
1 (Carrier E) 2 (Carrier D) 4 (Carrier A) 8 (Carrier B) 16 (Carrier C)	FAIL	There is a problem with one or both Power Unit(s) on the recycled carrier. 1. Since the Power Unit Recycle Test failed, both Power Units in the recycled carrier should have been powered off by the system software. Both power units should be showing a red status LED, instead of a green one. Since the Power Unit Query Test is a subset of the Power Unit Recycle Test, the Power Unit Query Test (#127) should also fail. Run the Power Unit Query Test by using the test environment P command where P is the appropriate port network number. 2. If the test fails, follow the repair procedures described for Test #127. If problem persists, follow normal escalation procedures.
	PASS	Both power units in the recycled carrier were found to be healthy by the Maintenance/Tape Processor in a Standard system PPN, the Duplication Interface circuit pack in a PPN for a system with High or Critical Reliability, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system after the power units were powered down and back up. If the status LEDs on both power units are not showing green, then the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the power units. Look for and resolve any alarms on these MOs.

Power Unit Query Test (#127)

This test queries the Maintenance/Tape Processor in a Standard system PPN, the Duplication Interface circuit pack in a PPN for a system with High or Critical Reliability, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of pair of power units in the specified carrier. If both power units are on and functioning, then the test passes. If both are not on and functioning, it fails.

Table 10-88. TEST #127 Power Unit Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to ABORT with error code 2000, check for system powering problems with the A carrier (PPN or EPN). Look for and resolve all AC-POWER and CARR-POW alarms in a multicarrier cabinet system or DC-POWER alarms in a single-carrier cabinet system. Then, repeat the test. 3. If the test continues to ABORT with a 2000 error code, check for and resolve all DUPINT (Duplication Interface) errors in a Duplicated Option PPN, PR-MAINT (Maintenance/Tape Processor) errors in a standard PPN, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test. 4. If the test continues to ABORT with a 2000 error code, escalate the problem.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-88. TEST #127 Power Unit Query Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	There is a problem with one or both power units on the tested carrier. - For each power unit that has all sttus LEDs OFF, check the AC input to the power unit at the power unit outlet (see Figure 10-12 and Figure 10-13). If there is no AC, then check the appropriate fuses (see Figure 10-14) for the affected power unit. If the fuses are blown out, replace the fuses (see). If the fuses blow out again or AC does not show up at the power unit outlet, then there is probably a power wiring problem in the cabinet. Follow normal escalation procedures. - At this point AC should be present at the power unit outlet. If the carrier being tested is the 1A or 2A carrier or the 1B carrier in a High or Critical Reliability system, refer to "Troubleshooting Control Carrier Power Units" in Chapter 5, "Routine Maintenance Procedures". Otherwise, use the recycle carrier PC command (where PC is the appropriate port network and carrier) in an attempt to bring back the power units for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one power unit, or both, in the tested carrier is defective. If only one power unit is defective, the status LEDs on the healthy power unit light green for a moment. When the recycle test determines that both power units are defective, the software turns off power to both the good and defective power units. This causes the status LED(s) on the good power unit to light red. - Unplug both power units, and wait about one minute to allow the power units to cool down. Plug in the power units. If either power unit is operating properly (that is, the status LEDs show green), then replace the defective power unit(s). See "Power Unit Replacement Procedures" in this section.

Continued on next page

Table 10-88. TEST #127 Power Unit Query Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL (cont'd.)	4. If the replaced power unit still does not operate properly, then a circuit pack or a defective telephone connected to a circuit pack in the affected carrier may be causing an electrical load which is preventing the power unit from operating properly. Unseat all the circuit packs in the carrier and reissue the recycle carrier command. a. If the recycle passes, then the power units are healthy, and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, replace the defective circuit pack. If the status LED still shows red, remove the Amphenol. connector on the back of the slot containing this circuit pack and reissue the recycle carrier command. If the status LED shows green, the problem is with one of the telephones or the wiring to one of the telephones on this slot. If the status LED still shows red, escalate the problem. b. If either power unit still shows a red status LED, check for bent pins and cable placement in the affected carrier. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that are not detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If no other problems can be found, escalate the problem.
	PASS	Both power units in the tested carrier were found to be healthy by the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a system with High or Critical Reliability, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system. If the status LEDs on both power units are not showing green, the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the power units. Look for and resolve any alarms on these MOs.

CARR-POW (Carrier Port Power Unit) for DC-Powered Systems

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CARR-POW	MAJOR	recycle carrier PC	Carrier Port Power Unit

1. Recycle the carrier indicated by the Port field in the Alarm Log.

Generic 1 offers two basic cabinet type configurations: (1) the multicarrier cabinet system and (2) the single-carrier cabinet system. Both cabinet system configurations may be powered by either an external AC or DC power source.

NOTE:
For environment maintenance, the PPN or EPN cabinet configuration aspects for a High or Critical Reliability system are irrelevant.

The environment maintenance strategy to be used depends on both the cabinet configuration and the type of powering. Therefore, refer to the following list to find the appropriate MO section(s).

- For a single-carrier cabinet system, refer to the "DC-POWER (Single-Carrier Cabinet Power)" Maintenance documentation for environment maintenance strategy.
- For a multicarrier cabinet system using an external AC power source, refer to one or more of the following Maintenance documentation sections: "AC-POWER (AC Power) for AC-Powered Systems", "CUST-ALM (Customer-Provided Alarming Device)", or "POWER (Battery & Battery Charger) for AC-Powered Systems".
- For a multicarrier cabinet system using an external DC power source, refer to one or more of the following Maintenance documentation sections: "AC-POWER (AC Power) for DC-Powered Systems", "CUST-ALM (Customer-Provided Alarming Device)", or "POWER (Battery & Battery Charger) for DC-Powered Systems".

Every carrier in the system must be supplied with +5 volt, -48 volt, and -5 volt DC power for the various circuit packs to operate properly. A multicarrier system can be supplied by an external AC power source or an external DC power source.

In a DC-powered system, power is supplied to the carriers as follows: DC power from an external device comes into Power Distribution Units (PDU J58890CF and PDU J58890CF-1), which distribute the power via circuit breakers (CB1-CB12 for PDU J58890CF, CB1-CB6 for J58890Cf-1) to the carrier power units. Each carrier in the system is equipped with two power units, the 644A and the 645B, which together supply the required voltages to the carrier. Figure 10-17 illustrates the position of the carrier power units and PDU J58890CF and shows which power unit each circuit breaker controls (Figure 10-17 also shows other Environment

maintenance-related items that can be ignored for this section on Carrier Port Power Unit). Figure 10-18 shows the position of the circuit breakers on the PDU J58890CF. Figure 10-19 illustrates the position of the carrier power units and PDU J58890CF-1 and shows which power unit each circuit breaker controls (Figure 10-19 also shows other Environment maintenance-related items that can be ignored for this section on Carrier Port Power Unit). Figure 10-20 shows the position of the circuit breakers on the PDU J58890CF-1. The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins. Refer to Chapter 2 in *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test*, 555-230-104. The CARR-POW (Carrier Port Power Unit) MO represents the pair of power units for each carrier in a multicarrier cabinet system. If a problem is reported by hardware for a power unit on a port carrier, the system can recycle the pair of power units in a port carrier; however, if the problem is reported on a control carrier, the system cannot recycle the pair of power units in a control carrier. In a standard multicarrier cabinet (PPN or EPN), carrier A is the control carrier, and carriers B, C, D, and E are the port carriers. In a High or Critical Reliability system multicarrier cabinet (PPN or EPN), carriers A and B are the control carriers, and carriers C, D, and E are the port carriers. However, carrier B in the EPN can be recycled only if the Active Expansion Interface Link and Active Tone-Clock circuit pack are in the A carrier.

The carrier port power unit has one LED: the yellow LED on means operating as normal and the LED off means no external power is being supplied or that the power unit has a fault.

Loss of the 645B Carrier Port Power Unit in the active control carrier (the A carrier for a standard system and either the A or B carrier for a High or Critical Reliability system) causes loss of the administration terminal. In a High or Critical Reliability system, the Active SPE should switch to the Standby SPE if there is a CARR-POW alarm.

Recycling a carrier turns off the pair of carrier power units and turns them back on two seconds later.

**WARNING:**

Recycling carriers disrupts service for all circuit packs on the carrier.

Generic 1 can also support neon message waiting lamps on analog telephones. If this is required, then the carrier(s) that contains the TN769 Analog Neon circuit packs must also be supplied with 165 volt DC power to power the neon lights. The 165 volt DC power can only be supplied by a TN752 or a TN755B power unit circuit pack. The following table lists the power units and power-related circuit packs that can be used in a DC-powered system and indicates the voltages they can supply. Figure 10-21 and Figure 10-22 show a schematic of the 644A and 645B power supplies, respectively. The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins.

Refer to Chapter 2 in *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test*, 555-230-104.

Power Supply	+5V	-48V	-5V	165V	Cabinet Position
644A	yes	no	no	no	Left Side
645B	no	yes	yes	no	Right Side
TN736	no	no	yes	no	-
TN752	no	no	yes	yes	-
TN755B	no	no	no	yes	-

Port Carrier Power Unit Replacement Procedures

The procedures for replacing a 644A or 645B carrier DC power unit are given below.

If the port carrier power unit to be replaced is in a control carrier of a PPN system, refer to the "Removing Power" and "Restoring Power" sections in Chapter 5, "Routine Maintenance Procedures" before replacing the port carrier power unit. To replace the port carrier power unit, follow the procedure below:

1. If this is a 645B power unit, set the power switch to OFF.
2. Unplug the power cord.
3. Move the locking slide on the power unit to the extreme left position, and unlatch the locking lever.
4. Remove the power unit from the carrier.
5. Move the locking slide on the replacement power unit to the extreme left position and open the locking lever.

6. Insert the power unit into the carrier until some resistance is felt.
7. Lift the locking lever upward until it latches.
8. Move the locking lever slide on the power unit to the extreme right position.
9. Connect the power cord.
10. If this is a 645B power unit, set the power switch to ON.

Hardware Error Log Entries and Test to Clear Values

Carrier Port Power Unit Error Log Entries					
Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test environment P sh r 1
1(a)(b)	0 or 1	Power Unit Query Test (#127)	MAJOR	ON	test environment P r 2

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. Where P is an appropriate port network number taken for the Port field of the Error Log.
- b. Run the Power Unit Query Test (#127) first using the **test environment P r 2** command. Then, if a carrier must be recycled to clear the CARR-POW alarm, use the **recycle carrier PC** command to run the Power Unit Recycle Test (#126). The Power Unit Recycle Test (#126) is not included in either the long or Short Test Sequences.

 **WARNING:**
The Power Unit Recycle Test (#126) is destructive. For more information, refer to the description of this test.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Battery & Battery Charger Query Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Battery & Battery Charger Query Test (#5) (a)	X	X	ND
AC Power Query Test (#78) (b)	X	X	ND
Power Unit Query Test (carrier E) (#127)	X	X	ND
Power Unit Query Test (carrier D) (#127)	X	X	ND
Power Unit Query Test (carrier A) (#127)	X	X	ND
Power Unit Query Test (carrier B) (#127)	X	X	ND
Power Unit Query Test (carrier C) (#127)	X	X	ND
Emergency Transfer Query Test (#124) (c)	X	X	ND
Cabinet Temperature Query Test (#122) (d)	X	X	ND
External Alarm Lead Query Test (#120) (e)	X	X	ND
Analog Ring Generator Initialization Test (#117) (f)	X	X	ND
Analog Ring Generator Query Test (#118) (f)	X	X	ND

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to POWER (Battery & Battery Charger) Maintenance documentation for a description of this test.
- b. Refer to AC-POWER (AC Power) Maintenance documentation for a description of this test.
- c. Refer to EMG-XFER (Emergency Transfer) Maintenance documentation for a description of this test.
- d. Refer to CABINET (Cabinet Sensors) Maintenance documentation for a description of this test.
- e. Refer to EXT-DEV (External Alarm) Maintenance documentation for a description of this test.
- f. Refer to RING-GEN (Analog Ring Generator) Maintenance documentation for a description of this test.

NOTE:

This test only shows up in the test sequence if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Power Unit Recycle Test (#126)
This test is destructive.

This test is destructive because it requires all circuit packs in the recycled carrier to be removed and inserted. These actions cause all calls originating or terminating on circuit packs in this carrier to be dropped. The pair of port carrier power units in the specified carrier is recycled. Both port carrier power units in the carrier are turned off for two seconds and then back on. After the port carrier power units have been turned back on, the test queries the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of the pair of port carrier power units in the specified carrier. If both port carrier power units are on and functioning, then the test passes. If both port carrier power units are not on and functioning, the test fails, and BOTH port carrier power units are turned off.

Table 10-89. TEST #126 Power Unit Recycle Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1129	ABORT	Only occurs when recycling carrier 2B. Indicates that the Active Tone-Clock for the EPN is in carrier 2B. 1. Issue the set tone-clock 2A command. 2. Rerun the test.
1130	ABORT	Only occurs when recycling carrier 2B. Indicates that the Active Expansion Interface Link for the EPN is in carrier 2B. 1. Issue the set expansion-link A01 command. 2. Rerun the test.
2000	ABORT	Response to the test request was not received within the allowable time period.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-89. TEST #126 Power Unit Recycle Test — Continued

Error Code	Test Result	Description/ Recommendation
1 (Carrier E) 2 (Carrier D) 4 (Carrier A) 8 (Carrier B) 16 (Carrier C)	FAIL	There is a problem with one or both port carrier power units on the recycled carrier. 1. Since the Power Unit Recycle Test failed, both port carrier power supplies in the recycled carrier should have been powered off by the system software. Both port carrier power units should be showing a red status LED, instead of a green one. Since the Power Unit Query Test is a subset of the Power Unit Recycle Test, the Power Unit Query Test (#127) should also fail. Run the Power Unit Query Test by using the test environment P command where P is the appropriate port network number. 2. If the test fails, follow the repair procedures described for Test #127. If the problem persists, follow normal escalation procedures.
	PASS	Both port carrier power units in the recycled carrier were found to be healthy by the Maintenance/Tape Processor in Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system after the port carrier power units were powered-down and powered up again. If the status LEDs on both port carrier power units are not showing green, then the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the port carrier power units. Look for and resolve any alarms on these MOs.

Power Unit Query Test (#127)

This test queries the Maintenance/Tape Processor in a Standard system PPN, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system for the status of the pair of port carrier power units in the specified carrier. If both port carrier units are on and functioning, the test passes. If both are not on and functioning, the test fails.

Table 10-90. TEST #127 Power Unit Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available.
2000	ABORT	Response to the test request was not received within the allowable time period.
2029	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	There is a problem with one or both port carrier power units on the tested carrier. 1. For each port carrier power unit that has all status LEDs OFF, check the DC input to the port carrier power unit at the port carrier power unit outlet (see Figures 11-19 through 11-22). If there is no DC, then check the appropriate circuit breakers for the affected port carrier power unit. If the circuit breaker has tripped (that is, it is in the down position), reset the circuit breaker. If the circuit breaker trips again or DC is not present at the port carrier power unit outlet, there is probably a power wiring problem in the cabinet. Follow normal escalation procedures. 2. At this point, DC should be present at the port carrier power supply outlet. If the carrier being tested is the 1A or 2A carrier, or the 1B carrier in a High or Critical Reliability system, refer to "Troubleshooting Control Carrier Power Units" in Chapter 5, "Routine Maintenance Procedures". Otherwise, use the recycle carrier PC command (where PC is the appropriate port network and carrier) in an attempt to bring back the power units for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one port carrier power unit, or both, in the tested carrier is defective. If only one port carrier power unit is defective, the status LEDs on the healthy port carrier power unit light green for a moment. When the recycle test determines that both port carrier power units are defective, the software turns off power to both the good and defective port carrier power units. This causes the status LED(s) on the good port carrier power unit to light red.

Continued on next page

Table 10-90. TEST #127 Power Unit Query Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL (cont'd.)	3. Unplug both port carrier power units, and wait about one-minute to allow the port carrier power units to cool down. Plug in the port carrier power units. If either port carrier power unit is operating properly (that is, the status LEDs show green), then replace the defective port carrier power unit(s). See "Port Carrier Power Unit Replacement Procedures" in this section. 4. If the replaced port carrier power unit(s) still does (do) not operate properly, then a circuit pack or a defective telephone connected to a circuit pack in the affected carrier could be causing an electrical load which is preventing the port carrier power unit from operating properly. Unseat all the circuit packs in the carrier, and reissue the recycle carrier command. a. If the recycle passes, then the port carrier power units are healthy, and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, replace the defective circuit pack. If the status LED still shows red, remove the Amphenol connector on the back of the slot containing this circuit pack and reissue the recycle carrier command. If the status LED shows green, the problem is with one of the telephones or the wiring to one of the telephones on this slot. If the status LED still shows red, escalate the problem. b. If either port carrier power unit still shows a red status LED, check for bent pins and cable placement in the affected carrier. There are failures that can occur on the Maintenance/Tape Processor, Duplication Interface, and EPN Maintenance circuit pack that are not detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. If no other problems can be found, escalate the problem.
	PASS	Both port carrier power units in the tested carrier were found to be healthy by the Maintenance/Tape Processor in a PPN for a High or Critical Reliability system, the Duplication Interface circuit pack in a PPN for a High or Critical Reliability system, or the EPN Maintenance circuit pack in an EPN multicarrier cabinet system. If the status LEDs on both port carrier power units are not showing green, the PR-MAINT (Maintenance/Tape Processor), DUPINT (Duplication Interface) circuit pack, or the EPN MAINT (Maintenance) circuit pack may have incorrectly reported the state of the port carrier power units. Look for and resolve any alarms on these MOs.

CLSFY-BD (Call Classifier Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CLSFY-BD	MIN	test board PCSS sh	Call Classifier Circuit Pack
CLSFY-BD	WRN	test board PCSS sh	Call Classifier Circuit Pack

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also Call Classifier Port (CLSFY-PT) Maintenance documentation for related port information.

CLSFY-PT (Call Classifier Port)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CLSFY-PT(a)	MAJOR	test port PCSSpp sh	Call Classifier Port Maintenance
CLSFY-PT	MINOR	test port PCSSpp sh	Call Classifier Port Maintenance
CLSFY-PT	WARNING	release port PCSSpp	Call Classifier Port Maintenance

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (e.g., A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (e.g., 01, 02, ..., etc.); and pp is the 2-digit port number (e.g., 01).

The TN744 Call Classifier (CLSFY-BD) circuit pack is a service circuit pack that enables usage of the Outbound Call Management (OCM) and the Inbound Call Management (ICM) features. On a G3iV2-386 system, the TN744 also enables usage of R2-MFC signaling for incoming and outgoing feature operation. There are eight ports (CLSFY-PTs) on the Call Classifier circuit pack. Each port can handle call classification, touch-tone reception, or, for G3iV2-386 systems, MFC tone generation and detection or touch-tone reception.

The CLSFY-PT maintenance feature defines a set of tests to ensure that the Call Classifier circuit pack ports are capable of detecting tones for call classification, and detecting and generating necessary tones for correct MFC feature operation.

Hardware Error Log Entries and Test to Clear Values

Table 10-91. Call Classifier Port (CLSFY-PT) Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1	any	Tone Detector Audit/Update Test (#43)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 2
18		Port has been busied out by system technician	WARNING	OFF	release port PCSSpp
257 (b)	17666	Test (#43)	MAJOR/ MINOR(a)	ON	test port PCSSpp r 3

Table 91. Call Classifier Port (CLSFY-PT) Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
513 (c)	any	Tone Detection Verification Test (#42)	MAJOR/ MINOR (a)	ON	test port PCSSpp r 3

Notes:

- a. There are two possible alarm levels for this error type: major alarm and minor alarm. A major alarm is raised if the total number of call classifier ports currently in-service is less than or equal to 1/2 of the administered threshold number. Otherwise, a minor alarm is raised. In either case, run the short test sequence against the port and follow the error code procedures for the individual tests.

The threshold number of call classifier ports for service is administered using the **change system-parameters maintenance** command. For details, refer to Chapter 5, "Routine Maintenance Procedures".

- b. The call classifier port lost its translation. Testing the call classifier port is sufficient to reload its translation. If testing the call classifier port does not clear the error, then the call classifier circuit pack containing the defective call classifier port should be replaced.
- c. This error indicates the call classifier port is having problems detecting system tones (DTMF, etc.) or detecting and generating necessary R2-MFC tones. This error should accompany some percentage of failed calls. If this error type is persistently logged, then the call classifier circuit pack containing the defective call classifier port should be replaced.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Tone Detection Verification Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Tone Detection Verification Test (#42)	X	X	ND
Tone Detection Audit/Update Test (#43)	X	X	ND

1. D = Destructive; ND = Nondestructive

Tone Detection Verification Test (#42)

This test checks out each port in both the touch-tone receiver mode and in the R2-MFC tone detection/generation mode. During the first half of the test, the touch-tone receiver mode is tested. In the second half of the test, each port is put into the R2-MFC mode. During this portion of the test, each port's ability to accurately detect and generate all forward and backward MFC tones is verified.

Table 10-92. TEST #42 Tone Detection Verification Test

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test OR there was an Internal System Error.
1	ABORT	The system could not allocate all the resources needed to test the tones.
1001	ABORT	The system was unable to put the Call Classifier port in the appropriate mode to test it.
1002	ABORT	The system could not allocate time slots for the test connection. This situation could occur when the system is heavily loaded. If the system is not heavily loaded, then test the TDM-BUS via the test tdm [1 2] command. Refer to the TDM-BUS (TDM Bus) Maintenance documentation for details. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a Tone-Clock circuit pack for the test connection. This situation could occur when the system is heavily loaded or if a Tone-Clock circuit pack is not present in the port network when this test is executed. 1. Verify the existence of a Tone-Clock circuit pack in the same port network. 2. If a Tone-Clock circuit pack is missing, install one in the same port network. 3. Allow approximately one minute for the Tone-Clock circuit pack maintenance to run on the newly inserted Tone-Clock circuit pack. 4. Retry the command at one minute intervals a maximum of five times. 5. If the test continues to abort, escalate the problem.

Table 10-92. TEST #42 Tone Detection Verification Test — Continued

Error Code	Test Result	Description/ Recommendation
2006	ABORT	This abort code indicates that the active Tone-Clock circuit pack might not be functioning properly. If there is more than one Tone Detector circuit pack in the system, then the problem can be either with the Tone-Clock circuit pack or the Tone Detector circuit pack. This could also be caused by the companding mode administered for the system not matching that of the Tone Detector circuit pack [G3iV2-386]. 1. [G3iV2-386] Make sure that the companding mode of the system matches that of the Tone Detector (TN748 for Mu-law systems and TN420 for A-law systems). 2. Test the active Tone-Clock circuit pack in the port network. This test is being executed via the test tone-clock qualifier system technician command. ("qualifier" is the carrier of the active Tone-Clock circuit pack to be tested. Valid qualifiers are: a, b, 1a, 1b, 2a, and 2b.) Refer to the TONE-BD (Tone-Clock Circuit Pack) Maintenance documentation for details. 3. Retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1-3	FAIL	DTMF digits were not detected correctly. This may or may not impact reception of R2-MFC calls. 1. Run the short test sequence via the test port PCSSpp sh r 1 command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the Call Classifier circuit pack containing the defective CLSFY-PT (Call Classifier Port).
101-122	FAIL	Forward or Backward MFC signals were not correctly generated or detected. This impacts reception of incoming MFC calls. 1. Run the short test sequence via the test port PCSSpp sh r 1 command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the Call Classifier circuit pack containing the defective CLSFY-PT (Call Classifier Port).

Table 10-92. TEST #42 Tone Detection Verification Test — Continued

Error Code	Test Result	Description/ Recommendation
	PASS	Tone Detection Verification is successful. The Call Classifier Port (CLSFY-PT) is able to detect/generate all necessary tones.

Tone Detector Audit/Update Test (#43)

A sanity audit is performed on the CLSFY-PT (Call Classifier Port).

Table 10-93. Tone Detector Audit/Update Test (#43)

Error Code	Test Result	Description/ Recommendation
none	ABORT	The system was not able to allocate all the resources needed for this test. 1. Wait one-minute, and repeat the command a maximum of five times.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Hardware audit failed. 1. Run the short test sequence via the test port PCSSpp sh r 1 command. 2. If the problem persists, the system is still operating properly but system capacity will be reduced. In order to restore system performance to normal, replace the CLSFY-BD (Call Classifier circuit pack) containing the defective CLSFY-PT (Call Classifier Port).
	PASS	The (CLSFY-PT) Call Classifier Port has passed the sanity inquiry.

CO-BD (Central Office Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CO-BD	MIN	test board PCSS sh	Central Office Trunk Circuit Pack
CO-BD	WRN	test board PCSS sh	Central Office Trunk Circuit Pack

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also CO-TRK (CO Trunk) Maintenance documentation for related trunk information.

CO-DS1 (DS1 CO Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
CO-DS1	MAJOR ¹	test trunk <grp/mbr> l	DS1CO Trunk
CO-DS1	MINOR	test trunk <grp/mbr> l	DS1CO Trunk
CO-DS1	WARNING	test trunk <grp/mbr>	DS1CO Trunk

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

A DS1CO (central office) trunk provides a communications channel between the system and a central office switch through either a 1.544 Mbps or a 2.048 Mbps [G3iV2-386] DS1 link. A 24 channel DS1 link consists of 24 digital DS1CO trunks. A 32 channel DS1 link [G3iV2-386] consists of 30 digital DS1CO trunks. A DS1CO trunk can be used for both voice and data communication.

The DS1CO Trunk Maintenance provides a strategy in the system to maintain a CO trunk via a port on the DS1 Interface circuit pack. The TN767 and TN464 [G3iV2-386] DS1 Interface circuit packs support the low level CO trunk signaling interfaces, ground-start and loop-start. This strategy covers the in-line errors log, initialization tests, periodic tests, system technician-demanded tests, and alarm resolution and escalation.

Three trunk service states are specified in the DS1CO trunk maintenance. They are: *out-of-service* in which the trunk is in a deactivated state and cannot be used for either incoming or outgoing calls; *in-service* in which the trunk is in an activated state and can be used for both incoming and outgoing calls; *disconnect* (ready-for-service) in which the trunk is in an activated state but can only be used for an incoming call. If the DS1 Interface circuit pack is out-of-service, then all trunks on the DS1 Interface circuit pack are also in the out-of-service state, and a Warning alarm is raised for each trunk.

Hardware Error Log Entries and Test to Clear Values

Table 10-94. DS1 CO Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value

1537		NPE Crosstalk Test (#6)	MAJ/MIN/WRN ³	ON	test trunk <grp>/<mbr> r 3
1793 (h)				ON	test board PCSS I
2562(ii)	16665				
2817(j)	52992				
3840 (k)		Port Audit and Update Test (#36)			

-
- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
 - This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
 - Minor alarms on this maintenance object (MO) may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this group are alarmed.

Notes:

- a. Error Type 1—Aux Data 57408—No tip ground is detected on an outgoing call.
- Aux Data 57487—PBX could not get "loop close" signal (TN767).

The DS1 Interface circuit pack detected a hardware fault. These errors cause the Dial Tone Test (#314) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1025 also shows up). In this case, the trunk may be put in ready-for-service state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#314) and follow its outlined procedures.

- b. Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).
- c. Error Type 18—System Technician has busied-out the trunk to the out-of-service state. No calls can be made on this trunk except the Facility Access Test Call. For details on this feature, refer to "Facility Test Calls" section in Chapter 5, "Routine Maintenance Procedures".
- d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. Error Type 257—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type: 57392—no external release on PBX disconnect [E030]. Escalate the problem.
- f. Error Type 513—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type: 57393—belated external release on PBX disconnect [E031]. Escalate the problem.
- g. Error Type 769—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type:—57484, fault is detected on tip/ring [E08C]. Escalate the error.
- h. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for DS1-BD errors in the Hardware Error Log. Refer to the DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details.
- i. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- j. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure Test (#314) and follow those procedures.
- k. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back into in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1CO Trunk Seizure Test (#314)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) resides on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-95. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-95. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to the TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-95. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Continued on next page

Table 10-95. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see note below). 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.  NOTE: Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the list config command but the 'Vintage' field reports that there is no board (when there really is a board), then the busyout board and the release busy board commands will not work (even though the reset board command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 10-96. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted. System resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1002	ABORT	The test was aborted. The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. Refer to the TDM-BUS (TDM bus) maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the list measurements tone-receiver command to display basic information about the system's tone receivers. 1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV maintenance documentation. 2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT maintenance documentation. 3. If neither condition exists, retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

Table 10-96. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port has been seized by a user for a valid call. Use the status station or status trunk command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n.' To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 10-96. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	1. Enter the 'list configuration board UUCSS' command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later.The error log may have error type 1281 entries. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see Note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the CO. Make sure that the switch, the CO, and any NTCE equipment (the CSU's) have the correct administration. 6. Replace the circuit pack. ⇒ NOTE: If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance Documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance Documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 10-96. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see note below). 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.  NOTE: Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the list config command but the 'Vintage' field reports that there is no board (when there really is a board), then the busyout board and the release busy board commands will not work (even though the reset board command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 Interface circuit pack and in the switch software.

Table 10-97. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. Issue the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Test failed due to internal system error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test does not run, but returns to PASS. To verify that the trunk is in-service: 1. Enter status trunk command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter release-trunk command to put trunk back into in-service. 3. Retry the test command.

Continued on next page

Table 10-97. TEST #36 Port Audit and Update Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This result could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see note below). 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted. Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the list config command but the 'Vintage' field reports that there is no board (when there really is a board), then the busyout board and the release busy board commands will not work (even though the reset board command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

DS1 CO Dial Tone Seizure Test (#314)

DS1CO Dial Tone Seizure Test checks the trunk's signaling capability provided by the DS1 Interface circuit pack. The maintenance software initiates the test by sending a "seizure" message to the DS1 Interface circuit pack and expects an "active" reply from the DS1 interface circuit pack. If the "active" message is received, then the test passes. If no message is received and the timer expires, the test is aborted. If the DS1 Interface circuit pack sends a "reorder" message back to maintenance software, then the test fails.

The test **CANNOT** be run on a trunk if one of the following cases is true:

- a. The trunk direction is administered as an incoming only trunk.
- b. The trunk has been seized by a normal trunk call.
- c. The trunk is administered with maintenance test disabled.

Table 10-98. TEST #314 DS1CO Dial Tone Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	The test was aborted because system resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the error log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1004	ABORT	The test was aborted because the port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Verify the following fields on the trunk group administration screen: Is trunk direction incoming only? Is trunk the port 24 of the DS1 Interface circuit pack while common control channel signaling is specified? Is trunk group type the automatic CO (for example, FX)? 2. If the trunk has been administered using the above information, then this test should abort.

Continued on next page

Table 10-98. TEST #314 DS1CO Dial Tone Seizure Test — Continued

Error Code	Test Result	Description/ Recommendation
1018	ABORT	Thest is disabled via tranlsation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n'. To enable the test, issue the change trunk-group x command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y'. 2. Repeat the test.
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for DS1-BD errors in the Hardware Error Log. If present, refer to DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
1040	ABORT	The test was aborted because this port may be an access endpoint. 1. Verify that this port is an access endpoint by issuing the display port command. 2. If the port has been administered as an access endpoint, then this is a normal abort.
2000	ABORT	Response to the test request was not received within the allowable time period.
2012	ABORT	The test was aborted due to an internal system error. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals for a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-98. TEST #314 DS1CO Dial Tone Seizure Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The trunk cannot be seized for an outgoing call. This could cause in-line failures to be reported against the trunk (no answer would report error type 257 with auxiliary data 57487 in the error log). 1. Verify that the Trunk Type field on the trunk administration screen form matches the trunk type administered on far end switch. 2. Look for DS1-BD/UDS1-BD errors in Hardware Error Log. If present, refer to the appropriate DS1-BD/UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 3. Retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to fail, escalate the problem.
2000	FAIL	Response to the seizure message was not received within the allowable time period. 1. Enter the list configuration board PCSS command. If the circuit pack is a TN767B vintage 8 or 9, a failure of test 314 causes a subsequent failure of test 7 due to a firmware bug. Eventually, the board and all of its ports will be taken out of service and extraneous on-board alarms will be generated. Replace the circuit pack with a TN767C V3 or later. 2. Verify that the 'Trunk Type' field on the 'Trunk Administration' screen matches the trunk type administered on far-end switch. 3. Look for DS1-BD or UDS1-BD errors in the hardware error log. If present, refer to the DS1-BD (DS1 trunk circuit pack) maintenance documentation or to the UDS1-BD (UDS1 trunk circuit pack) maintenance documentation. 4. Retry the test at 1-minute intervals for a maximum of 5 times. 5. If the test continues to fail, escalate the problem.
2053	FAIL	At least one of the following errors was found on the DS1 circuit pack: loss of signal (1281), blue alarm (1793), red alarm (2049), yellow alarm (2305), or hyperactivity (1537). 1. Look for these error types in the hardware error log and then follow the procedures given in the maintenance documentation that is appropriate for the error type that was found.
	PASS	The trunk can be seized for an outgoing call.

Continued on next page

Table 10-98. TEST #314 DS1CO Dial Tone Seizure Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, an insane board is inserted, or the board is hyperactive (see Note below). 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, dispatch to check to ensure that there is a valid board inserted.  NOTE: Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after issuing the list config command but the 'Vintage' field reports that there is no board (when there really is a board), then the busyout board and the release busy board commands will not work (even though the reset board command will work). The software will put the hyperactive board back in service after the hyperactivity clears.

CO-TRK (CO Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CO-TRK	MAJOR ²	test port PCSSpp l	CO Trunk
CO-TRK	MINOR	test port PCSSpp l	CO Trunk
CO-TRK	WARNING	test port PCSSpp l	CO Trunk

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); c is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...etc.).
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

⇒ **NOTE:**

If ATMS testing is enabled, check the error log for ATMS Errors #3840 and #3841. If the error log indicates that measurements exceeded acceptable thresholds, and if no other trouble is found with the **test trunk** command, run the ATMS test call with the **test analog-testcall port UUCCSSpp full** command.

Central Office (CO) trunks are 2-wire analog lines to the CO which support both incoming and outgoing calls. A CO trunk circuit pack provides an interface between the 2-wire analog line from the CO and the system's (4-wire) Time Division Multiplex (TDM) Bus. The CO Trunk circuit packs include:

- TN747B (United States), 8 port loop start or ground start CO, foreign exchange (FX), or Wide Area Telecommunications (WATS) trunks.
- TN438B (Australia), 8 port loop start.
- TN447 (United Kingdom), 8 port ground start.
- TN465 (multiple countries), 8 port loop start.
- TN2138 (Italy), 8 port loop start.
- TN2147 (multiple countries), 8 port loop start and United Kingdom Earth Calling or Loop Calling Guarded Clearing.

LOOP START AND UK LOOP CALLING GUARDED CLEARING OPERATION

Idle State - Tip _ ground, Ring = CO Battery

A. Outgoing Call

1. PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop
- a. CO Response: DC loop current + Dial tone

2. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
 - a. CO Response: CO goes to idle state (see Note)

B. Incoming Call

1. CO Applies Ringing Voltage
 - a. PBX Response: Detect ringing current
2. PBX Off-Hook (Answer Message): Close loop
 - a. CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
 - a. CO Response: CO goes to idle state (see Note)

NOTE:

Except for the Netherlands Loop Start and UK Loop Calling Guarded Clearing trunks, CO does not normally provide an On-Hook (Disconnect) signal.

GROUND START AND UK EARTH CALLING OPERATION

Idle state - Tip _ open, Ring = CO Battery

A. Outgoing Call

1. PBX Off-Hook(Seize Message): Places ground on Ring
 - a. CO Response: Places ground on Tip
 - b. PBX Response: close the loop
 - c. CO Response: provide loop current
 - d. PBX response: dial out digits
2. PBX On-Hook first (Drop Message): Open the Tip-Ring Loop, no loop current
 - a. CO Response: Open circuit on Tip
3. CO On-Hook first (Disconnect): Open circuit on Tip, no loop current.
 - a. PBX Response: Open Tip-Ring loop

B. Incoming Call

1. CO Off-Hook (Seizure): CO applies ground on Tip, CO applies ringing voltage
 - a. PBX Response: Detect ringing, ring destination
2. PBX Off-Hook (Answer Message): Close loop
 - a. CO Response: Trip ringing, provide loop current

3. PBX On-Hook first (Drop Message): Open the Tip-Ring Loop, no loop current
- a. CO Response: Open circuit on Tip
4. CO On-Hook first (Disconnect): Open circuit on Tip, no loop current

Hardware Error Log Entries and Test to Clear Values

Table 10-99. CO Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	57347	None			
15 (b)	any	Port Audit Update Test (#36)			
18	0	busyout trunk <grp>/<mbr>	WARNING	OFF	release trunk <grp>/<mbr>

2817 (a)	57393	None			

Table 10-99. CO Trunk Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
2817 (d)	57484	Dial Tone Test (#0)	MAJ/MIN/ WRN ²	OFF	test port PCSS l r 1
3073 (d)	57376	None			
3329 (d)	57408	None			
3329 (d)	57484	Dial Tone Test (#0)	MAJ/MIN/ WRN ²	OFF	test port PCSS l r 1
3585 (d)	57424	None			
3840 (f)	8000	Analog Transmission (#844-848)		OFF	
3841 (f)		Analog Transmission (#844-848)	MINOR	OFF	test analog testcall UUCSS pp r 2

- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- Minor alarms on this MO may be downgraded to warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

- 
- These are in-line errors that have no specific test associated with them. Refer to Table 10-93 for an explanation and appropriate action.
 - This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).
 - This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
 - Aux data 57345 -- Single polarity ringing current
Aux data 57376 -- No loop current on incoming call
Aux data 57408 -- No tip ground detected on outgoing call
Aux data 57424 -- No loop current on outgoing call
Aux data 57484 -- No dial tone on outgoing call

These errors cause the Dial Tone Test (#0) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1537 also shows up). In this case, the trunk may be put in "Ready-for-Service" state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#0) and follow its outlined procedures.

If error count associated with this error type is very high (that is, 255) and if Alarm Status on the Hardware Error Report is "n" (not alarmed), then the existence of this error type indicates that, despite the fact that many in-line error messages have been received, all Call Seizure Tests have passed. Problems at the CO may cause this condition rather than problems with the PBX.

- e. These errors are logged for all versions of the CO-TRK/CO-BD. However, no MINOR alarms are generated for Central Office Trunks [TN747B] with vintages V8 or greater. Any failures received by this test are still logged as Error type 1025/1281 as additional information for the system technician person.

The system technician person should check for the use of MFT/Range extenders. If there are extenders present, and there are no other complaints or maintenance errors against this trunk, then there is a good chance that Test #3 failed due to excessive loop current and may be ignored.

- f. Test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements that were outside the acceptable limits. Use the **list testcall detail** command to examine specific transmission parameters that are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, the limits administered on the "change trunk" screen should be changed.

Table 10-100. CO Trunk Errors with NO Tests

Error Type	Aux Data	Description and System Action	System Technician Action
1	57347	Port error. Ringing without ground. This error is detected on an incoming call on a ground-start CO trunk. The CO trunk circuit pack has not detected a Tip ground before ringing current is detected. This may indicate that the ground detector is not working. However, the call is accepted.	See Note 1 at end of table.

Continued on next page

Table 10-100. CO Trunk Errors with NO Tests — Continued

Error Type	Aux Data	Description and System Action	System Technician Action
257	50176	Battery reversal detected. This is usually caused by the CO (often seen with step-by-step and cross-bar offices in connection with outgoing calls). This is detected if the direction of the loop current changes from normal to reverse for at least 40 msec. Could occur if the trunk was just installed and for some reason the Tip and Ring wires were reversed at the PBX. If battery reversals occur during dialing, wrong numbers may result. The CO should be asked to remove the battery reversal option.	Refer problem to CO.
513	57364	Ground detector stuck active. After several occurrences, an on-board minor alarm is generated.	Run short test. If test aborts with Error Code 1000, disconnect Tip and Ring and repeat short test. If test still aborts, replace circuit pack. If test passes, refer problem to CO. If any other error code is received, pursue that problem.
769	57392	CO not releasing after call is dropped from PBX end (off-board alarm after several occurrences), or the loop is not open after a disconnect (on-board alarm after several occurrences).	For off-board alarm, refer problem to CO. For on-board alarm, the circuit pack has an on-board problem (for example, stuck relay) and should be replaced.
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) Another cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test also fails. The last cause could be that certain types of noise are present on the CO line during the silent period of ringing.	Check for other errors first and then see Note 4 at end of table.

Continued on next page

Table 10-100. CO Trunk Errors with NO Tests — Continued

Error Type	Aux Data	Description and System Action	System Technician Action
2817	57360	Ground but no ringing. This error occurs on an incoming call on a ground-start trunk. If ringing is not detected within 5 seconds of the Tip being grounded, the call is still accepted. If the CO is of the No. 5ESS switch type, ringing delays of more than 5 seconds during heavy traffic are fairly common.	Check for other errors.
2817	57393	On the TN465, the loop is opening too slowly after a disconnect. This error indicates an on-board problem, although the trunk may be functional. On the TN2138, CO released the trunk at least 4 minutes after the PBX dropped the call. This error code is log-only and causes no other testing to occur. No alarm is generated.	Check for other errors.
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and all outgoing calls should also fail.	Check for other errors.
3329	57408	Trunk error. No Tip ground detected on outgoing call. This error occurs when an attempt is made to seize a ground-start CO trunk for an outgoing call and Tip ground is not detected or the caller hangs up before Tip ground is detected.	See Notes 1 and 2 at end of table.
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected.	See Note 3 at end of table.

Notes:

1. At the administration terminal, busyout the affected port, and run a Long Test Sequence. Observe the test results. If any tests fail, refer to the description of the tests and the associated error codes. Release the port. If users continue to report troubles, check for other errors and make test calls to determine whether the problem should be escalated or referred to the CO.

2. At the administration terminal, busyout the affected port, and run a Long Test Sequence. If Dial Tone Test #0 passes, ignore this error. Release the port.
3. At the administration terminal, busyout the affected port, and run a Long Test Sequence. If CO Demand Diagnostic Test #3 passes and this error keeps occurring, refer problems to CO. Release the port.
4. If the error count associated with this error type is very high (that is, 255) and all tests pass, then either the reverse current detector is defective or the CO line is noisy. If the CO line is suspected, Tip and Ring observations should be made. If the line is determined to be noisy, the problem should be referred to the CO. If the reverse current detector is defective, ignore this error.

System Technician-Demanded Tests:

Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
CO Demand Diagnostic Test (#3) (a)	X	X	ND
Loop Around and Conference Test (#33)		X	ND
Audit Update Test (#36) Analog Transmission Test (#844-848) (b)	X (c)	X (c)	ND

1. D = Destructive; ND = Nondestructive

Notes:

- a. A demand test of Diagnostic Test (#3) always returns a PASS indication for CO-TRK/CO-BD [TN747B] version 8 or greater. However, any errors produced as a result of this test are logged and produce no alarms.
- If errors logged by Test #3 are the only complaints against this trunk, then the system technician person should check if MFT/Range Extenders are being used. If extenders are present, then there is a good chance that there is excessive loop current, which causes Test #3 to log errors.

However, all else being normal, these errors should not affect the customer.

- b. Refer to TIE-TRK (Tie Trunk) Maintenance documentation for a description of this test.
- c. ATMS test are not part of either sequence. They are run either on demand with the **test analog-testcall** command or via the ATMS schedule.

Dial Tone Test (#0)

This test attempts to seize a port and checks for the return of a dial tone.

Table 10-101. TEST #0 Dial Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the command display port PCSSpp to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test were not available. This could be due to a failure to seize the port. 1. Retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 10-101. TEST #0 Dial Tone Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Trunk has been administered as incoming-only; dial tone can only be obtained on outgoing trunks. This is a normal condition.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n". To enable the test, issue the change trunk-group x command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-101. TEST #0 Dial Tone Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Trunk was seized, but dial tone could not be detected. 1. Test all administered outgoing ports on the board. Failure of 1 indicates a problem toward the CO. 2. If all fail, see note below. 3. Check for errors on the TONE-BD or TONE-PT. Clear any errors found, and repeat the test. 4. If the error has still not cleared, refer the problem to the CO. 5. If no service problems exist on the port, continue to use the port until the circuit pack can be replaced (as a last resort). Perform a trunk test call to see if the trunk is operable.  NOTE: If the dial tone test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation.
2002	FAIL	Seizure portion of test failed due to hardware problem. Fault is usually caused by a disconnected trunk. 1. If the CO Demand Diagnostic Test (#3) also failed, display the Hardware Error Log. If the CO Demand Diagnostic Test failed because it could not detect ground (indicated by Error Type 1281 in the Hardware Error Log) AND Error Type 3329 or 3585 appears in the Hardware Error Log (with the same last occurred time as Error Type 1281 and 1537), replace the circuit pack. 2. Check trunk wiring to ensure good connection; repeat test if wiring correction made. 3. Locate another identical CO trunk and swap its wiring with one under test. Repeat test on both trunks and determine if problem follows trunk or remains at original port. If problem follows trunk, refer problem to CO. If problem remains at port, replace circuit pack and repeat test. 4. If replacing circuit pack does not clear failure, escalate the problem.

Table 10-101. TEST #0 Dial Tone Test — Continued

Error Code	Test Result	Description/ Recommendation
1009	PASS	Detected tone was not pure dial tone. [G1, G3iV1.1-286] No action required.
	PASS	Trunk was seized, and dial tone was detected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

CO Demand Diagnostic Test (#3)

For ground start trunks only, port circuit pack relays are operated and checks are made to see if the port can detect and apply ground on the Tip lead. This test also verifies that there is no external ground on the Ring lead. In the absence of other failures, the circuit pack should be replaced only if this test fails with the CO line disconnected.

For the TN2147 World Class Central Office circuit pack, this test also checks the on-board programmable transmission circuitry that allows the circuit pack to support the transmission characteristics of several countries.

Table 10-102. TEST #3 CO Demand Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-102. TEST #3 CO Demand Diagnostic Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1005	ABORT	Test inapplicable to present configuration. This is a normal condition.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n". To enable the test, issue the change trunk-group x command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the request was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-102. TEST #3 CO Demand Diagnostic Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Failure to detect ground or faulty ground detected on Ring lead. Display the hardware errors for this trunk, to determine if the fault was on- or-off board. Look for Error Type 1025 or 1281 (if both appear in the Hardware Error Log, pick the most recent error). Error Type 1025 indicates a faulty ground detected on Ring lead (an off-board fault) and Error Type 1281 indicates failure to detect (internally generated) ground (an on-board fault). Faulty ground detected on Ring lead (Error Type 1025):  NOTE: On TN747B vintage 8 and greater circuit packs, an incoming seizure during this test may cause it to fail with an off-board fault. 1. Repeat test. If test passes, ignore the original failure. If test aborts, follow the recommended procedures. 2. Repeat test with CO line removed. 3. If test fails, replace the circuit pack. 4. If test passes, refer problem to CO. Failure to detect ground (Error Type 1281): 1. Run the long test sequence. If the CO Demand Diagnostic Test fails, the Dial Tone Test (#0) fails with Error Code 2002, AND Error Type 3329 or 3585 appears in the Hardware Error Log (with the same last occurred time as Error Type 1281 and 1537), replace the circuit pack. 2. Repeat test with CO line removed. 3. If test fails, replace the circuit pack. 4. If test passes, the CO may be drawing too much current. Refer problem to CO.
57481	FAIL	On-board test of programmable transmission circuitry failed. 1. Replace the circuit pack.
	PASS	This test verifies that the port is able to apply ground for outgoing calls and detect ground for incoming calls; however, it does not provide information on whether a CO line is actually connected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Continued on next page

Table 10-102. TEST #3 CO Demand Diagnostic Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and noisy connections may be observed. This test is usually only part of a port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 10-103. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-103. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. Check the CO wiring, check for excessive loop current, and check the trunk translations. (If the trunk is translated incorrectly, this test will abort.) 2. If the port status is idle, busyout and release the trunk, and then retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test still aborts, replace the circuit pack. 4. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM-Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-103. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop around and conference capabilities of a CO port circuit. The test uses 404-Hz, 1004-Hz, and 2804-Hz tones. Each tone is transmitted separately through the loop and checked.

Table 10-104. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
7 129 131 133	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Conference Circuit Test aborted.
	ABORT	The 404-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
		The 1004-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period.
1000	ABORT	The 2804-Hz reflective loop around test aborted. Response to the test request was not received within the allowable time period. 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If test continues to abort, escalate the problem.
		System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 769 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS Maintenance to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-104. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized force. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the command at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	The test was disabled via administration. Verify that the 'Maintenance Test' field on the 'Trunk Group' form is set to 'n'. To enable the test, issue the 'change trunk-group x' command (x equals the number of the trunk group to be tested). Then, change the entry in the 'Maintenance Test' field on the form to 'y'. 1. Retry the command at 1 minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-104. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
7, 129, 131, or 133	FAIL	The conference capabilities of the port failed (Error Code 7). The reflective 404-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 129). The reflective 1004-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 131). The reflective 2804-Hz Tone Test failed. No transmission was detected to or from the port (Error Code 133). FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see notes on the next page). 1. To make sure the problem is on-board, disconnect the port from the CO and retry the test. Coordinate this with the CO, or do it after busy hours; otherwise, the CO may put the connection out of service. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test. If the retry passes and troubles have been reported, refer the problem to the CO.  NOTE: If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see FAULT ISOLATION above.
	PASS	CO Trunk Loop Around and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Table 10-104. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

2

Port Audit Update Test (#36)

This test sends updates of the CO port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 10-105. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-105. TEST #36 Port Audit Update Test — Continued

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The port has been placed out of service, perhaps by craft busyout. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test were not available. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal system error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter status-command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter release-trunk command to put trunk back into in-service. 3. Retry the test command.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

Transmission Test (#844-848)

This test is non-destructive.

⇒ NOTE:
Tests #844-848 are not supported on a International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run on demand with the **test analog-testcall** command or as part of ATMS scheduled testing.

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of "marginal" or "unacceptable" thresholds. Detail and summary measurement reports are obtainable via the **list testcalls** command.

Table 10-106. TEST #844-848 Transmission Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use display port PCSSpp to determine the trunk group/member number of the port. Use the "status trunk" command to determine the service state of the port. If the service state indicates that the port is in use, then the port unavailable for this test. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description all possible states). You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
1002	ABORT	The system could not allocate timeslots for the test. The system may be under heavy traffic conditions or it may have timeslots out of service due to TDM bus errors. Refer to TDM Bus Maintenance to diagnose any active TDM bus errors. 1. If system has no TDM bus errors and is not handling heavy traffic, repeat test at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.

Table 10-106. TEST #844-848 Transmission Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port has been seized by a user for a valid call. Use status trunk to determine when the port is available for testing. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	Trunk has been administered as incoming-only; transmission tests can only be run on outgoing trunks.
1115	ABORT	The near end test line on the TN771 circuit pack could not be allocated. 1. Verify that the TN771 circuit pack is in service and that port 1 is administered and in service with the status port command. 2. retry the command at 1 minute intervals for a maximum of 5 retries. 3. If the test continues to abort escalate the problem.
1900	ABORT	The test completion message was not received from the TN771 circuit pack. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1901	ABORT	This error occurs when the TN771 circuit pack uplinks a message that is not the proper response for this test. The anticipated uplink messages are seize, ring or answer. 1. Verify that the Trunk is administered properly. 2. If the test continues to abort, escalate the problem.
1905	ABORT	Intercept tone detected from far end. 1. Get the test line data from theand verify it with the far end. Dial the test number manually to see if the TTL is reached. If it is not, then either the number is wrong, or the far end is administered incorrectly. 2. If the test continues to abort escalate the problem.
1906	ABORT	Reorder tone detected from far end. 1. See actions for error code 1905.
1907	ABORT	Other unexpected tone detected from far end. 1. See actions for error code 1905.
1913	ABORT	Audible Ring detected from far end. 1. See actions for error code 1905.
1914	ABORT	Unidentified interrupted tone detected from far end. 1. See actions for error code 1905

Table 10-106. TEST #844-848 Transmission Test — Continued

Error Code	Test Result	Description/ Recommendation
1915	ABORT	Busy tone detected from far end. 1. Since the test line at the far end was busy. Try the test again. 2. If the test continues to abort, the problem is with the far end system.
1918	ABORT	Test progress tone not removed from far end (type 105 test line only). 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1919	ABORT	Unexpected far end release 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1920	ABORT	No response from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1921	ABORT	No data returned from far end. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).
1922	ABORT	Steady, unidentifiable tone from far end 1. See actions for error code 1905.
1923	ABORT	Broadband energy detected from far end (such as voice or announcement). 1. See actions for error code 1905.
1924	ABORT	No test tone from far end 1. See actions for error code 1905.
1938	ABORT	Near-end self test failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1939	ABORT	Loss self check at 0dBm at 1004 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1940	ABORT	Far end noise self check failed. 1. The problem is with the far end system; a technician at the far end should test the test line (TN771 or ADFTC).

Continued on next page

Table 10-106. TEST #844-848 Transmission Test — Continued

Error Code	Test Result	Description/ Recommendation
1941	ABORT	High frequency singing return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1942	ABORT	Echo return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1943	ABORT	Singing return loss self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1944	ABORT	Loss self check at -16 dBm at 1004 Hz failed. 1. Test the TN771 circuit packs 2. If the test continues to abort escalate the problem.
1945	ABORT	Loss self check at -16 dBm at 404 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1946	ABORT	Loss self check at -16 dBm at 2804 Hz failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
1947	ABORT	Noise with tone self check failed. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
2000	ABORT	The test timed out while waiting for a response from the TN771 circuit pack. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
2012	ABORT	An internal software error occurred. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.
2053	ABORT	The test call could not be established, but no information on why is available. 1. Retry the command at 1 minute intervals for a maximum of 5 retries. 2. If the test continues to abort escalate the problem.

Table 10-106. TEST #844-848 Transmission Test — Continued

Error Code	Test Result	Description/ Recommendation
2056	ABORT	An error occurred while trying to obtain results from the TN771 circuit pack. 1. Test the TN771 circuit packs. 2. If the test continues to abort escalate the problem.
	FAIL	Measured transmission performance was in the unacceptable range as administered on the trunk group form. Retrieve a measurement report via the list testcalls command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form. Besides the facility, test failures can be caused by faulty test lines or switch paths. If the measurements point to a facility problem, report the results to the trunk vendor.
8000	FAIL	Measured transmission performance was in the marginal range as administered on the trunk group form. This generally means that the trunk is usable but has an undesirable amount of noise or loss. If the user does not report unacceptable effects, it may not be necessary to take any action. Retrieve a measurement report via the list testcalls command. Make sure that ATMS thresholds are set properly on page 4 of the trunk group form.

CONFIG (System Configuration)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
CONFIG	none	none	System Configuration

The System Configuration maintenance object (MO) oversees logical insertion and removal of circuit packs in the system. When Switch Control detects that a circuit pack is present in a port slot, it informs System Configuration and System Configuration queries the circuit pack to determine the type and vintage of the circuit pack. Similarly, when Switch Control detects that a circuit pack has been removed from a port slot, it informs System Configuration.

There are no alarms or tests for System Configuration, but three types of errors are logged to the Hardware Error Log (see below).

Hardware Error Log Entries and Test to Clear Values

System Configuration Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	none
2-117(a)	0-2	none			
257(b)		none			
1002-1117(c)	0-2	none			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates that a Port circuit pack in the system did not respond to a circuit pack type inquiry. Follow the procedures outlined in (b) to determine if there is an error.
- b. This error indicates that less than 25% of Trunk Group is available.
- c. This error indicates that a Port circuit pack in the system did not respond to a vintage inquiry.

As a result of either of these errors, a Port circuit pack may be physically inserted in a Port slot, but the system may not recognize its existence. The Error Type and Aux Data fields specify the location of the port circuit pack that caused the error as indicated in Table 10-100. If the Error Type field is greater than 1000, subtract 1000 from the Error Type field before consulting the table.

If more than one CONFIG error is logged with an Aux Data of 1 at the same time, investigate any EXP-INTF (Expansion Interface) errors before proceeding.

Once the Port circuit pack location has been determined from Table 10-100, use the **list configuration all** command to determine if the circuit pack is inserted. If not, insert the pack. If the circuit pack has already been inserted but the error persists, replace the circuit pack.

CUST-ALM (Customer-Provided Alarming Device)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
CUST-ALM	none	test customer-alarm PC	Customer-Provided Alarming Device

1. Where PC is an appropriate port network number and carrier (for a High or Critical Reliability system, specify 1a or 1b).

The system provides customers a way to connect their own alarm indication device to a switch. The CUST-ALM maintenance object represents this Customer-Provided Alarming Device (CPAD). When an alarm occurs at least to the level to which the CPAD is administered, the CPAD in the Processor Port Network (PPN) and in the Expansion Port Network (EPN) are activated. The CPAD is administered by the Maintenance-Related System Parameters Form (CPE Alarm Activation Level field). The CPAD is connected to the Maintenance/Tape Processor in the PPN (in a High or Critical Reliability system, the CPAD is connected to both Maintenance/Tape Processors) and to the EPN Maintenance circuit pack in the EPN. The valid levels to which to set the CPE Alarm Activation Level are: *none*, *warning*, *minor*, or *major*. The CPAD is also activated within a cabinet whenever Emergency Transfer is invoked within that cabinet. The CUST-ALM MO is not maintained by the system, and does not generate any alarms. If a problem is suspected with the CPAD, it may be tested using the **test customer-alarm** command, which activates the device by closing the relay on either the Maintenance/Tape Processor or the EPN Maintenance circuit pack (whichever is specified) for 1 minute. In a High or Critical Reliability system, the CPAD on the PPN is connected to the Maintenance/Tape Processor on both carrier A and carrier B, and the **test customer-alarm** command can specify which Maintenance/Tape Processor should close its relay. The repeat parameter may be used to close the relay for a longer length of time (5 minutes is the suggested repeat value).

The CPAD is also activated within a cabinet whenever Emergency Transfer is invoked within that cabinet. The CUST-ALM MO is not maintained by the system, and does not generate any alarms. If a problem is suspected with the CPAD, it may be tested using the **test customer-alarm** command, which activates the device by closing the relay on either the Maintenance/Tape Processor or the EPN Maintenance circuit pack (whichever is specified) for 1 minute. In a High or Critical Reliability system, the CPAD on the PPN is connected to the Maintenance/Tape Processor on both carrier A and carrier B, and the **test customer-alarm** command can specify which Maintenance/Tape Processor should close its relay. The repeat parameter may be used to close the relay for a longer length of time (5 minutes is the suggested repeat value).

none	none	none			

System Technician-Demanded Tests:
Descriptions and Error Codes

There are no errors associated with the CPAD CUST-ALM MO. The **test customer-alarm PC** command is provided to allow a technician to check that the customer-provided alarming device is correctly installed and functional. It is recommended that this test be run at least once after both the switch and the customer alarm have been installed.

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Customer-Provided Alarming Device Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Customer-Provided Alarming Device Test (#115)	X	X	ND

1. D = Destructive; ND = Nondestructive

Customer-Provided Alarming Device Test (#115)

This test closes the relay that activates the CPAD for 1 minute only within the port network specified. If it takes longer than 1 minute to check that the CPAD has been activated, the Repeat field on the **test customer-alarm PC** command can be used to close the relay for up to 99 minutes. Note that when the repeat option is used, the results for Test #115 come back immediately and, for each test that passed, the CPAD is kept on for that many minutes. The CPAD does not go off after 1 minute and then come back on. Instead, the CPAD is kept on continuously for the entire time. If the CPAD is being activated and deactivated in a flickering fashion, there is a problem with either the CPAD, or the Maintenance/Tape Processor, or the EPN Maintenance circuit pack.

Table 10-109. TEST #115 Customer-Provided Alarming Device Test

Error Code	Test Result	Description/Recommendation
(blank) 1000 2029	ABORT	Internal system error 1. Try the command at 1-minute intervals a maximum of 5 times.
	PASS	The switch software successfully sent the request to the Maintenance/Tape Processor or EPN Maintenance circuit pack to turn on the CPAD. The CPAD must be physically inspected to verify that it is working. If the CPAD is working and the customer has complained that the CPAD did not indicate a system alarm when it occurred, then check the administered levels for turning on the CPAD via the Display System-Parameter Maintenance screen form. Compare these levels with the customer's specifications. If Test #115 passes, and the CPAD is not being activated, check the connection of the CPAD to the Maintenance/Tape Processor or EPN Maintenance circuit pack. If the CPAD can be activated but cannot be deactivated, first check to make sure Emergency Transfer is not activated in the affected port network via the status system command. Emergency Transfer can be forced to manual OFF by the Emergency Transfer switch on the Maintenance/Tape Processor or EPN Maintenance circuit pack. If Emergency Transfer is OFF and the CPAD still cannot be deactivated, check the administered levels for the CPAD via the Display System-Parameter Maintenance screen form and compare against the alarm levels currently present in the system (display alarms command).

DATA-BD (Network Control Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DATA-BD	WARNING	test network-control	Network Control Circuit Pack
DATA-BD	MINOR	test network-control	Network Control Circuit Pack
DATA-BD	WARNING	test network-control	Network Control Circuit Pack

The TN777 or TN777B Network Control circuit pack contains the following objects: the SW-CTL (Switch Control), four DATA-CHLs (Network Control Data Channels), the DATA-CON (Network Control Driver), and the generic hardware that interfaces with the TDM Bus (that is, DATA-BD). The generic hardware DATA-BD is described here.

All circuit packs that have an interface with the TDM Bus have a common set of generic hardware that provides the TDM Bus interface. Consequently, these circuit packs share a common set of tests that verify the integrity of the generic hardware. The circuit packs and common set of tests that they share are described in XXX-BD (Common Port Circuit Pack) Maintenance documentation. Because the Network Control circuit pack has this common set of hardware, it is classified in the XXX-BD Maintenance documentation as a service port circuit pack.

A DEFINITY system with a single SPE has a single Network Control circuit pack. A High or Critical Reliability system has two Network Control circuit packs: one that resides in the Active SPE control carrier, and one that resides in the Standby SPE control carrier. Refer to Chapter 6, "Reliability Systems: A Maintenance Aid", and the STBY-SPE (Standby SPE) Maintenance documentation for a description of High and Critical Reliability systems.

Because the Network Control circuit pack is a SPE circuit pack, it has two important characteristics that make maintenance on the DATA-BD MO different from the maintenance on other XXX-BD (Common Port Circuit Pack) MOs. First, because the Network Control circuit pack has the SW-CTL (Switch Control) on it, it must always be physically installed in the system. Therefore, the DATA-BD MO is always logically administered. Second, because the Network Control circuit pack is a SPE circuit pack, it has no PCSS designation. Therefore, the DATA-BD MO **cannot** be accessed by system technician via the **test board PCSS**, **reset board PCSS**, **busyout board PCSS**, or **release board PCSS** commands. The only system technician access to the DATA-BD MO is via the **test network-control [a | b] [short | long]** command.

Error Log Entries and Test to Clear Values

Table 10-110. Network Control Circuit Pack Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test data-module <ext> sh r 1
1 (a)	0	Data Channel Reset Test (#107)	MINOR	ON	test data-module <ext> l
23 (b)	0	None	WARNING	OFF	
257	Any	Control Channel Test (#52)	MINOR	ON	test network-control [a b] sh r 20
257 (c)	0	None			
513 (d)	Any	None			
769 (e)	4358	None			
1025 (f)	4363	NPE Audit Test (#50)			test network-control [a b] sh
1538 (g)		Data Channel Reset Test (#107)	MINOR	ON	test data-module <ext> l
3840 (h)	Any	None			
3841(i)	Any	None			
3999(j)	Any	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error indicates the DATA-BD portion of the Network Control circuit pack stopped functioning. Since the Network Control circuit pack cannot be reset via the **reset board PCSS** command, the Data Channel Reset Test (#107) in the Long Test Sequence for the DATA-CHLs and DATA-CON must be used to reset it as follows:
1. Issue the **list data** command to determine if one, or more, Network Control Data Channels (DATA-CHLs) is administered.

-  **NOTE:**
A Network Control Data Channel (DATA-CHL) is identified by a "type" value of "netcon."
2. If a Network Control Data Channel (DATA-CHL) is not administered, use the **add data-module [<ext> | next]** command to administer a DATA-CHL.

3. From the form resulting from the **list data** command, choose a Network Control Data Channel (DATA-CHL) whose port field value indicates that it is on the same carrier (A or B) as the Network Control circuit pack to be reset.
4. Issue the **test data-module <ext> long** command using the extension for the DATA-CHL chosen in Step 3.

WARNING:

Issuing this command drops all data channel extensions. See DATA-CHL (Network Control Data Channel) Maintenance documentation first.

If the red LED stays on, then replace the circuit pack.

- b. The circuit pack has been logically administered but not physically installed. The alarm is cleared when the circuit pack is installed.
- c. This error indicates transient communications problems with this circuit pack. This error is not service-affecting and no action is required.
- d. This error indicates the circuit pack has reported a hardware failure on the circuit pack. The circuit pack should be replaced.
- e. This error can be ignored, but look for other errors on this circuit pack.
- f. This error is not service-affecting and no action is required.
- g. This error indicates the DATA-BD portion of the Network Control circuit pack is out-of-service. Since the Network Control circuit pack cannot be reset via the **reset board PCSS** command, the Data Channel Reset Test (#107) in the Long Test Sequence for the DATA-CHL and DATA-CON must be used to reset it as follows:

1. Issue the **list data** command to determine if one or more Network Control Data Channels (DATA-CHLs) are administered.

NOTE:

A Network Control Data Channel (DATA-CHL) is identified by a "type" value of "netcon."

2. If a Network Control Data Channel (DATA-CHL) is not administered, use the **add data-module [<ext> | next]** command to administer a DATA-CHL.
3. From the form resulting from the **list data** command, choose a Network Control Data Channel (DATA-CHL) whose port field value indicates that it is on the same carrier (A or B) as the Network Control circuit pack to be reset.

- Refer to “DATA-CHL” before issuing the **test network-control [a | b] long** command to determine if CDR, System Printer, Journal Printer, and/or PMS Links are using the DATA-CHLs and how to busyout these links prior to running destructive tests on the DATA-CHLs.
 - Refer to “SW-CTL” before issuing the **test network-control [a | b] long** command to determine the consequences of running the Switch Control Reset Test (Test #93).
4. Issue the **test data-module <ext> long** command using the extension for the DATA-CHL chosen in Step 3.

If the error happens again within 15 minutes, then replace the circuit pack.

- h. This error is not service-affecting and no action is required.
- i. In a High Critical Reliability system, the vintage number of the TN777B Network Control circuit pack must be greater than or equal to 17. The aux value for error 3841 indicates the vintage of the current TN777B installed.
- j. Error type 3999— Indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below. By clearing error codes associated with the *NPE Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Audit Test (#50) (a)		X	ND
Control Channel Loop Around Test (#52)	X	X	ND

1. D = Destructive; ND = Nondestructive

- Note:
- a. Refer to “DATA-CHL” and “SW-CTL” for other tests associated with DATA-BD maintenance.

NPE Audit Test (#50)

The system sends a message to the on-board microprocessor to update the network connectivity information for all the NPEs on the circuit pack.

Table 10-111. TEST #50 NPE Audit Test

Error Code	Test Result	Description/Recommendation
2100 1019	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Could not allocate the necessary system resources to run this test.
	ABORT	Test already in progress.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The circuit pack’s NPEs have been updated with their translation.

Control Channel Loop Around Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 10-112. TEST #52 Control Channel Loop Around Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	Communication with this circuit pack is successful.

DATA-CHL (Network Control Data Channel)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DATA-CHL ¹	MINOR	test data-module l <ext>	Network Control Data Channel
DATA-CHL ²	WARNING	test data-module sh <ext> ³	Network Control Data Channel

1. The **test data-module <ext> long** command drops all sessions on all of the Network Control ports. Refer to Data Channel Reset Test (#107).
2. <ext> is the extension of the Data Channel to be tested. The extension can be determined by issuing the **list data-module** command from the administration terminal. The resulting form provides a mapping from the 1CXXpp designation of the Data Channel to its corresponding extension, where pp indicates which one of the four Data Channels is alarmed (01, 02, 03, or 04) and C indicates the carrier on which the alarmed Data Channel resides (A for carrier A or B for carrier B).
3. The **test data-module <ext> long** command drops all sessions on all of the Network Control ports. Refer to Data Channel Reset Test (#107).

The TN777 or TN777B Network Control circuit pack contains the following objects: the SW-CTL (Switch Control), four Data Channels, the Driver, and the generic hardware that interfaces with the TDM Bus (that is, DATA-BD). The Data Channels are the subject of this section. The Driver is also described.

Together, the four DATA-CHLs and the DATA-CON provide a data communications interface that allows data terminal equipment connected to port circuit packs to communicate with software applications running on the system. The DATA-CON represents the interface to the control channel of the TDM Bus. Each DATA-CHL represents a dial-up/dial-out asynchronous communications port that interfaces to the TDM Bus. The DATA-CON supports the signaling required to establish and tear down a connection between the terminal equipment and a software application. Data is transported between the terminal equipment and the software application over the connection established over the DATA-CHL.

A system with a single SPE has a single Network Control circuit pack (DATA-BD). Thus, there is single set of four DATA-CHLs. A High or Critical Reliability system has two Network Control circuit packs: one that resides in the Active SPE control carrier, and one that resides in the Standby SPE control carrier. Refer to Chapter 6, "Reliability Systems: A Maintenance Aid", and the STBY-SPE (Standby SPE) Maintenance documentation for descriptions of High and Critical Reliability systems.

Network Control Data Channels (DATA-CHLs) may be used to support the following features and functions:

- Establishment of a connection over which to log CDR data to a printer or other storage unit. This connection is called PRI-CDR/SEC-CDR (PRI-CDR Link).
- Establishment of connection(s) over which to log PMS, Automatic Wakeup, and Emergency Access to Attendant data to a Journal printer. This connection is called PMS-PRINT/JRNL-PRNT (PMS Printer Link).
- Establishment of a connection to a customer-owned PMS. This connection is called the PMS-LINK.
- Establishment of a connection to system printer. This connection is called the System Printer Link (SYS-PRNT).
- Establishment of connection(s) for up to two secondary administration terminals.
- Saving announcements from the ANN-BD (Announcement Circuit Pack) to tape.
- Restoring announcements from tape to the ANN-BD (Announcement Circuit Pack).
- Maintenance testing of the DATA-CHLs and DATA-CON.

From the viewpoint of administration, the four DATA-CHLs on a Network Control circuit pack are numbered 01 through 04. In a system with a single SPE or in the Active SPE of a system with High or Critical Reliability, each DATA-CHL may be assigned a unique extension using the **add data-module [<ext> | next]** command. These extensions are called *active* extensions. When assigning an active extension to a DATA-CHL XX (where XX is 01, 02, 03, or 04) the Add Data-Module form also requires the user to assign a unique *maintenance* extension to the corresponding Standby SPE DATA-CHL XX. The maintenance extension is required even when the system does not High or Critical Reliability; that is, even when there are no Standby SPE DATA-CHLs. In a High or Critical Reliability system, a Standby SPE DATA-CHL is tested by using its maintenance extension to identify it.

**NOTE:**

If a DATA-CHL or the DATA-CON becomes defective on the Network Control in a system with a single SPE, the Network Control circuit pack cannot be replaced without powering down the system.

Figure 10-24 illustrates the logical decomposition of DATA-CHL (Network Control Channel) and the DATA-CON (Network Control Driver) into software and hardware components. The figure also shows the interface to the switch software via the memory bus and to terminal equipment via the TDM Bus and port circuit packs.

As indicated in the figure, DATA-CHLs 1 and 2 share a common Dual Port RAM (DPR) and TDM Bus interface hardware, and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if

DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

1. Determine if CDR, System Printer, Journal Printer, and/or PMS Links are using the DATA-CHLs and busyout these links if it is necessary to use the **test network-control [a | b] long** command.
2. Refer to SW-CTL (Switch Control) Maintenance documentation before executing the **test network-control [a | b] long** command to determine the consequences of running the Switch Control Reset Test (Test #93).

Figure 10-24. DATA-CON (Network Control Driver)

Status of Network Control Data Channels

In order to perform maintenance testing on the Network Control DATA-CHLs, the DATA-CHLs cannot be busy with one of the functions described previously. A series of system technician commands can be used to determine if the DATA-CHLs are busy and, if so, to determine the function for which they are being used. This series of system technician commands is described below and should be done before testing the DATA-CHLs.

Issue the **list data-module** command to determine the extensions for the administered Network Control Data Channels (DATA-CHLs).

⇒ NOTE:

A Network Control Data Channel (DATA-CHL) is identified by a "type" value of "netcon."

For each Network Control Data Channel (DATA-CHL) on the Active SPE, determine if the DATA-CHL is busy by issuing the **status data-module <ext>** command using the DATA-CHL's extension. If the DATA-CHL is busy, the Service State field in the resulting form will be in service/active. However, the form does not indicate the reason the DATA-CHL is busy. This must be determined using other system technician commands.

Use the procedures below to determine whether busy Network Control Data Channels (DATA-CHLs) are being used for CDR, Journal Printer, or PMS Links. If a DATA-CHL is busy with one of these links then, in order to test the DATA-CHL, the link must be busied out using **busyout smdr-link**, **busyout journal-printer wakeup-log**, **busyout journal-printer pms-log**, or **busyout pms-link** command, respectively. Do not issue any of these busyout commands unless instructed to do so while investigating Error Codes according to the "System Technician-Demanded Tests: Descriptions and Error Codes" subsection. If one of these links must be busied out to perform maintenance testing, restore the link to service according to PRI-CDR/SEC-CDR (PRI-CDR Link), PMS-PRNT/JNL-PRNT (PMS Printer Link), and PMS-LINK Maintenance documentation, respectively.

If a DATA-CHL is busy but is not being used for one of these links, then it is being used for a secondary administration terminal connection or for maintenance testing. If it is being used for a secondary administration terminal connection, then in order to test the DATA-CHL that the connection is using, the DATA-CHL must be busied out using the **busyout data-module <ext>** command.

⇒ NOTE:

The **busyout data-module <ext>** command causes the connection over the associated DATA-CHL to be dropped. Do not issue this command unless instructed to do so.

If the DATA-CHL must be busied out in order to perform maintenance testing, the secondary administration terminal connection must be re-established by redialing the DATA-CHL.

CDR Links

1. Issue the **status smdr-link** command to see if an CDR Link has been established. If the Link State field is "Up," then the CDR Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system features** command and go to the CDR subsection on Page 2 of the resulting form. Note the values in the Primary Output Extension and Secondary Output Extension fields. If the values are extensions, then the CDR Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For each of the extensions in the Primary Output Extension and Secondary Output Extension fields, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, then the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate each port indicated in the Connected Ports fields, and determine if that port has a "type" value of "netcon." If so, then there is an CDR Link over that DATA-CHL.

System Printer Links

1. Issue the **status sp-link** command to see if a System Printer Link has been established. If the Link State field is "Up," then the System Printer Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system features** command and go to the System Printer subsection on Page 2 of the resulting form. Note the values in the Primary Output Extension and Secondary Output Extension fields. If the values are extensions, then the System Printer Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For each of the extensions in the Primary Output Extension and Secondary Output Extension fields, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, then the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate each port indicated in the Connected Ports fields, and determine if that port has a "type" value of "netcon." If so, then there is a System Printer Link over that DATA-CHL.

Journal Printer Links

1. Issue the **status journal-link wakeup-log** and **status journal-link pms-log** commands to see if one or both of these Journal Printer Links have been established. If the Link State field is "Up" for either of these, then that Journal Printer Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system hospitality** command and note the values in the Extension of Journal/System Printer and Extension of PMS Log Printer fields. If either of these values are extensions, then that Journal Printer Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For each of the extensions in the Extension of Journal/Schedule Printer and Extension of PMS Log Printer fields, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, then the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate each port indicated in the Connected Ports fields, and determine if that port has a "type" value of "netcon." If so, then there is a Journal Printer Link over that DATA-CHL.

PMS Link

1. Issue the **status pms-link** command to see if a PMS Link has been established. If the Link State field is "Up," the PMS Link may be using one of the Network Control Data Channels (DATA-CHLs).
2. Issue the **display system hospitality** command and note the value in the Extension of the PMS field. If this value is an extension, the PMS Link is using one of the Network Control Data Channels (DATA-CHLs).
3. For the extension in the Extension of PMS field, issue the **status data-module <ext>** command using the extension. Note the value in the Connected Ports field of the resulting form. If there is a port value in the field, the indicated port is a Network Control Data Channel (DATA-CHL).
4. Issue the **list data-module** command, locate the port indicated in the Connected Ports field, and determine if that port has a "type" value of "netcon." If so, there is a PMS Link over that DATA-CHL.

Error Log Entries and Test to Clear Values

Table 10-113. Network Control Data Channel Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹ (a)	0	Any	Any	Any	test data-module <ext> sh r 1
1	Any	Local Loop Back Test (#111)	MINOR	ON	test data-module <ext> sh r 3
18 (b)	0	busyout data-module <ext>	WARNING	OFF	release data-module <ext>
130		None	WARNING	ON	test data-module <ext> sh
257	Any	Remote Maintenance Loop Around Test (#109)	MINOR	ON	test data-module <ext> sh r 5
513	Any	Crosstalk Test (#110)	MINOR	ON	test data-module <ext> sh r 3
769	Any	Dual Port RAM Test (#108)	MINOR	ON	test data-module <ext> l r 3

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- b. In a system with the duplication option, a busyout of the DATA-CHL is preserved across an SPE interchange. When an SPE interchange occurs, and the DATA-CHL is busied out, the busyout state is transferred to the corresponding DATA-CHL on the new active SPE while the DATA-CHL on the former active SPE is released.

System Technician-Demanded Tests:
Descriptions and Error Codes

There are two system technician test commands that include the Network Control Data Channels (DATA-CHLs). The **test data-module <ext> [short | long]** command tests the single DATA-CHL that has the extension specified by <ext>. The **test network-control [a | b] [short | long]** command tests each administered DATA-CHL that resides on the Network Control circuit pack in the specified carrier.

Always investigate tests in the order presented in the following tables when inspecting errors in the system. By clearing error codes associated with the *Data*

Channel Reset Test, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Data Channel Reset Test (#107) (a)		X	D
Data Channel Dual Port Ram Test (#108) (a)		X	D
Data Channel Remote Maintenance Loop Around Test (#109)	X	X	ND
Data Channel Local Loop Back Test (#111)	X	X	ND
Data Channel Crosstalk Test (#110)	X	X	ND

1. D = Destructive; ND = Nondestructive

- Note:
- a. Determine if CDR, System Printer, Journal Printer, and/or PMS Links are using the DATA-CHLs and busyout these links if it is necessary to use the **test network-control [a | b] long** command.

Table 10-114. System Technician-Demanded Tests: DATA-CHL

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Control Channel Test (Common Port Circuit Pack) (#52) (a)		X	ND
NPE Audit Test (Common Port Circuit Pack) (#50) (a)	X	X	ND
Data Channel Reset Test (#107)		X	D
Data Channel DPR Test (#108)		X	D
Data Channel Maintenance Loop Around Test (#109)	X	X	ND
Data Channel Crosstalk Test (#110)	X	X	ND

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Memory Card Insertion Test (#695) (c)	X	X	ND
Memory Card Format and Read Test (#696) (c)	X	X	ND
Memory Card Match Test (#697) (c)	X	X	ND
Memory Card Write-Protected Test (#698) (c)	X	X	ND
Memory Card Directory Recovery Test (#699) (c)	X	X	ND
Memory Card Translation Data Integrity Test (#694) (c)		X	ND
Memory Card Erase/Write/Read Test (#693) (c)	X		ND

1. D = Destructive, ND = Non-destructive

Notes:

- a. Refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation for a description of these tests.
- b. Refer to SW-CTL (Switch Control) Maintenance documentation for a description of these tests.
- c. Refer to the CARD-MEM MO section for information on this test.

Data Channel Reset Test (#107)

This test is destructive.

This test resets the entire data communications interface provided by the DATA-CON and the four DATA-CHLs. All existing connections over the DATA-CHLs are dropped.

Table 10-115. TEST #107 Data Channel Reset Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Try the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-115. TEST #107 Data Channel Reset Test — Continued

Error Code	Test Result	Description/Recommendation
2011 2012 2013 2016 2017 2020 2022 2030	ABORT	Refer to STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
2100	ABORT ABORT	System resources required for this test are unavailable. An ABORT has one of two different meanings: 1. System resources required to run this test are not available. 2. Internal system error
10704	ABORT	Internal system error 1. Try the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The circuit pack failed to reset. 1. Execute the command again. 2. If the problem persists, replace the TN777 Network Control circuit pack. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. If this is a high or critical reliability system, set the Time-of-Day clocks as described in Chapter 6, "Reliability Systems: A Maintenance Aid", to ensure that the clocks on both Network Control circuit packs are synchronized.
	PASS	The circuit pack initializes correctly.

Data Channel Dual Port RAM Test (#108)

This test is destructive.

This is a coordinated test of the dual port RAM that is shared between the hardware and software composing the DATA-CON. Control messages and data are passed through this dual port RAM to establish and tear down connections over the DATA-CHLs. This test requests each side to read and write the dual port RAM, first one at a time and then simultaneously in alternate locations.

This test prevents any control stimuli from being received from or sent to the TDM Bus control channel preventing the establishment of new connections over the DATA-CHLs. However, existing connections are not (and cannot) be dropped.

Table 10-116. TEST #108 Data Channel Dual Port RAM Test

Error Code	Test Result	Description/Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2020	ABORT	Refer to “STBY-SPE” for a description of these error codes.
	FAIL	The DATA-CON dual port RAM is not functioning correctly. Either the software cannot correctly read from it and/or write to it or the hardware cannot correctly read from it and/or write to it. Connections cannot be established over the DATA-CHLs. 1. Execute the command again. 2. If the problem persists, replace the TN777 Network Control circuit pack. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command.
	PASS	The DATA-CON dual port RAM is functioning. Connections can be established over the DATA-CHLs.

Data Channel Remote Maintenance Loop Around
Test (#109)

This test verifies the integrity of the entire DATA-CHL (that is, the software, dual port RAM, and hardware that compose it). It verifies that a connection can be established over the DATA-CHL and that the DATA-CHL can correctly send and receive data over the connection (that is, over the TDM Bus). The test actually involves two DATA-CHLs: the DATA-CHL that is the target of the test and a second, arbitrary, unbusy DATA-CHL. A connection is set up by placing a call out from the arbitrary DATA-CHL and into the target DATA-CHL. Data is looped over the connection in each direction (that is, the target DATA-CHL is tested as both a sender of data and a receiver of data). The test checks that the data received by one DATA-CHL is the same as the data that was sent by the other DATA-CHL.

Because it establishes a connection between two Network Control Data Channels (DATA-CHLs) across the TDM Bus, this test does more than just verify the integrity of the target DATA-CHL. It also verifies the integrity of the DATA-CON (by establishing the connection) and of the TDM Bus and Tone-Clock circuit pack (by sending and receiving data).

If this test aborts or fails, it is impossible to determine from this test alone whether the defective DATA-CHL is the target DATA-CHL or the arbitrarily chosen DATA-CHL, or if the problem lies with the DATA-CON, TDM Bus, or Tone-Clock

circuit pack. The results of running Tests #107, #108, #110, and #111 on the DATA-CHL can be used to determine whether the target DATA-CHL is defective.

Finally, recall from the description of that DATA-CHLs 1 and 2 share a common Dual Port RAM (DPR) and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if this test finds that DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if this test finds that DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

NOTE:
If an Error Code is encountered recommending that an CDR, System Printer, Journal Printer, and/or PMS Link be busied out, restore each busied out link to service according to PRI-CDR/SEC-CDR (PRI-CDR Link), SYS-PRNT (System Printer Link), JNL-PRNT (Journal Printer Link), or PMS-PRNT/JNL-PRNT (PMS Printer Link) Maintenance documentation, respectively, before concluding work on the problem.

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test

Error Code	Test Result	Description/Recommendation
4	ABORT	For this test, an Error Code of 4 can have 1 of 2 different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. Internal system error Note the results of Tests #110 and #111 in the Short Test Sequence for the target DATA-CHL. If the results of Tests #110 and #111 are both PASS, then there is a high probability that the target DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL: 1. Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL. 2. If the target DATA-CHL is in use for some other function, busyout the function (CDR Link, System Printer Link, Journal Printer Link, PMS Link) or the DATA-CHL (secondary administration terminal connection only). 3. Retry the command at 1-minute intervals a maximum of 5 times.Restore any busied out CDR, System Printer, Journal Printer, or PMS Link to service before moving on to another activity.

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
30 31 32 33 40 41 70 75	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	For this test, an Error Code of 1000 can have one of several different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. No other DATA-CHLs are administered and, therefore, not available to place the call to the target DATA-CHL. c. All other DATA-CHLs are busy and, therefore, not available to place the call to the target DATA-CHL. d. System resources required to run this test are not available. e. Internal system error Note the results of Tests #110 and #111 in the Short Test Sequence for the target DATA-CHL. If the results of Tests #110 and #111 are both PASS, then there is a high probability that the target DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL: 1. Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL. 2. If the target DATA-CHL is in use for some other function, busyout the function (CDR Link, System Printer Link, Journal Printer Link, PMS Link) or the DATA-CHL (secondary administration terminal connection only).

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
1000 (cont'd.)		3. Issue the list data-module command to determine if other DATA-CHLs are administered. If no other DATA-CHLs are administered, administer at least one at this time. 4. Determine if the DATA-CHLs OTHER THAN the target DATA-CHL are all in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of Network Control Data Channels" section. If so, and if it is necessary to completely test the target DATA-CHL, use the following preference guidelines to free one of the DATA-CHLs for testing. a. If a DATA-CHL is being used for a secondary administration terminal connection, busyout that DATA-CHL. b. Otherwise, if a DATA-CHL is being used for a PMS Link, busyout the PMS Link. c. Otherwise, if a DATA-CHL is being used for a Journal Printer Link, busyout the Journal Printer Link. d. Otherwise, if a DATA-CHL is being used for an CDR Link, busyout the CDR Link. e. Otherwise, if a DATA-CHL is being used for a System Printer Link, busyout the System Printer Link. 5. Retry the command at 1-minute intervals a maximum of 5 times. 6. Restore any busied out CDR, System Printer, Journal Printer, or PMS Link to service before moving on to another activity.
1006	ABORT	For this test, an Error Code of 1006 can have one of several different meanings: a. No other DATA-CHLs are administered and, therefore, not available to place the call to the target DATA-CHL. b. All other DATA-CHLs are busy and, therefore, not available to place the call to the target DATA-CHL. c. System resources required to run this test are not available. d. Internal system error Note the results of Tests #110 and #111 in the Short Test Sequence for the target DATA-CHL. If the results of Tests #110 and #111 are both PASS, then there is a high probability that the target DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL:

Continued on next page

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
1006 (cont'd.)		1. Issue the list data-module command to determine if other DATA-CHLs are administered. If no other CATA-CHLs are administered, administer at least one at this time. 2. Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL. a. If a DATA-CHL is being used for a secondary administration terminal connection, busyout that DATA-CHL. b. Otherwise, if a DATA-CHL is being used for a PMS Link, busyout the PMS Link. c. Otherwise, if a DATA-CHL is being used for a Journal Printer Link, busyout the Journal Printer Link. d. Otherwise, if a DATA-CHL is being used for an CDR Link, busyout the CDR Link. e. Otherwise, if a DATA-CHL is being used for a System Printer Link, busyout the System Printer Link. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. Restore any busied out CDR, System Printer, Journal Printer, or PMS Link to service before moving on to another activity.
1016	ABORT	Resources for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via software patch.
2003	ABORT	Internal system error
2004	ABORT	Internal system error 1. Check the dial plan to make sure that the extensions of the data channel are set up as local extensions rather than remote or UDP extensions. 2. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
2011 2012 2013 2016 2017 2020 2022 2051	ABORT	Refer to STBY-SPE (Standby SPE) Maintenance documentation for a description of these error codes.
40 41 2000 2003 2004	FAIL	In the case of Error Codes 40 and 41, the Remote Maintenance Loop Around Test failed because the data received over the connection did not match the data sent over the connection (data was corrupted). In the case of Error Codes 2000, 2003, and 2004, the Remote Maintenance Loop Around Test failed because the data looped over the connection was not received (data was lost). However, because it involves two DATA-CHLs, the test's failure is not sufficient to indict either one of the two DATA-CHLs as defective. 1. Check the dial plan to make sure that the extensions of the data channel are set up as local extensions rather than remote or UDP extensions. 2. Determine which of the DATA-CHLs is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described in the "Status of Network Control Data Channels" section. 3. Note the test results for Tests #110 and #111 in the Short Test Sequence for the target DATA-CHL and refer to Steps 4, 5, and/or 6 to determine the appropriate actions to take based on those results.

Continued on next page

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
40 41 2000 2003 2004 (cont'd.)		4. If the result of Test #110 is PASS and the result of Test #111 is PASS for the target DATA-CHL, then the most likely problem is that the arbitrarily chosen DATA-CHL is defective. ■ Run the Short Test Sequence for each DATA-CHL that is not in use for some other function. Note the test results for Tests #110 and #111 for each of them. ■ If the results of Tests #110 and #111 are both FAIL for at least one of the other DATA-CHLs, investigate the possibility of a defective arbitrarily chosen DATA-CHL. a. Issue the remove data-module <ext> for each DATA-CHL for which the results of Tests #110 and #111 were both FAIL to remove the DATA-CHL from operation. b. Repeat the test. c. Replace the Network Control circuit pack at your earliest convenience. Replace the circuit pack as described in Chapter 5, "Routine Maintenance Procedures". After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. ■ If the results of Tests #110 and #111 are not both FAIL for any one of the other DATA-CHLs that are not in use for some other function, investigate the possibility of a defective TDM Bus as described in Step 5. 5. If the result of Test #110 is FAIL and the result of Test #111 is PASS for the target DATA-CHL, then the most likely problem is that the TDM Bus or Tone-Clock circuit pack is defective. ■ Check for the existence of TDM Bus (TDM-BUS) and/or Tone-Clock circuit pack (TONE-BD, TONE-PT, and TDM-CLK) errors and alarms. If they exist: a. Refer to the corresponding Maintenance documentation to clear the errors and alarms. b. Repeat the test. ■ If TDM Bus (TDM-BUS) and/or Tone-Clock circuit pack (TONE-BD, TONE-PT, and TDM-CLK) errors and alarms do not exist, investigate the possibility that the target DATA-CHL, the DATA-CON, or the Network Control circuit pack is defective as described in Step 6.

Continued on next page

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
40 41 2000 2003 2004 (cont'd.)		6. If the result of Test #110 is either PASS or FAIL and the result of test #111 is FAIL for the target DATA-CHL, then the most likely problem is that the target DATA-CHL is defective, the DATA-CON is defective, or the TN777 Network Control circuit pack is defective. ■ Busyout all functions that are using the Network Control Data Channels (DATA-CHLs).  CAUTION: <i>All functions must be busied out because Test #107 is destructive and terminates all established connections over the DATA-CHLs.</i> ■ Issue the test data-module <ext> long for the target DATA-CHL. Note the test results for Test #107 and #108. a. If the result of Test #107 is FAIL, then the TN777 Network Control circuit pack is defective. ■ Replace the Network Control circuit pack immediately. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. ■ Repeat the test. b. If the result of Test #107 is PASS and the result of Test #108 is FAIL, then the DATA-CON is defective. ■ Although all DATA-CHLs are unusable, the SW-CTL is still operational. Based on the customer's use of DATA-CHLs, replace the Network Control circuit pack at the customer's convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. ■ Repeat the test.
40 41 2000 2003 2004 (cont'd.)		If the result of Test #107 is PASS and the result of Test #108 is PASS, then the target DATA-CHL is defective. ■ Issue the remove data-module <ext> for the target DATA-CHL to remove it from operation. ■ Replace the Network Control circuit pack at your earliest convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. 7. Restore any busied out CDR, Journal Printer, System Printer, or PMS Link to service before moving on to another activity.

Table 10-117. TEST #109 Data Channel Remote Maintenance Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
	PASS	The target DATA-CHL, DATA-CON, TN777 Network Control circuit pack, TDM Bus (TDM-BUS), and Tone-Clock circuit pack (TONE-BD, TONE-PT, TDM-CLK) are functioning. Connections can be established over the DATA-CHLs.

Data Channel Crosstalk Test (#110)

This test verifies the integrity of the entire DATA-CHL, that is, the software, dual port RAM, and hardware that composes it. However, unlike the Remote Maintenance Loop Around Test (#109), this test only involves the single DATA-CHL that is the target of the test. A loop around connection is established over the TDM Bus from the DATA-CHL back to itself. Data is looped over the connection in each direction, that is, the DATA-CHL is tested as both a sender of data and a receiver of data. The test checks that the data received by the DATA-CHL is the same as the data that was sent by the DATA-CHL.

Because it establishes a loop around connection from the Network Control DATA-CHL back to itself across the TDM Bus, this test does more than just verify the integrity of the target DATA-CHL. It also verifies the integrity of the DATA-CON (by establishing the connection) and of the TDM Bus and Tone-Clock circuit pack (by sending and receiving data).

If this test aborts or fails, it is impossible to determine from this test alone whether the target DATA-CHL is defective or if the problem lies with the DATA-CON, TDM Bus, or Tone-Clock circuit pack. The results of running Tests #107, #108, and #111 on the DATA-CHL can be used to determine whether the target DATA-CHL is defective.

Finally, recall from the description of that DATA-CHLs 1 and 2 share a common DPR and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if this test finds that DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if this test finds that DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

➤ NOTE:
If an Error Code is encountered that recommends that an CDR Link, System Printer Link, PMS Log Printer, Wakeup-Log Printer Link, and/or PMS Link be busied out, restore each busied-out link to service according to the PRI-CDR/SEC-CDR (PRI-CDR Link), SYS-PRNT, or PMS-LINK Maintenance documentation, respectively, before concluding work on the problem.

Table 10-118. TEST #110 Data Channel Crosstalk Test

Error Code	Test Result	Description/Recommendation
4	ABORT	For this test, an Error Code of 4 can have one of two different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. Internal system error Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL: 1. If the target DATA-CHL is in use for some other function, busyout the function (CDR Link, System Printer Link, Journal Printer Link, PMS Link) or the DATA-CHL (secondary administration terminal connection only<EMPH>). 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. Restore any busied out CDR, System Printer, Journal Printer, or PMS Link to service before moving on to another activity.
40 70 75	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-118. TEST #110 Data Channel Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
1000	ABORT	For this test, an Error Code of 1000 can have one of several different meanings: - The target DATA-CHL is busy and, therefore, not available for use. - System resources required to run this test are not available. - Internal system error Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL: - If the target DATA-CHL is in use for some other function, busyout the function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) or the DATA-CHL (secondary administration terminal connection only). - Retry the command at 1-minute intervals a maximum of 5 times. - Restore any busied out PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK MOs to service before moving on to another activity.
1002	ABORT	For this test, an Error Code of 1002 can have one of two different meanings: - System resources required to run this test are not available. - Internal system error
1006	ABORT	System resources required to run this test are not available.
1016	ABORT	Resources for the test are not available. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via software patch.
2000	ABORT	Resources for the test are not available.
2003	ABORT	Internal system error Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-118. TEST #110 Data Channel Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
2011 2012 2013 2016 2017 2020 2022 2051	ABORT	Refer to STBY-SPE (Standby SPE) for a description of these error codes.
14 16 40 2000 2003 2004	FAIL	In the case of Error Code 40, the Crosstalk Test failed because the data received over the connection did not match the data sent over the connection (data was corrupted). In the case of Error Code 2000, 2003, and 2004, the crosstalk test failed because the data looped over the connection was not received (data was lost). - Determine which of the DATA-CHLs are in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of Network Control Data Channels" section. - Note the test result for Test #111 in the Short Test Sequence for the target DATA-CHL and refer to Steps 3 and/or 4 to determine the appropriate actions to take based on those results. - If the result of Test #111 is PASS, then the most likely problem is that the TDM Bus or Tone-Clock circuit pack is defective. - Check for the existence of TDM Bus (TDM-BUS) and/or Tone-Clock circuit pack (TONE-BD, TONE-PT, and TDM-CLK) errors and alarms. If they exist: - Refer to the corresponding Maintenance documentation to clear the errors and alarms. - Repeat the test. - If TDM Bus (TDM-BUS) and/or Tone-Clock circuit pack (TONE-BD, TONE-PT, and TDM-CLK) errors and alarms do not exist, investigate the possibility that the target DATA-CHL, the DATA-CON, or the Network Control circuit pack is defective as described in Step 4.

Table 10-118. TEST #110 Data Channel Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
14 16 40 2000 2003 2004 (cont'd.)		4. If the result of Test #111 is FAIL, then the most likely problem is that the target DATA-CHL is defective, the DATA-CON is defective, or the TN777 Network Control circuit pack is defective. Busyout all functions that are using the Network Control Data Channels (DATA-CHLs).  CAUTION: <i>All functions must be busied out because Test #107 is destructive and terminates all established connections over the DATA-CHLs.</i> a. Issue the test data-module <ext> long command for the target DATA-CHL. Note the test results for Tests #107 and #108. 1. If the result of Test #107 is FAIL, then the TN777 Network Control circuit pack is defective. (a). Replace the Network Control circuit pack immediately. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. (b). Repeat the test. 2. If the result of Test #107 is PASS and the result of Test #108 is FAIL, then the DATA-CON is defective. (a). Although all DATA-CHLs are unusable, the SW-CTL is still operational. Based on the customer's use of DATA-CHLs, replace the Network Control circuit pack at the customer's convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. (b). Repeat the test. 3. If the result of Test #107 is PASS and the result of Test #108 is PASS, then the target DATA-CHL is defective. (a). Issue the remove data-module <ext> command for the target DATA-CHL to remove it from operation. (b). Replace the Network Control circuit pack at your earliest convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. 5. Restore any busied out function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) to service before moving on to another activity.

Table 10-118. TEST #110 Data Channel Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
	PASS	The target DATA-CHL, DATA-CON, TN777 Network Control circuit pack, TDM Bus (TDM-BUS), and Tone-Clock circuit pack (TONE-BD, TONE-PT, TDM-CLK) are functioning. Connections can be established over the target DATA-CHL.

Data Channel Local Loop Back Test (#111)

This test verifies the integrity of the dual port RAM that is shared between the software and hardware that composes the DATA-CHL. The dual port RAM is placed in local loop back mode such that data to be sent by the DATA-CHL is instead looped back to be received by the DATA-CHL. The loop back is done within the dual port RAM, that is, the data is never sent over the TDM Bus. The test checks that the data received by the DATA-CHL is the same as the data that was sent by the DATA-CHL.

This test actually does more than just verify the integrity of the target DATA-CHL. Because it is the DATA-CON that actually puts the Dual Port RAM in local loop back mode and loops the data from the Dual Port RAM back into the Dual Port RAM, the test also verifies the integrity of the DATA-CON.

If this test aborts or fails, it is impossible to determine from this test alone whether the target DATA-CHL is defective or if the problem lies with the DATA-CON. The results of running Tests #107 and #108 on the DATA-CHL can be used to determine whether the target DATA-CHL is defective.

Finally, recall from the description of that DATA-CHLs 1 and 2 share a common Dual Port RAM (DPR) and TDM Bus interface hardware and DATA-CHLs 3 and 4 share a common DPR and TDM Bus interface hardware. Thus, if this test finds that DATA-CHL 1 is defective, then DATA-CHL 2 is likely to be defective and vice versa. Similarly, if this test finds that DATA-CHL 3 is defective, then DATA-CHL 4 is likely to be defective and vice versa.

 **NOTE:**
If an Error Code is encountered that recommends that an CDR Link, System Printer Link, PMS Log Printer, Wakeup-Log Printer, and/or PMS Link be busied out, restore each busied-out link to service according to the PRI-CDR/SEC-CDR (PRI-CDR Link), SYS-PRNT (System Printer Link), PMS-PRNT/JNL-PRNT (PMS Printer Link), or PMS-LINK (Property Management System Link) Maintenance documentation, respectively, before concluding work on the problem.

Table 10-119. TEST #111 Data Channel Local Loop Back Test

Error Code	Test Result	Description/Recommendation
4	ABORT	For this test, an Error Code of 4 can have one of two different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. Internal system error Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL. 1. If the target DATA-CHL is in use for some other function, busyout the function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) or the DATA-CHL (secondary administration terminal connection only). 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. Restore any busied out PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK MOs to service before moving on to another activity.
40 70 75	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-119. TEST #111 Data Channel Local Loop Back Test — Continued

Error Code	Test Result	Description/Recommendation
1000	ABORT	For this test, an Error Code of 1000 can have one of several different meanings: a. The target DATA-CHL is busy and, therefore, not available for use. b. System resources required to run this test are not available. c. Internal system error Determine if the target DATA-CHL is in use for some other function (that is, CDR Link, System Printer Link, Journal Printer Link, PMS Link, or secondary administration terminal connection) as described previously in the "Status of network Control Data Channels" section. If so, check for errors on the function that is using the DATA-CHL. If there are no errors, there is a high probability that the DATA-CHL is not defective. Proceed with the remaining steps only if it is necessary to completely test the target DATA-CHL: 1. If the target DATA-CHL is in use for some other function, busyout the function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) or the DATA-CHL (secondary administration terminal connection only). 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. Restore any busied out PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK MOs to service before moving on to another activity.
1006	ABORT	For this test, an Error Code of 1006 can have one of several different meanings: a. System resources required to run this test are not available. b. Internal system error. Retry the command at 1-minute intervals a maximum of 5 times.
1016	ABORT	Resources for the test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1018	ABORT	Test disabled via software patch.
2000	ABORT	Internal system error
2003	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-119. TEST #111 Data Channel Local Loop Back Test — Continued

Error Code	Test Result	Description/Recommendation
40 2000 2003 2004 (cont'd.)	FAIL	2. The most likely problem is that the target DATA-CHL is defective or the DATA-CON is defective. Busycut all functions that are using the Network Control Data Channels (DATA-CHLs).  CAUTION: <i>All functions must be busied out because Test #107 is destructive and terminates all established connections over the DATA-CHLs.</i> 3. Issue the test data-module <ext> long command for the target DATA-CHL. Note the test results for Tests #107 and #108. a. If the result of Test #107 is FAIL, then the TN777 Network Control circuit pack is defective. 1. Replace the Network Control circuit pack immediately. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. 2. Repeat the test. b. If the result of Test #107 is PASS and the result of Test #108 is FAIL, then the DATA-CON is defective. 1. Although all DATA-CHLs are unusable, the SW-CTL is still operational. Based on the customer's use of DATA-CHLs, replace the Network Control circuit pack at the customer's convenience. After the Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. 2. Repeat the test.
	FAIL	c. If the result of Test #107 is PASS and the result of Test #108 is PASS, then the target DATA-CHL is defective. 1. Issue the remove data-module command. ■ Replace the Network Control circuit pack at your earliest convenience. After the TN777 Network Control circuit pack has been replaced, its Time-of-Day clock must be set using the set time command. 2. Restore any busied out function (PRI-CDR/SEC-CDR, SYS-PRNT, PMS-PRNT/JNL-PRNT, PMS-LINK) to service before moving on to another activity.
	PASS	The target DATA-CHL and DATA-CON are functioning. Connections can be established over the target DATA-CHL.

DATA-CON (Network Control Driver)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DATA-CON	MINOR	none	Network Control Driver

The TN777B Network Control circuit pack contains the following objects: the SW-CTL (Switch Control), four DATA-CHLs (Data Channels), the DATA-CON (Network Control Driver), and the generic hardware that interfaces with the TDM Bus (DATA-BD). The DATA-CON (Network Control Driver) is the subject of this section. The DATA-CHLs (Network Control Channels) are also described.

Together the four DATA-CHLs and the DATA-CON provide a data communications interface that allows DTE equipment connected to port circuit packs to communicate with software applications running on the system. The DATA-CON represents the interface to the control channel of the TDM Bus. Each DATA-CHL represents a dial-up/dial-out asynchronous communication port that interfaces to the TDM Bus. The DATA-CON supports the signaling required to establish and tear down a connection between the terminal equipment and a software application. Data is transported between the terminal equipment and the software over the connection established over the DATA-CHL.

A system with a single SPE has a single Network Control circuit pack. Thus, there is a single DATA-CON. A High or Critical Reliability system has two Network Control circuit packs, one in each of the two SPEs. Thus, there is a DATA-CON on the Network Control circuit pack that resides in the Active SPE control carrier and a DATA-CON on the Network Control circuit pack that resides in the Standby SPE control carrier. Refer to Chapter 6, "Reliability Systems: A Maintenance Aid", and the STBY-SPE (Standby SPE) Maintenance documentation for discussions of High and Critical Reliability systems.

From an external (user) point of view, the DATA-CON is not directly accessible via a system technician command; that is, there is no object command word that represents it. Instead, the DATA-CON is tested under the guise of the DATA-CHLs that it controls. The **test data-module <ext> [short | long]** command tests the DATA-CON along with the DATA-CHL designated by <ext> but all Test Results are associated with the DATA-CHL Maintenance Name.

From an internal (system software) point of view, the DATA-CON uses the same set of tests as the DATA-CHLs. Therefore, the DATA-CON assumes the same Error Type and Aux Data values as the DATA-CHLs in the Hardware Error Log. It is also alarmed at the same Alarm Level (that is, MINOR, ON BOARD) in the Alarm Log. In both logs, the Maintenance Name is DATA-CON.

Error Log Entries and Test to Clear Values

Table 10-120. Network Control Driver Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value (a)
0 ¹	0	Any	Any	Any	none
1		Local Loop Back Test (#111)	MINOR	ON	none
257	Any	Remote Maintenance Loop Around Test (#109)	MINOR	ON	none
513		Crosstalk Test (#110)	MINOR	ON	none
769	Any	Dual Port RAM Test (#108)	MINOR	ON	none

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Note:

- a. As previously described, the DATA-CON is not directly accessible via a system technician command so there is no Test to Clear value that can be used to directly clear errors and alarms raised against the DATA-CON. However, since the DATA-CON and the DATA-CHLs share the same set of tests (that is, test the same set of hardware, firmware, and software), DATA-CON errors and alarms are accompanied by DATA-CHL errors and alarms.

Therefore, the strategy to clear DATA-CON errors and alarms is to first clear all DATA-CHL errors and alarms. After DATA-CHL errors and alarms have been cleared, allow about 60 minutes for maintenance software to run internally and to automatically clear the DATA-CON errors and alarms.

System Technician-Demanded Tests:
Descriptions and Error Codes

Because the DATA-CON uses the same set of tests as the DATA-CHLs, refer to the "System Technician-Demanded Tests: Descriptions and Error Codes" in the DATA-CHL (Network Control Data Channel) Maintenance documentation for a description of the tests and their associated error codes.

DAT-LINE (Data Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DAT-LINE	MINOR	test port PCSSpp l	Data Line
DAT-LINE	WARNING	test port PCSSpp sh	Data Line

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

The TN726 Data Line circuit pack is a port circuit that provides connectivity from the system to asynchronous CPE having RS232-compatible serial interfaces. There are eight data lines (DAT-LINES) on the Data Line circuit pack. If there are errors associated with the DT-LN-BD (Data Line Circuit Pack), refer to the XXX-BD (Common Port Circuit Pack) Maintenance documentation.

Data Lines are administered via the administration terminal **add data-module** command. The data module type is *data-line*. The **list data-module** command lists all administered data modules in the system.

The TN750 Announcement circuit pack has one Data Line on it. The Data Line is used for saving and restoring announcements. For a description of this feature, refer to ANN-BD (Announcement Circuit Pack) Maintenance documentation. Also, if there are errors associated with the Announcement circuit pack, refer to the ANN-BD Maintenance documentation.

 **NOTE:**

If the tests for the Data Line in question pass and there are still user-reported problems, there is probably an external problem. Test the ADU, following the procedures outlined in *User Manual Z3A Asynchronous Data Unit*, 555-401-701. If the ADU appears to be working properly, check the external wiring and, finally, check the customer equipment.

Error Log Entries and Test to Clear Value

Table 10-121. Data Line Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1		Digital Loop Around Test (#171)	MINOR	ON	test port PCSSpp sh r 2
15(a)	Any	Audit Update Test (#36)			
18	0	busyout port PCSSpp	WARNING	OFF	release port PCSSpp
130 (b)		None	WARNING	ON	test port PCSSpp sh
257		Conference Circuit Test (#7)	MINOR	ON	test port PCSSpp l r 2
513		NPE Crosstalk Test (#6)	MINOR	ON	test port PCSSpp l r 2
769(a)	Any (c)	None			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

Notes:

- a. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate errors (if any).
- b. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- c. This error is logged when the Data Line circuit pack finds an error with the transmit/receive circuitry of an administered Data Line on circuit pack insertion. Perform the following procedure:
 - 1. Issue the **busyout board PCSS** command to busyout the Data Line circuit pack on which this port resides.
 - 2. Issue the **reset board PCSS** command. Check the Hardware Error Log to determine if Error Type 769 is logged again for the DAT-LINE MO.

 **NOTE:**
When displaying errors, set the Active Alarms Only field to "n."

If Error Type 769 reappears, replace the DAT-LINE circuit pack. If Error Type 769 does not reappear, proceed to Step 3.

3. Issue the **release board PCSS** command to release the Data Line circuit pack on which this port resides.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Digital Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Digital Loop Around Test (#171)	X	X	ND
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-122. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use status data-module to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1minute intervals a maximum of 5 times.

Table 10-122. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to “TDM-BUS” to diagnose TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any “TTR-LEV” errors. 2. Resolve any “TONE-PT” errors. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	The port has been seized by a user for a valid call. Use status data-module to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Refer to the procedure for Error Type 769. If Error Type 769 still occurs on this port, replace the circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests, examining the ADU, external wiring, and customer equipment.

Conference Circuit Test (#7)

The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

Table 10-123. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use status data-module to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use status data-module to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Refer to the procedure for Error Type 769. If Error Type 769 still occurs on this port, replace the circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
Any	FAIL	The conference circuit test failed (possible off-board problem). 1. Busyout and release the port (data line), and then retest. 2. Replace the circuit pack if the test continues to fail.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests, examining the ADU, external wiring, and customer equipment.

Audit Update Test (#36)

This audit makes sure that the hardware state of the Data Line is consistent with the system translations. When this audit is run, the port is queried for the switchhook state, and the software state is updated according to the returned value. Also, the data line options are sent down to the port.

Table 10-124. TEST #36 Audit Update Test

Error Code	Test Result	Description/ Recommendation
1006	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Refer to the procedure for Error Type 769. If Error Type 769 still occurs on this port, replace the circuit pack.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
7	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The hardware port state is consistent with the software state. User-reported troubles on this port should be investigated using other port tests, examining the ADU, external wiring, and customer equipment.

Digital Loop Around Test (#171)

The Digital Loop Around Test checks the Data Line’s ability to transmit and receive data on the TDM Bus. Data is sent through Network Control Data Channel 3 (data channel port 3) over the TDM Bus, internally looped through the Data Line back onto the TDM Bus, and received again by Network Control Data Channel 3.

If data channel 3 is in use or not administered, this test aborts. This test may fail if Network Control Data Channel 3 is not functioning properly. If there are any DATA-CHL errors in the Error Log, refer to the DATA-BD (Network Control Circuit Pack) Maintenance documentation to clear them up first. This test passes regardless of any customer equipment that may be connected to the port, as long as the port is not in use by the equipment.

Table 10-125. TEST #171 Digital Loop Around Test

Error Code	Test Result	Description/Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use status data-module to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005 1007	ABORT	Network Control Data Channel 3 is not administered. This port is required to run this test. 1. Verify that data channel 3 is not administered with the list data-module command. Administer data channel 3 with the add data-module command, and run this test again.
1016	ABORT	Network Control Data Channel 3 is busy. The port may be in use on a valid call. Use status data-module to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1020	ABORT	The test did not run due to an already existing error on this port (Error Type 769). 1. Reseat the circuit pack and look in the Error Log. If Error Type 769 still occurs on this port, replace the circuit pack.
2003	ABORT	Failed to receive an off-hook from the Data Line. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2004 2005	ABORT ABORT	Failed to receive an off-hook from the Network Control Data Channel. The handshake between the data channel and the data line port failed. 1. Look for DATA-CHL errors in the Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test still aborts, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-125. TEST #171 Digital Loop Around Test — Continued

Error Code	Test Result	Description/Recommendation
	FAIL	The test failed because the data received did not match the data sent. This would indicate that there is a fault somewhere in the transmit/receive path to the TDM Bus, which probably results in data corruption over this port. This test may fail if Network Control Data Channel 3 is not functioning properly. 1. Look for DATA-CHL errors in the Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 2. Repeat this test. 3. If the test fails again, replace the Data Line circuit pack.
2000	FAIL	The test failed waiting for the transmitted data to be looped back. 1. Look for DATA-CHL errors in the Error Log. If present, refer to DATA-BD (Network Control Circuit Pack) Maintenance documentation. 2. Repeat this test. 3. If the test fails again, replace the Data Line circuit pack.
	PASS	The port can correctly transmit/receive data. User-reported troubles on this port should be investigated by examining the ADU, external wiring, and customer equipment.

DC-POWER

Single-Carrier Cabinet Power

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DC-POWER	MAJOR	test environment P	Single-Carrier Cabinet Power

1. Where P is an appropriate port network number determined from the PORT field of the alarm log.

NOTE:

For environment maintenance, the high or critical reliability system, PPN, or EPN cabinet configuration aspects are irrelevant.

The DC-POWER MO represents all the environmental maintenance for a single-carrier cabinet system. It includes an external power unit and all the port power units in the Port Network. The external power unit can be either a DC or an AC power source. If the external power unit is AC, then the Carrier Port Power Units must be WP-91153 power units. If the external power unit is DC, then the Carrier Port Power Units must be 676B power units. If the hardware detects a problem with any one of these elements, it reports the information to the system software through a single lead. The system software cannot differentiate between different environmental failures. All environmental alarms on a single-carrier cabinet system are logged as a major DC-POWER alarm. Therefore, it is possible to get a DC-POWER alarm when there is still power to the system. The yellow LED on the power unit means operating as normal. If the LED is off, no external power is being supplied or that the power unit has a fault.

NOTE:

Physically removing a Carrier Port Power Unit from a single-carrier cabinet system does not raise a DC-POWER alarm. The removal of the power unit is equivalent to the carrier being physically absent since DC-POWER maintenance cannot distinguish between these two situations.

A single-carrier cabinet system powered by an AC external power source with WP-91153 Carrier Port Power Units has a minimal Nominal Power Holdover (NPH) for the PPN only in standard, high, and critical reliability systems. There is no NPH for a DC- powered PPN or for an AC- or DC-powered EPN. NPH in the PPN of an AC-powered system without high or critical reliability provides full powering for 0.25 seconds, and power to the control complex for an additional two minutes.

WARNING:

Before powering down a cabinet or carrier that contains DEFINITY AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the

"DEFINITY AUDIX System Power Procedures" in Chapter 5, "Routine Maintenance Procedures", on the circuit pack, and in DEFINITY AUDIX documentation.

Error Log Entries and Test to Clear Values

Table 10-126. Single-Carrier Cabinet Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test environment P sh r 1
513	0	Single-Carrier Cabinet	MAJOR	ON	test environment P r 2
		Power Query Test (#79)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the following table. By clearing error codes associated with the *Single-Carrier Cabinet Power Query Test*, for example, you may also clear errors generated from other tests in the testing sequence. Test descriptions and recommended maintenance procedures follow for all errors that can occur during system technician-demanded testing.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Single-Carrier Cabinet Power Query Test (#79)	X	X	ND
Emergency Transfer Query Test (#124) (a)	X	X	ND
External Alarm Lead Query Test (#120) (b)	X	X	ND
Analog Ring Generator Initialization Test (#117) (c)	X	X	ND
Analog Ring Generator Query Test (#118) (c)	X	X	ND

1. D = Destructive; ND = Nondestructive

Notes:

- a. Refer to "EMG-XFER" for a description of this test.
- b. Refer to "EXT-DEV" for a description of this test.
- c. Refer to "RING-GEN" for a description of this test.

⇒ NOTE:
Tests #117 and #118 only show up in the test sequence if there is a TN768 Tone-Clock circuit pack in the port network being tested.

Single-Carrier Cabinet Power Query Test (#79)

This test queries the Maintenance/Tape Processor (in a PPN) or the EPN Maintenance circuit pack (in an EPN) about the status of the power in a single-carrier cabinet system. This test can only detect power problems in carriers in the Port Network for which the Carrier Port Power Unit is physically present.

Table 10-127. TEST #79 Single-Carrier Cabinet Power Query Test

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. 1. Retry the command at 1minute intervals a maximum of 5 times.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1minute intervals a maximum of 5 times. 2. If the test continues to ABORT with Error Code 2000, check for system powering problems with the A cabinet (PPN or EPN). Resolve all DC-POWER alarms. Then, repeat the test. If the test continues to ABORT with a 2000 Error Code, resolve all DUPINT (Duplication Interface Circuit Pack) errors in a PPN for a high or critical reliability system, or MAINT (EPN Maintenance circuit pack) errors in an EPN. Then, repeat the test.
2029	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-127. TEST #79 Single-Carrier Cabinet Power Query Test — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL	There is a problem with the environment of the power system. - The power unit for any one of the cabinets may have been lost. - Verify and, if necessary, restore power units for each cabinet. - Rerun the test. If the test still fails, proceed to Step 2. - Either the WP-91153 AC power unit or the 676B DC power unit for one of the cabinets could be defective. Refer to the "Removing Power" and "Restoring Power" sections in Chapter 5, "Routine Maintenance Procedures". - If the yellow LED on the WP-91153 AC power unit or the 676B DC power unit is off, replace the power unit. - If the Active Tone-Clock circuit pack loses power, the system performs a Cold-2 restart to finish (the login prompt appears at the administration terminal). - Rerun the test. If the test still fails, proceed with Step 3. - The DUPINT (Duplication Interface Circuit Pack), or the MAINT (EPN Maintenance Circuit Pack) could be incorrectly reporting this error. Resolve all alarms on these MOs, and rerun the test. There are failures that can occur on the Duplication Interface and EPN Maintenance circuit pack that are not detected by the respective maintenance, but that cause many, if not all, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.
	PASS	The DUPINT (Duplication Interface Circuit Pack), or the MAINT (EPN Maintenance Circuit Pack) has reported no problem with the power.

DETR-BD

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DETR-BD	MINOR	test board PCSS	Tone Detector Circuit Pack
DETR-BD	WARNING	test board PCSS	Tone Detector Circuit Pack

1. Where P is the port network number (1 for PPN, 2 for EPN, and 3 for EPN2); C is the carrier number (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

G1, G3iV1.1-286, and those G3iV2-386 systems that use the Mu-law companding mode use TN748 Tone Detector circuit packs or TN756 combination Tone Detector-Tone-Clock circuit packs. G3iV2-386 systems that use the A-Law companding mode use TN420B (and higher suffixes) Tone Detector circuit packs. The companding mode of the DETR-BD circuit pack must match that administered for the system for proper tone detection. The companding mode is administered on the System-Parameters Country-Options form. Refer to *DEFINITY Communications System Generic 3 Implementation*, 555-230-653.

For all DETR-BD circuit pack level errors, refer to XXX-BD (Common Port Board) Maintenance documentation.

DID-BD (Direct Inward Dial Trunk Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DID-BD	MIN	test board PCSS sh	Direct Inward Dial Trunk Circuit Pack
DID-BD	WRN	test board PCSS sh	Direct Inward Dial Trunk Circuit Pack

1. Where P is the port network number (1 for PPN and 2 or; C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also DID-TRK (DID Trunk) Maintenance documentation for related trunk information.

DID-DS1 (DS1 DID Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DID-DS1	MAJOR ¹	test trunk <grp>/<mbr> l	Direct Inward Dial Trunk
DID-DS1	MINOR	test trunk <grp>/<mbr> l	Direct Inward Dial Trunk
DID-DS1	WARNING	test trunk <grp>/<mbr>	Direct Inward Dial Trunk

1. A major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

The DID-DS1 trunk provides a digital DID trunk from a CO switch into the system through a DS1 link. A 24 channel DS1 link can support up to 24 DID-DS1 trunk calls simultaneously. A 32 channel DS1 link [G3iV2-386] can support up to 30 DID-DS1 trunk calls simultaneously. A DID-DS1 trunk can be used for both voice and data communications with appropriate DS1 signaling mode (for example, common channel signaling). Only the TN767 and TN464 [G3iV2-386] DS1 Interface circuit packs support the DID-DS1 trunk call processing signalings, wink-start, and immediate-start.

DID-DS1 trunk maintenance provides a means to maintain a DID trunk on a port of DS1 Interface circuit pack. Information included covers the in-line errors log, initialization tests, periodic tests, system technician demand tests, and alarms escalation and elimination. Two trunk service states are specified in the DID-DS1 trunk maintenance. They are: *out-of-service*, the trunk is in a deactivated state and can't be used for incoming calls; *in-service*, the trunk is in an activated state and can be used for incoming calls. If the DS1 Interface circuit pack is out-of-service, then all trunks on the DS1 Interface circuit pack are put into out-of-service state and a Warning alarm is raised.

Hardware Error Log Entries and Test to Clear Values

Table 10-128. DID-DS1 Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test trunk <grp>/<mbr> sh r 1
1 (a)	Any				
15 (b)	Any	Port Audit and Update Test (#36)			

Table 10-128. DID-DS1 Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
18 (c)			WARNING	OFF	release trunk <grp>/<mbr>
130 (d)		None	WARNING	ON	test trunk <grp>/<mbr>
257 (e)	57474 57473				
513 (f)	57392	None	MIN/MAJ ²	OFF	
769 (g)	57393	None	MIN/MAJ ²	OFF	
1281		Conference Circuit Test (#7)	MAJ/MIN/ WRN ³	ON	test trunk <grp>/<mbr> I
1537		NPE Crosstalk Test (#6)	MAJ/MIN/ WRN ³	ON	test trunk <grp>/<mbr> I
1793 (h)				ON	test board PCSS I
2305(i)	50944	None	MIN/MAJ ²	OFF	
3840 (j)		Port Audit and Update Test (#36)			

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
3. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

- a. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57476, on-hook before wink; 57477, on-hook before ready to receive digits; 57485, wink too short for valid signal. Escalate the error.
- b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate errors (if any).
- c. System Technician has busied out the trunk to out-of-service state. No calls can be made on this trunk.
- d. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

- e. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57474, rotary dial rate above 12 pulses per second; 57473, rotary dial rate below eight pulses per second. Escalate the error.
- f. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57392, no external release on PBX disconnect. Escalate the error.
- g. DS1 Interface circuit pack detects a hardware error. The Aux Data field contains the Error Type: 57393, belated external release on PBX disconnect. Escalate the error.
- h. DS1 Interface circuit pack is out-of-service. Look for DS1-BD errors in Hardware Error Log. Refer to the DS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details.
- i. Error Type 2305—This error indicates that a signaling change was detected by the PBX trunk circuit pack which is inconsistent with the present state of the trunk.
- j. Port Audit and Update Test (#36) failed due to an internal system error. Enter **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back to in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence..

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Port Audit and Update Test (#36)		X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel

talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-129. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM BUS error. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM Bus errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-129. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 10-129. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The test failed. This can be due to on-board or off-board problems. Off-board problems of concern include EXP-PN and EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-PN and/or EXP-INTF errors in the error log. If present, refer to the EXP-PN and the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD and the TONE-PT Maintenance documentation. 4. Retest when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the llst config command and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Conference Circuit Test (#7)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is

instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passed.

Table 10-130. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions, or it may have time slots out of service due to TDM-BUS errors. Refer to the TDM-BUS (TDM bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic and the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some of the tone detectors may be out of service. Issue the list measurements tone-receiver command to display basic information about the system's tone receivers. 1. Look for TTR-LEV errors in the error log. If present, refer to the TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the error log. If present, refer to the TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at 1 minute intervals for a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

Table 10-130. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a user for a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Issue the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1018	ABORT	The test was disabled via translation. You may want to determine why the test has been disabled before you enable it. 1. Verify that the 'Maintenance Test' field on the 'Trunk Administration' screen is set to 'n'. To enable the test, change the trunk administration and enter 'y' into the 'Maintenance Test' field. 2. Repeat the test.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal, 1793—Blue Alarm, 2049—Red Alarm, 2305—Yellow Alarm, 1537—Hyperactivity. Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Continued on next page

Table 10-130. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port did not conference the tones correctly. This can cause noisy and unreliable connections. 1. Enter the list configuration board UUCSS command. If the circuit pack is a TN767B vintage 8 or 9, replace the circuit pack with a TN767C V3 or later. The error log may have error type 1281. 2. Test all administered trunks on the board. If one fails, this could be an off-board problem (such as an incoming seizure or an off-hook port seizure during the test). Retest the board. 3. If all of the ports fail, check the CARR-POW (see note below). 4. If several ports fail, check the error log for TONE-BD or TONE-PT errors. If there are such errors, take the appropriate action. When the TONE errors have cleared, rerun the test. 5. If the retry passes and troubles have been reported, coordinate isolation with the CO. Make sure that the switch, the CO, and any NTCE equipment (the CSUs) have the correct administration. 6. Replace the circuit pack.  NOTE: If the conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the 'CARR-POW (carrier port power unit for AC-powered systems) Maintenance Documentation'. To investigate problems with a 645B DC power unit, refer to the 'CARR-POW (carrier port power unit for DC-powered systems) Maintenance Documentation'. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.  NOTE: This test always passes for TN712 Analog circuit packs prior to Vintage 14 and for TN742 prior to Vintage 4.

Continued on next page

Table 10-130. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the l1st config command and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

Port Audit and Update Test (#36)

This test sends port level translation data from the switch processor to the DS1 Interface circuit pack to assure that the trunk's translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of the trunk as kept in the DS1 Interface circuit pack and in the switch software.

Table 10-131. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-131. TEST #36 Port Audit and Update Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	The port may be busy with a valid call. Issue the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), check the error log for error type 1025 (see the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
1006	ABORT	The test was aborted because the trunk is out of service. 1. Use the status trunk command to verify that the trunk is out of service. 2. If the trunk is out of service, determine why. 3. If it is OK to put the trunk back in service, issue the release trunk command to put the trunk back in service, and then retry the test. 4. If the test continues to abort, escalate the problem.
2000 2100	ABORT ABORT	Response to the test was not received within the allowable time period. Could not allocate resources to run this test. 1. Retry the command at 1 minute intervals for a maximum of 5 times. If the test continues to abort, escalate the problem
	FAIL	Test failed due to Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter status-command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter release-trunk command to put trunk back into in-service. 3. Retry the test command.

Continued on next page

Table 10-131. TEST #36 Port Audit and Update Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the list config command, and resolve any problems that are found. 2. If the board was found to be correctly inserted in step 1, issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board long command. This should re-establish the linkage between the internal ID and the port. If this is not the case, check to see that there is a valid board inserted.

DID-TRK (DID Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DID-TRK	MAJOR ²	test port PCSSpp l	DID Trunk
DID-TRK	MINOR	test port PCSSpp l	DID Trunk
DID-TRK	WARNING	test port PCSSpp l	DID Trunk

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).
2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

Direct Inward Dial (DID) trunks coming from the Central Office (CO) allow outside parties to call directly to an extension in the system. DID Trunk circuit packs include:

- TN753 [G1, G3iV1.1-286, G3iV2-386]United States
- TN2146 [G3iV2-386]Belgium and the Netherlands
- TN2139 [G3iV2-386]Italy
- TN 436 [G3iV2-386]Australia
- TN459 [G3iV2-386]United Kingdom

The DID Trunk circuit packs support eight, incoming-only, ports. Each port provides an interface between the 2-wire analog line from the CO and the DEFINITY system. The DID port receives 3 to 5 digits from the CO that is used to directly connect an outside caller to the called station without assistance from an attendant. See Figure 10-25.

Figure 10-25. DID Trunk Interactions

For each call, the CO switch signals the system by opening and closing individual DID loops (one of the eight ports) and causing the starting or stopping of loop current.

A DID trunk operation involves three significant aspects:

1. Transmission—deals with the interface requirements regarding all AC signals. Transmission includes gain, analog to digital encoding, and digital to analog decoding.
2. Signaling—involves interpretation of DC signals appearing on Tip and Ring to and from the CO. These signals include off-hook, on-hook, and dial pulse detection.
3. Switch Connection—involves the connection between the trunk circuitry and the TDM Bus of the system. It operates the switchhook connection to the TDM Bus.

Four tests are implemented to diagnose the health of a DID trunk. All of them test on-board circuitry only. They are:

1. Loop Around and Conference Circuit Test—verifies the transmission operation of the circuit pack (loop around within the port), and checks the conference capabilities of all ports.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration Test field. (This also disables the port diagnostic test).

2. NPE Crosstalk Test—verifies the switch connection operation of the circuit pack. The test also verifies that the trunk circuitry only talks on the selected time slot on the TDM Bus and never crosses over to time slots reserved for other connections.
3. Port Diagnostic Test—the battery feed circuitry is tested for hook detection.
4. Port Audit Update Test—updates the DID translation information on individual ports of the DID trunk. The port translation data consists of signaling parameters whose values depend on the CO switch connected to the trunk. These parameters include:
 - wink (signal indicating PBX is ready to receive digits) or immediate start
 - dial tone or rotary dialing trunk
 - rotary dialing inter-digit timing
 - network balance R/RC
 - disconnect timing

Additional in-line testing is performed while a call is in progress. Thus, in-line errors may occur during operation. See Error Log table for a description of these errors. These errors may be reproduced by using the trunk (that is, placing a call) and checking their occurrence in the Hardware Error Log.

Problems detected during signaling may be caused by faults off-board (in the CO switch or connections) for which a Warning alarm is raised.

Before a maintenance test can be run on a port, the port must be idle. If an incoming call seizes the port which is being tested by maintenance, the test is aborted, and the incoming call proceeds.

For transmission and signaling standard specification, refer to Digital PBX Standards document RS4648.

Hardware Error Log Entries and Test to Clear Values

Table 10-132. DID Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
1 (a)	Any	None	WRN	OFF	
1 (b)	57476	None	WRN	OFF	
1 (c)	57477	None	WRN	OFF	
1 (d)	57483	None	WRN	OFF	
15 (e)	Any	Port Audit Update (#36)			
18	0	busyout trunk <grp/mbr>	WRN	OFF	release trunk <grp/mbr>
130 (f)		None	WRN	ON	test trunk <grp>/<mbr>
257 (g)	57472	None	WRN	OFF	
257 (h)	57473	None	WRN	OFF	
257 (i)	57474	None	WRN	OFF	
257 (j)	57475	None	WRN	OFF	
513 (k)	57392	None	MAJ/MIN/WRN ²	OFF	
510 (l)	57393	None			
769	Any	Port Diagnostic (#35)	MAJ/MIN/WRN ²	ON	test port PCSSpp r 3

Table 10-132. DID Trunk Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
1025		Loop Around and Conference (#33)	MAJ/MIN/ WRN ²	ON	test port PCSSpp r 3
1281		NPE Crosstalk (#6)	MAJ/MIN/ WRN ²	ON	test port PCSSpp r 3
1537	Any	Port Diagnostic (#35)	MAJ/MIN/ WRN ²	OFF	test port PCSSpp r 3
1793 (m)	57489	None	None		

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

A common trouble on DID trunks, which reports no errors or alarms, occurs when the CO busies out the port (disconnects port). This situation occurs when the CO thinks there are problems with the DID port. In this case, no incoming calls are possible through this port. In addition to complaints received from outside callers trying unsuccessfully to call in, this problem can be diagnosed by listing measurements on lightly used trunks. If a particular port is detected as not in use, a call to the CO is necessary to get the connection back in service.

- a. This condition occurs when the tone detector times out waiting for digits.
 - 1 – Verify trunk administered wink/immediate-start parameter.
 - 2 – Verify the dial type.
 - 3 – Refer problem to the CO.
- b. Rotary dial before wink – This condition occurs when the CO starts dialing before the PBX sends wink on a wink-start trunk.
 - 1 – Verify trunk administered wink/immediate-start parameter.
 - 2 – Refer problem to CO.
- c. Rotary dial too early – This condition occurs when the CO starts dialing too soon after seizure on an immediate-start trunk.
 - 1 – Verify trunk administered wink/immediate-start parameter.
 - 2 – Refer problem to CO.
- d. Rotary dial pulse during wink – This condition occurs when the CO sends rotary dial digits too soon after seizure on a wink-start trunk.

- 1 – Verify trunk administered wink/immediate-start parameter.
- 2 – Refer problem to CO.
- e. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).
- f. This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- g. Rotary dial pulse on-hook longer than 105 msec – Break between rotary pulses is too long.
 - 1 – Test trunk by performing an incoming test call.
 - 2 – Refer problem to CO.
- h. Rotary dial rate below eight pulses/sec – More than 135 msec between two successive breaks.
 - 1 – Verify trunk administered interdigit-timing parameters.
 - 2 – Refer problem to CO.
- i. Rotary dial rate above 12 pulses/sec – Less than 75 msec between two successive breaks.
 - 1 – Verify trunk administered interdigit-timing parameters.
 - 2 – Refer problem to CO.
- j. Digit detection – Co is starting new rotary dial digit within 150 msec of previous digit.
 - 1 – Verify trunk administered interdigit timing parameters.
 - 2 – Refer problem to CO.
- k. Loop current active – CO not releasing trunk after PBX disconnect. Occurs when the PBX end drops first and the CO does not release the trunk within four minutes.
 - 1 – Verify the interface to the network with a hand telephone set. If calls are placed correctly, then refer problem to the CO.
 - 2 – If unable to place calls or this equipment is not available, check the status on port using the **status trunk** command. If active but not connected, disconnect bridging clips at the network interface. Check status on the trunk. If trunk went idle, then replace clips. If trunk is still active but unable to place calls, refer problem to the CO.
- l. Late CO trunk release – This event only happens after the occurrence of Error Type 513. The CO released the trunk four minutes after the PBX dropped the call. This event decrements the severity (error count) of Error Type 513, or may mean the problem related to Error Type 513 has been fixed.
 - 1 – Verify that Error Type 513 does not occur again. Refer to Error 513.

- m. Incomplete Dial timer expired. This error applies only to the TN459.
Problem with incoming dialing stream. Refer problem to the CO.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *DID-TRK Loop Around and Conference Circuit Test*, for example, you may also clear errors generated from subsequent tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Port Diagnostic Test (#35)	X	X	ND
Loop Around and Conference Circuit Test (#33)		X	ND
Port Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-133. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-133. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension, attendant number, or trunk group/member number of the port. Use the status station, status attendant, or status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is active but the port is not in use (no calls), then check the Error Log for Error Type 513 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.

Table 10-133. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension, attendant number, or trunk group/member number of the port. Use the status station, status attendant, or status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	This test can fail due to on-board or off-board problems. Off-board problems of concern include EXP-INTF faults, TDM-BUS faults, and faults associated with the tone detectors/tone generators. Clear all off-board problems before replacing the board. Keep in mind that a TDM-BUS problem is usually the result of a faulty board connected to the backplane or bent pins on the backplane. 1. Look for EXP-INTF errors in the error log. If present, refer to the EXP-INTF Maintenance documentation. 2. Look for TDM-BUS errors in the error log. If present, refer to the TDM-BUS Maintenance documentation. 3. Look for TONE-BD and/or TONE-PT errors in the error log. If present, refer to the TONE-BD Maintenance documentation and the TONE-PT Maintenance documentation. 4. Test the board when the faults from steps 1, 2, and 3 are cleared. Replace the board only if the test fails..
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and by examining station, trunk, or external wiring.

Continued on next page

Table 10-133. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective and non-reflective loop around and conference capabilities of a DID port circuit. The test that uses 404-Hz, 1004-Hz, and 2804-Hz tones is an on-board test only. Each tone is separately transmitted to and from the port (loop around within the port) and verified.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration Test field. (This also disables the port diagnostic test.

Table 10-134. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. This could be due to a failure to seize the port. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-134. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension, attendant number, or trunk group/member number of the port. Use the status station, status attendant, or status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is active but the port is not in use (no calls), check the Error Log for Error Type 513 (see Error Log table for description of this error and required actions). The port may be locked up. 2. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 3. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension, attendant number, or trunk group/member number of the port. Use the status station, status attendant, or status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook), if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via administration. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the change trunk-group x command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-134. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
2100	ABORT	System resources required to run this test are not available. This may be due to the port being seized. 1. This abort code is usually associated with tone-clock (TONE-BD, TONE-PT, and TDM-CLK) resources. First, clear any tone errors in the error log. 2. Retry the command at 1 minute intervals for a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
3	FAIL	The nonreflective 1004 Hz tone test of the port failed. An echo was detected from the port. Poor quality transmission was detected to or from the port. The problem may be off-board.
7		The conference capabilities of the port failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
129		The reflective 404-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
131		The reflective 1004-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.
133		The reflective 2804-Hz tone test failed. Poor quality transmission was detected to or from the port. The problem may be off-board.  CAUTION: <i>The port may still be operational, or the fault may be off-board (connections or CO). Off-board problems also include incoming seizures or off-hook port seizures during the test and, perhaps somewhat unlikely, noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company to temporarily alleviate the alarm caused by the failure of this test. The test may be disabled from trunk administration 'Test' field. This turns off all testing for that trunk group except for tests 6 and 36.</i> <i>More information continues on the next page.</i>

Continued on next page

Table 10-134. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
3 7 129 131 133 (cont'd.)	FAIL (cont'd.)	FAULT ISOLATION: Proceed as follows unless power or tone problems are suspected (see note below). 1. To make sure the problem is on-board, disconnect the port from the far-end and retry the test. Coordinate this with the CO, or do it after busy hours. 2. If the retry fails, replace the circuit pack. 3. If the retry passes and no troubles have been reported, disable the test in the trunk group administration. If the retry passes and troubles have been reported, coordinate isolation with the CO.  NOTE: If the loop around and conference circuit test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with a 631DB AC power unit, refer to the CARR-POW (carrier port power unit for AC-powered systems) Maintenance documentation. To investigate problems with a 645B DC power unit, refer to the CARR-POW (carrier port power unit for DC-powered systems) Maintenance documentation. If a red LED on TN736 or TN752 power unit circuit pack is on, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors, take appropriate actions. When the tone errors are cleared, rerun the test. If the test fails again, see 'FAULT ISOLATION' above.
	PASS	DID Trunk Loop Around and Conference Test is successful. This port is functioning properly. 1. If users are reporting troubles, examine loop connections to the port and refer problem to the CO.

Continued on next page

Table 10-134. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

Port Diagnostic Test (#35)

This test checks a port’s battery feed circuitry. The battery feed circuitry is tested for on-/off-hook detection, battery shutdown, and battery reversal (WINK) capabilities.

Table 10-135. TEST #35 Port Diagnostic Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required to run this test were not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-135. TEST #35 Port Diagnostic Test — Continued

Error Code	Test Result	Description/ Recommendation
1000	ABORT	System resources required to run this test were not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. You must wait until the port is idle before retesting. 1. If the port status is active but the port is not in use (no calls), then check the error log for error type 513 (refer to the Error Log table for a description of this error and required actions). The port may be locked up. 2. If the port status is idle, busyout and release the trunk, and then retry the command at 1-minute intervals for a maximum of 5 times. 3. If the test continues to abort, check for wiring errors toward the CO which may cause the trunk to lock up. 4. If the wiring is OK and the test continues to abort, replace the TN753.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the station extension, attendant number, or trunk group/member number of the port. Use the status station, status attendant, or status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test has been disabled by trunk group administration. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the change trunk-group x command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 10-135. TEST #35 Port Diagnostic Test — Continued

Error Code	Test Result	Description/ Recommendation
61446	FAIL	Battery feed test failed. A loop current fault was detected. This is most probably an incoming CO-line problem. This failure code is only reported by the TN2139 Italian DID circuit pack. 1. Check the incoming CO-line for loop current. If none is detected refer the problem to the CO. 2. If the CO-line checks out OK, the failure must be on the DID port. Replace the circuit pack.
61456	FAIL	Battery feed test failed. An on-board problem was detected. This port is out-of-service. 1. Replace circuit pack.
61472	FAIL	Battery feed test failed. A problem with the incoming CO-line was detected. 1. Check the incoming CO-line for proper operation. If warranted, refer the problem to the CO. 2. If the CO-line checks out OK, the failure must be on the DID port. Replace the circuit pack.
	PASS	Current flow was detected for this port. 1. User-reported troubles on this port should be investigated using other port tests and by examining connections. 2. Refer problem to the CO.
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

Port Audit Update Test (#36)

This test sends updates of the DID port translation for all ports on the circuit pack that have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation

updates. The port translation data includes: wink or immediate start trunk, dial tone or rotary dialing trunk, rotary dialing inter-digit timing, Network balance R/RC, and disconnect timing.

Table 10-136. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1006	ABORT	The port has been placed out of service, perhaps by craft busyout. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is out of service, then the port is unavailable for certain tests. You must wait until the port is in service and idle before retesting. 1. If the port status is in service and idle, then retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT FAIL	Could not allocate the necessary system resources to run the test. Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. 1. If signaling troubles are reported (Error Types 1, 257, or 513 in Error Log table), verify translation information for this port. 2. Refer problem to the CO. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter status-command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter release-trunk command to put trunk back into in-service. 3. Retry the test command.

Table 10-136. TEST #36 Port Audit Update Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). 1. Check to ensure that the board translations are correct. Translate the board, if necessary. 2. Issue the busyout board command. 3. Issue the reset board command. 4. Issue the release busy board command. 5. Issue the test board command. This should re-establish the linkage between the internal ID and the port.

DIG-BD (Digital Line Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DIG-BD	MIN	test board PCSS sh	Digital Line Circuit Pack
DIG-BD	WRN	test board PCSS sh	Digital Line Circuit Pack

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.).

Refer to XXX-BD (Common Port Circuit Pack) Maintenance documentation for circuit pack level errors. See also DIG-LINE (Digital Line) Maintenance documentation for related line information.

DIG-LINE (Digital Line)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DIG-LINE	MINOR	test port PCSSpp l	Digital Line
DIG-LINE	WARNING	test port PCSSpp sh	Digital Line

1. Where P is the port network number (1 for PPN and 2 or 3 for EPN); C is the carrier designation (for example, A, B, C, D, or E); SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ..., etc.); and pp is the 2-digit port number (for example, 01).

DIG-LINE maintenance monitors and tests ports on Digital Line circuit packs and the hardware connected to those ports for lines administered as a digital station. These include stations with just a digital voice terminal and stations with a digital voice terminal and a linked data module. Stand-alone data modules, and data adaptors in stand-alone mode, are covered by the PDMODULE and TDMODULE maintenance objects. Circuit pack-level maintenance is covered by DIG-BD whose strategy is described in the XXX-BD section of this chapter. The following circuit packs support digital lines:

Table 10-137. Digital Line Circuit Packs

Code	Ports	Type	Companding	Endpoints
TN413	8	4-wire DCP	A-law	7400 series digital voice terminals, attendant consoles, 510D personal terminals, MT515 BCTs, DCP data modules
TN754	8	4-wire DCP	mu-law	
TN754B	8	4-wire DCP	A-law/mu-law	
TN2181	16	2-wire IDCP	A-law/mu-law	
TN2224	24	2-wire IDCP	A-law/mu-law	
TN2136	8	2-Wire IDCP	A-law/mu-law	Data Adaptors (DA), Italtel Digital Telephone Models 1 and 2 (IDT1/2).
TN2177	16	2-wire IDCP	A-law/mu-law	
TN2181	16	2-wire IDCP	A-law/mu-law	
TN2224	24	2-wire IDCP	A-law/mu-law	

G3r V1 systems support only TN754 and TN754B. TN413 and TN754 are found only in upgraded cabinets.

Each digital line port supports two 64 kbps information channels (primary and secondary) and one 8kbps signaling channel. Digital voice terminals always use the primary information channel. Thus only one voice terminal can be connected to each port. The secondary information channel can be used to connect a data terminal via a Digital Terminal Data Module (DTDM) or a Data Adaptor (DA). All other devices currently supported by Digital Line circuit packs communicate on

the primary information channel. Figure 10-26 shows examples of digital line connectivity.

Only the TN754B or TN2136 should be used in out-of-building applications. For important information pertaining to protection required for out-of-building digital voice terminals, see *DEFINITY Communications System Generic 1 and Generic 3 Installation and Test*, 555-230-104.

It should be noted that TN2181 and TN2224 supports both modes as shown in Figure 10-26 and Figure 10-27.

Figure 10-26. Digital Line Connectivity

Figure 10-27. Digital Line Connectivity

Only 2-wire Italtel Digital Telephone Models 1 and 2 (IDT1/2) or DAs can be directly connected to a TN2136. AT&T DCP (4-wire) digital voice terminals and data modules can be connected to these circuit packs via Italtel's 2/4-wire adapter. DAs can operate in either of two modes which are covered by different maintenance objects:

DA Mode	Administered as:	Endpoint	Maintenance Object
Stand-alone	PDM	Data endpoint only	PDMODULE
Linked	DTDM	IDT1/2 and optional data terminal	DIG-LINE

Digital Line maintenance interacts with Digital Line circuit pack (DIG-BD) maintenance, and results of DIG-LINE testing can be affected by the health of the Digital Line circuit pack. Keep this in mind when investigating reported Digital Line problems.

There are instances where the service state of a station is mentioned. It is helpful to understand what is meant by the different service states that may exist. The

different service states which apply to digital line station are explained as follows.:

Out-of-Service	The port, and thus the station, have been removed from service. Busyouts put the port in the out-of-service state.
Ready-for-Service	The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.
In-Service	The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally. It can also be forced into the in-service state by going off-hook.

Downloading of Terminal Parameters

Programmable Terminals

The following information is presented as background information to help understand how maintenance software interacts with terminal parameter downloading.

Terminal Types:

The following terminals can be downloaded for Definity G3V3 and later versions:

- a. 84xx multibutton digital voice terminals (8403D01A, 8410B, 8410D02A, 8434D01A) with optional expansion module.
- b. 603A1 and 603D1 Callmaster terminals for telemarketing applications.
- c. 302B1 attendant console.

Circuit Packs:

- 1. 8400x, 302B1 Terminals
 - a. TN754 (4-wire, Mu-law)
Minimum usable vintage for 8410D and 8434D terminals - V11
 - b. TN413 (4-wire, A-law)
 - c. TN754B (4-wire, A-law/Mu-law selectable)
 - d. TN2177 (2-wire, 16-port, A-law/Mu-law selectable)
 - e. TN2181 (2-wire, 16-port, A-law/Mu-law selectable)
 - f. TN2224 (2-wire, 24-port, A-law/mu-law selectable)
- 2. 603A1/D1 Terminals

- a. TN754 (4-wire, Mu-law),
- b. TN413 (4-wire, A-law)
- c. TN754B (4-wire, A-law/Mu-law selectable)

Downloadable Terminal Parameters

The following parameters are downloaded to programmable terminals:

Table 10-138. Downloadable Parameters

Parameter	Scope	Terminal
International Flags (A-law/Mu-law, Display Mode, DLI Voltage level)	System level	84xx, 603x, 302B1
Primary Levels (Transmission & Sidetone)	System level	84xx, 603x, 302B1
Adjunct Levels (Transmission & Sidetone)	System level	84xx
Handset Expander Option	System level	84xx
Administrable Options (Speakerphone & Mute Button)	Per-terminal	84xx
Administrable Softkeys	Per-terminal, System level	8410D, 8434D

Nonvolatile Memory

Nonvolatile memory is used to store downloadable parameters in programmable terminals. Therefore, once the terminal has been downloaded, it is not be necessary to download it again, even if power is removed from the terminal.

If the nonvolatile memory fails with power still present, the terminal will revert to its default factory settings except for its A-law/Mu-law companding settings which are stored in RAM. If power is removed after the nonvolatile memory fails, the terminal will revert to its factory default settings.

Mu-law companding is assigned as a default setting at the factory, so, for domestic use, a programmable terminal can place calls even though it has not been downloaded from the PBX.

Download Actions

There are several different scenarios that will cause a terminal to be downloaded. As described below, these can occur as part of background maintenance activity or on demand from the System Access Terminal or from a station.

For the background actions described below, the terminal will be downloaded automatically if a download retry flag for the terminal is set in software. This flag is set at the time translation is loaded at boot time, when translation which affects the parameters of a terminal is changed as part of system administration actions, and when a port is inserted in software as a result of board insertion or translation change.

Automatic Download Actions

1. System Reboot/Restart

A global download action is started when periodic maintenance tests start after a system reboot/restart regardless of whether the parameters have been downloaded previously.

2. Periodic Tests

If the download flag is still set when periodic tests are run on a terminal, a download action will occur. This operation is required in case a terminal could not be downloaded previously because it was off-hook at the time the system first booted or because the terminal was off-hook at the time translation associated with downloadable parameters was changed.

Note that it may take more than an hour for periodic tests to reach the terminal that needs to be downloaded.

3. Terminal Administration

A downloadable terminal is automatically downloaded when translation changes associated with downloadable parameters are made as part of system administration. As shown in Table 10-128, these changes can be for a specified terminal or may be system-wide. If the change is for system-level parameter, a background global update request is made to download all programmable terminals.

This global update may take more than an hour for a system with several thousand programmable terminals.

4. Port Insertion

Whenever maintenance software initiates a request to place a port into service, a terminal download action is started on that terminal if that terminal is programmable. This port insertion action occurs under the following circumstances:

- a. A digital line circuit pack that is physically inserted into the system has ports currently administered for programmable terminals.

If more than 20 port insertion requests are received within a few seconds, a global download request is started up as a background task. This action updates all programmable terminals instead of just those being inserted. This is done to avoid system overload for situations where there is massive board insertion. This could occur when connectivity to an EPN is reestablished after that EPN was down.

- b. A station port is added to the system by a **"add station"** or **"change station"** command.
 - c. A TTI port is activated.
- 5. Audits

As part of periodic maintenance, the hardware status audit test queries programmable terminals to determine which levels and/or options are being used. If the reported values are not equal to the administered values, the system will initiate a terminal download action. This audit does NOT check the parameters used for softkeys.

6. Activation of TTI

A terminal is downloaded automatically when it is activated using the Terminal Translation Initialization feature. Therefore, no special user actions are required for TTI.

 NOTE:

Plugging the station cord into a terminal does not automatically cause the terminal to be downloaded. If this terminal has factory defaults or if the terminal has been previously downloaded with parameters different than those desired, use one of the demand download actions described below to download the terminal.

Demand Download Actions

1. Busyout/Release Command

A maintenance demand busyout/release request for a station will cause the terminal to be downloaded regardless of its previous download status.

2. Feature Access Code

A Refresh Terminal Parameters Feature Access Code can be used to request a terminal download action. When this code is followed by a "#", the programmable parameters for the current terminal are downloaded when the terminal goes on hook. When this code is followed by an extension, the programmable parameters for the specified station are downloaded.

This Refresh Terminal Parameters Feature Access Code is assigned on the second page of the "feature-access-codes" screen.

A confirmation is returned if the download request is accepted. A busy tone is returned if the request is made from a different station when the target station is off-hook.

The first three green call appearance LEDs on the 84xx 603x terminal will be turned on for three seconds if the station was successfully downloaded as a result of an entry of a Refresh Terminal Parameters Facility Access Code. This is not true for the 302B1 terminal.

There is no visible display on a station for the other background or demand download actions. As described below, the "status station" and "status attendant" screens can be used to check the download status of a specified terminal.

Status of Parameter Downloads

The "status station" and "status attendant" screens display the current download status of individual 84xx, 603, and 301B1 terminals in the Download Status field. The possible download states are:

Table 10-139. Terminal Download Status

Status	Terminal Down Load State
Complete	Terminal successfully downloaded sometime in the past.
Pending	System waiting to download the terminal. This may require the execution of a background periodic test which could take more than an hour. A demand download as described above may also be used to initiate an immediate download.
Not Applicable	Not a programmable terminal.

Possible reasons for terminal being not downloaded include:

- Terminal is off-hook.
- Terminal detected a bad checksum.
- Terminal detected a bad or missing EEPROM (refer to hardware error log).
- Terminal is busy programming data from a previous PROGRAM message.
- Terminal is in the Programming Disabled state.
- Terminal is in the Local Program Options Mode.
- Terminal is disconnected or out of service (use **status station** command).

Hardware Error Log Entries and Test to Clear Values

3840 (l)	40989	None			
3841 (m)	41029	None			

-
- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
 - Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.
 - Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

-
- a. Could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of

wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

- b. This Error Type and Aux Data will occur when at least 15 off-board problems have been detected with the link to the terminal. When an error with the link is detected, an on-board counter is incremented.

The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.

- c. This error type is logged when the port in question is busied out by maintenance personnel. Make sure port is released from busyout via the **release port PCSSpp** command.
- d. This error type indicates that the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.
- e. Problems transmitting to the voice terminal. This problem can be caused by defective wiring. Defective wiring can cause varying degrees of problems on different types of sets. Sets such as the 7410 appear to be more susceptible to wiring problems than other sets. This is usually an on-board problem and can be ignored if no user complaints are received.
- f. This is an in-line event that produces this error type when a favorable response is received from running the Digital Line Electronic Power Feed Test (#11). No craft action is necessary. This alarm will be resolved with the passing of time.
- g. With Aux Data 40963, this error type is a result of an unfavorable response to the Electronic Power Feed/ Positive Temperature Coefficient Test (#11). With Aux Data 40988, this error type indicates that the EPF/PTC circuit has been turned off due to an overcurrent condition.

For TN754 vintage 13 or earlier and TN413, the EPF circuit senses an overcurrent condition at the voice terminal. Check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

For TN754 vintage 14 or later, TN754B and TN2136, the PTC will open if there is a short on the power line for 1/2 second or longer. The voice terminal is probably not operating properly. Unplug the voice terminal for 30 seconds and then plug it back in. If the voice terminal still does not operate, then check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

Once the problem has been resolved, it may take up to 1 hour for the alarm to clear due to "leaky bucket" strategy. If the problem cannot be resolved by one of the steps above, then replace the circuit pack.

- h. An in-line maintenance error has generated an off-board warning due to some problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.
- i. This indicates that the station went off-hook while it was in the ready-for-service state. Use the **status station** command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No craft action is necessary.
- j. This is the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No craft action is necessary.
- k. No terminal is connected to the Digital Line board. No maintenance action is required.
- l. An uplink message has been logged indicating that the Electric Power Feed (EPF) is on with no load on it. No action is necessary.
- m. The circuit pack's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.
- n. Internal system error. No action is necessary.
- o. There is a problem with the voice terminal EEPROM. When the voice terminal is repaired the alarm will be resolved with the passing of time.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order presented in the table below when inspecting errors in the system. By clearing error codes associated with the *Voice and Control Channel Local Loop Around Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Table 10-141. System Technician-Demanded Tests: DIG-LINE

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Digital Terminal Remote Loop Around Test (#1201)		X	D
Voice and Control Channel Local Loop Around Test (#13)		X	ND
Digital Line NPE Crosstalk Test (#9)		X	ND

Table 10-141. System Technician-Demanded Tests: DIG-LINE — Continued

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Digital Line Electronic Power Feed Test (#11)		X	ND
DIG-LINE Station Lamp Updates Test (#16)	X	X	ND
Station (Digital) Audits Test (#17)	X	X	ND

1. D = Destructive, ND = Non-destructive

Digital Terminal Remote Loop Around Test (#1201)

This test checks the integrity of the connection between the SPE and the attached Digital Terminal and the ability of the terminal and the associated port to send and receive data. This test is based, in principal, on procedure 622 used in system 85 to help isolate digital terminal problems.

A request is presented to the terminal to go into loop back mode. Then data is sent to the terminal and when received back, checked for consistency. This test is run as a part of the craft command "test long" procedure. It is not included in any error recovery strategy and generates no Error Log entries or alarms. To begin the test, Maintenance will ask Call Processing to make the associated end point and port "Maintenance Busy". This test will succeed if the endpoint is "idle". If the reserve request fails then the test will abort. If the request succeeds then the SPE sends a message to loop around both information channels for the digital terminal. First the primary information (voice, Information Channel 1 or I1) channel loop back test is run. The test is performed by sending a digital count from the Tone/Clock circuit pack on the primary information channel time slot and receiving the same digital count with a general purpose tone detector.

If the primary information channel test is successful, the loop around test for the secondary information (data, Information Channel 2 or I2) channel is then performed. This test is the same as the primary information channel loop around test and is performed only if a DTDM is administered, which is also the case for a linked DA.

Only one value (Pass, Fail, or Abort) is generated as a result of the two tests run. If any test fails aborts, the sequence is stopped. Upon completion of this test the associated endpoint and port are moved back into the previous service state.

Table 10-142. TEST #1201 Digital Terminal Remote Loop Around Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain test. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before re-testing. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM-Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out of service. 1. Look for TTR-LEV errors in the Error Log. If present refer to TTR-LEV (TTR-Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exist, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-142. TEST #1201 Digital Terminal Remote Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display portPCSSpp command to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain test. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before resetting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1005	ABORT	The installed circuit pack does not support this operation.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	System resources required to run this test are not available. 1. Make sure terminal is connected and repeat test. 2. If the test continues to abort, escalate the problem. 3. If test fails replace terminal and repeat test. 4. Retry the command at 1-minute intervals a maximum of 5 times.
14	FAIL	The primary channel (voice, Information Channel 1 or I1) is not operating properly. User impact may range from noticing nothing to not being able to use the port. Check the results of Voice and Control Channel Local Loop Test (#13). If that test fails, suspect the Digital Line circuit pack. If that test passes then replace the terminal. If both tests fail and component replacement does not change the results, then: 1. Run circuit pack tests to check the tone generator circuit pack and the Tone Detector circuit pack using the test board PCSSpp command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit pack are functioning properly, and the tests still fail, escalate the problem.

Continued on next page

Table 10-142. TEST #1201 Digital Terminal Remote Loop Around Test — Continued

Error Code	Test Result	Description/ Recommendation
1015	ABORT	The system will not allow this test to be run because the station is/has not been busied out. Busy out the station with the busyout station command.
16	FAIL	The secondary channel (data Information Channel 2 or I2 is not operating properly. User impact may range from noticing nothing to not being able to use this terminal. Check the results of Voice and Control Channel Local Loop Test (#13). If that test fails, suspect the Digital Line circuit pack. If that test passes then replace the terminal. If both test fail, and component replacement does not change the results, then: 1. Run circuit pack tests to check the tone generator circuit pack and the Tone Detector circuit pack using the test board PCSSpp command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit pack are functioning properly, and the tests still fail, escalate the problem.
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of ten times to make sure it continues to pass. 2. If complaints persist (noisy connections for voice. corrupted data transfer for data), examine the station, connections, and wiring.

Digital Line NPE Crosstalk Test (#9)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete. Crosstalk testing is performed on both the primary information channel (voice) and the secondary information channel (data) associated with each digital station port. If this test fails on either channel, the station and the DTDM are taken out-of-service.

Table 10-143. TEST #9 Digital Line NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	During testing of the primary information channel, system resources may not have been available. Also, the port may have been busy during the test. 1. Check the port status. Use the display port PCSSpp command to determine the station extension of the port. Use the status station command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for this test. You will have to wait until the port is idle. 2. If the port status is idle, then retry the command a 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
2	ABORT	During testing of DTDm, system resources may not have been available. Also, the port may have been busy during the test. 1. Check if port is being used. If possible, disconnect by toggling disconnect button on DTDm. Retry command after 1 minute.  WARNING: <i>This action will drop the call in progress.</i> 2. If the test continues to abort after 5 attempts, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use display port PCSSpp to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-143. TEST #9 Digital Line NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use display port PCSSpp to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out.
1020	ABORT	Test disabled via background testing. Use status station command to determine when station is available for testing.
2000	ABORT	Response to the test request was not received within the allowable time period. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1 2	FAIL	The Network Processing Element (NPE) of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. Failure code 1 indicates that the Crosstalk test failed on the primary channel. Failure code 2 indicates that the Crosstalk test failed on the secondary channel. 1. Replace circuit pack.

Table 10-143. TEST #9 Digital Line NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
	PASS	The port is correctly using its allocated time slots. - To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. - If complaints persist, examine the station, connections, and wiring.

Continued on next page

Digital Line Electronic Power Feed/Positive Temperature Coefficient/PPF Test(#11)

For TN413, and TN754 vintage 13 or earlier, this is an Electronic Power Feed (EPF) restoral test. In this test, the processor requests that the EPF be turned on for a given port, and an attempt is made to turn on the power supply to the station. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed, there may be a short in the loop. A message is returned reporting that either the EPF was successfully turned on, or that an overcurrent condition was sensed. This test is repeated again 5 seconds later.

For TN754 vintage 14 or later, TN754B and TN2136 this is a Positive Temperature Coefficient (PTC) restoral test. In this test, the processor requests that the PTC be turned on for a given port, and an attempt is made to turn on the power supply to the station. If an overcurrent condition is sensed, there is probably a short on the power line that causing the PTC to open and disconnect the voice terminal. Since the PTC does not have self-restoral capability, the voice terminal must be manually unplugged for 30 seconds and then plugged back in to restore the PTC. A message is returned reporting that either the PTC was successfully turned on successfully with no problem or an overcurrent condition was sensed. This test is repeated again 5 seconds later.

TN2181 and TN2224 boards carry a Protected Power Feed (PPF) relays, one for each port. Therefore this will be a Protected Power Feed restoral test. The test procedure and its response is same as that of EPF. One of differences between EFP and PPF is that, if the port goes into a overcurrent state, PPF does not report this change of state because it is a transient state which will not last more than 50ms. If the over current persists the power will be shut off automatically and an EPF_off_overcurrent message is sent uplink.

Table 10-144. TEST #11 Digital Line Electronic Power Feed Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use display port PCSSpp to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	Electronic Power Feed Test passed. The message to turn on the power to the station was successfully sent to the port. 1. Although this test will never actually return a FAIL result except for the Internal System Error (naught/FAIL) described above, it will log an error indicating the real results of the test. Check the Error Log for any entries with Error Types 767 or 769 after the test completes. 2. If Error Type 767 appears in the Error Log, this should indicate that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that all the feature buttons are operating. 3. If Error Type 769 appears in the Error Log, this indicates some problem with the power to the station. Check for a short in the wiring, a damaged jack, a defective voice terminal, or an incorrect type of terminal.

Voice and Control Channel Local Loop Test (#13)

These tests check the information and control channels between the Switch Processing Element (SPE) and the Digital Line port circuit. The SPE sends a message to loop around both the information and control channels for the port.

First, the primary information (voice) channel loop back test is run. The test is performed by sending a digital count from the Tone-Clock circuit pack on the primary information channel time slot and receiving the same digital count with a general purpose Tone Detector.

While the primary information channel is still looped around, the Control Channel Loop Around Test is performed. This test consists of sending four different transparent patterns to the on-board microprocessor, receiving them back, and comparing them.

The Loop Around Test for the secondary information (data) channel is then performed. This test is the same as the primary information channel loop around test and is performed only if a DTDM is administered.

A Conference Test is done next for the primary information channel. This test is the same as Conference Test #6.

Only one value (Pass, Fail, or Abort) is generated as a result of four tests run. If any test fails or aborts, the sequence is stopped.

Table 10-145. TEST #13 Voice and Control Channel Local Loop Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use display port PCSSpp to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	System resources required to run this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Table 10-145. TEST #13 Voice and Control Channel Local Loop Test — Continued

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use display port PCSSpp to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort and the port is not in use, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Rerun the test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-145. TEST #13 Voice and Control Channel Local Loop Test — Continued

Error Code	Test Result	Description/ Recommendation
7	FAIL	Conference Test failed on primary channel. In some cases, users may not notice disruption in service. In extreme cases, conferencing feature may not work at all.
14	FAIL	The primary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port.
15	FAIL	The control channel between the processor and digital circuit pack is not transmitting properly. User impact may range from noticing nothing to not being able to use the port. Could also be disruptive to other users.
16	FAIL	The secondary voice channel is not transmitting properly. User impact may range from noticing nothing to not being able to use this port. 1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack using the test board PCSSpp command. 2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack. 3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the Digital Line circuit pack.
	PASS	Voice and Control Channel Local Loop test passed. All channels are transmitting properly. 1. To be sure that this is not an intermittent problem, repeat this test up to a maximum of 10 times to make sure it continues to pass. 2. If complaints persist (noisy connections for voice, corrupted data for data transfer), examine the station, connections, and wiring.

DIG-LINE Station Lamp Updates Test (#16)

This test lights all lamps on the terminal as specified. The lamp updates will run only if the station is in-service. The status of the station is checked and the lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

Table 10-146. TEST #16 DIG-LINE Station Lamp Updates Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, then release the port via the release station <extension> command and run the test again. 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
3	ABORT	Station may be in ready-for-service or out-of-service state. 1. Use status station command to verify state of station. 2. Make sure the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use display port PCSSpp to determine the station extension or attendant number of the port. Use status station or status attendant to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (See Chapter 10, "Maintenance Commands and Trouble-Clearing Aids", for a full description of all possible states.) You must wait until the port is idle before retesting. Attendants are always in use (off-hook) if the handset is plugged in and the port is not busied out. 1. If the port status is idle, then retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the display port command (the display shows that the port is a TTI port) or the list config command (the display shows a t for the port). 2. If either list config or display port indicates that the port is <i>not</i> a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.

Continued on next page

Table 10-146. TEST #16 DIG-LINE Station Lamp Updates Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
	PASS	The message to light all of the station lamps was sent successfully to the port. 1. Observe the station lamps being lit when running the test. If all lamps do not light successfully, the other Digital Line test results may indicate related problems that will not allow the lamps to light. 2. Investigate by using other Digital Line port tests, and by examining the station, wiring, and connections.

Digital Station Audits Test (#17)

This is a series of six tests which are classified as audits. The SPE sends messages to the on-board microprocessor to perform the following tests. These audits run only if the station is in-service.

- Switchhook Inquiry Test — This is an update of the SPE records according to the circuit pack's records. This inquiry is sent all the way to the voice terminal.
- Bad Scan Inquiry Test — A message is sent uplink which contains a count that is generated due to certain events relating to the link conditions. This can be an indication of communications problems between the Processor and Digital Port circuit pack.
- EPF/PTC Inquiry Test — For a TN413 or a TN754 vintage 13 or earlier, the status of the Electronic Power Feed (EPF) is sent uplink. Possible conditions are: EPF-on-ok, EPF-off, and EPF-no-load. For TN754 vintage 14 or later, TN754B or TN2136, TN2181, TN2224, the status of the Positive Temperature Coefficient (PTC) is sent uplink. Possible conditions are: PTC-on-ok, PTC-off, and PTC-no-load.
- ID Request Test — A request is made to the station for its status. The station sends its configuration information and health information back. This information is checked and a pass/fail result is provided.
- Ringer Update Test — This updates the digital telephone ringer state according to the processor records.

- DTMF Administration Update Test — This is a message to the digital station to refresh the default value which causes the station to send touch-tones only in the primary information channel. This value is set initially when the station is put in-service and every time the station's state changes from other states to in-service.

Table 10-147. TEST #17 Station (Digital) Audits Test

Error Code	Test Result	Description/ Recommendation
1	ABORT	Switchhook audit timed out.
2	ABORT	ID request fails, health bit returned from voice terminal is bad. 1. Make sure voice terminal is connected and repeat test. 2. If test fails, replace voice terminal and repeat test. 3. If the test continues to abort, escalate the problem.
3	ABORT	The EPF/PTC has detected an overcurrent condition. 1. For a TN754 vintage 13 or earlier Digital Line circuit pack, issue the test PCSSpp long command. If Test #11 passes, then the EPF/PTC condition has been cleared. Rerun the Short Test Sequence. If Test #11 does not pass, follow the repair procedures described for Test #11. 2. Look for Error Type 769 logged against DIG-LINE and follow the procedures in the associated footnote. If any additional problems are found after completion of maintenance procedures, rerun the test. 3. If the test continues to abort, escalate the problem.
4	ABORT	Internal System Error 1. Resolve any outstanding circuit pack maintenance problems. 2. Retry the command at 1-minute intervals a maximum of 5 times. 3. If the test continues to abort, escalate the problem.
5	ABORT	Ringer update aborted due to station being in ready-for-service or out-of-service state.
6	ABORT	This port may have been busied out by system technician. 1. Look in the Error Log for Error Type 18 (port busied out) for this port. If this error type is present, the release the port via the release station 2. Make sure that the terminal is connected. 3. Retry the command at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available.

Table 10-147. TEST #17 Station (Digital) Audits Test — Continued

Error Code	Test Result	Description/ Recommendation
1392	ABORT	This port is currently a TTI port and the test will not execute on it. 1. Verify that the port is a TTI port using either the display port command (the display shows that the port is a TTI port) or the list config command (the display shows a t for the port). 2. If either list config or display port indicate that the port is <i>not</i> a TTI port, escalate the problem. If both commands indicate that the port is a TTI port, the abort is correct, and no action is necessary.
2000	ABORT	Response to the test request was not received within the allowable time period.
	FAIL	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to fail, escalate the problem.
	PASS	Station Audits passed. This Digital Port circuit pack is functioning properly. 1. If complaints persist, investigate by using other port tests, and by examining the station, wiring, and connections.

DIOD-DS1 (DS1 DIOD Trunk)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DIOD-DS1	MAJOR ¹	test trunk <i>group# member# l</i>	DS1 DIOD Trunk
DIOD-DS1	MINOR	test trunk <i>group# member# l</i>	DS1 DIOD Trunk
DIOD-DS1	WARNING	test trunk <i>group# member#</i>	DS1 DIOD Trunk

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed. For more information on the **set options** command, see Chapter 10, "Maintenance Commands and Trouble-Clearing Aids".

 **NOTE:**

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far-end. Refer to *DEFINITY Communications System Generic 3 V2 Implementation*, 555-230-653, for information on how to administer trunks. The Application Notes section of that book shows the correct settings for administrable timers and other parameters on a country-by-country basis.

A DS1 DIOD trunk provides a link for digitized voice or data communications between the system and a central office switch. There are two types of DS1 interfaces:

- 24 DS0 channels on a 1.544 Mbps link
- 31 DS0 channels + 1 framing channel on a 2.048 Mbps link
- 32-channel mode is supported only on TN464 circuit packs and on G3r V2 systems.

The DS1-DIOD maintenance object monitors and maintains a DIOD trunk port on a TN464 UDS1 Interface circuit pack. See UDS1-BD in this chapter for more information about this circuit pack. The DS1 circuit pack supports low level CO trunk signaling interfaces for both ground-start and loop-start trunks. This maintenance strategy covers the in-line errors log, initialization tests, periodic tests, scheduled tests, demand tests, and alarm resolution and escalation.

Three trunk service states are specified by DS1 DIOD trunk maintenance:

- out-of-service

The trunk is in a deactivated state and cannot be used for either incoming or outgoing calls.
- in-service

The trunk is in an activated state and can be used for both incoming and outgoing calls.
- disconnect (ready-for-service)

The trunk is in an activated state but can only be used for an incoming call.

2305(k)	50944				
2562(l)	16665				
2817(m)	52992				
3840(n)		Port Audit and Update Test (#36)			

- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- This alarm will only be raised when the System-Parameter Country form has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
- Major alarms on this MO may be downgraded to Warning alarms based on the value used in the set options command.

Notes:

- Error Type 1—Aux Data 57408—No tip ground is detected on an outgoing call.

Aux Data 57476—Rotary Dial before Wink.

Aux Data 57477—Rotary Dial pulse too early.

Aux Data 57485—Wink too short for a valid signal.

Aux Data 57487—PBX could not get “loop close” signal

The DS1 Interface circuit pack detected a hardware fault. These errors will cause the Dial Tone Test (#314) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in the ready-for-service state (shown as “disconnected” by the status command), which allows only incoming calls. Run the Dial Tone Test (#314) and follow the procedures.
- Error Type 15—This is a software audit error that does not indicate any hardware malfunction. Run Short Test Sequence and investigate associated errors (if any).
- Error Type 18—System Technician has busied out the trunk to the out-of-service state. No calls can be made on this trunk except the Facility Access Test Call. For details on this feature, refer to "Facility Test Calls" section in Chapter 5, "Routine Maintenance Procedures".

- d. Error Type 130—This error type indicates that the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. Error Type 257—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57392 indicates no external release on PBX disconnect. Escalate the problem.
- f. Error Type 513—The DS1 Interface circuit pack detects a hardware fault. Aux Data 57393 indicates belated external release on PBX disconnect. Escalate the problem.
- g. Error Type 769—The DS1 Interface circuit pack detects a hardware fault. The Aux Data field contains the following error type:—57484, fault is detected on tip/ring. Escalate the error.
- h. The DS1Interface circuit pack detects a hardware fault, and the Aux Data field contains the following error type: 51200, port is unavailable. Run the Dial Tone Test (#314) and follow procedures.
- i. Error Type 1793—DS1 Interface circuit pack is out-of-service. Look for UDS1-BD errors in the Hardware Error Log if the port is on a TN464 UDS1 board. Refer to the UDS1-BD (DS1 Trunk Circuit Pack) Maintenance documentation for details
- j. Error Type 2049—With the following Aux Data:
 - Aux Data 57473—Rotary dial rate below 8 pulses per second.
 - Aux Data 57474—Rotary dial rate above 12 pulses per second.
 - Aux Data 57475—Rotary Dial interdigit time is too short.

The DS1 interface circuit pack detects a hardware error on the DS1 DIOD trunk. The trunk can not communicate with the far-end because it is unable to interpret digits sent from the far-end switch. Check with the far-end switch or Operating Company for proper trunk connection.

- k. Error Type 2305—Recorder message, trunk could not be seized (Aux Data 50944). Run Test #314 and follow the outlined procedures.
- l. Error Type 2562—Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- m. Error Type 2817—Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a two-way trunk from both the near-end and the far-end. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure Test (#314) and follow those procedures.

- n. Error Type 3840—Port Audit and Update Test (#36) failed due to an internal system error. Enter the **status trunk** command to verify the status of the trunk. If the trunk is out-of-service, then enter the **release trunk** command to put it back into in-service. Retry the test command. If the test continues to abort, then escalate the problem.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 Dial Tone Test (#314)	X	X	ND
Port Audit and Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

NPE Crosstalk Test (#6)

One or more Network Processing Elements (NPEs) resides on each circuit pack with a TDM Bus interface. (The TN464 UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips.) The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is usually only part of a port's Long Test Sequence and takes about 20 to 30 seconds to complete.

Table 10-149. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the status station or status trunk command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1001	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. The status health command can be used to determine if the system is experiencing heavy traffic. Refer to the TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some tone detectors may be out-of-service. The list measurements tone-receiver command will display information on the system's tone receivers. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV (TTR Level) Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT (Tone Generator) Maintenance documentation. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the status trunk command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.

Table 10-149. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the already existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal 1793—Blue Alarm 2049—Red Alarm 2305—Yellow Alarm 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The NPE of the tested port was found to be transmitting in error. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated using other port tests and examining station, trunk, or external wiring.

Conference Circuit Test (#7)

One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. (The TN464 UDS1 circuit pack has one SCOTCH-NPE chip instead of several NPE chips). The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The Conference Circuit Test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a tone detector port. If the level of the tone is within a certain range, the test passes.

Table 10-150. TEST #7 Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the status station or status trunk command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the status station or status trunk command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1018	ABORT	Test disabled via administration. This only applies to analog stations. 1. To enable test, set the Test field on the station administration screen for the particular analog station being tested to "y." Use the change station extension command.
1020	ABORT	The test did not run due to a previously existing error on the specific port or a more general circuit pack error. 1. Examine Error Log for existing errors against this port or the circuit pack and attempt to diagnose the previously existing error.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal 1793—Blue Alarm 2049—Red Alarm 2305—Yellow Alarm 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.

Table 10-150. TEST #7 Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The NPE of the tested port did not conference the tones correctly. This will cause noisy and unreliable connections. 1. Replace the circuit pack.
	PASS	The port can correctly conference multiple connections. User-reported troubles on this port should be investigated by using other port tests and by examining station, trunk, or external wiring.

Port Audit and Update Test (#36)

This test sends port level translation data from switch processor to the DS1 Interface circuit pack to assure that the trunk’s translation is correct. Translation updates include the following data: trunk type (in/out), dial type, timing parameters, and signaling bits enabled. The port audit operation verifies the consistency of the current state of trunk kept in the DS1 Interface circuit pack and in the switch software.

Table 10-151. TEST #36 Port Audit and Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test.

Continued on next page

Table 10-151. TEST #36 Port Audit and Update Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	Test failed due to internal system error. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If test continues to fail, escalate the problem.
	PASS	Trunk translation has been updated successfully. The current trunk states kept in the DS1 Interface circuit pack and switch software are consistent. If the trunk is busied out, the test will not run but will return PASS. To verify that the trunk is in-service: 1. Enter the status trunk command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to step 2. 2. Enter the release trunk command to put the trunk back into in-service. 3. Retry the test command.

DS1 CO Dial Tone Seizure Test (#314)

DS1 CO Dial Tone Seizure Test checks the trunk’s signaling capability provided by the DS1 Interface circuit pack. The maintenance software initiates the test by sending a “seizure” message to the DS1 Interface circuit pack and expects an “active” reply from the DS1 interface circuit pack. If the “active” message is received, then the test passes. If no message is received and the timer expires, the test is aborted. If the DS1 Interface circuit pack sends a “reorder” message back to maintenance software, then the test fails.

This test cannot be run on a trunk in any of the following conditions:

- The trunk direction is administered as an incoming only trunk.
- The trunk has been seized by a normal trunk call.
- The trunk is administered with maintenance test disabled.

Table 10-152. TEST #314 DS1 CO Dial Tone Seizure Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal System Error 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be in use on a valid call. Use the status trunk command to determine when the port is available for testing.
1004	ABORT	The port has been seized by a user for a valid call. Use the status trunk command to determine when the port is available for testing. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the test continues to abort, and the port is not in use, escalate the problem.
1005	ABORT	Test failed due to incompatible configuration administered in trunk group form. 1. Look at the trunk group administration form and see whether the trunk is incoming only, port 24 on a DS1 Interface with common control channel signaling, or an automatic CO type such as FX. Under any of these conditions this is a normal abort.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests" field on the Trunk Group Form is set to "n." To enable the test, issue the change trunk-group x command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests" field on the form to "y." 2. Repeat the test.
1020	ABORT	The DS1 Interface circuit pack is out-of-service. 1. Look for UDS1-BD errors in the Hardware Error Log. If present, refer to the UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 2. Retry the command. 3. If the test continues to abort, escalate the problem.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times. 2. If the test continues to abort, escalate the problem.

Table 10-152. TEST #314 DS1 CO Dial Tone Seizure Test — Continued

Error Code	Test Result	Description/ Recommendation
2053	ABORT	At least one of the following errors is found on the DS1 circuit pack: 1281—Loss of signal 1793—Blue Alarm 2049—Red Alarm 2305—Yellow Alarm 1537—Hyperactivity Look for the above error types in the Hardware Error Log and follow the procedures given in the appropriate DS1-BD or UDS1-BD maintenance documentation for the listed error types.
	FAIL	The trunk cannot be seized for an outgoing call. 1. Verify that the Trunk Type field on the trunk administration screen form matches the trunk type administered on far end switch. 2. Look for UDS1-BD errors in Hardware Error Log. If present, refer to the UDS1-BD (DS1/UDS1 Trunk Circuit Pack) Maintenance documentation. 3. Retry the test at 1-minute intervals for a maximum of 5 times. 4. If the test continues to fail, escalate the problem.
	PASS	The trunk can be seized for an outgoing call.

DIOD-TRK (DIOD Trunk), DIOD-BD (DIOD Circuit Pack) [G1.2SE]

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DIOD-BD ²	MINOR	test port PCSS s	DIOD Circuit Pack

-
1.

Where P is the port network number (1 for PPN, 2 for EPN, and 3 for the second EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...etc.)
2.

Where **1** is Long, **s** is Short, and **r** is repeat. Refer to the XXX-BD (Common Port Board) Maintenance Documentation.

DIOD-TRK (DIOD Trunk) [G1.2SE]

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DIOD-TRK	MAJOR ²	test port PCSSpp l	DIOD Trunk
DIOD-TRK	MINOR	test port PCSSpp l	DIOD Trunk
DIOD-TRK	WARNING	test port PCSSpp l	DIOD Trunk

1.

Where P is the port network number (1 for PPN, 2 for EPN, and 3 for the second EPN); C is the carrier designation (for example, A, B, C, D, or E); and SS is the address of the slot in the carrier where the circuit pack is located (for example, 01, 02, ...etc.).
2.

A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options** command and that at least 75 percent of the trunks in this trunk group are alarmed.

Direct Inward and Outward Dial (TN429 DIOD) trunks are 2-wire analog lines to the CO which support the following services:

- both incoming and outgoing CO calls
- DID trunk
- DID Trunk and 1-way Outgoing DIOD

The DIOD Trunk circuit pack provides eight ports for loop-start CO. The circuit pack is an interface between the 2-wire analog line from the CO and the system's (4-wire) TDM Bus.

LOOP START OPERATION

Idle State - Tip = ground, Ring = CO Battery

A. Outgoing Call

1.

PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop
 - a. CO Response: DC loop current + Dial tone
2.

PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
 - a. CO Response: CO goes to idle state (see Note)

B. Incoming Call

1.

CO Applies Ringing Voltage
 - a. PBX Response: Detect ringing current
2.

PBX Off-Hook (Answer Message): Close loop
 - a. CO Response: Trip ringing, provide loop current

3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
- a. CO Response: CO goes to idle state (see Note)

C. Direct Inward Dialing (DID)

1. CO Applies Ringing Voltage
- a. PBX Response: Detect ringing current and close loop
- b. CO Response: Send DTMF digits
- c. PBX Response: Acknowledge of Number dialed and open loop
2. PBX Off-Hook (Answer Message): Close loop
- a. CO Response: Trip ringing, provide loop current
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
- a. CO Response: CO goes to idle state (see Note)

 **NOTE:**

CO does not normally provide an On-Hook (Disconnect) signal.

Hardware Error Log Entries and Test to Clear Values

Table 10-153. DIOD Trunk Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
0 ¹	0	Any	Any	Any	test port PCSSpp sh r 1
15 (b)	any	Port Audit Update Test (#36)			
18	0	busyout trunk <grp>/<mbr>			
769 (a)	57392	None	MAJ/MIN/WRN ²	ON	
1537		Dial Tone Test (#0)	MAJ/MIN/WRN ²	ON	test port PCSS l r 2
1793		Loop Around and Conference Test (#33)	MAJ/MIN/WRN ²	ON	test port PCSS l r 3
2049		NPE Cross Talk Test (#6)	MAJ/MIN/WRN ²	ON	test port PCSS l r 3
2561 (a,d)	57345	None			
2817 (a,e)	57393	None			

Table 10-153. DIOD Trunk Error Log Entries — Continued

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Test to Clear Value
3073 (a,c)	57376	None			
3073 (a,c)	57424	None			
3585 (a,c)	57424	None			

- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- Minor alarms on this MO may be downgraded to warning alarms based on the values used in the **set options** command. If the Minor alarm is not downgraded by the **set-options** values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Notes:

- a. These are in-line errors that have no specific test associated with them. Refer to the following table for an explanation and appropriate action.
- b. This is a software audit error that does not indicate any hardware malfunction. Run the Short Test Sequence and investigate associated errors (if any).
- c. Aux data 57376 - No loop current on incoming call
Aux data 57424 - No loop current on outgoing call

These errors cause the Dial Tone Test (#0) to run and are only considered a problem if the Dial Tone Test fails (in which case Error Type 1537 also shows up). In this case, the trunk may be put in "Ready-for-Service" state (shown as "disconnected" by status command), which allows only incoming calls. Run the Dial Tone Test (#0) and follow its outlined procedures.
- d. Single polarity ringing current - This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. This error code is only logged as an informational event and causes no other testing to occur.
- e. Late CO Trunk release - This error indicates that the CO releases the trunk at least four minutes after the PBX dropped the call. This error code is only logged as an informational event and causes no other testing to occur.

Table 10-154. DIOD Trunk Errors with NO Tests

Error Type	Aux Data	Description and System Action	System Technician Action
769	57392	CO not releasing after call is dropped from PBX end (TN747B), or the loop is not open after a disconnect (TN765). After several occurrences, an off-board (TN747B) or on-board (TN465) warning alarm is generated.	Refer problem to CO.
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) The other cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test also fails.	Check for other errors.
2817	57393	CO released the trunk at least four minutes after the PBX dropped the call. This error code is log only and causes no other testing to occur. No alarm is generated.	Check for other errors.
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and all outgoing calls should also fail.	Check for other errors.
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected.	See Note at end of table.

 **NOTE:**
At the administration terminal, busyout the affected port, and run a Long test. If Dial Tone Test #0 passes, ignore this error. Release the port.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order they are presented in the table below when inspecting errors in the system. By clearing error codes associated with the *NPE Crosstalk Test*, for example, you may also clear errors generated from other tests in the testing sequence.

For example, you may also clear errors generated from other tests in the testing sequence.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
Loop Around and Conference Test (#33)		X	ND
Audit Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

Dial Tone Test (#0)

This test attempts to seize a port and checks for the return of a dial tone.

Table 10-155. TEST #0 Dial Tone Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the command display port PCSSpp to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Table 10-155. TEST #0 Dial Tone Test — Continued

Error Code	Test Result	Description/ Recommendation
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If the system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the status trunk command to determine when the port is available for testing. 1. Retry the command at one minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.
1018	ABORT	Test has been disabled via administration. 1. Verify that the "Maintenance Tests?" field on the Trunk Group Form is set to "n." To enable the test, issue the change trunk-group x command where "x" equals the number of the trunk group to be tested. Then change the entry in the "Maintenance Tests?" field on the form to "y."
1005	ABORT	Trunk has been administered as incoming-only; or DID trunk group type; dial tone can only be obtained on outgoing trunks. This is a normal condition.
2000	ABORT	Response to the test was not received within the allowable time period. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
	FAIL	Trunk was seized, but dial tone could not be detected. 1. Check for errors on TONE-BD or TONE-PT. Clear any errors found and repeat test. 2. If error has still not cleared, refer problem to CO.
2002	FAIL	Seizure portion of test failed due to hardware problem. Fault is usually caused by a disconnected trunk. 1. Check trunk wiring to ensure good connection; repeat test if wiring correction made. 2. Locate another identical CO trunk and swap its wiring with one under test. Repeat test on both trunks and determine if problem follows trunk or remains at original port. If problem follows trunk, refer problem to CO. If problem remains at port, replace circuit pack and repeat test. 3. If replacing circuit pack does not clear failure, escalate the problem.

Continued on next page

Table 10-155. TEST #0 Dial Tone Test — Continued

Error Code	Test Result	Description/ Recommendation
1009	PASS	Detected tone was not pure dial tone. No action required.
	PASS	Trunk was seized, and dial tone was detected. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

NPE Crosstalk Test (#6)

One or more NPEs reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per port basis. The NPE Crosstalk Test verifies that this port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one way and noisy connections may be observed. This test is usually only part of a port's long test sequence and takes approximately 20 to 30 seconds to complete.

Table 10-156. TEST #6 NPE Crosstalk Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1000	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.

Continued on next page

Table 10-156. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
1001	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to TDM-BUS (TDM-Bus) Maintenance documentation to diagnose any active TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of tone detectors present or some tone detectors may be out-of-service. 1. Look for TTR-LEV errors in the Error Log. If present, refer to TTR-LEV Maintenance documentation. 2. Look for TONE-PT errors in the Error Log. If present, refer to TONE-PT Maintenance documentation. 3. If neither condition exists, retry the test at one-minute intervals a maximum of five times. 4. If the test continues to abort, escalate the problem.
1004	ABORT	The port was seized by a valid call during the test. The test has been aborted. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting.
2000	ABORT	Response to the test request was not received within the allowable time period.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
Any	FAIL	The NPE of the tested port was found to be transmitting in error. This causes noisy and unreliable connections. 1. Replace the circuit pack.

Table 10-156. TEST #6 NPE Crosstalk Test — Continued

Error Code	Test Result	Description/ Recommendation
	PASS	The port is correctly using its allocated time slots. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Loop Around and Conference Circuit Test (#33)

This test checks the reflective loop and conference abilities of a CO port circuit. The test uses 404 Hz, 1004 Hz, and 2804 Hz tones. Each tone is transmitted separately through the loop and checked.

Table 10-157. TEST #33 Loop Around and Conference Circuit Test

Error Code	Test Result	Description/ Recommendation
7 1000	ABORT	Could not allocate system resources to run this test.
	ABORT	Conference Circuit Test aborted.
	ABORT	System resources required to run this test are not available. The port may be busy with a valid call. Use the display port PCSSpp command to determine the trunk group/member number of the port. Use the status trunk command to determine the service state of the port. If the service state indicates that the port is in use, then the port is unavailable for certain tests. (Refer to the "Status Commands" section in Chapter 10, "Maintenance Commands and Trouble-Clearing Aids" for a full description of all possible states.) You must wait until the port is idle before retesting. 1. If the port status is idle, then retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
1004	ABORT	The port has been seized by a user for a valid call. Use the status trunk command to determine when the port is available for testing. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort and the port is not in use, escalate the problem.

Continued on next page

Table 10-157. TEST #33 Loop Around and Conference Circuit Test — Continued

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
7	FAIL	1. Check for errors on TONE-BD or TONE-PT. If there are errors, take the appropriate actions. 2. If the Reflective Loop Around Test fails for all ports on a circuit pack, a -5 volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, check the circuit pack for a red LED. If the red LED is on, then replace the appropriate power unit circuit pack. If neither the TN736 nor the TN752 power unit circuit pack is present, then the OLS631DB AC power unit may be defective. The system may contain a TN736 or TN752 power unit circuit pack OR an OLS631DB AC power unit, BUT NOT BOTH TYPES OF POWER UNITS.  NOTE: To investigate problems with an OLD631DB AC power source, refer to CARR-POW Maintenance documentation. 3. Rerun the test. 4. If the test fails again, replace the circuit pack.
	PASS	CO Trunk Loop Around and Conference Test is successful. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring.

Port Audit Update Test (#36)

This test sends updates of the CO port translation for all ports on the circuit pack which have been translated. The update is non-disruptive and guards against possible corruption of translation data contained on the circuit pack. No response message is expected from the circuit pack once it receives translation updates. The port translation data includes: ground or loop start trunk, tone or rotary dialing trunk, rotary dialing inter-digit timing, network balance R/RC, and disconnect timing.

Table 10-158. TEST #36 Port Audit Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at one-minute intervals a maximum of five times. 2. If the test continues to abort, escalate the problem.
2100	ABORT	Could not allocate the necessary system resources to run the test.
	FAIL	Internal System Error. 1. Retry the command at one-minute intervals a maximum of five times. 2. If test continues to fail, escalate the problem.
	PASS	This test passed. Translation information was successfully updated on the circuit pack. User-reported troubles on this port should be investigated by using other port tests and by examining trunk or external wiring. If the trunk is busied out, the test does not run, but returns PASS. To verify that the trunk is in-service: 1. Enter status-command to verify that the trunk is in-service. If the trunk is in-service, no further action is necessary. If the trunk is out-of-service, continue to Step 2. 2. Enter release-trunk command to put trunk back into in-service. 3. Retry the test command.

DLY-MTCE (MO-DAILY)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run	Full Name of MO
DLY-MTCE	MINOR	NONE	DLY-MTCE
DLY-MTCE	MAJOR	NONE	DLY-MTCE

The DLY-MTCE maintenance object monitors daily translation saves. If a translation save times out or fails to run, an error is logged against this maintenance object. If the save fails three times in a row, a MINOR alarm is raised; if the save fails for seven consecutive attempts, a MAJOR alarm is raised.

DS1-BD (DS1 Interface Circuit Pack)

MO Name (in Alarm Log)	Alarm Level	Initial Command to Run ¹	Full Name of MO
DS1-BD	MAJOR	test board PCSS sh	DS1 Interface Circuit Pack
DS1-BD	MINOR	test board PCSS l	DS1 Interface Circuit Pack
DS1-BD	WARNING	test board PCSS sh	DS1 Interface Circuit Pack

1. UU is the universal cabinet number (1 for PPN, 2 - 44 for EPNs). C is the carrier designation (A, B, C, D, or E). SS is the number of the slot in which the circuit pack resides (01 to 21).

The DS1 Interface circuit pack provides an interface to an external DS1 facility and supports 24 DS0 channels carried on a 1.544 Mbps DS1 link. These DS0 channels can be administered as either trunks to other switches or lines to off-premises stations. The TN464C and later suffix Universal DS1 Interface also supports a 32-channel interface on a 2.048Mbps link. The functions and maintenance strategy for the TN464 circuit packs are covered under a separate maintenance object, UDS1-BD.

DS1-BD maintenance logs in-line errors reported by the DS1 Interface circuit pack, runs tests for error diagnosis and recovery, and raises and clears alarms. The following table shows the capabilities of each DS1 circuit pack. The TN722 and TN722B are not supported on G3r V1 or later systems.

Circuit Pack Code	24 Channel	32 Channel	Tie Trunk Signaling	CO Trunk Signaling	DID Trunk Signaling	OPS Line Signaling
TN722/B	x		x			
TN767/B/C/D/E	x		x	x	x	x
TN464C/D/E/F	x	x	x	x	x	x (24-chl only)

ISDN-PRI Trunk signaling (for example, Q.921, Q.931) requires a TN464D and is handled by system software. The TN464 is covered in the "UDS1-BD (UDS1 Interface Circuit Pack)" section of Chapter 9.

Each trunk and line have their own maintenance strategies. However, they all depend on the health of the DS1 Interface circuit pack. Refer to the following sections for details: TIE-DS1, CO-DS1, DID-DS1, OPS-LINE, ISDN-TRK, and ISDN-PLK. Signaling over the DS1 link must be synchronized between the transmitting and receiving ends to ensure error-free communication. Refer to "SYNC (Synchronization)" for details.

The TN767E circuit pack combined with AT&T's new 120A1 CSU Module forms an Enhanced Integrated CSU. The new 120A1 CSU Module, when combined with the functionality provided by the TN767E hardware and firmware, and new switch software, provides functionality equivalent to an external stand-alone AT&T ESF T1 CSU. The 120A1 CSU Module connects to the TN767E circuit pack on the I/O connector panel on the back of the port carrier. The new CSU Module, thus becomes an integrated part of the DEFINITY. system. Throughout the document, the term 120A1 will mean a 120A1 or later suffix CSU Module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544 Mbps DS1 service. For further details on the 120A1 CSU Module see *DEFINITY. Communications System Generic 1, Generic 2, and Generic 3 V1 and V2 - Integrated CSU Module Installation and Operation, 555-230-193.*

The TN767E and 120A1 CSU Module support on-demand loopback tests that assist in the detection of faults between the TN767E circuit pack and the CSU Module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU. These loopback tests are explained in detail later in this DS1-BD section, but Figure 10-28 gives a high level overview of the loopback points.

The following list of acronym definitions are for Figure 10-28:

- PLB = Payload Loopback
- BLB = Board Loopback
- ELB = Equipment Loopback
- LLB = Line Loopback
- RLB = Repeater Loopback
- CLJ = Loopback Jack Loopback
- R-LLB = Remote Line Loopback
- SMRT = Smart Jack
- LPBK = Loopback

For more information about DS1 interfaces, see the *DEFINITY Communications System DS1/CEPT1/ISDN-PRI Reference, 555-025-107.*

Figure 10-28. High Level Overview Of Loopback Points

-
- Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
 - If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.

3. Off-board minor alarms on this maintenance object may be downgraded to Warning alarms based on the values used in the **set options** command.

Notes:

- a. This error indicates that the circuit pack has stopped functioning or is not completely administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI Test (#53) fails.

To be completely administered, a DS1 circuit pack must meet all 3 of the following conditions:

1. Have an entry in the circuit plan via the **change circuit pack** command
2. Be administered via the **add ds1 PCSS** command
3. Be physically inserted in the appropriate slot

If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error either

1. Make sure all conditions for administration are met and that a functioning DS1 circuit pack is inserted in the correct slot.
2. Completely remove the DS1-BD from the system using the following steps:
 - a. Remove any administered DS1 trunks or access endpoints associated with the circuit pack from their trunk groups.
 - b. Execute the **remove ds1 PCSS** and **change circuit pack PCSS commands**.

If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions for *LED Alarms with Error Type 1* in Chapter 7.

- b. The DS1 Interface circuit pack has been busied out by a **busy-out board PCSS** command.
- c. The DS1-BD circuit pack is not completely administered. A completely administered DS1-BD circuit pack should have an entry in the circuit plan via the **change circuit pack** command, should have been administered via the **add ds1 PCSS** command, and should have been inserted into the appropriate port slot.
- d. The circuit pack in the slot does not match the type administered to that position. Either replace the circuit pack with one of the type administered, or use **change circuit-pack** to readminister the slot. This error may also indicate that the 24/32-channel selection on the DS1 administration form does not match the configuration of the circuit pack.

- e. This error is associated with the Common Port Circuit Pack Maintenance Test. Refer to "XXX-BD (Common Port Circuit Pack)" for details.
- f. The DS1 Interface circuit pack has detected a transient hardware problem (for example, external RAM failure, internal RAM failure, internal ROM failure, or instruction set failure). This error will disappear when no faults are detected for 30 minutes. The value in the Aux Data field indicates the type of hardware problem. However, when this error is reported with Aux Data in the range of 4352 to 4358, it indicates the circuit pack has reported a hardware failure such that the circuit pack should be replaced.
- g. The DS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data field indicates the type of hardware problem.
- h. CSU Module missing. The Near -End CSU Type field on the **add ds1** form has been administered as integrated but the 120A1 CSU Module is not physically connected (or is improperly connected) to the TN767E board on the back of the port carrier.

If using the 120A1 CSU Module, plug (or replug) the CSU Module into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the Near -End CSU Type field using the **change ds1** form to other.

If this error remains after plugging the CSU Module into the board's connector, there could be a problem with the I/O connector panel.

- i. CSU Module not expected. The 120A1 CSU Module is physically connected to the TN767E board on the back of the port carrier but the Near -End CSU Type field on the **add ds1** form has not been administered as integrated.

If the 120A1 CSU Module is to be used, use the **change ds1** command to change the Near -End CSU Type field to integrated. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier.

- j. DS1 configuration error. Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America.
- k. DS1 circuit pack suffix incorrect for CSU Module. The Near -End CSU Type field on the **add ds1** form has been administered as integrated but the DS1 circuit pack is not a TN767E or later suffix DS1 board.

If the 120A1 CSU Module is to be used, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise, use the **change ds1** command to change the Near -End CSU Type field to other.

- l. BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using the following commands: **busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, release board PCSS**. If the BLB test continues to fail, then the TN767E circuit pack needs to be replaced.
- m. ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e., TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command **test ds1-loop PCSS ds1/csu-loopback-tests**.

Attempt to clear the alarm via the following commands: **busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, and release board PCSS**. If the ELB test continues to fail, then either the TN767E board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate where the failure is occurring by re-executing the test by replacing one piece of hardware at a time.

- n. RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed by the I-CSU during I-CSU power-up/reset (i.e., TN767E board physically inserted and 120A1 CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command **test ds1-loop PCSS ds1/csu-loopback-tests**.

Attempt to clear the alarm via the following commands: **busyout board PCSS, test ds1-loop PCSS ds1/csu-loopback-tests, and release board PCSS**. If the RLB test continues to fail, then the CSU Module needs to be replaced.

- o. CPE Loopback Jack deactivation error. This error occurs when the TN767E circuit pack could not deactivate a CPE Loopback Jack loopback.

Attempt to clear the alarm via the following commands: **busyout board PCSS, test ds1-loop PCSS end-loopback/span-test, and release board PCSS**. If the attempt to deactivate the CPE Loopback Jack loopback continues to fail, other steps must be taken to deactivate the loopback.

- p. Far CSU Loopback deactivation error. This error occurs when the TN767E circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

Attempt to clear the alarm via the following commands: *busyout board PCSS, test ds1-loop PCSS end-loopback/span-test, release board PCSS*. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

- q. The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
1. The common circuit pack level tests such as Test #51 and/or Test #220 are aborting with error code 2000.
 2. The tests run on the ports of this circuit pack are returning NO BOARD.
 3. A busy-out/release of the circuit pack has no affect on test results.
 4. A **list configuration** command shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and all trunks of this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 Interface circuit pack is restored to normal operation. All trunks of the DS1 Interface circuit pack are then returned to the in-service state. If the error recurs after 15 minutes, then replace the circuit pack.

- r. For later releases of G3V4 and beyond, only error 3073 will show that this board is receiving Slips and the AUX data shows the last Slip count that was reported.
- s. For later releases of G3V4 and beyond, only error 3329 will show that this board is receiving misframes and the AUX data shows the last misframe count that was reported.
- t. This error is not service-affecting and can be ignored.
- u. Error 3900 is used to give status information on a CPE Loopback Jack Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

- v. Error 3901 is used to give status information on a Far CSU Loopback Test. The value in the Aux Data field indicates the status of the loopback test.

1 — Test is currently running.

2 — Test failed because loopback could not be activated.

3 — Test failed because test pattern could not be detected.

4 — Test has been terminated.

- w. Error 3902 is used to give status information on a One-Way Span Test. The value in the Aux Data field indicates the status of the span test.
- 1 — Test is currently running.
 - 2 — Test has failed because test could not be activated.
 - 3 — Test pattern was not received from the far end.
 - 4 — Test has been terminated.
- x. Error type 3999 indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If error type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If error type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this error type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

System Technician-Demanded Tests:
Descriptions and Error Codes

Always investigate tests in the order they are presented in Table 10-145. By clearing error codes associated with the *NPE Connection Audit Test*, for example, you may also clear errors generated from other tests in the testing sequence

Table 10-160. System Technician-Demanded Tests: DS1-BD

Order of Investigation	Short Test Sequence	Long Test Sequence	Reset Board Sequence	test ds1-loop Command	D/ND ¹

End Loopback/Span Test (#1216)				X	D

1. D = Destructive, ND = Non-destructive

NPE Connection Audit Test (#50):

The system sends a message to the on-board microprocessor to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

Table 10-161. TEST #50 NPE Connection Audit Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available.

Continued on next page

Table 10-161. TEST #50 NPE Connection Audit Test — Continued

Error Code	Test Result	Description/ Recommendation
1019	ABORT	Test already in progress.
	FAIL	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	PASS	The circuit pack's NPEs have been updated with their translation.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. Issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the linkage between the internal ID and the port.

Control Channel Looparound Test (#52)

This test queries the circuit pack for its circuit pack code and vintage and verifies its records.

Table 10-162. TEST #52 Control Channel Looparound Test

Error Code	Test Result	Description/ Recommendation
None 2100	ABORT	System resources required for this test are not available.
		1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-162. TEST #52 Control Channel Looparound Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The test failed because the circuit pack did not return the circuit pack code or vintage.  NOTE: Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as Test 138 and Test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test result. 4. A list config command shows that the circuit pack and the ports are properly installed. When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack. 1. Retry the command for a maximum of 5 times. 2. If the problem continues, check for hyperactivity. Resolve the problem, as appropriate. 3. If there is no longer hyperactivity, retry the command for a maximum of 5 times. 4. If the test continues to fail, replace the circuit pack.
	PASS	Communication with this circuit pack is successful.

Continued on next page

Table 10-162. TEST #52 Control Channel Looparound Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the linkage between the internal ID and the port.

SAKI Sanity Test (#53)

This test is destructive. This test resets the circuit pack.

Table 10-163. TEST #53 SAKI Sanity Test

Error Code	Test Result	Description/ Recommendation
None	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1005	ABORT	Wrong circuit pack configuration to run this test. This error applies only to DS1 Interface circuit packs. It means the DS1 Interface circuit pack is providing timing for the system and, therefore, it cannot be reset without major system disruptions. 1. If the circuit pack needs to be reset, then set synchronization to another DS1 Interface circuit pack or to the Tone-Clock circuit pack and try again. Refer to "SYNC (Synchronization)".

Table 10-163. TEST #53 SAKI Sanity Test — Continued

Error Code	Test Result	Description/ Recommendation
1015	ABORT	Port is not out-of-service. 1. Busyout the circuit pack. 2. Execute the command again.
2100	ABORT	System resources required for this test are not available. 1. Retry the command at 1-minute intervals a maximum of 5 times.
1	FAIL	The circuit pack failed to reset.
2	FAIL	The circuit pack failed to restart. 1. Execute the command again. 2. If the problem persists, replace the circuit pack.
	PASS	The circuit pack initializes correctly. 1. Run the Short Test Sequence.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the linkage between the internal ID and the port.

Internal Looparound Test (#135)

This test is destructive.

The Internal Looparound Test is run by looping the transmitted DS1 bit stream back into the DS1's board receiver. The loop occurs just before the DS1 facility

interface. The test is highly destructive and can only be initiated by a system technician-demanded **reset board PCSS** command.

All trunks on the DS1 Interface circuit pack must be busied out via the system technician **busy-out board** command before running the Internal Looparound Test. When the Internal Looparound Test is initiated, maintenance software sends appropriate messages to the DS1 Interface circuit pack to start the test. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk are different, the test fails.

When the test is complete, the maintenance software sends a stop loop around message to the DS1 Interface circuit pack to put the circuit pack back into the normal operation mode. All trunks of the DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

Table 10-164. TEST #135 Internal Looparound Test

Error Code	Test Result	Description/ Recommendation
2012	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
1002	ABORT	The system could not allocate time slots for the test. The system may be under heavy traffic conditions or it may have time slots out-of-service due to TDM-BUS errors. Refer to "TDM-BUS" to diagnose TDM-BUS errors. 1. If system has no TDM-BUS errors and is not handling heavy traffic, repeat test at 1-minute intervals a maximum of 5 times.
1003	ABORT	The system could not allocate a tone receiver for the test. The system may be oversized for the number of Tone Detectors present or some Tone Detectors may be out-of-service. 1. Resolve any "TTR-LEV" errors in the Error Log. 2. Resolve any "TONE-PT" errors in the Error Log. 3. If neither condition exists, retry the test at 1-minute intervals a maximum of 5 times.
1004	ABORT	Received an incoming call on a port of the DS1 circuit pack during the test. 1. Enter the busy-out board PCSS command to put all trunks of DS1 Interface circuit pack to out-of-service state. 2. Retry the command at 1-minute intervals a maximum of 5 times.
1015	ABORT	Ports on DS1 Interface circuit pack have not been busied out. 1. Enter the busy-out board PCSS command to put all trunks of the DS1 Interface circuit pack into out-of-service state. 2. Retry the command.

Table 10-164. TEST #135 Internal Looparound Test — Continued

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Therefore, it cannot be reset without major system disruption. 1. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: ■ Issue the disable synchronization-switch command. ■ Next, issue the set synchronization PCSS command. ■ Lastly, issue the enable synchronization-switch command.
2000	ABORT	The test was aborted. Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as Test 139 and Test 140) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
2100	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Continued on next page

Table 10-164. TEST #135 Internal Looparound Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	DS1 Interface circuit pack failed in the Internal Looparound Test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 Interface circuit pack is TN767, enter the list measurement ds1-log PCSS command to read the error seconds measurement. Otherwise, skip this step. 3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. Check the physical connectivity of DS1 Interface circuit packs and cable. 5. If all of the above are OK, replace the local DS1 Interface circuit pack and repeat the test. 6. Contact T1 Network Service to diagnose remote DS1 endpoint.
	PASS	All administered trunks of DS1 Interface circuit pack pass the Internal Looparound Test. The bit pattern consistency test is executed successfully over the path that covers a DS1 port, cable, and the external NCTE device.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the linkage between the internal ID and the port.

Loss of Signal Alarm Inquiry Test (#138)

This test verifies the synchronization status and continuity of the DS1 link. The Loss of Signal alarm indicates that the DS1 Interface circuit pack is unable to derive the synchronization clock from the DS1 facility. When the DS1 Interface

circuit pack detects a Loss of Signal alarm, it stops providing the synchronization clock for the system if it is administered as a timing source and transmits a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, the maintenance software places all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored. The DS1 Interface circuit pack raises a Loss of Signal alarm after the signal has been lost for about 1second. It will not retire the alarm until the signal has returned for about 10 seconds.

This test is also used to maintain the new 120A CSU Module. This Module, when combined with the functionality provided by the TN767E circuit pack, provides functionality equivalent to an external standalone ESF T1 CSU.

If a TN767E circuit pack detects certain ICSU hardware errors, it will notify maintenance. When the maintenance subsystem receives notification of the I-CSU error, it will execute this Loss of Signal Inquiry test. The test, in addition to querying for a Loss Of Signal alarm condition, will also query the TN767E board to confirm the I-CSU error. A Minor or Warning alarm will be raised depending on the severity of the ICSU error. The trunks on the board may be taken out of service if the ICSU error is deemed serious.

If a Loss Of Signal alarm and an ICSU error co-exist, the Loss Of Signal alarm condition will take priority and the board and all trunks on the board will be put in the out-of-service state. Errors will be logged, however, for both.

When the maintenance subsystem receives notification that the ICSU hardware error condition no longer exists, maintenance will restore the board and all trunks to their previous service state if the alarm can be cleared (no other ICSU errors or Loss Of Signal alarm exist)

Table 10-165. TEST #138 Loss of Signal Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-165. TEST #138 Loss of Signal Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
	FAIL	DS1 Interface circuit pack detects a Loss of Signal alarm. The physical link is broken or the remote DS1 endpoint is down. All trunks or ports of this DS1 interface circuit pack are out-of-service. If the DS1 Interface circuit pack is designated as the supplier of the system synchronization source, then the system synchronization maintenance will adopt a source elsewhere. Refer to "SYNC (Synchronization)" section for details. 1. If the DS1 Interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 2. Check the physical connection of the DS1 Interface circuit pack and the cable. If a 120A1 CSU Module is physically connected to a TN767E board on the back of the port carrier, check the physical connection of the CSU Module and make sure the Network Interface cable is plugged into the CSU Module's NETWORK jack.

Continued on next page

Table 10-165. TEST #138 Loss of Signal Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
1300	FAIL	The CSU Module is missing. The <i>Near-End CSU Type</i> field on the <i>add ds1</i> form has been administered as <i>integrated</i> but the 120A1 CSU Module is not physically connected to the TN767E board on the back of the port carrier. 1. If using the 120A1 CSU Module, plug the CSU Module into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the <i>Near-End CSU Type</i> field using the <i>change ds1</i> form to <i>other</i>. 2. Run the test again.
1301	FAIL	The 120A1 CSU Module is physically connected to the TN767E board on the back of the port carrier but the <i>Near-End CSU Type</i> field on the <i>add ds1</i> form has not been administered as <i>integrated</i>. 1. If the 120A1 CSU Module is to be used, use the <i>change ds1</i> command to change the <i>Near-End CSU Type</i> field to <i>integrated</i>. Otherwise, physically remove the 120A1 CSU Module from the back of the port carrier. 2. Run the test again.
1302	FAIL	Attempting to use the 120A1 CSU Module with a TN767E circuit pack that is configured for 32-channel (2.048 Mbps) operation. The CSU Module only works with a DS1 board configured for 24-channel (1.544 Mbps) operation in the United States of America. 1. If the 120A1 CSU Module is to be used, physically remove the TN767E circuit pack and reconfigure for 24-channel (1.544 Mbps) operation. 2. Reinsert the circuit pack and run the test again.
1303	FAIL	The DS1 circuit pack Suffix is incorrect for CSU Module administration. The <i>Near-End CSU Type</i> field on the <i>add ds1</i> form has been administered as <i>integrated</i> but the DS1 circuit pack is not a TN767E or later suffix DS1 board. 1. If the CSU Module is to be used, and the <i>Near-End CSU Type</i> field is set to <i>integrated</i>, to allow for CSU module administration, remove the circuit pack and replace it with a TN767E or later suffix board. Otherwise use the <i>change ds1</i> command to change the <i>Near-End CSU Type</i> field to <i>other</i>.
1310	FAIL	The DS1 Board Loopback (BLB) demand test (#1209) failed. 1. Repeat the test using the <i>test ds1-loop PCSS ds1/csu-loopback-tests</i> command. 2. If the BLB test continues to fail, then replace the TN767E circuit pack. 3. Run this test again.

Continued on next page

Table 10-165. TEST #138 Loss of Signal Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
1311	FAIL	The Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test (#1210) failed. This test is executed by the ICSU during ICSU power-up/reset (TN767E board physically inserted and 120A CSU Module already installed) or when the 120A CSU Module is plugged on to an already initialized DS1 board. The ELB test is also executed as part of the command test ds1-loop PCSS ds1/csu-loopback-tests. 1. Execute test ds1-loop PCSS ds1/csu-loopback-tests. 2. If the ELB test continues to fail, then either the TN767E board, the CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. Begin by replacing the CSU Module and running the test ds1-loop PCSS ds1/csu-loopback-tests command again. 3. If the ELB test continues to fail, then replace the TN767E board and run test ds1-loop PCSS ds1/csu-loopback-tests again. 4. If the ELB test continues to fail, the problem could be in the I/O cable between the backplane and the CSU module.
1312	FAIL	The Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test (#1211) failed. This test is executed by the ICSU during ICSU power-up/reset (TN767E board physically inserted and 120A CSU Module already installed) or when the 120A1 CSU Module is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command test ds1-loop PCSS ds1/csu-loopback-tests. 1. Execute test ds1-loop PCSS ds1/csu-loopback-tests. 2. If the RLB test continues to fail, then replace the CSU Module. 3. Run this test again.
1313	FAIL	The TN767E circuit pack could not deactivate a CPE Loopback Jack loopback. 1. Execute test ds1-loop PCSS end-loopback/span-test. 2. If the attempt to deactivate the CPE Loopback Jack is not successful, check the cabling and investigate the problem at the CPE Loopback Jack. 3. Run the test again.
1314	FAIL	The TN767E circuit pack could not deactivate a far-end CSU loopback. 1. Execute test ds1-loop PCSS end-loopback/span-test.

Continued on next page

Table 10-165. TEST #138 Loss of Signal Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
1320	FAIL	A 120A1 CSU module hardware failure or an ICSU serial interface audit failure was detected by the TN767E DS1 circuit pack. 1. Replace the CSU module, and then run the test again. 2. If the test continues to fail with this error code, replace the TN767E and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1321	FAIL	DTE LOS (loss of signal) was detected between the TN767E DS1 board and the 120A1 CSU Module. Either the TN767E board, the 120A1 CSU Module, or the I/O cable between the backplane and the CSU module (or any combination thereof) has failed. Attempt to isolate the problem to one of these areas. 1. Replace the CSU Module and run the test again. 2. If the test continues to fail with this error code, then replace the TN767E board and run the test again. 3. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1322	FAIL	No 5 volts power detected from the TN767E circuit pack to the 120A1 CSU Module. Problem probably due to an open fuse on the DS1 board or a faulty ICSU. NOTE <i>Do not swap DS1 boards as this may open the fuse on the new board.</i> 1. Remove the TN767E from the system and reinsert. 2. Run the test again once the board has finished its reset. 3. If the test continues to fail with this error code, then replace the CSU Module and run the test again. 4. If the test continues to fail with this error code, then replace the TN767E board and run the test again. 5. If the test continues to fail with this error code, the problem could be in the I/O cable between the backplane and the CSU module.
1323	FAIL	A service affecting CSU Module audit failure was detected by the TN767E DS1 circuit pack. All administered ports on the DS1 circuit pack are affected and maintenance software will place the ports into the out-of-service state. 1. Replace the 120A1 CSU Module.
1324	FAIL	A non-service affecting CSU Module audit failure was detected by the TN767E DS1 circuit pack. No ports should be affected. No immediate action is required. These errors indicate that the CSU Module hardware may have a problem, and that it should be replaced when practical to avoid further deterioration.

Continued on next page

Table 10-165. TEST #138 Loss of Signal Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
	PASS	DS1 signal is present and the physical link is healthy. In addition, no Integrated CSU errors are detected.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

Blue Alarm Inquiry Test (#139)

The Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the blue alarm status of the remote DS1 endpoint.

When the DS1 Interface circuit pack detects a Blue Alarm signal from the remote DS1 endpoint, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a BLUE ALARM message to the maintenance software. When the Blue alarm is confirmed, the maintenance software places all trunks of the DS1 Interface circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Blue alarm is cleared.

The DS1 Interface circuit pack takes 2 seconds to recognize and report a Blue alarm and 16 seconds to recognize and report the resolution of a Blue alarm. When the Blue alarm is cleared, the DS1 Interface circuit pack stops transmitting the Yellow alarm and places the trunks back into the service state before the Blue alarm occurs.

Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the ICSU or DS1 into a loopback mode. When the ICSU or DS1 Board is in the LLB mode, the arriving bit pattern is regenerated and sent back. Line Loopback (LLB) Alarm is activated when the in-band activate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line. LLB is deactivated when the in-band deactivate LLB bit pattern has been arriving continuously for 5 seconds on the DS1 line.

Since LLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm.

Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. PLB Alarm is activated when a network protocol activate bit pattern arrives over the 4-Kbps ESF data link on the DS1 line. PLB is deactivated when a network protocol deactivate bit pattern arrives over the 4-Kbps ESF data link on the DS1 line.

Since PLB is a maintenance condition rendering all DS0 channels unavailable for signaling or bearer traffic, maintenance software treats this the same as a Blue Alarm

Table 10-166. TEST #139 Blue Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-166. TEST #139 Blue Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
	FAIL	The remote DS1 endpoint is out-of-service. 1. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote endpoint. 2. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint.
1794	FAIL	The DS1 Interface circuit pack detects a Line Loopback Alarm (LLB). 1. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. 2. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. If the DS1 interface circuit pack connects directly to a line-side terminating device (for example, a PRI terminal adapter), call the vendor of the terminating device to diagnose the equipment.

Table 10-166. TEST #139 Blue Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
1795	FAIL	The DS1 Interface circuit pack detects a Payload Loopback Alarm (PLB). If the DS1 Interface circuit pack connects to a leased T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 Interface circuit pack connects directly to another DS1 board, call the system technician of the remote switch to diagnose the DS1 endpoint.
	PASS	Remote DS1 endpoint is in-service. Neither a Blue alarm nor a Line Loopback alarm nor a Payload Loopback alarm is detected in the DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

Red Alarm Inquiry Test (#140)

DS1 Interface circuit pack raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry Test checks the framing status of a DS1 Interface circuit pack. DS1 Interface circuit pack takes 3 seconds to recognize and report a Red alarm and 10 seconds to recognize and report the resolution of a Red alarm.

When the DS1 Interface circuit pack detects a Red alarm, the circuit pack will transmit a Yellow alarm to the remote DS1 endpoint and send a RED ALARM message to the maintenance software. After the Red alarm is confirmed, the maintenance software places all trunks of the circuit pack into the out-of-service state. The inquiry test will be run every 10 minutes until the Red alarm is cleared.

When the Red alarm is cleared, the DS1 Interface circuit pack will stop transmitting the Yellow alarm to the remote DS1 endpoint. The maintenance software restores all trunks of the DS1 Interface circuit pack to the service state before the Red alarm occurs.

Loss of Multiframe Alarm: If the DS1 Interface circuit pack is administered using DMI-BOS signaling, the DS1 Interface circuit pack raises a Loss of Multiframe Alarm (LMA) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24th channel. Once DS1 Interface circuit pack detects an LMA, the circuit pack will transmit a Remote Multiframe Alarm (RMA) to the remote DS1 endpoint. Maintenance software handles both Red alarm and LMA alarm(s) using the same mechanism.

Table 10-167. TEST #140 Red Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 10-167. TEST #140 Red Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The DS1 Interface circuit pack detects a Red alarm. An out-of-frame condition occurs on the DS1 Interface circuit pack. DS1 Interface circuit pack will transmit a Yellow alarm to the remote DS1 endpoint until the Red alarm is retired. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSU's are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. Replace the local DS1 interface circuit pack, and repeat the test.
1	FAIL	The DS1 interface circuit pack detected a loss of multiframe alarm (LMA). An out of frame condition occurred on the DS1 interface circuit pack. The DS1 interface circuit pack will transmit a remote multiframe alarm (RMA) to the remote DS1 endpoint until the LMA is retired. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSU's are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. Replace the local DS1 interface circuit pack, and repeat the test.
	PASS	No Red alarm is detected on DS1 Interface circuit pack.

Table 10-167. TEST #140 Red Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the linkage between the internal ID and the port.

Yellow Alarm Inquiry Test (#141)

Receiving a Yellow alarm from remote DS1 endpoint indicates that the remote DS1 endpoint has an out-of-frame condition. The Yellow Alarm Inquiry Test is used to determine whether the remote DS1 endpoint is transmitting a Yellow alarm. The DS1 Interface circuit pack takes 500 msec to recognize and report a Yellow alarm and 500 msec to recognize and report that a Yellow alarm condition is cleared.

When the DS1 Interface circuit pack detects a Yellow alarm from the remote DS1 endpoint, it will send a YELLOW-ALARM uplink message to the maintenance software. After the maintenance software receives the YELLOW-ALARM message, the Yellow Alarm Inquiry Test is run to confirm the Yellow alarm. Once the Yellow alarm is confirmed, the maintenance software places all trunks on the circuit pack into the out-of-service state. The Inquiry Test will be run every 10 minutes until the Yellow alarm is cleared.

When the Yellow alarm is cleared, the maintenance software restores all trunks on the DS1 Interface circuit pack back to their previous service state before the Yellow alarm is raised.

This Yellow Alarm corresponds to the yellow F2 state documented in CCITT recommendation I.431.

Remote Multiframe Alarm: Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the DS1 Interface circuit pack is administered using the DMI-BOS common channel signaling. The RMA is handled as a Yellow alarm.

Yellow F5 State Alarm: For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431

Table 10-168. TEST #141 Yellow Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may appear. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 10-168. TEST #141 Yellow Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
1	FAIL	The DS1 interface circuit pack detected a yellow alarm sent by the remote DS1 endpoint. An out of frame condition occurred at the DS1 endpoint.
	FAIL	The DS1 Interface circuit pack detects a Remote Multiframe Alarm sent by the remote DS1 endpoint. An out-of-frame condition occurs on the remote DS1 endpoint.
	FAIL	The DS1 Interface circuit pack is reporting a yellow F5 State alarm. There is a fault in the user-network interface from the user (PBX) to the network. 1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. Likewise, verify that any intermediate CSUs are administered correctly. 2. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 3. Check the physical connectivity of the DS1 pack and of the cable. 4. Replace the local DS1 interface circuit pack, and repeat the test.
	PASS	No Yellow alarm nor Remote Multiframe Alarm nor F5 State Alarm is received from the remote DS1 endpoint.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the linkage between the internal ID and the port.

Major Alarm Inquiry Test (#142)

The Major alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1000. The Major Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 16 seconds to recognize and report a Major alarm and 16 seconds to recognize and report that a Major alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 seconds to recognize and report a Major alarm and 10 seconds to recognize and report that a Major alarm condition is cleared.

When the DS1 Interface circuit pack detects a Major alarm, it will send a MAJOR-ALARM message to the maintenance software. After the maintenance software receives a MAJOR-ALARM message, the Major Alarm Inquiry Test is initiated to confirm the Major alarm on the DS1 Interface circuit pack. The Inquiry Test will be run every 10 minutes until the Major alarm is cleared. The maintenance software places all trunks on the circuit pack in the out-of-service state if the Major alarm persists for more than 20 minutes.

When the Major alarm is cleared, the maintenance software restores all trunks on the circuit pack to their previous service state before a Major alarm occurs.

Table 10-169. TEST #142 Major Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Table 10-169. TEST #142 Major Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
	FAIL	The DS1 Interface circuit pack detects a Major alarm. The DS1 bit error rate is greater than 1/1000. 1. The performance of DS1 link between DS1 Interface circuit pack and remote DS1 endpoint is very poor. If the DS1 Interface circuit pack is TN767, enter list measurement ds1-log PCSS command to read the error seconds measurement. 2. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 3. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 4. Check the physical connectivity of the DS1 pack and of the cable. 5. Replace the local DS1 interface circuit pack, and repeat the test.
	PASS	No Major alarm is detected in DS1 Interface circuit pack.

Table 10-169. TEST #142 Major Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

Minor Alarm Inquiry Test (#143)

The Minor alarm raised by a DS1 Interface circuit pack indicates that the average bit error rate on the DS1 facility is greater than 1/1,000,000, but less than 1/1000. The Minor Alarm Inquiry Test is used to determine that the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. When D4 framing mode is selected, the DS1 Interface circuit pack takes 41 minutes to recognize and report a Minor alarm and 41 minutes to recognize and report that a Minor alarm condition is cleared. If ESF framing mode is selected, the DS1 Interface circuit pack takes 10 minutes to recognize and report a Minor alarm and 10 minutes to recognize and report that a Minor alarm condition is cleared.

When the DS1 Interface circuit pack detects a Minor alarm condition, it will send a MINOR-ALARM message to the maintenance software. After the maintenance software receives a MINOR-ALARM message, the Minor Alarm Inquiry Test is initiated to confirm the Minor alarm. All trunks on the circuit pack are kept in the in-service state after the Minor alarm is confirmed. The Minor Alarm Inquiry Test is run every 10 minutes until the Minor alarm is cleared.

Table 10-170. TEST #143 Minor Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed. ⇒ NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 16-170. TEST #143 Minor Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
	FAIL	The DS1 Interface circuit pack detects a Minor alarm. The DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000. 1. The performance of DS1 link between DS1 Interface circuit pack and remote DS1 endpoint is poor. If DS1 Interface circuit pack is TN767, enter list measurement ds1-log PCSS command to read the error seconds measurement. 2. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 3. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 4. Check the physical connection of the DS1 pack and of the cable. 5. Replace the local DS1 interface circuit pack, and repeat the test.
	PASS	No Minor alarm is detected in DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

Slip Alarm Inquiry Test (144)

Slips occur when transmitter and receiver are not running at precisely the same clock rate. The DS1 Interface circuit pack can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test is used to acquire the total number of slips occurred on a DS1 link.

When the DS1 Interface circuit pack detects a slip condition, the circuit pack will increase the on-board slip counter by 1. A SLIP-COUNT message is spontaneously sent to the system software after the counter reaches a threshold (for example, 88). When the maintenance software receives the SLIP-COUNT message, the Slip Alarm Inquiry Test is initiated to query the slip counters on DS1 Interface circuit pack and total the slip counts in the maintenance software.

If the count of slips is over the threshold, a Minor alarm is raised against the DS1 Interface circuit pack. All trunks of the DS1 Interface circuit pack are still in the in-service state. If the DS1 Interface circuit pack is used to supply the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See "TDM-BUS" and "SYNC (Synchronization)" for details.

Table 10-171. TEST #144 Slip Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Table 10-171. TEST #144 Slip Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
1 to 88	FAIL	The DS1 interface circuit pack detected a slip alarm. The error code equals the number of slips detected by the DS1 interface circuit pack since the last slip alarm inquiry test. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN767, enter the list measurement ds1-log PCSS command to read the error seconds measurement. 3. Verify that both endpoints and all intermediate equipment of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 5. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 6. Check the physical connectivity of the DS1 pack and of the cable. 7. Replace the local DS1 interface circuit pack and repeat the test.
	PASS	No Slip alarm is detected on the DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

Misframe Alarm Inquiry Test (#145)

Misframe Alarm indicates that framing bits observed on a DS1 Interface circuit pack are in error. Misframe Alarm Inquiry Test queries the total number of misframes that occurred on a DS1 Interface circuit pack since the last inquiry.

When the DS1 Interface circuit pack detects a misframe error, it will increase its misframe counter by 1. If the counter reaches the threshold, a MISFRAME-COUNT message is automatically sent to the switch maintenance software. After the maintenance software receives the MISFRAME-COUNT message, the Misframe Alarm Inquiry Test is initiated to collect the misframe counts from the DS1 Interface circuit pack.

When the threshold of misframes is reached, if the DS1 Interface circuit pack is supplying the system synchronization source, then a switching synchronization source message is sent to the TDM Bus Clock. See TDM-BUS (TDM Bus) Maintenance documentation for details. A Minor alarm against the DS1 Interface circuit pack is raised, but all trunks of the DS1 Interface circuit pack are still in the in-service state.

Table 10-172. TEST #145 Misframe Alarm Inquiry Test

Error Code	Test Result	Description/ Recommendation
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals a maximum of 5 times.

Continued on next page

Table 10-172. TEST #145 Misframe Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may appear. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.

Continued on next page

Table 10-172. TEST #145 Misframe Alarm Inquiry Test — Continued

Error Code	Test Result	Description/ Recommendation
ANY	FAIL	The test failed because the DS1 interface circuit pack detected errors in the received framing bits pattern. The error code equals the number of misframes detected by the DS1 interface circuit pack since the last misframe alarm inquiry test. Major bit and minor bit error rate (error types 2561 and 2817) error logs often accompany misframe alarms. Clearing the cause of these error logs may clear the misframes which are occurring. 1. Retry the command at 1-minute intervals a maximum of 5 times. 2. If the DS1 interface circuit pack is a TN767, enter the list measurement ds1-log PCSS command to read the error seconds measurement. 3. Verify that both endpoints and all intermediate equipment of the DS1 link are administered using the same signaling mode, framing mode, and line coding. 4. If the DS1 interface circuit pack connects to a T1 facility, call the vendor of the T1 carrier to diagnose the remote DS1 endpoint. If the DS1 interface circuit pack connects directly to a switch, call the system technician of the remote switch to diagnose the DS1 endpoint. 5. Check the active alarm and error logs for recent alarms and errors against the synchronization (SYNC). Follow the suggested repair procedure for these errors. 6. Check the physical connection of the DS1 pack and of the cable. 7. Replace the local DS1 interface circuit pack, and repeat the test.
	PASS	No Misframe alarm is detected on the DS1 Interface circuit pack.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

Translation Update Test (#146)

The Translation Update Test sends the circuit-pack-level information specified by System Administration to the DS1 Interface circuit pack. Translation includes the following data administered for a DS1 Interface circuit pack (see output of **display ds1 PCSS** command): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

If a TN767E or later DS1 circuit pack is combined with a 120A CSU Module to form an Integrated CSU Module, this test will also send the administration for this Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU Module is done using the DS1 circuit pack administration form. Translation for the CSU Module includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power?, and so forth.

Table 10-173. TEST #146 Translation Update Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry the command at 1-minute intervals a maximum of 5 times.
	FAIL	Internal system software error. 1. Enter the display ds1 PCSS command to verify the DS1 Interface circuit pack translation.
	PASS	Translation data has been downloaded to the DS1 Interface circuit pack successfully.
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

DS1 Board Loopback Test (#1209)

This test is destructive.

The DS1 Board Loopback (BLB) Test causes a loopback at the TN767E DS1 board edge and tests DS1 board internal circuitry.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the BLB Test.

When the BLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the BLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

Table 10-174. TEST #1209 DS1 Board Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry test ds1-loop PCSS ds1/csu-loopback-tests at 1-minute intervals a maximum of 5 times.
1005	ABORT	DS1 Board Loopback Test cannot be executed in the current configuration. To run this Test, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter busyout board PCSS to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.

Continued on next page

Table 10-174. TEST #1209 DS1 Board Loopback Test — Continued

Error Code	Test Result	Description/ Recommendation
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the disable synchronization-switch command. 2. Next, issue the set synchronization PCSS command. 3. Lastly, issue the enable synchronization-switch command.
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time. Thus, if a loopback/span test is already active, that test must be terminated via the <i>test ds1-loop PCSS end-loopback/span-test</i> command in order to execute this test.
2100	ABORT	Internal system error
	ABORT	Could not allocate the necessary system resources to run this test. 1. Retry the command at 1-minute intervals for a maximum of 5 times.

Table 10-174. TEST #1209 DS1 Board Loopback Test — Continued

Error Code	Test Result	Description/ Recommendation
2000	ABORT	Response to the test was not received within the allowable time period. This may be due to hyperactivity. Error type 1538 in the error log indicates hyperactivity. The hyperactive circuit pack is out of service and one or more of the following symptoms may be exhibited. 1. The DS1-BD tests (such as test 138 and test 139) are aborting with error code 2000. 2. The tests run on the ports of this circuit pack are returning a no board result. 3. A busyout or a release command has no affect on the test results. 4. A list config command shows that the circuit pack and the ports are properly installed.  NOTE: When hyperactivity occurs, the circuit pack is isolated from the system, and all of the trunks for this circuit pack are placed into the out of service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 interface circuit pack is restored to normal operation. All of the trunks for the DS1 interface circuit pack are then returned to the in service state. Hyperactivity is often caused by the associated facility. In such a case, faults (such as slips, misframes, or blue alarms) would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits. If the facility is OK and the error occurs again after 15 minutes, replace the circuit pack.
	FAIL	DS1 Interface circuit pack failed the DS1 Board Loopback Test. 1. Retry test ds1-loop PCSS ds1/csu-loopback-tests. 2. If the BLB test continues to fail, then replace the DS1 circuit pack.
	PASS	The BLB test executed successfully. The test pattern was transmitted and received successfully up to the TN767E DS1 board edge.

Table 10-174. TEST #1209 DS1 Board Loopback Test — Continued

Error Code	Test Result	Description/ Recommendation
0	NO BOARD	The test could not relate the internal ID to the port (no board). This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted. 1. Check to ensure that the board translations are correct. Use the add ds1 PCSS command to administer the DS1 interface if it is not already administered. 2. If board was already administered correctly, check the error log to determine if the board is hyperactive. If this is the case, the board is shut down. Reseating the board will re-initialize the board. 3. If the board was found to be correctly inserted in step 1, issue the busyout board command. 4. Issue the reset board command. 5. Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

CSU Equipment Loopback Test (#1210)

This test is destructive.

The CSU Equipment Loopback (ELB) Test causes a loopback at the near-edge of the local 120A CSU Module and tests the connection from the TN767E DS1 board to the CSU Module (DS1 board edge interconnecting cable, and CSU Module edge). This test will only be performed if the 120A CSU Module is present, administered, and connected to a 1.544Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the ELB Test.

When the ELB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board sets up the ELB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered.

Table 10-175. TEST #1210 CSU Equipment Loopback Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry test ds1-loop PCSS ds1/csu-loopback-tests at 1-minute intervals a maximum of 5 times.
1005	ABORT	CSU Equipment Loopback Test cannot be executed in the current configuration. To run this test, the <i>Near-End CSU Type</i> field on the DS1 circuit pack administration form must be set to <i>integrated</i> and the "Bit Rate" field must be set to "1.544" (24-channel operation). 1. Use the change ds1 PCSS command to set the <i>Near-End CSU Type</i> field on the DS1 circuit pack administration form to <i>integrated</i> , and/or change the "Bit Rate" field to "1.544" if the board is to be used in the 24-channel configuration. 2. Retry test ds1-loop PCSS ds1/csu-loopback-tests .
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the busyout board PCSS command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the disable synchronization-switch command. 2. Next, issue the set synchronization PCSS command. 3. Lastly, issue the enable synchronization-switch command.

Issue the release busy board command. 6. Issue the test board long command. This should re-establish the link between the internal ID and the port.

CSU Repeater Loopback Test (#1211)

This test is destructive.

The CSU Repeater Loopback (RLB) Test causes a loopback at the far-edge of the local 120A CSU Module and tests the connection from the TN767E DS1 board to and including the CSU Module circuitry. This test will only be performed

if the 120A CSU Module is present, administered, and connected to a 1.544 Mbps TN767E DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS ds1/csu-loopback-tests** command.

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the RLB Test.

When the RLB Test is initiated, maintenance software sends an appropriate message to the TN767E DS1 Interface circuit pack to start the test. The board will set up the RLB loopback, transmit a test pattern, and verify that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

In addition, the DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires which may not be detected by the loopback pattern.

When the test is complete, all trunks or ports on the TN767E DS1 Interface circuit pack are restored to the in-service state after the **release board** command is entered

CPE Loopback Jack Test (#1212)

This test is destructive.

The CPE Loopback Jack (CLJ-LB) Test causes a loopback at the CPE Loopback Jack and tests the building wiring connection between the TN767E DS1 board and the CPE Loopback Jack.

The test is highly destructive and can only be initiated by a system technician demanded **test ds1-loop PCSS cpe-loopback-jack-test-begin [number-of-bits bit-pattern]** command. The System technician has the choice of entering a loopback activation code on the command line or using the default code (0x47F).

All trunks or ports on the DS1 Interface circuit pack must be busied out via the system technician **busyout board** command before running the CPE Loopback Jack Test.

The CPE Loopback Jack Test has the TN767E DS1 Interface circuit pack transmit a loopback activation code to the CPE Loopback Jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully

sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback Jack test will be available in the hardware error log via error type 3900. Several distinct aux values will be used to give the user information of the status of the test.

The **list measurements ds1 summary** command will display the length of time the test has been running (*Test Duration* field) and number of bit errors detected (*Loopback/Span Test Bit-Error Count* field). If the test pattern is being passed through the loopback cleanly, the number of bit errors should be very low. The command will also display the type of loopback/span test executing (*Test* field), the type of pattern generated for the loopback/span test (*Pattern* field), and whether the pattern (*3-in-24 Pattern*) is synchronized (*Synchronized Field*).

To terminate the test, enter **test ds1-loop PCSS end-loopback/span-test** command or the **release board**. Using the **release board** command restores all trunks or ports on the TN767E DS1 Interface circuit pack to the in-service state.

Table 10-177. TEST #1212 CPE Loopback Jack Test

Error Code	Test Result	Description/ Recommendation
	ABORT	Internal system error 1. Retry test ds1-loop PCSS cpe-loopback-jack-test-begin at 1-minute intervals a maximum of 5 times.
1005	ABORT	CPE Loopback Jack Test cannot be executed in the current configuration. To run this Test, the TN767E or later suffix DS1 must be administered for 24-channel operation. The "Bit Rate" field on the DS1 circuit pack administration form must be set to "1.544" for 24-channel operation.
1015	ABORT	Ports on the DS1 Interface circuit pack have not been busied out to out-of-service. 1. Enter the busyout board PCSS command to put all trunks or ports of the DS1 Interface circuit pack into the out-of-service state. 2. Retry the command.
1039	ABORT	The DS1 Interface circuit pack is providing timing for the system. Executing this test could cause major system disruption. If the DS1 Interface circuit pack needs to be tested, set the synchronization reference to another DS1 Interface circuit pack or to the Tone-Clock circuit pack via the following command sequence: 1. Issue the disable synchronization-switch command. 2. Next, issue the set synchronization PCSS command. 3. Lastly, issue the enable synchronization-switch command.

Table 10-177. TEST #1212 CPE Loopback Jack Test — Continued

Error Code	Test Result	Description/ Recommendation
1950	ABORT	Another loopback/span test is already executing on the DS1 board or the board is in a network requested loopback mode (Line loopback or Payload loopback). The hardware error log will indicate whether a Customer Loopback Jack Test, Far CSU Loopback Test, or the One-Way Span Test is executing or if the board is in line loopback or payload loopback mode. Only one long-duration loopback/span test can be active at a given time.
